Returns the client connection label for the current session.

**Syntax**

```sql
GET_CLIENT_LABEL()
```

**Privileges**

None

**Examples**

Return the current client connection label:

```sql
=> SELECT GET_CLIENT_LABEL();
   GET_CLIENT_LABEL
-----------------------
   data_load_application
(1 row)
```

**See Also**

[Setting a Client Connection Label](#)
**RESET_LOAD_BALANCE_POLICY**

Resets the counter each host in the cluster maintains, to track which host it will refer a client to when the native connection load balancing scheme is set to ROUNDROBIN. To reset the counter, run this function on all cluster nodes.

**Syntax**

RESET_LOAD_BALANCE_POLICY()

**Privileges**

Superuser

**Example**

```sql
=> SELECT RESET_LOAD_BALANCE_POLICY();

RESET_LOAD_BALANCE_POLICY

Successfully reset stateful client load balance policies: "roundrobin".
(1 row)
```

**SET_CLIENT_LABEL**

Assigns a label to a client connection for the current session. You can use this label to distinguish client connections.

Labels appear in the v_monitor.sessions table. However, they are not updated in Data Collector tables because the change occurs after Vertica makes the connection.

**Syntax**

SET_CLIENT_LABEL('Label-name')

**Parameters**

| Label-name | VARCHAR name assigned to the client connection label. |
Privileges
None

Examples
Assign label data_load_application to the current client connection:

```sql
=> SELECT SET_CLIENT_LABEL('data_load_application');
SET_CLIENT_LABEL
-----------------------
client_label set to data_load_application
(1 row)
```

See Also
Setting a Client Connection Label

SET_LOAD_BALANCE_POLICY

Sets how native connection load balancing chooses a host to handle a client connection.

Syntax

```
SET_LOAD_BALANCE_POLICY('policy')
```

Parameters

<table>
<thead>
<tr>
<th>policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policy</td>
<td>The name of the load balancing policy to use, one of the following:</td>
</tr>
<tr>
<td></td>
<td>- NONE (default): Disables native connection load balancing.</td>
</tr>
<tr>
<td></td>
<td>- ROUNDROBIN: Chooses the next host from a circular list of hosts in the cluster that are up—for example, in a three-node cluster, iterates over node1, node2, and node3, then wraps back to node1. Each host in the cluster maintains its own pointer to the next host in the circular list, rather than there being a single cluster-wide state.</td>
</tr>
<tr>
<td></td>
<td>- RANDOM: Randomly chooses a host from among all hosts in the cluster that are up.</td>
</tr>
</tbody>
</table>
Note: Even if the load balancing policy is set on the server to something other than NONE, clients must indicate they want their connections to be load balanced by setting a connection property.

Privileges
Superuser

Example

The following example demonstrates enabling native connection load balancing on the server by setting the load balancing scheme to ROUNDROBIN:

```sql
=> SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');
SET_LOAD_BALANCE_POLICY
--------------------------------------------------------------
Successfully changed the client initiator load balancing policy to: roundrobin
(1 row)
```

See Also

About Native Connection Load Balancing

Cluster Management Functions

This section contains functions that manage spread deployment on large, distributed database clusters.

**REALIGN_CONTROL_NODES**

Chooses control nodes (spread hosts) from all cluster nodes and assigns the rest of the nodes in the cluster to a control node. Calling this function respects existing fault groups, which you can view by querying the `V_CATALOG.CLUSTER_LAYOUT` system table. This view also lets you see the proposed new layout for nodes in the cluster.

**Syntax**

```sql
REALIGN_CONTROL_NODES()
```
Privileges
Superuser

Example
Choose control nodes from all cluster nodes and assign the remaining nodes to a control node:

```sql
=> SELECT REALIGN_CONTROL_NODES;
```

See Also
Defining and Realigning Control Nodes on an Existing Cluster

REBALANCE_CLUSTER

Rebalances the database cluster synchronously as a session foreground task. REBALANCE_CLUSTER returns only after the rebalance operation is complete. If the current session ends, the operation immediately aborts. To rebalance the cluster as a background task, call START_REBALANCE_CLUSTER.

On large cluster arrangements, you typically call REBALANCE_CLUSTER in a flow (see Defining and Realigning Control Nodes in the Administrator's Guide). After you change the number and distribution of control nodes (spread hosts), you must run REBALANCE_CLUSTER() for fault tolerance to be realized.

For detailed information about rebalancing tasks, see Rebalancing Data Across Nodes.

Tip: By default, before performing a rebalance, Vertica queries system tables to compute the size of all projections involved in the rebalance task. This query can add significant overhead to the rebalance operation. To disable this query, set projection configuration parameter `RebalanceQueryStorageContainers` to 0.

Syntax

REBALANCE_CLUSTER()

Privileges
Superuser
Example

```sql
=> SELECT REBALANCE_CLUSTER();
REBALANCE_CLUSTER
-----------------------
REBALANCED
(1 row)
```

**RELOAD_SPREAD**

Updates cluster changes to the catalog's spread configuration file. These changes include:

- New or realigned control nodes
- New spread hosts or fault group
- New or dropped cluster nodes

This function is often used in a multi-step process for large and elastic cluster arrangements. Calling it might require you to restart the database. You must then rebalance the cluster to realize fault tolerance. For details, see Defining and Realigning Control Nodes in the Administrator's Guide.

**Syntax**

`RELOAD_SPREAD( true )`

**Parameters**

<table>
<thead>
<tr>
<th><code>true</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Updates cluster changes related to control message responsibilities to the spread configuration file.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**Example**

Update the cluster with changes to control messaging:
=> SELECT reload_spread(true);
reload_spread
-------------
reloaded
(1 row)

See Also

REBALANCE_CLUSTER

SET_CONTROL_SET_SIZE

Specifies the number of cluster nodes on which to deploy control messaging (spread). You can call this function only on a running database.

To determine whether the current spread hosts and the control designations in the catalog match, query system table LARGE_CLUSTER_CONFIGURATION_STATUS

Note: This function is equivalent to:

install_vertica --large cluster integer

For details, see Installing a Large Cluster in the Administrator's Guide.

Syntax

SET_CONTROL_SET_SIZE(integer)

Parameters

| integer   | The number of cluster hosts from the database cluster on which spread runs. |

Privileges

Superuser

Example

Run spread on two cluster nodes:
See Also

Defining and Realigning Control Nodes on an Existing Cluster
Cluster Scaling Functions

This section contains functions that control how the cluster organizes data for rebalancing.

CANCEL_REBALANCE_CLUSTER

Stops any rebalance task that is currently in progress or is waiting to execute.

Syntax

CANCEL_REBALANCE_CLUSTER()

Privileges

Superuser

Example

```sql
=> SELECT CANCEL_REBALANCE_CLUSTER();
CANCEL_REBALANCE_CLUSTER
------------------------
CANCELED
(1 row)
```

See Also

- START_REBALANCE_CLUSTER
- REBALANCE_CLUSTER

DISABLE_ELASTIC_CLUSTER

Disables elastic cluster scaling, which prevents Vertica from bundling data into chunks that are easily transportable to other nodes when performing cluster resizing. The main reason to disable elastic clustering is if you find that the slightly unequal data distribution in your cluster caused by grouping data into discrete blocks results in performance issues.
Syntax

DISABLE_ELASTIC_CLUSTER()

Privileges

Superuser

Example

```sql
=> SELECT DISABLE_ELASTIC_CLUSTER();
DISABLE_ELASTIC_CLUSTER
------------------------
DISABLED
(1 row)
```

See Also

- [ENABLE_ELASTIC_CLUSTER](#)

**DISABLE_LOCAL_SEGMENTS**

Disables local data segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. See [Local Data Segmentation](#) in the Administrator's Guide for details.

Syntax

DISABLE_LOCAL_SEGMENTS()

Privileges

Superuser

Example

```sql
=> SELECT DISABLE_LOCAL_SEGMENTS();
DISABLE_LOCAL_SEGMENTS
------------------------
DISABLED
```
ENABLE_ELASTIC_CLUSTER

Enables elastic cluster scaling, which makes enlarging or reducing the size of your database cluster more efficient by segmenting a node's data into chunks that can be easily moved to other hosts.

Syntax

ENABLE_ELASTIC_CLUSTER()

Privileges

Superuser

Example

=> SELECT ENABLE_ELASTIC_CLUSTER();
 ENABLE_ELASTIC_CLUSTER
 ------------------------
 ENABLED
 (1 row)

See Also

- DISABLE_ELASTIC_CLUSTER

ENABLE_LOCAL_SEGMENTS

Enables local storage segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. See Local Data Segmentation in the Administrator's Guide for more information.

Syntax

ENABLE_LOCAL_SEGMENTS()
Privileges
Superuser

Example

```sql
=> SELECT ENABLE_LOCAL_SEGMENTS();
   ENABLE_LOCAL_SEGMENTS
--------------------------
   ENABLED
   (1 row)
```

SET_SCALING_FACTOR

Sets the scaling factor that determines the number of storage containers used when rebalancing the database and when using local data segmentation is enabled. See Cluster Scaling for details.

Syntax

```
SET_SCALING_FACTOR( factor )
```

Parameters

| factor | An integer value between 1 and 32. Vertica uses this value to calculate the number of storage containers each projection is broken into when rebalancing or when local data segmentation is enabled. |

Privileges
Superuser

Best Practices

The scaling factor determines the number of storage containers that Vertica uses to store each projection across the database during rebalancing when local segmentation is enabled. When setting the scaling factor, follow these guidelines:
The number of storage containers should be greater than or equal to the number of partitions multiplied by the number of local segments:

\[ \text{num-storage-containers} \geq (\text{num-partitions} \times \text{num-local-segments}) \]

Set the scaling factor high enough so rebalance can transfer local segments to satisfy the skew threshold, but small enough so the number of storage containers does not result in too many ROS containers, and cause ROS pushback. The maximum number of ROS containers is 1024.

Example

```sql
=> SELECT SET_SCALING_FACTOR(12);
SET_SCALING_FACTOR
------------------------
SET
(1 row)
```

**START_REBALANCE_CLUSTER**

Asynchronously rebalances the database cluster as a background task. This function returns immediately after the rebalancing operation is complete. Rebalancing persists until the operation is complete, even if you close the current session or the database shuts down. In the case of shutdown, rebalancing resumes after the cluster restarts. To stop the rebalance operation, call `CANCEL_REBALANCE_CLUSTER`.

For detailed information about rebalancing tasks, see [Rebalancing Data Across Nodes](#).

Syntax

```
START_REBALANCE_CLUSTER()
```

Privileges

Superuser

Example

```sql
=> SELECT START_REBALANCE_CLUSTER();
START_REBALANCE_CLUSTER
--------------------------
```
See Also

REBALANCE_CLUSTER

Communications Functions

This section contains communication functions specific to Vertica.

NOTIFY

Specifies the text message to include with a notification.

Syntax

```
NOTIFY ('message', 'notifier', 'target-topic')
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>The message to send to the end point.</td>
</tr>
<tr>
<td>notifier</td>
<td>The name of the notifier used to deliver the message.</td>
</tr>
<tr>
<td>target-topic</td>
<td>The name of the destination Kafka topic for the message.</td>
</tr>
</tbody>
</table>

Privileges

Superuser

Examples

Send a message to confirm that an ETL job is complete:

```
=> SELECT NOTIFY('ETL Done!', 'my_notifier', 'DB_activity_topic');
```
Constraint Management Functions

This section contains constraint management functions specific to Vertica.
See also SQL system table \texttt{V\_CATALOG\_TABLE\_CONSTRAINTS}.

\textbf{ANALYZE\_CONSTRAINTS}

Analyzes and reports on constraint violations within the specified scope

You can enable automatic enforcement of primary key, unique key, and check constraints when \texttt{INSERT}, \texttt{UPDATE}, \texttt{MERGE}, or \texttt{COPY} statements execute. Alternatively, you can use \texttt{ANALYZE\_CONSTRAINTS} to validate constraints after issuing these statements. Refer to \texttt{Enforcing Primary Key, Unique Key, and Check Constraints Automatically} for more information.

\texttt{ANALYZE\_CONSTRAINTS} performs a lock in the same way that \texttt{SELECT * FROM \textit{table}} holds a lock on \textit{table}. See \texttt{LOCKS} for additional information.

\textbf{Syntax}

\texttt{ANALYZE\_CONSTRAINTS (\'[[database.]schema.]table \'} [, \texttt{column},...]\texttt{\})}

\textbf{Parameters}

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{database}</td>
<td>Specifies a schema, by default public. If \textit{schema} is any schema other than public, you must supply the schema name. For example: \texttt{myschema.thisDbObject} If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>\textit{table}</td>
<td>Identifies the table to analyze. If you omit specifying a schema, Vertica uses the current schema search path. If set to an empty string, Vertica analyzes all tables in the current schema.</td>
</tr>
<tr>
<td>\textit{column}</td>
<td>The column in \textit{table} to analyze. You can specify multiple comma-delimited columns. Vertica narrows the scope of the analysis to the specified columns. If you omit specifying a column, Vertica analyzes all columns in \textit{table}.</td>
</tr>
</tbody>
</table>
Privileges

- SELECT privilege on table
- USAGE privilege on schema

Detecting Constraint Violations During a Load Process

Vertica checks for constraint violations when queries are run, not when data is loaded. To detect constraint violations as part of the load process, use a `COPY` statement with the `NO COMMIT` option. By loading data without committing it, you can run a post-load check of your data using the `ANALYZE_CONSTRAINTS` function. If the function finds constraint violations, you can roll back the load because you have not committed it.

If `ANALYZE_CONSTRAINTS` finds violations, such as when you insert a duplicate value into a primary key, you can correct errors using the following functions. Effects last until the end of the session only:

- `DISABLE_DUPLICATE_KEY_ERROR`
- `REENABLE_DUPLICATE_KEY_ERROR`

Important: If a check constraint SQL expression evaluates to an unknown for a given row because a column within the expression contains a null, the row passes the constraint condition.

Return Values

`ANALYZE_CONSTRAINTS` returns results in a structured set (see table below) that lists the schema name, table name, column name, constraint name, constraint type, and the column values that caused the violation.

If the result set is empty, then no constraint violations exist; for example:

```
> SELECT ANALYZE_CONSTRAINTS ('public.product_dimension', 'product_key');
```

```
<table>
<thead>
<tr>
<th>Schema Name</th>
<th>Table Name</th>
<th>Column Names</th>
<th>Constraint Name</th>
<th>Constraint Type</th>
<th>Column Values</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(0 rows)
```

The following result set shows a primary key violation, along with the value that caused the violation (`'10'`):

```
<table>
<thead>
<tr>
<th>Schema Name</th>
<th>Table Name</th>
<th>Column Names</th>
<th>Constraint Name</th>
<th>Constraint Type</th>
<th>Column Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>product_dimension</td>
<td>product_key</td>
<td>PRIMARY KEY</td>
<td></td>
<td>10</td>
</tr>
</tbody>
</table>
(1 row)
```
The result set columns are described in further detail in the following table:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema Name</td>
<td>VARCHAR</td>
<td>The name of the schema.</td>
</tr>
<tr>
<td>Table Name</td>
<td>VARCHAR</td>
<td>The name of the table, if specified.</td>
</tr>
<tr>
<td>Column Names</td>
<td>VARCHAR</td>
<td>A list of comma-delimited columns that contain constraints.</td>
</tr>
<tr>
<td>Constraint Name</td>
<td>VARCHAR</td>
<td>The given name of the primary key, foreign key, unique, check, or not null constraint, if specified.</td>
</tr>
<tr>
<td>Constraint Type</td>
<td>VARCHAR</td>
<td>Identified by one of the following strings:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PRIMARY KEY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FOREIGN KEY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UNIQUE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CHECK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• NOT NULL</td>
</tr>
<tr>
<td>Column Values</td>
<td>VARCHAR</td>
<td>Value of the constraint column, in the same order in which Column Names contains the value of that column in the violating row. When interpreted as SQL, the value of this column forms a list of values of the same type as the columns in Column Names; for example: ('1'), ('1', 'z')</td>
</tr>
</tbody>
</table>

Examples

See Detecting Constraint Violations with ANALYZE_CONSTRAINTS in the Administrator's Guide.
ANALYZE_CORRELATIONS

Analyzes the specified tables for pairs of columns that are strongly correlated. ANALYZE_CORRELATIONS stores the 20 pairs with the strongest correlation. ANALYZE_CORRELATIONS also analyzes statistics.

ANALYZE_CORRELATIONS analyzes only pairwise single-column correlations.

For example, state name and country name columns are strongly correlated because the city name usually, but perhaps not always, identifies the state name. The city of Conshohoken is uniquely associated with Pennsylvania, while the city of Boston exists in Georgia, Indiana, Kentucky, New York, Virginia, and Massachusetts. In this case, city name is strongly correlated with state name.

Behavior Type

Immutable

Syntax

ANALYZE_CORRELATIONS ( '[[[database.]schema.]table ]', [ 'recalculate' ] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| [database.]schema | Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:  

myschema.thisDbObject  

If you specify a database, it must be the current database. |
| table-name | Identifies the table to analyze. If you omit specifying a schema, Vertica uses the current schema search path. If set to an empty string, Vertica analyzes all tables in the current schema. |
| recalculate | Boolean that specifies whether to analyze correlated columns that were previously analyzed.  

**Note**: Column correlation analysis typically needs to be done only once. |
| Default: false | |

Vertica Documentation  
SQL Reference Manual
Privileges

One of the following:

- Superuser
- User with USAGE privilege on the design schema

Analysis Follow-Up

To take advantage of the correlations that ANALYZE_CORRELATIONS discovers, run Database Designer programmatically. Run DESIGNER_SET_ANALYZE_CORRELATIONS_MODE to specify that Database Designer consider existing column correlations. Be sure to specify that Database Designer not analyze statistics so it does not override existing statistics.

Example

In the following example, ANALYZE_CORRELATIONS analyzes column correlations for all tables in the public schema, even if they currently exist. The correlations that ANALYZE_CORRELATIONS finds are saved, so Database Designer can use them the next time it runs on the VMart database:

```sql
=> SELECT ANALYZE_CORRELATIONS ('public.*', 'true');
ANALYZE_CORRELATIONS
--------------------
0
(1 row)
```

**DISABLE_DUPLICATE_KEY_ERROR**

Disables error messaging when Vertica finds duplicate primary or unique key values at run time (for use with key constraints that are not automatically enabled). Queries execute as though no constraints are defined on the schema. Effects are session scoped.

Syntax

```
DISABLE_DUPLICATE_KEY_ERROR();
```

Privileges

Superuser
Examples

When you call DISABLE_DUPLICATE_KEY_ERROR, Vertica issues warnings letting you know that duplicate values will be ignored, and incorrect results are possible. DISABLE_DUPLICATE_KEY_ERROR is for use only for key constraints that are not automatically enabled.

```sql
=> select DISABLE_DUPLICATE_KEY_ERROR();
WARNING 3152: Duplicate values in columns marked as UNIQUE will now be ignored for the remainder of your session or until reenable_duplicate_key_error() is called
WARNING 3539: Incorrect results are possible. Please contact Vertica Support if unsure
disable_duplicate_key_error
Duplicate key error disabled
(1 row)
```

See Also

ANALYZE_CONSTRAINTS

LAST_INSERT_ID

Returns the last value of an AUTO_INCREMENT/IDENTITY column. If multiple sessions concurrently load the same table with an AUTO_INCREMENT/IDENTITY column, the function returns the last value generated for that column.

Note: This function works only with AUTO_INCREMENT/IDENTITY columns. It does not work with named sequences.

Behavior Type

Volatile

Syntax

LAST_INSERT_ID()

Privileges

- Table owner
- USAGE privileges on the table schema
Examples

See `AUTO_INCREMENT` and `IDENTITY Sequences` in the Administrator's Guide.

**REENABLE_DUPLICATE_KEY_ERROR**

Restores the default behavior of error reporting by reversing the effects of `DISABLE_DUPLICATE_KEY_ERROR`. Effects are session-scoped.

Syntax

```sql
REENABLE_DUPLICATE_KEY_ERROR();
```

Privileges

Superuser

Examples

```sql
=> SELECT REENABLE_DUPLICATE_KEY_ERROR();
REENABLE_DUPLICATE_KEY_ERROR
-----------------------------
Duplicate key error enabled
(1 row)
```

`ANALYZE_CONSTRAINTS`
Data Collector Functions

The Vertica Data Collector is a utility that extends system table functionality by providing a framework for recording events. It gathers and retains monitoring information about your database cluster and makes that information available in system tables, requiring few configuration parameter tweaks, and having negligible impact on performance.

Collected data is stored on disk in the DataCollector directory under the Vertica /catalog path. You can use the information the Data Collector retains to query the past state of system tables and extract aggregate information, as well as do the following:

- See what actions users have taken
- Locate performance bottlenecks
- Identify potential improvements to Vertica configuration

Data Collector works in conjunction with an advisor tool called Workload Analyzer, which intelligently monitors the performance of SQL queries and workloads and recommends tuning actions based on observations of the actual workload history.

By default, Data Collector is on and retains information for all sessions. If performance issues arise, a superuser can disable DC. See Data Collector Parameters and Enabling and Disabling Data Collector in the Administrator's Guide.

This section describes the Data Collection control functions.

Related Topics

V_MONITOR.DATA_COLLECTOR
Retaining Monitoring Information and Analyzing Workloads in the Administrator's Guide

CLEAR_DATA_COLLECTOR

Clears all memory and disk records on the Data Collector tables and functions and resets collection statistics in the system table DATA_COLLECTOR. A superuser can clear Data Collector data for all components or specify an individual component

After you clear the Data Collector log, the information is no longer available for querying.
Syntax

CLEAR_DATA_COLLECTOR( [ 'component' ] )

Parameters

| component | Clears memory and disk records for the specified component only. If you provide no argument, the function clears all Data Collector memory and disk records for all components. For the current list of component names, query the system table DATA_COLLECTOR. |

Privileges

Superuser

Examples

The following command clears memory and disk records for the ResourceAcquisitions component:

```sql
=> SELECT clear_data_collector('ResourceAcquisitions');
clear_data_collector
-----------------------
CLEAR
(1 row)
```

The following command clears data collection for all components on all nodes:

```sql
=> SELECT clear_data_collector();
clear_data_collector
-----------------------
CLEAR
(1 row)
```

See Also

- DATA_COLLECTOR
- Retaining Monitoring Information
DATA_COLLECTOR_HELP

Returns online usage instructions about the Data Collector, the DATA_COLLECTOR system table, and the Data Collector control functions.

Syntax

DATA_COLLECTOR_HELP()

Privileges

None

Returns

The DATA_COLLECTOR_HELP() function returns the following information:

```sql
=> SELECT DATA_COLLECTOR_HELP();

Usage Data Collector
The data collector retains history of important system activities.
This data can be used as a reference of what actions have been taken
by users, but it can also be used to locate performance bottlenecks,
or identify potential improvements to the Vertica configuration.
This data is queryable via Vertica system tables.

Access a list of data collector components, and some statistics, by running:
SELECT * FROM v_monitor.data_collector;

The amount of data retained by size and time can be controlled with several functions.
To just set the size amount:
set_data_collector_policy(<component>,
<memory retention (KB)>,
<disk retention (KB)>);

To set both the size and time amounts (the smaller one will dominate):
set_data_collector_policy(<component>,
<memory retention (KB)>,
<disk retention (KB)>,
<interval>);

To set just the time amount:
set_data_collector_time_policy(<component>,
<interval>);

To set the time amount for all tables:
set_data_collector_time_policy(<interval>);
```
The current retention policy for a component can be queried with:

\[\text{get\_data\_collector\_policy(}<\text{component}>);\]

Data on disk is kept in the "DataCollector" directory under the Vertica \catalog path. This directory also contains instructions on how to load the monitoring data into another Vertica database.

To move the data collector logs and instructions to other storage locations, create labeled storage locations using \text{add\_location} and then use:

\[\text{set\_data\_collector\_storage\_location(}<\text{storage\_label}>);\]

Additional commands can be used to configure the data collection logs.

The log can be cleared with:

\[\text{clear\_data\_collector(}[<\text{optional\ component}>]);\]

The log can be synchronized with the disk storage using:

\[\text{flush\_data\_collector(}[<\text{optional\ component}>]);\]

See Also

- DATA_COLLECTOR
- TUNING_RECOMMENDATIONS
- Analyzing Workloads
- Retaining Monitoring Information

**FLUSH_DATA_COLLECTOR**

Waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the log with the disk storage. A superuser can flush Data Collector information for an individual component or for all components.

**Syntax**

\[\text{FLUSH\_DATA\_COLLECTOR(}[\ 'component'\ ] )\]

**Parameters**

| component | Flushes the specified component. If you provide no argument, the function flushes the Data Collector in full. For the current list of component names, query the V_MONITOR.DATA_|
COLLECTOR system table.

Privileges
Superuser

Examples

The following command flushes the Data Collector for the ResourceAcquisitions component:

```sql
=> SELECT flush_data_collector('ResourceAcquisitions');
flush_data_collector
------------------
FLUSH
(1 row)
```

The following command flushes data collection for all components:

```sql
=> SELECT flush_data_collector();
flush_data_collector
------------------
FLUSH
(1 row)
```

See Also

- DATA_COLLECTOR
- Retaining Monitoring Information

GET_DATA_COLLECTOR_POLICY

Retrieves a brief statement about the retention policy for the specified component.

Syntax

```
GET_DATA_COLLECTOR_POLICY( 'component' )
```

Parameters

| component | Returns the retention policy for the specified component. |
For a current list of component names, query the V_MONITOR.DATA_COLLECTOR system table

Privileges

None

Example

The following query returns the history of all resource acquisitions by specifying the ResourceAcquisitions component:

```sql
=> SELECT get_data_collector_policy('ResourceAcquisitions');
get_data_collector_policy
-------------------------------------
1000KB kept in memory, 10000KB kept on disk.
(1 row)
```

See Also

- DATA_COLLECTOR
- Retaining Monitoring Information

SET_DATA_COLLECTOR_POLICY

Sets a size restraint (memory and disk space in kilobytes) for the specified Data Collector table on all nodes. If nodes are down, the failed nodes receive the setting when they rejoin the cluster.

You can use this function to set a size restraint only, or you can include the optional `interval` argument to set disk capacity for both size and time in a single command.

If you specify `interval`, Vertica enforces the setting that is exceeded first (size or time). Before you include a time restraint, verify that the disk size capacity is sufficiently large.

If you want to specify just a time restraint, or you want to turn off a time restraint you set using this function, see `SET_DATA_COLLECTOR_TIME_POLICY()`.

Syntax

```sql
SET_DATA_COLLECTOR_POLICY('component', 'memoryKB', 'diskKB' [, 'interval'] )
```
Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>component</code></td>
<td>Configures the retention policy for the specified component.</td>
</tr>
<tr>
<td><code>memoryKB</code></td>
<td>Specifies the memory size to retain in kilobytes.</td>
</tr>
<tr>
<td><code>diskKB</code></td>
<td>Specifies the disk size in kilobytes.</td>
</tr>
<tr>
<td><code>interval</code></td>
<td>[Default off] Takes an optional <code>interval</code> argument to specify how long to retain the specified component on disk. To disable a time restraint, set <code>interval</code> to -1.</td>
</tr>
</tbody>
</table>

Note: Any negative input turns off the time restraint

Privileges

Superuser

Notes

- Before you change a retention policy, view its current setting by calling the `GET_DATA_COLLECTOR_POLICY()` function.

- If you don't know the name of a component, query the `V_MONITOR.DATA_COLLECTOR` system table for a list; for example:

  ```
  => SELECT DISTINCT component, description FROM data_collector
  ORDER BY 1 ASC;
  ```

Examples

The following command returns the retention policy for the `ResourceAcquisitions` component:

```
=> SELECT get_data_collector_policy('ResourceAcquisitions');
get_data_collector_policy
----------------------------------------
1000KB kept in memory, 10000KB kept on disk.
(1 row)
```
This command changes the memory and disk setting for ResourceAcquisitions from its current setting of 1,000 KB memory and 10,000 KB disk space to 1500 KB and 25000 KB, respectively:

```sql
=> SELECT set_data_collector_policy('ResourceAcquisitions', '1500', '25000');
set_data_collector_policy
------------------------
SET
(1 row)
```

This command sets the RequestsIssued component to 1500 KB memory and 11000 KB on disk, and includes a 3-minute time restraint:

```sql
=> SELECT set_data_collector_policy('RequestsIssued', '1500', '11000', '3 minutes '::interval);
set_data_collector_policy
------------------------
SET
(1 row)
```

The following command disables the 3-minute retention policy for the RequestsIssued component, using SET_DATA_COLLECTOR_TIME_POLICY:

```sql
=> SELECT set_data_collector_time_policy('RequestsIssued', '-1');
set_data_collector_time_policy
------------------------
SET
(1 row)
```

See Also

- GET_DATA_COLLECTOR_POLICY
- SET_DATA_COLLECTOR_TIME_POLICY()
- DATA_COLLECTOR
- Retaining Monitoring Information in the Administrator's Guide

**SET_DATA_COLLECTOR_TIME_POLICY**

Sets a time capacity for individual Data Collector tables on all nodes. If nodes are down, the failed nodes receive the setting when they rejoin the cluster.

If you specify *interval*, Vertica enforces the setting that is exceeded first (size or time). Before you include a time restraint, verify that the disk size capacity is sufficiently large.

If you want to configure both time and size restraints at the same time, see SET_DATA_COLLECTOR_POLICY.
Syntax

```
SET_DATA_COLLECTOR_TIME_POLICY( ['component'], 'interval' )
```

Parameters

| component | [Optional] Configures the time retention policy for the specified component. If you omit the component argument, Vertica sets the specified time capacity for all Data Collector tables. |
| interval | Specifies the time restraint on disk using an INTERVAL type. To disable a time restraint, set interval to -1. |

Note: Any negative input turns off the time restraint

Privileges

Superuser

Usage Considerations

- Before you change a retention policy, view its current setting by calling the `GET_DATA_COLLECTOR_POLICY` function.

- If you don't know the name of a component, query the V_MONITOR.DATA_COLLECTOR system table for a list. For example:

  ```
  => SELECT DISTINCT component, description FROM data_collector
  ORDER BY 1 ASC;
  ```

Setting the Time Interval for System Tables

You can also use the `interval` argument to query system tables the same way you query Data Collector tables; for example:

```
set_data_collector_time_policy('<system-table>', '<interval>');
```

To illustrate, the following command in the left column is equivalent to running the series of commands on the right:
Run one command | Instead of a series of commands
-----------------|--------------------------------------
SELECT set_data_collector_time_policy ('v_monitor.query_requests', '3 minutes'::interval); | SELECT set_data_collector_time_policy ('RequestsIssued', '3 minutes'::interval);

SELECT set_data_collector_time_policy ('RequestsCompleted', '3 minutes'::interval);

SELECT set_data_collector_time_policy ('RequestsCompleted', '3 minutes'::interval);

SELECT set_data_collector_time_policy ('RequestsCompleted', '3 minutes'::interval);

The **SET_DATA_COLLECTOR_TIME_POLICY** function updates the time capacity for all Data Collector tables in the V_MONITOR.QUERY_REQUESTS view. The new setting overrides any previous settings for every Data Collector table in that view.

Examples

The following command configures the Backups component to be retained on disk for 1 day:

```sql
=> SELECT set_data_collector_time_policy('Backups', '1 day'::interval);
set_data_collector_time_policy
----------------------------------
 SET
(1 row)
```

This command disables the 1-day restraint for the Backups component:

```sql
=> SELECT set_data_collector_time_policy('Backups', '-1');
set_data_collector_time_policy
--------------------------
 SET
(1 row)
```

This command sets a 30-minute time capacity for all Data Collector tables in a single command:

```sql
=> SELECT set_data_collector_time_policy('30 minutes'::interval);
set_data_collector_time_policy
--------------------------
 SET
(1 row)
```

To view current retention policy settings for each Data Collector table, call the **GET_DATA_COLLECTION_POLICY( )** function. In the next example, the time restraint is included.
=> SELECT get_data_collector_policy('RequestsIssued');
                   get_data_collector_policy
-----------------------------------------------
2000KB kept in memory, 50000KB kept on disk. 2 years 3 days 15:08 hours kept on disk.
(1 row)

If the time policy setting is disabled, the output of GET_DATA_COLLECTION_POLICY() returns "Time based retention disabled."

2000KB kept in memory, 50000KB kept on disk. Time based retention disabled.

Database Designer Functions

Database Designer functions perform the following operations, generally performed in the following order:

1. **Create a design.**
2. **Set design properties.**
3. **Populate a design.**
4. **Create design and deployment scripts.**
5. **Get design data.**
6. **Clean up.**

For detailed information, see *Workflow for Running Database Designer Programmatically*. For information on required privileges, see *Privileges for Running Database Designer Functions* in the Administrator's Guide.

Create a design

**DESIGNER_CREATE дизайн** directs Database Designer to create a design.

Set design properties

The following functions let you specify properties of a particular design:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESIGNER_SET_DESIGN_TYPE</td>
<td>Specifies whether the design is comprehensive or incremental.</td>
</tr>
<tr>
<td>DESIGNER_DESIGN_PROJECTION_ENCODINGS</td>
<td>Analyzes encoding in the specified projections and creates a script that implements encoding recommendations.</td>
</tr>
<tr>
<td>DESIGNER_SET_DESIGN_KSAFETY</td>
<td>Sets the K-safety value for a comprehensive design.</td>
</tr>
<tr>
<td>DESIGNER_SET_OPTIMIZATION_OBJECTIVE</td>
<td>Specifies whether the design optimizes for query or load performance.</td>
</tr>
</tbody>
</table>
**DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS**

Enables inclusion of unsegmented projections in the design.

**DESIGNER_SET_ANALYZE_CORRELATIONS_MODE**

Determines how the design handles column correlations.

---

## Populate a design

The following functions let you add tables and queries to your Database Designer design:

<table>
<thead>
<tr>
<th><strong>FUNCTION</strong></th>
<th><strong>DESCRIPTION</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DESIGNER_ADDDESIGN_TABLES</strong></td>
<td>Adds the specified tables to a design.</td>
</tr>
<tr>
<td><strong>DESIGNER_ADDDESIGN_QUERY</strong></td>
<td>Adds queries to the design and weights them.</td>
</tr>
<tr>
<td><strong>DESIGNER_ADDDESIGN_QUERIES</strong></td>
<td></td>
</tr>
<tr>
<td><strong>DESIGNER_ADDDESIGN_QUERIES_FROMRESULTS</strong></td>
<td></td>
</tr>
</tbody>
</table>

---

## Create design and deployment scripts

The following functions populate the Database Designer workspace and create design and deployment scripts. You can also analyze statistics, deploy the design automatically, and drop the workspace after the deployment:

<table>
<thead>
<tr>
<th><strong>FUNCTION</strong></th>
<th><strong>DESCRIPTION</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DESIGNER_RUN_POPULATEDESIGN_AND_DEPLOY</strong></td>
<td>Populates the design and creates design and deployment scripts.</td>
</tr>
<tr>
<td><strong>DESIGNER_WAITFORDESIGN</strong></td>
<td>Waits for a currently running design to complete.</td>
</tr>
</tbody>
</table>

---

## Reset a design

**DESIGNER_RESETDESIGN** discards all the run-specific information of the previous Database Designer build or deployment of the specified design but retains its configuration.

## Get design data

The following functions display information about projections and scripts that the Database Designer created:
DESIGNER_OUTPUT_ALL Design_PROJECTIONS Sends to standard output DDL statements that define design projections.

DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT Sends to standard output a design's deployment script.

Clean up

The following functions cancel any running Database Designer operation or drop a Database Designer design and all its contents:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESIGNER_CANCEL_POPULATE_DESIGN</td>
<td>Cancels population or deployment operation for the specified design if it is currently running.</td>
</tr>
<tr>
<td>DESIGNER_DROP_DESIGN</td>
<td>Removes the schema associated with the specified design and all its contents.</td>
</tr>
<tr>
<td>DESIGNER_DROP_ALL_DESIGNS</td>
<td>Removes all Database Designer-related schemas associated with the current user.</td>
</tr>
</tbody>
</table>

**DESIGNER_ADD_DESIGN_QUERIES**

Reads and evaluates queries from an input file, and adds the queries that it accepts to the specified design. All accepted queries are assigned a weight of 1 (see DESIGNER_ADD_DESIGN_QUERIES).

The following requirements apply:

- All queried tables must previously be added to the design with DESIGNER_ADD_DESIGN_TABLES.
- If the design type is incremental, the Database Designer reads only the first 100 queries in the input file, and ignores all queries beyond that number.

All accepted queries are added to the system table DESIGN_QUERIES.

Behavior Type

Immutable
Syntax

DESIGNER_ADDDESIGN_QUERIES ( 'design-name', 'input-file' [, 'return-results'] )

Parameters

<table>
<thead>
<tr>
<th>design-name</th>
<th>Name of the target design.</th>
</tr>
</thead>
<tbody>
<tr>
<td>input-file</td>
<td>Absolute path to the queries file.</td>
</tr>
<tr>
<td>return-results</td>
<td>Boolean, optionally specifies whether to return results of the add operation to standard output. If set to true, Database Designer returns the following results:</td>
</tr>
</tbody>
</table>

- Number of accepted queries
- Number of queries referencing non-design tables
- Number of unsupported queries
- Number of illegal queries

Privileges

Read access to the input file, and one of the following:

- Superuser
- Design creator with all privileges that pertain to the input file queries (see Privileges Required for Common Database Operations).

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
  - External or system tables only
  - Local temporary or other non-design tables
DELETE or UPDATE query has one or more subqueries.

INSERT query does not include a SELECT clause.

Database Designer cannot optimize the query.

Examples

The following example adds queries from vmart_queries.sql to the VMART_DESIGN design. This file contains nine queries. The statement includes a third argument of true, so Database Designer returns results of the add operation:

```sql
=> SELECT DESIGNER_ADD DESIGN QUERIES ('VMART_DESIGN', '/tmp/examples/vmart_queries.sql', 'true');
...
DESIGNER_ADD DESIGN QUERIES
---------------------------------------------
Number of accepted queries = 9
Number of queries referencing non-design tables = 0
Number of unsupported queries = 0
Number of illegal queries = 0
(1 row)
```

See Also

Running Database Designer Programmatically

**DESIGNER_ADD DESIGN QUERIES_FROM_RESULTS**

Executes the specified query and evaluates results in the following columns:

- **QUERY_TEXT** (required): Text of potential design queries.

- **QUERY_WEIGHT** (optional): The weight assigned to each query that indicates its importance relative to other queries, a real number >0 and ≤ 1. Database Designer uses this setting when creating the design to prioritize the query. If DESIGNER_ADD DESIGN QUERIES_FROM_RESULTS returns any results that omit this value, Database Designer sets their weight to 1.

After evaluating the queries in QUERY_TEXT, DESIGNER_ADD DESIGN QUERIES_FROM_RESULTS adds all accepted queries to the design. An unlimited number of queries can be added to the design.

Before you add queries to a design, you must add the queried tables with DESIGNER_ADD DESIGN TABLES.
Behavior Type
Immutable

Syntax

DESIGNER_ADD_DESIGN QUERIES_FROM_RESULTS ( 'design-name', 'query' )

Parameters

<table>
<thead>
<tr>
<th>design-name</th>
<th>Name of the target design.</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>A valid SQL query whose results contain columns named QUERY_TEXT and, optionally, QUERY_WEIGHT.</td>
</tr>
</tbody>
</table>

Privileges

- Superuser
- Design creator with all privileges that pertain to the specified query and all queries that this function returns (see Privileges Required for Common Database Operations).

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
  - External or system tables only
  - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.
Example

The following example queries the system table `QUERY_REQUESTS` for all long-running queries (> 1 million microseconds) and adds them to the VMART_DESIGN design. The query returns no information on query weights, so all queries are assigned a weight of 1:

```sql
=> SELECT DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS ('VMART_DESIGN',
   'SELECT request as query_text FROM query_requests where request_duration_ms > 1000000 AND request_type = "QUERY";');
```

See Also

Running Database Designer Programmatically

**DESIGNER_ADD_DESIGN_QUERY**

Reads and parses the specified query, and if accepted, adds it to the design. Before you add queries to a design, you must add the queried tables with `DESIGNER_ADD_DESIGN_TABLES`. All accepted queries are added to the system table `DESIGN_QUERIES`.

**Behavior Type**

Immutable

**Syntax**

`DESIGNER_ADD_DESIGN_QUERY ( 'design-name', 'design-query' [, query-weight] )`

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>design-name</code></td>
<td>Name of the target design.</td>
</tr>
<tr>
<td><code>design-query</code></td>
<td>Executable SQL query.</td>
</tr>
<tr>
<td><code>query-weight</code></td>
<td>Optionally assigns a weight to each query that indicates its importance</td>
</tr>
<tr>
<td></td>
<td>relative to other queries, a real number &gt;0 and ≤ 1. Database Designer</td>
</tr>
<tr>
<td></td>
<td>uses this setting to prioritize queries in the design.</td>
</tr>
<tr>
<td></td>
<td>If you omit this parameter, Database Designer assigns a weight of 1.</td>
</tr>
</tbody>
</table>
Privileges

One of the following:

- Superuser
- Design creator with all privileges that pertain to the specified query (see Privileges Required for Common Database Operations).

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
  - External or system tables only
  - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example adds the specified query to the VMART_DESIGN design and assigns that query a weight of 0.5:

```sql
-> SELECT DESIGNER_ADD DESIGN_QUERY (  
   'VMART_DESIGN',  
   'SELECT customer_name, customer_type FROM customer_dimension ORDER BY customer_name ASC;', 0.5  
);
```

See Also

Running Database Designer Programmatically
DESIGNER_ADD_DESIGN_TABLES

Adds the specified tables to a design. You must run DESIGNER_ADD_DESIGN_TABLES before adding design queries to the design. If no tables are added to the design, Vertica does not accept design queries.

Behavior Type

Immutable

Syntax

DESIGNER_ADD_DESIGN_TABLES ( 'design-name', '[ table-spec[, ...] ]' [, 'analyze-statistics' ] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>design-name</td>
<td>Name of the Database Designer design.</td>
</tr>
<tr>
<td>table-spec[, ...]</td>
<td>One or more comma-delimited arguments that specify which tables to add to the design, where each table-spec argument can specify tables as follows:</td>
</tr>
<tr>
<td></td>
<td>• [schema.]table</td>
</tr>
<tr>
<td></td>
<td>Add table to the design.</td>
</tr>
<tr>
<td></td>
<td>• schema.*</td>
</tr>
<tr>
<td></td>
<td>Add all tables in schema.</td>
</tr>
<tr>
<td>analyze-statistics</td>
<td>Boolean that optionally specifies whether to run ANALYZE_STATISTICS after adding the specified tables to the design, by default set to False.</td>
</tr>
<tr>
<td></td>
<td>Accurate statistics help Database Designer optimize compression and query performance. Updating statistics takes time and resources.</td>
</tr>
</tbody>
</table>
Privileges

One of the following:

- Superuser
- DBDUSER who created the design, has USAGE privilege on the design table schema, and owns the design table.

Examples

The following example adds to design VMART_DESIGN all tables from schemas online_sales and store, and analyzes statistics for those tables:

```sql
=> SELECT DESIGNER_ADD DESIGN TABLES ('VMART DESIGN', 'online_sales.*', 'store.*', 'true');
DESIGNER_ADD DESIGN TABLES
-----------------------------
  7

(1 row)
```

See Also

Running Database Designer Programmatically

**DESIGNERCANCEL_POPULATEDESIGN**

Cancels population or deployment operation for the specified design if it is currently running. When you cancel a deployment, the Database Designer cancels the projection refresh operation. It does not roll back projections that it already deployed and refreshed.

Behavior Type

Immutable

Syntax

```
DESIGNERCANCEL_POPULATEDESIGN ( 'design-name' )
```

Parameters

| design-name | Name of the design operation to cancel. |
Privileges

One of the following:

- Superuser
- Design creator

Examples

The following example cancels a currently running design for VMART_DESIGN and then drops the design:

```sql
=> SELECT DESIGNER_CANCEL_POPULATE_DESIGN ('VMART_DESIGN');
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN', 'true');
```

See Also

Running Database Designer Programmatically

**DESIGNER_CREATE_DESIGN**

Creates a design with the specified name.

Note: Be sure to back up the current design using the function `EXPORT_CATALOG` before running the Database Designer functions on an existing schema. You must explicitly back up the existing design when using Database Designer programmatically.

If any of the following V_MONITOR tables do not already exist from previous designs, DESIGNER_CREATE_DESIGN creates them:

- **DESIGNS**
- **DESIGN_TABLES**
- **DEPLOYMENT_PROJECTIONS**
- **DEPLOYMENT_PROJECTION_STATEMENTS**
- **DESIGN QUERIES**
Behavior Type
Immutable

Syntax

DESIGNER_CREATE_DESIGN ( 'design-name' )

Parameters

| design-name | Name of the design to create, can contain only alphanumeric and underscore (_) characters. Two users cannot have designs with the same name at the same time. |

Privileges
One of the following:

- Superuser
- DBDUSER

Examples
The following example creates the design VMART_DESIGN:

```sql
=> SELECT DESIGNER_CREATE_DESIGN('VMART_DESIGN');
DESIGNER_CREATE_DESIGN
-----------------------
0
(1 row)
```

See Also

Running Database Designer Programatically
**DESIGNER_DESIGN_PROJECTION_ENCODINGS**

Analyzes encoding in the specified projections, creates a script to implement encoding recommendations, and optionally deploys the recommendations.

**Behavior Type**

Immutable

**Syntax**

```sql
DESIGNER_DESIGN_PROJECTION_ENCODINGS ( '[ proj-spec[, ... ] ]', 'destination' [, 'deploy'] [, 'reanalyze-encodings'] )
```

**Parameters**

<table>
<thead>
<tr>
<th><code>proj-spec[, ...]</code></th>
<th>One or more comma-delimited projections to add to the design. Each projection can be specified in one of the following ways:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• [[schema.]table.]projection</td>
</tr>
<tr>
<td></td>
<td>Specifies to analyze projection.</td>
</tr>
<tr>
<td></td>
<td>• schema.*</td>
</tr>
<tr>
<td></td>
<td>Specifies to analyze all projections in the named schema.</td>
</tr>
<tr>
<td></td>
<td>• [schema.]table</td>
</tr>
<tr>
<td></td>
<td>Specifies to analyze all projections of the named table.</td>
</tr>
<tr>
<td></td>
<td>If set to an empty string, Vertica analyzes all projections in the database to which the user has access.</td>
</tr>
<tr>
<td></td>
<td>For example, the following statement specifies to analyze all projections in schema private, and send the results to the file encodings.sql:</td>
</tr>
<tr>
<td></td>
<td>=&gt; SELECT DESIGNER_DESIGN_PROJECTION_ENCODINGS ('mydb.private.*','encodings.sql');</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><code>destination</code></th>
<th>Specifies where to send output, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• An empty string ('') writes the script to standard output.</td>
</tr>
</tbody>
</table>
The path and name of a SQL output file. If you specify a file that does not exist, the function creates one. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.

| **deploy** | Boolean that optionally specifies whether to deploy encoding changes, by default set to false. |
| **reanalyze-encodings** | Boolean that optionally specifies whether DESIGNER_DESIGN_PROJECTION_ENCODINGS analyzes encodings in a projection where all columns are already encoded: 
- false (default): Analyzes no columns and generates no recommendations if all columns are encoded.
- true: Ignores existing encodings and generates recommendations. |

Privileges

The following requirements pertain to the target projections:

- OWNER of all projections to analyze
- USAGE privilege on the schema for the specified projections

Examples

The following example requests that Database Designer analyze encodings of all projections in the schema online_sales, as follows:

- The second parameter destination is set to an empty string, so the script is sent to standard output (shown truncated below).
- The last two parameters deploy and reanalyze-encodings are omitted, so Database Designer does not execute the script or reanalyze existing encodings:

```sql
=> SELECT DESIGNER_DESIGN_PROJECTION_ENCODINGS ('online_sales.*','');
CREATE PROJECTION online_page_dimension_DBD_1_seg_EncodingDesign /*+Createtype(D)*/
(
  online_page_key ENCODING COMMONDELTA_COMP,
  start_date ENCODING DELTAVAL,
```
end_date ENCODING DELTAVAL,
page_number ENCODING DELTAVAL,
page_description,
page_type
)
AS
SELECT online_page_dimension.online_page_key,
    online_page_dimension.start_date,
    online_page_dimension.end_date,
    online_page_dimension.page_number,
    online_page_dimension.page_description,
    online_page_dimension.page_type
FROM online_sales.online_page_dimension
ORDER BY online_page_dimension.online_page_key
SEGMENTED BY hash(online_page_dimension.online_page_key) ALL NODES KSAFE 1;

select refresh('online_sales.online_page_dimension');
select make_ahm_now();

DROP PROJECTION online_sales.online_page_dimension CASCADE;

ALTER PROJECTION online_sales.online_page_dimension_DBD_1_seg_EncodingDesign RENAME TO online_page_dimension;
...
(1 row)

See Also

Running Database Designer Programmatically

DESIGNER_DROP_ALL_DESIGNS

Removes all Database Designer-related schemas associated with the current user. Use this function to remove database objects after one or more Database Designer sessions complete execution.

Behavior Type

Immutable

Syntax

DESIGNER_DROP_ALL_DESIGNS()
Parameters

None.

Privileges

One of the following:

- Superuser: Drops all designs.
- Design creator: Drops all designs created by this user.

Example

The following example removes all schema and their contents associated with the current user. DESIGNER_DROP_ALL DESIGNS returns the number of designs dropped:

```sql
=> SELECT DESIGNER_DROP_ALL_DESIGNS();
DESIGNER_DROP_ALL_DESIGNS
-----------------------
   2
(1 row)
```

See Also

- DESIGNER_CANCEL_POPULATE_DESIGN
- DESIGNER_DROP_DESIGN

DESIGNER_DROP_DESIGN

Removes the schema associated with the specified design and all its contents. Use DESIGNER_DROP_DESIGN after a Database Designer design or deployment completes successfully. You must also use it to drop a design before creating another one under the same name.

To drop all designs that you created, use DESIGNER_DROP_ALL_DESIGNS.

Behavior Type

Immutable
Syntax

```
DESIGNER_DROP_DESIGN ( 'design-name' [, force-drop ] )
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>design-name</code></td>
<td>Name of the design to drop.</td>
</tr>
<tr>
<td><code>force-drop</code></td>
<td>Boolean that overrides any dependencies that otherwise prevent Vertica from executing this function—for example, the design is in use or is currently being deployed. If you omit this parameter, Vertica sets it to false.</td>
</tr>
</tbody>
</table>

Privileges

One of the following:

- Superuser
- Design creator

Example

The following example deletes the Database Designer design VMART_DESIGN and all its contents:

```sql
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN');
```

See Also

- Running Database Designer Programmatically

**DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS**

Displays the DDL statements that define the design projections to standard output.

Behavior Type

Immutable
Syntax

DESIGNER_OUTPUT_ALL DESIGN PROJECTIONS ( 'design-name' )

Parameters

| design-name | Name of the target design. |

Privileges

One of the following:

- Superuser
- DBDUSER role

Examples

The following example returns the design projection DDL statements for vmart_design:

```sql
=> SELECT DESIGNER_OUTPUT_ALL DESIGN PROJECTIONS('vmart_design');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/
( customer_key ENCODING DELTAVAL,
  customer_type ENCODING AUTO,
  customer_name ENCODING AUTO,
  customer_gender ENCODING REL,
  title ENCODING AUTO,
  household_id ENCODING DELTAVAL,
  customer_address ENCODING AUTO,
  customer_city ENCODING AUTO,
  customer_state ENCODING AUTO,
  customer_region ENCODING AUTO,
  marital_status ENCODING AUTO,
  customer_age ENCODING DELTAVAL,
  number_of_children ENCODING BLOCKDICT_COMP,
  annual_income ENCODING DELTARANGE_COMP,
  occupation ENCODING AUTO,
  largest_bill_amount ENCODING DELTAVAL,
  store_membership_card ENCODING BLOCKDICT_COMP,
  customer_since ENCODING DELTAVAL,
  deal_stage ENCODING AUTO,
  deal_size ENCODING DELTARANGE_COMP,
  last_deal_update ENCODING DELTARANGE_COMP )
AS
SELECT customer_key,
  customer_type,
  customer_name,
```
See Also
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT

DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT

Displays the deployment script for the specified design to standard output. If the design is already deployed, Vertica ignores this function.

To output only the CREATE PROJECTION commands in a design script, use DESIGNER_OUTPUT_ALL DESIGN PROJECTIONS.

Behavior Type
Immutable

Syntax
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT ( 'design-name' )
Parameters

| design-name | Name of the target design. |

Privileges

One of the following:

- Superuser
- Design creator

Examples

The following example displays the deployment script for VMART_DESIGN:

```sql
=> SELECT DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT('VMART_DESIGN');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)/
...
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)/
...
select refresh('public.customer_dimension,
    public.product_dimension,
    public.promotion.dimension,
    public.date_dimension');
select make_ahm_now();
DROP PROJECTION public.customer_dimension_super CASCADE;
DROP PROJECTION public.product_dimension_super CASCADE;
...
```

See Also

DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS

DESIGNER_RESET_DESIGN

Discards all run-specific information of the previous Database Designer build or deployment of the specified design but keeps its configuration. You can make changes to the design as needed, for example, by changing parameters or adding additional tables and/or queries, before running the design again.

Behavior Type

Immutable
**Syntax**

```
DESIGNER_RESET_DESIGN ( 'design-name' )
```

**Parameters**

| design-name | Name of the design to reset. |

**Privileges**

- Superuser
- Design creator

**Example**

The following example resets the Database Designer design VMART_DESIGN:

```
=> SELECT DESIGNER_RESET_DESIGN ('VMART_DESIGN');
```

**DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY**

Populates the design and creates the design and deployment scripts. DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY can also analyze statistics, deploy the design, and drop the workspace after the deployment.

**Caution:** DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY does not create a backup copy of the current design before deploying the new design. Before running this function, back up the existing schema design with EXPORT_CATALOG.

**Behavior Type**

Immutable

**Syntax**

```
DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY ( 'design-name',
                                             'output-design-file',
                                             'output-deployment-file')
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>design-name</td>
<td>Name of the design to populate and deploy.</td>
</tr>
<tr>
<td>output-design-file</td>
<td>Specifies where to save the file with DDL statements to create design projections, where output-design-file is an absolute path to the node where the session is connected.</td>
</tr>
<tr>
<td>output-deployment-file</td>
<td>Specifies where to save the file that contains the deployment script, where output-deployment-file is an absolute path to the node where the session is connected.</td>
</tr>
<tr>
<td>analyze-statistics</td>
<td>Specifies whether to collect or refresh statistics for the tables before populating the design. If set to true, Vertica Invokes ANALYZE_STATISTICS. Accurate statistics help Database Designer optimize compression and query performance. However, updating statistics requires time and resources. Default: false</td>
</tr>
<tr>
<td>deploy</td>
<td>Specifies whether to deploy the Database Designer design using the deployment script created by this function.                                                                                               Default: true</td>
</tr>
<tr>
<td>drop-design-workspace</td>
<td>Specifies whether to drop the design workspace after the design is deployed.                                                                                                                                  Default: true</td>
</tr>
<tr>
<td>continue-after-error</td>
<td>Specifies whether DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY continues to run after an error occurs. By default, an error causes this function to terminate.                                                     Default: false</td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.0.x)
Privileges

- Superuser
- Design creator with WRITE privileges on storage locations of design and deployment scripts; otherwise DESIGNER_RUN_POPULATEDESIGN_AND_DEPLOY cannot save the design and deployment scripts.

Requirements

Before calling this function, you must:

- Create a design, a logical schema with tables.
- Associate tables with the design.
- Load queries to the design.
- Set design properties (K-safety level, mode, and policy).

Examples

The following example creates projections for and deploys the VMART_DESIGN design, and analyzes statistics about the design tables.

```sql
=> SELECT DESIGNER_RUN_POPULATEDESIGN_AND_DEPLOY (
    'VMART_DESIGN',
    '/tmp/examples/vmart_design_files/vmart_design_DDL',
    '/tmp/examples/vmart_design_files/vmart_design_deployment_scripts',
    'true',
    'false',
    'false',
    'false'
);```

See Also

Running Database Designer Programatically

DESIGNER_SET_ANALYZE_CORRELATIONS_MODE

Specifies how Database Designer handles column correlations in a design. A design's mode determines whether Database Designer analyzes or re-analyzes existing column correlations.
and considers them in the design that it creates.

The following recommendations apply:

- You typically need to analyze column correlations only once.
- Analyze correlations when the table row count is at least \texttt{DBDCorrelationSampleRowCount}—by default, 4000.

\begin{Verbatim}
\textbf{Important:} Database Designer analyzes column correlations for a design only if you enable analysis with this function.
\end{Verbatim}

\textbf{Behavior Type}

Immutable

\textbf{Syntax}

\texttt{DESIGNER\_SET\_ANALYZE\_CORRELATIONS\_MODE ( \texttt{design-name}, mode )}

\textbf{Parameters}

<table>
<thead>
<tr>
<th>\textit{design-name}</th>
<th>Name of the design that specifies how Database Designer handles correlated columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{mode}</td>
<td>Specifies how to handle correlations in the design tables, one of the following integer settings:</td>
</tr>
<tr>
<td>0</td>
<td>Ignore column correlations in the design tables.</td>
</tr>
<tr>
<td>1</td>
<td>Consider existing correlations in tables when creating the design. If no existing correlations exist, Database Designer sets none in the design.</td>
</tr>
<tr>
<td>2</td>
<td>Analyze column correlations on tables where correlation analysis was not previously performed. When creating the design, consider all column correlations, new and existing.</td>
</tr>
<tr>
<td>3</td>
<td>Analyze all tables for column correlations and consider them when creating the design. If correlations already exist for a table, ignore them and re-analyze the table.</td>
</tr>
</tbody>
</table>
Setting the correlation analysis mode does not affect whether Database Designer analyzes statistics when creating a design.

Privileges

One of the following:

- Superuser
- DBDUSER role with USAGE privilege on the design schema.

Example

The following example specifies that Database Designer analyze all tables for correlated columns and consider them when creating a design:

```sql
=> SELECT DESIGNER_SET_ANALYZE_CORRELATIONS_MODE ('VMARTDESIGN', 3);
DESIGNER_SET_ANALYZE_CORRELATIONS_MODE
-----------------------------
            3
(1 row)
```

See Also

- `ANALYZE_CORRELATIONS`
- `Running Database Designer Programmatically`

**DESIGNER_SET_DESIGN_KSAFETY**

Sets K-safety for a comprehensive design and stores the K-safety value in the `DESIGNS` table. Database Designer ignores this function for incremental designs.

Behavior Type

Immutable

Syntax

```sql
DESIGNER_SET_DESIGN_KSAFETY ( 'design-name' [, k-level ]
)
```
## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>design-name</strong></td>
<td>Name of the design for which you want to set the K-safety value, type VARCHAR.</td>
</tr>
</tbody>
</table>
| **k-level**     | An integer between 0 and 2 that specifies the level of K-safety for the target design. This value must be compatible with the number of nodes in the database cluster:  
- **k-level** = 0: ≥ 1 nodes  
- **k-level** = 1: ≥ 3 nodes  
- **k-level** = 2: ≥ 5 nodes  
If you omit this parameter, Vertica sets K-safety for this design to 0 or 1, according to the number of nodes: 1 if the cluster contains ≥ 3 nodes, otherwise 0.  
If you are a DBADMIN user and **k-level** differs from system K-safety, Vertica changes system K-safety as follows:  
- If **k-level** is less than system K-safety, Vertica changes system K-safety to the lower level after the design is deployed.  
- If **k-level** is greater than system K-safety and is valid for the database cluster, Vertica creates the required number of buddy projections for the tables in this design. If the design applies to all database tables, or all tables in the database have the required number of buddy projections, Database Designer changes system K-safety to **k-level**.  
If the design excludes some database tables and the number of their buddy projections is less than **k-level**, Database Designer leaves system K-safety unchanged. Instead, it returns a warning and indicates which tables need new buddy projections in order to adjust system K-safety.  
If you are a DBDUSER, Vertica ignores this parameter. |

## Privileges

One of the following:
Examples

The following example set K-safety for the VMART_DESIGN design to 1:

```sql
=> SELECT DESIGNER_SET_DESIGN_KSAFETY('VMART_DESIGN', 1);
```

See Also

Running Database Designer Programmatically

**DESIGNER_SET_DESIGN_TYPE**

Specifies whether Database Designer should create a comprehensive or incremental design. DESIGNER_SET_DESIGN_TYPE stores the design mode in the DESIGNS table.

If you do not explicitly set a design mode with this function, Database Designer creates a comprehensive design.

**Behavior Type**

Immutable

**Syntax**

```
DESIGNER_SET_DESIGN_TYPE ( 'design-name', 'mode' )
```

**Parameters**

<table>
<thead>
<tr>
<th>design-name</th>
<th>Name of the target design.</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>Name of the mode that Database Designer should use when designing the database, one of the following:</td>
</tr>
</tbody>
</table>

- COMPREHENSIVE: Creates an initial or replacement design for all tables in the specified schemas. You typically create a comprehensive design for a new database.
• **INCREMENTAL**: Modifies an existing design with additional projection that are optimized for new or modified queries.

For more information, see [Design Types](#) in the Administrator's Guide.

**Privileges**

One of the following:

- Superuser
- Design creator

**Notes**

Incremental designs always inherit the K-safety value of the database.

**Examples**

The following examples show the two design mode options for the `VMART_DESIGN` design:

```sql
=> SELECT DESIGNER_SETDESIGN_TYPE('VMART_DESIGN', 'COMPREHENSIVE');
DESIGNER_SETDESIGN_TYPE
--------------------------
0
(1 row)

=> SELECT DESIGNER_SETDESIGN_TYPE('VMART_DESIGN', 'INCREMENTAL');
DESIGNER_SETDESIGN_TYPE
--------------------------
0
(1 row)
```

**See Also**

[Running Database Designer Programmatically](#)

**DESIGNER_SET_OPTIMIZATION_OBJECTIVE**

Valid only for comprehensive database designs, specifies the optimization objective Database Designer uses. Database Designer ignores this function for incremental designs.
DESIGNER_SET_OPTIMIZATION_OBJECTIVE stores the optimization objective in the DESIGNS table.

Behavior Type
Immutable

Syntax
DESIGNER_SET_OPTIMIZATION_OBJECTIVE ( 'design-name', 'policy' )

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>design-name</td>
<td>Name of the target design.</td>
</tr>
<tr>
<td>policy</td>
<td>Specifies the design's optimization policy, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• QUERY: Optimize for query performance. This can result in a larger</td>
</tr>
<tr>
<td></td>
<td>database storage footprint because additional projections might be</td>
</tr>
<tr>
<td></td>
<td>created.</td>
</tr>
<tr>
<td></td>
<td>• LOAD: Optimize for load performance so database size is minimized.</td>
</tr>
<tr>
<td></td>
<td>This can result in slower query performance.</td>
</tr>
<tr>
<td></td>
<td>• BALANCED: Balance the design between query performance and database size.</td>
</tr>
</tbody>
</table>

Privileges
One of the following:

• Superuser
• Design creator

Examples
The following example sets the optimization objective option for the VMART_DESIGN design:

```sql
=> SELECT DESIGNER_SET_OPTIMIZATION_OBJECTIVE( 'VMART_DESIGN', 'QUERY' );
DESIGNER_SET_OPTIMIZATION_OBJECTIVE
```
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS

Specifies whether a design can include unsegmented projections. Vertica ignores this function on a one-node cluster, where all projections must be unsegmented.

Behavior Type
Immutable

Syntax
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS ( 'design-name', unsegmented )

Parameters

<table>
<thead>
<tr>
<th>design-name</th>
<th>Name of the target design.</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsegmented</td>
<td>Boolean that specifies whether Database Designer can propose unsegmented projections for tables in this design. When you create a design, the propose_unsegmented_projections value in system table DESIGNS for this design is set to true. If DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS sets this value to false, Database Designer only proposes segmented projections for the design.</td>
</tr>
</tbody>
</table>

Privileges

One of the following:

- Superuser
- Design creator
Example

The following example specifies that Database Designer can propose only segmented projections for tables in the design VMART_DESIGN:

```sql
=> SELECT DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS('VMART_DESIGN', false);
```

See Also

Running Database Designer Programmatically

**DESIGNER_WAIT_FOR_DESIGN**

Waits for completion of operations that are populating and deploying the design. Ctrl+C cancels this operation and returns control to the user.

**Behavior Type**

Immutable

**Syntax**

```sql
DESIGNER_WAIT_FOR_DESIGN ( 'design-name' )
```

**Parameters**

| design-name | Name of the running design. |

**Privileges**

| Privileges |

One of the following:

- Superuser
- DBDUSER role with USAGE privilege on the design schema.
Examples

The following example requests to wait for the currently running design of VMART_DESIGN to complete:

```sql
=> SELECT DESIGNER_WAIT_FOR_DESIGN ('VMART_DESIGN');
```

See Also

- `DESIGNER_CANCEL_POPULATE_DESIGN`
- `DESIGNER_DROP_ALL_DESIGNS`
- `DESIGNER_DROP_DESIGN`
Database Management Functions

This section contains the database management functions specific to Vertica.

CLEAR_RESOURCE_REJECTIONS

Clears the content of the RESOURCE_REJECTIONS and DISK_RESOURCE_REJECTIONS system tables. Normally, these tables are only cleared during a node restart. This function lets you clear the tables whenever you need. For example, you might want to clear the system tables after you resolved a disk space issue that was causing disk resource rejections.

Syntax

CLEAR_RESOURCE_REJECTIONS();

Privileges

Superuser

Example

The following command clears the content of the RESOURCE_REJECTIONS and DISK_RESOURCE_REJECTIONS system tables:

```sql
=> SELECT clear_resource_rejections();
clear_resource_rejections
-------------------
   OK
(1 row)
```

See Also

- DISK_RESOURCE_REJECTIONS
- RESOURCE_REJECTIONS

CURRENT_SCHEMA

Returns the name of the current schema.
Behavior Type
Stable

Syntax
CURRENT_SCHEMA()

Note: You can call this function without parentheses.

Privileges
None

Examples
The following command returns the name of the current schema:

```sql
=> SELECT CURRENT_SCHEMA();
current_schema
--------------
public
(1 row)
```

The following command returns the same results without the parentheses:

```sql
=> SELECT CURRENT_SCHEMA;
current_schema
--------------
public
(1 row)
```

The following command shows the current schema, listed after the current user, in the search path:

```sql
=> SHOW SEARCH_PATH;
name | setting
--------------
search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

See Also

- SET SEARCH_PATH
**DUMP_LOCKTABLE**

Returns information about deadlocked clients and the resources they are waiting for.

**Syntax**

```
DUMP_LOCKTABLE()
```

**Privileges**

None

**Notes**

Use DUMP_LOCKTABLE if Vertica becomes unresponsive:

1. Open an additional vsql connection.
2. Execute the query:

   ```
   => SELECT DUMP_LOCKTABLE();
   ```

   The output is written to vsql. See Monitoring the Log Files.

You can also see who is connected using the following command:

```
=> SELECT * FROM SESSIONS;
```

Close all sessions using the following command:

```
=> SELECT CLOSE_ALL_SESSIONS();
```

Close a single session using the following command:

```
=> SELECT CLOSE_SESSION('session_id');
```

You get the session_id value from the V_MONITORSESSIONS system table.
See Also

- `CLOSE_ALL_SESSIONS`
- `CLOSE_SESSION`
- `LOCKS`
- `SESSIONS`

**DUMP_PARTITION_KEYS**

Dumps the partition keys of all projections in the system.

**Syntax**

```
DUMP_PARTITION_KEYS( )
```

**Note:** The ROS objects of partitioned tables without partition keys are ignored by the tuple mover and are not merged during automatic tuple mover operations.

**Privileges**

User must have select privileges on the table or usage privileges on the schema.

**Example**

```
=> SELECT DUMP_PARTITION_KEYS( );
Partition keys on node v_vmart_node0001
  Projection 'states_b0'
    Storage [ROS container]
      No of partition keys: 1
      Partition keys: NH
  Storage [ROS container]
    No of partition keys: 1
    Partition keys: MA
  Projection 'states_b1'
    Storage [ROS container]
      No of partition keys: 1
      Partition keys: VT
    Storage [ROS container]
      No of partition keys: 1
      Partition keys: ME
    Storage [ROS container]
      No of partition keys: 1
```

Partition keys: CT

See Also

- DUMP_PROJECTION_PARTITION_KEYS
- DUMP_TABLE_PARTITION_KEYS
- PARTITION_PROJECTION
- PARTITION_TABLE
- PARTITIONS
- Partitioning Tables in the Administrator's Guide

HAS_ROLE

Indicates, with a Boolean value, whether a role has been assigned to a user. This function is useful for letting you check your own role membership.

Behavior Type

Stable

Syntax 1

HAS_ROLE( [ 'user_name' ] , 'role_name' );

Syntax 2

HAS_ROLE( 'role_name' );

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_name</td>
<td>[Optional] The name of a user to look up. Currently, only a superuser can supply the user_name argument.</td>
</tr>
<tr>
<td>role_name</td>
<td>The name of the role you want to verify has been granted.</td>
</tr>
</tbody>
</table>
Privileges

Users can check their own role membership by calling HAS_ROLE('role_name'), but only a superuser can look up other users' memberships using the optional user_name parameter.

Notes

You can query V_CATALOG system tables ROLES, GRANTS, and USERS to show any directly-assigned roles; however, these tables do not indicate whether a role is available to a user when roles may be available through other roles (indirectly).

Examples

User Bob wants to see if he has been granted the commentor role:

```sql
=> SELECT HAS_ROLE('commentor');
```

Output t for true indicates that Bob has been assigned the commentor role:

```
<table>
<thead>
<tr>
<th>HAS_ROLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>
```

In the following function call, a superuser checks if the logadmin role has been granted to user Bob:

```sql
=> SELECT HAS_ROLE('Bob', 'logadmin');
```

```
<table>
<thead>
<tr>
<th>HAS_ROLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>
```

To view the names of all roles users can access, along with any roles that have been assigned to those roles, query the V_CATALOG.ROLES system table. An asterisk in the output means role granted WITH ADMIN OPTION.

```sql
=> SELECT * FROM roles;
```

```
<table>
<thead>
<tr>
<th>role_id</th>
<th>name</th>
<th>assigned_roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996273704964</td>
<td>public</td>
<td></td>
</tr>
<tr>
<td>45035996273704966</td>
<td>dbduser</td>
<td></td>
</tr>
<tr>
<td>45035996273704968</td>
<td>dbadmin</td>
<td>dbduser*</td>
</tr>
<tr>
<td>45035996273704972</td>
<td>pseudosuperuser</td>
<td>dbadmin*</td>
</tr>
<tr>
<td>45035996273704974</td>
<td>logreader</td>
<td></td>
</tr>
<tr>
<td>45035996273704976</td>
<td>logwriter</td>
<td></td>
</tr>
<tr>
<td>45035996273704978</td>
<td>logadmin</td>
<td>logreader,</td>
</tr>
</tbody>
</table>
```
See Also

- **ROLES**
- **USERS**
- **Managing Users and Privileges**
- **Viewing a User's Role**

**KERBEROS_CONFIG_CHECK**

Tests the Kerberos configuration of a Vertica cluster. The function succeeds if it can access the keytab file and use it to kinit, and reports errors otherwise.

**Syntax**

```sql
KERBEROS_CONFIG_CHECK()
```

**Parameters**

This function has no parameters.

**Privileges**

This function does not require privileges.

**Examples**

The following example shows the results when the Kerberos configuration is valid.

```sql
=> SELECT KERBEROS_CONFIG_CHECK();
  kerberos_config_check
---------------------------------------------------------------------------------------------------------------------
  ok: krb5 exists at [/etc/krb5.conf]
  ok: Vertica Keytab file is set to [/etc/vertica.keytab]
  ok: Vertica Keytab file exists at [/etc/vertica.keytab]
```
Kerberos configuration parameters set in the database
KerberosServiceName: [vertica]
KerberosHostname: [data.hadoop.com]
KerberosRealm: [EXAMPLE.COM]
KerberosKeytabFile: [/etc/vertica.keytab]
Vertica Principal: [vertica/data.hadoop.com@EXAMPLE.COM]

ok: Vertica can kinit using keytab file

(1 row)

RUN_INDEX_TOOL

Runs the Index tool on a Vertica database to perform one of these tasks:

- Run a per-block cyclic redundancy check (CRC) on data storage to verify data integrity.
- Check that the sort order in ROS containers is correct.

The function writes summary information about its operation to standard output; detailed information on results is logged in vertica.log on the current node. For more about evaluating tool output, see:

- Evaluating CRC Errors
- Evaluating Sort Order Errors

You can also run the Index tool on a database that is down, from the Linux command line. For details, see CRC and Sort Order Check.

Caution: Use this function only under guidance from Vertica Support.

Syntax

RUN_INDEX_TOOL ( 'task', global, '[projection]' [, num-threads ] );

Parameters

<table>
<thead>
<tr>
<th>task</th>
<th>Specifies the operation to run, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- checkcrc: Run a cyclic redundancy check (CRC) on each block of existing data storage to check the data integrity of ROS data blocks.</td>
</tr>
<tr>
<td></td>
<td>- checksort: Evaluate each ROS row to determine</td>
</tr>
</tbody>
</table>
whether it is sorted correctly. If ROS data is not sorted correctly in the projection's order, query results that rely on sorted data will be incorrect.

<table>
<thead>
<tr>
<th><strong>global</strong></th>
<th>Boolean, specifies whether to run the specified task on all nodes (true), or the current one (false).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>projection</strong></td>
<td>Specifies the scope of the operation:</td>
</tr>
<tr>
<td></td>
<td>• Empty string (''): Run the check on all projections.</td>
</tr>
<tr>
<td></td>
<td>• A string that specifies one or more projections as follows:</td>
</tr>
<tr>
<td></td>
<td>• <em>proj-name</em>: Run the check on this projection</td>
</tr>
<tr>
<td></td>
<td>• <em>proj-prefix</em>&quot;: Run the check on all projections that begin with the string <em>proj-prefix</em>.</td>
</tr>
<tr>
<td><strong>num-threads</strong></td>
<td>An unsigned (positive) or signed (negative) integer that specifies the number of threads used to run this operation:</td>
</tr>
<tr>
<td></td>
<td>• (n): Number of threads, (\geq 1)</td>
</tr>
<tr>
<td></td>
<td>• (-n): Negative integer, denotes a fraction of all CPU cores as follows:</td>
</tr>
<tr>
<td></td>
<td>(\frac{\text{num-cores}}{n})</td>
</tr>
<tr>
<td></td>
<td>Thus, (-1) specifies all cores, (-2), half the cores, (-3), a third of all cores, and so on.</td>
</tr>
<tr>
<td></td>
<td>Default: (1)</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**Optimizing Performance**

You can optimize meta-function performance by setting two parameters:

- **projection**: Narrows the scope of the operation to one or more projections.
- **num-threads**: Specifies the number of threads used to execute the function.
SET_CONFIG_PARAMETER

Specifies the value of a configuration parameter at the database level, or for a specific node.

**Important:** Vertica encourages use of ALTER NODE, ALTER DATABASE, and ALTER SESSION statements to set and clear configuration parameters. See Managing Configuration Parameters: VSQL for more information.

**Caution:** Vertica is designed to operate with minimal configuration changes, so use this capability sparingly. Carefully follow any documented guidelines for the parameter you wish to configure.

**Syntax**

`SET_CONFIG_PARAMETER( 'parameter-name', value, [ 'node-name' ] )`

**Parameters**

<table>
<thead>
<tr>
<th>parameter-name</th>
<th>The parameter value to set. See Configuration Parameters in the Administrator's Guide for a list of supported parameters, their purposes, and usage examples.</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The value to set for <em>parameter-name</em>. Syntax for this argument varies depending upon the parameter and its expected data type. For strings, enclose the argument in single quotes; integer arguments can be unquoted. If value is specified as NULL, the parameter is cleared.</td>
</tr>
<tr>
<td>node-name</td>
<td>The name of the node whose parameter value you wish to set. If you omit this parameter or set it to NULL, the parameter is set at the database level. If a parameter is explicitly set for a node, the node setting supersedes the database-level setting.</td>
</tr>
</tbody>
</table>

**Note:** Some parameters require restart for the value to take effect.

**Privileges**

Superuser
Examples

The following examples show how to use SET_CONFIG_PARAMETER in various situations.

Set a Configuration Parameter at Database Level

Set the AnalyzeRowCountInterval parameter to 3600 at the database level:

```
=> SELECT SET_CONFIG_PARAMETER ('AnalyzeRowCountInterval',3600);
```

Find Details on All Configuration Parameters

Find all configuration parameters and information about them, including their current and default values:

```
=> SELECT * FROM CONFIGURATION_PARAMETERS;
```

See Also

- Managing Configuration Parameters: VSQL
- CONFIGURATION_PARAMETERS

SHUTDOWN

Forces a database to shut down, even if there are users connected.

Syntax

```
SHUTDOWN ( [ 'false' | 'true' ])
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>false</strong></td>
<td>[Default] Returns a message if users are connected. Has the same effect as supplying no parameters.</td>
</tr>
<tr>
<td><strong>true</strong></td>
<td>Performs a moveout operation and forces the database to shut down, disallowing further connections.</td>
</tr>
</tbody>
</table>

Privileges

Superuser
Notes

- Quotes around the true or false arguments are optional.
- Issuing the shutdown command without arguments or with the default (false) argument returns a message if users are connected, and the shutdown fails. If no users are connected, the database performs a moveout operation and shuts down.
- Issuing the SHUTDOWN('true') command forces the database to shut down whether users are connected or not.
- You can check the status of the shutdown operation in the vertica.log file:

  2010-03-09 16:51:52.625 unknown:0x7fc6d6d2e700
  [Init] <INFO> Shutdown complete. Exiting.

- As an alternative to SHUTDOWN(), you can also temporarily set MaxClientSessions to 0 and then use CLOSE_ALL_SESSIONS(). New client connections cannot connect unless they connect using the dbadmin account. See CLOSE_ALL_SESSIONS for details.

Examples

The following command attempts to shut down the database. Because users are connected, the command fails:

```
=> SELECT SHUTDOWN('false');
NOTICE: Cannot shut down while users are connected
```

SHUTDOWN() and SHUTDOWN('false') perform the same operation:

```
=> SELECT SHUTDOWN();
NOTICE: Cannot shut down while users are connected
```

Using the 'true' parameter forces the database to shut down, even though clients might be connected:

```
=> SELECT SHUTDOWN('true');
```
Shutdown: moveout complete
(1 row)

- SESSIONS

Directed Queries Functions

The following meta-functions let you batch export query plans as directed queries from one Vertica database, and import those directed queries to another database.

**EXPORT_DIRECTED_QUERIES**

Generates SQL for creating directed queries from a set of input queries, and writes the SQL to the specified file or to standard output.

**Syntax**

```
EXPORT_DIRECTED_QUERIES('input-file', '[output-file]')
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input-file</td>
<td>A SQL file that contains one or more input queries. See <strong>Input Format</strong> below for details on format requirements.</td>
</tr>
<tr>
<td>output-file</td>
<td>Specifies where to write the generated SQL for creating directed queries. If the file name already exists, <strong>EXPORT_DIRECTED_QUERIES</strong> returns with an error. If you supply an empty string, Vertica writes the SQL to standard output. See <strong>Output Format</strong> below for details.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser
Input Format

The input file that you supply to EXPORT_DIRECTED_QUERIES contains one or more input queries. For each input query, you can optionally specify two fields that are used in the generated directed query:

- **DirQueryName** provides the directed query's unique identifier, a string that conforms to conventions described in Identifiers.

- **DirQueryComment** specifies a quote-delimited string, up to 128 characters.

You format each input query as follows:

```plaintext
--DirQueryName=query-name
--DirQueryComment='comment'
input-query
```

Output Format

EXPORT_DIRECTED_QUERIES generates SQL for creating directed queries, and writes the SQL to the specified file or to standard output. In both cases, output conforms to the following format:

```sql
/* Query: directed-query-name */
/* Comment: directed-query-comment */
SAVE QUERY input-query;
CREATE DIRECTED QUERY CUSTOM 'directed-query-name'
COMMENT 'directed-query-comment'
OPTVER 'vertica-release-num'
PSDATE 'timestamp'
annotated-query
```

Error Handling

If any errors or warnings occur during EXPORT_DIRECTED_QUERIES execution, it returns with a message like this one:

```plaintext
1 queries successfully exported.
1 warning message was generated.
Queries exported to /home/dbadmin/outputQueries.
See error report, /home/dbadmin/outputQueries.err for details.
```

EXPORT_DIRECTED_QUERIES writes all errors and warnings to a file that it creates on the same path as the output file, and uses the output file's base name.

For example:
WARNING: Name field not supplied. Using auto-generated name: 'Autoname:2016-04-25 15:03:32.115317.0'
Input Query: SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city = 'Boston':varchar(6)) ORDER BY employee_dimension.job_title;
END WARNING

Examples

See Batch Query Plan Export in the Administrator's Guide.

See Also

- Batch Query Plan Export
- IMPORT_DIRECTED_QUERIES

IMPORT_DIRECTED_QUERIES

Imports to the database catalog directed queries from a SQL file that was generated by EXPORT_DIRECTED_QUERIES. If no directed queries are specified, Vertica lists all directed queries in the SQL file.

Syntax

IMPORT_DIRECTED_QUERIES( 'export-file'[, 'directed-query-name[,...]' ] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>export-file</td>
<td>A SQL file generated by EXPORT_DIRECTED_QUERIES. When you run this file, Vertica creates the specified directed queries in the current database catalog.</td>
</tr>
<tr>
<td>directed-query-name</td>
<td>The name of a directed query that is defined in export-file. You can specify multiple comma-delimited directed query names. If you omit this parameter, Vertica lists the names of all directed queries in export-file.</td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.0.x)
Privileges
Superuser

- Batch Query Plan Export
- EXPORT_DIRECTED_QUERIES

Eon Functions
The following functions are meant to be used in Eon Mode.

ALTER_LOCATION_SIZE
Changes the size of the depot location on one node or all of the nodes in the database.
Decreasing the depot size can result in evictions if they are necessary to make space available.
Evictions occur when Vertica removes data from the depot.

Syntax
ALTER_LOCATION_SIZE( path, node_name, new_size)

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Where Vertica stores the depot. The type of filesystem on which the location is based determines the format of this argument. For depot locations on the Linux filesystem, path must be an absolute path to the directory where Vertica writes the depot's data.</td>
</tr>
<tr>
<td>node_name</td>
<td>The node on which you want to alter the depot's size. To alter the depot size of all nodes, you must pass an empty string.</td>
</tr>
<tr>
<td>new_size</td>
<td>The new size the depot:</td>
</tr>
<tr>
<td></td>
<td>- integer%: Percentage of total disk space</td>
</tr>
</tbody>
</table>
• **integer**{K|M|G|T}: Amount of disk space in kilobytes, megabytes, gigabytes, or terabytes.

  Default Value: 80% of the disk space on the node. If it was not set at creation time.

**Privileges**

Superuser

**Examples**

Change the depot size on all the nodes in the database to 60 gigabytes:

```
=> SELECT ALTER_LOCATION_SIZE('/home/dbadmin/depot/', '', '60G');

ALTER_LOCATION_SIZE

/home/dbadmin/depotSize changed.
(1 row)
```

Change the depot size of one node in the database to 50% of the total disk space on the node:

```
=> SELECT ALTER_LOCATION_SIZE('/home/dbadmin/depot/', 'v_eon_walkthrough_db_node0001', '50%');

ALTER_LOCATION_SIZE

/home/dbadmin/depotSize changed.
(1 row)
```

**See Also**

• [Depot](#)

**CLEAR_DATA_DEPOT**

Deletes the specified data from depots in the database. If you use a table name with the function, then the data for that table is deleted from the depots in the database.

**Syntax**

`CLEAR_DATA_DEPOT( [ table_name ] )`
Parameters

| table_name   | (Optional) The name of the table to delete from all of the depots in the cluster. |

Privileges

Superuser

Examples

Delete all of the data in the depots in the database:

```
=> SELECT CLEAR_DATA_DEPOT();
CLEAR_DATA_DEPOT
-------------------
Cache cleared
(1 row)
```

Delete the User_Experience_Data table from all of the depots in the cluster:

```
=> SELECT CLEAR_DATA_DEPOT('User_Experience_Data');
CLEAR_DATA_DEPOT
-------------------
Cache cleared
(1 row)
```

See Also

- Depot
- Eon Database Overview

**FINISH_FETCHING_FILES**

Fetches all the files that are queued for fetching from the communal storage.

Syntax

```
FINISH_FETCHING_FILES()
```
Privileges
Superuser

Examples

Get all the files queued from communal storage:

```sql
=> SELECT FINISH_FETCHING_FILES();
FINISH_FETCHING_FILES
-------------------------
Finished fetching all the files
(1 row)
```

See Also

- Eon Database Overview

**FLUSH_REAPER_QUEUE**

Deletes all of the data marked for deletion in the database. Use this function when you want to remove all of the data marked for deletion before the reaper performs its task.

Syntax

```sql
FLUSH_REAPER_QUEUE()
```

Privileges
Superuser

Examples

Removes all of the files that have been marked for deletion in the database:

```sql
=> SELECT FLUSH_REAPER_QUEUE();
FLUSH_REAPER_QUEUE
-------------------------------
Finished deleting all the files in the reaper queue
(1 row)
```
REBALANCE_SHARDS

Rebalances shard assignments across the cluster. If the current session ends, the operation immediately aborts.

Syntax

REBALANCE_SHARDS()

Privileges

Superuser

Examples

The following example rebalances the shards of all the nodes in the database:

```sql
=> SELECT REBALANCE_SHARDS();
REBALANCE_SHARDS
------------------------
REBALANCED_SHARDS
(1 row)
```

After running REBALANCE_SHARDS check the subscription status by querying the SESSION_SUBSCRIPTIONS table, for example:

```sql
=> SELECT * from session_subscriptions where is_participating='t' order by node_name, shard_name;
```

See Also

- [Shards and Subscriptions](#)
- [Eon Database Overview](#)
SYNC_CATALOG

Immediately synchronizes the catalog to shared storage to allow revive as of the current catalog version in the case of an imminent crash. When you run sync_catalog, Vertica synchronizes all pending Checkpoint and Transaction Logs to shared storage.

Syntax

SYNC_CATALOG( [ 'node_name' ] )

Parameters

| node_name | (Optional) The name of the node you want to synchronize. |

Privileges

Superuser

Examples

Synchronize the catalog on all nodes:

=> SELECT SYNC_CATALOG();

Synchronize the catalog on a specific node:

=> SELECT SYNC_CATALOG( 'node001' );
Epoch Management Functions

This section contains the epoch management functions specific to Vertica.

ADVANCE_EPOCH

Manually closes the current epoch and begins a new epoch.

Syntax

ADVANCE_EPOCH ( [ integer ] )

Parameters

| integer | Specifies the number of epochs to advance. |

Privileges

Superuser

Notes

This function is primarily maintained for backward compatibility with earlier versions of Vertica.

Example

The following command increments the epoch number by 1:

```sql
=> SELECT ADVANCE_EPOCH(1);
```

GET_AHM_EPOCH

Returns the number of the epoch in which the Ancient History Mark is located. Data deleted up to and including the AHM epoch can be purged from physical storage.
Syntax

GET_AHM_EPOCH()

Note: The AHM epoch is 0 (zero) by default (purge is disabled).

Privileges
None

Examples

=> SELECT GET_AHM_EPOCH();

Current AHM epoch: 0
(1 row)

GET_AHM_TIME

Returns a TIMESTAMP value representing the Ancient History Mark. Data deleted up to and including the AHM epoch can be purged from physical storage.

Syntax

GET_AHM_TIME()

Privileges
None

Examples

=> SELECT GET_AHM_TIME();

(1 row)
GET_CURRENT_EPOCH

The epoch into which data (COPY, INSERT, UPDATE, and DELETE operations) is currently being written.

Returns the number of the current epoch.

Syntax
GET_CURRENT_EPOCH()

Privileges
None

Examples

```sql
=> SELECT GET_CURRENT_EPOCH();
   GET_CURRENT_EPOCH
-----------------
       683
(1 row)
```

GET_LAST_GOOD_EPOCH

Returns the last good epoch number. If the database has no projections, the function returns an error.

Syntax
GET_LAST_GOOD_EPOCH()

Privileges
None
Examples

```sql
=> SELECT GET_LAST_GOOD_EPOCH();
GET_LAST_GOOD_EPOCH
---------------------
  682
(1 row)
```

**MAKE_AHM_NOW**

Sets the Ancient History Mark (AHM) to the greatest allowable value. This lets you purge all deleted data.

Caution: After running this function, you cannot query historical data that precedes the current epoch. Only database administrators should use this function.

MAKE_AHM_NOW performs the following operations:

- Advances the epoch.
- Performs a moveout operation on all projections.
- Sets the AHM to the last good epoch (LGE) — at least to the epoch that is current when you execute MAKE_AHM_NOW.

**Syntax**

```sql
MAKE_AHM_NOW ( [ true ] )
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>Allows AHM to advance when one of the conditions is true:</td>
</tr>
<tr>
<td></td>
<td>- One or more nodes are down.</td>
</tr>
<tr>
<td></td>
<td>- One projection is being refreshed from another (retentive refresh).</td>
</tr>
</tbody>
</table>

In either case, you must supply this argument to MAKE_AHM_NOW, otherwise Vertica returns an error. If you execute MAKE_AHM_NOW(true) during retentive refresh, Vertica rolls back the refresh operation and advances the AHM.
Privileges
Superuser

Setting AHM When Nodes Are Down

If you run MAKE_AHM_NOW while any node is down, you must supply an argument of true; otherwise, Vertica returns an error. In the following example, MAKE_AHM_NOW advances the AHM even though a node is down:

```sql
=> SELECT MAKE_AHM_NOW(true);
WARNING: Received no response from v_vmartdb_node0002 in get cluster LGE
WARNING: Received no response from v_vmartdb_node0002 in get cluster LGE
WARNING: Received no response from v_vmartdb_node0002 in set AHM
MAKE_AHM_NOW
AHM set (New AHM Epoch: 684)
(1 row)
```

Caution: If the AHM is advanced beyond the last good epoch of the failed nodes, those nodes must recover all data from scratch.

See Also
- `SET_AHM_EPOCH`
- `SET_AHM_TIME`

**SET_AHM_EPOCH**

Sets the Ancient History Mark (AHM) to the specified epoch. This function allows deleted data up to and including the AHM epoch to be purged from physical storage.

`SET_AHM_EPOCH` is normally used for testing purposes. Instead, consider using `SET_AHM_TIME` which is easier to use.

**Syntax**

```
SET_AHM_EPOCH ( epoch, [ true ])
```
Parameters

**epoch**  
Specifies one of the following:
- The number of the epoch in which to set the AHM
- Zero (0) (the default) disables PURGE

**true**  
Allows the AHM to advance when nodes are down.

Note: If the AHM is advanced after the last good epoch of the failed nodes, those nodes must recover all data from scratch. Use with care.

Privileges

Superuser

Restrictions

The number of the specified epoch must be:
- Greater than the current AHM epoch
- Less than the current epoch
- Less than or equal to the cluster last good epoch (the minimum of the last good epochs of the individual nodes in the cluster)

Use the **SYSTEM** table to see current values of various epochs related to the AHM, For example:

```sql
=> SELECT * from SYSTEM;
-[ RECORD 1 ]-------------------------------------------
current_timestamp | 2009-08-11 17:09:54.651413
current_epoch     | 1512
ahm_epoch         | 961
last_good_epoch   | 1510
refresh_epoch     | -1
designed_fault_tolerance | 1
node_count        | 4
node_down_count   | 0
current_fault_tolerance | 1
catalog_revision_number | 1590
wos_used_bytes    | 0
wos_row_count     | 0
```
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ros_used_bytes</td>
<td>41490783</td>
</tr>
<tr>
<td>ros_row_count</td>
<td>1298104</td>
</tr>
<tr>
<td>total_used_bytes</td>
<td>41490783</td>
</tr>
<tr>
<td>total_row_count</td>
<td>1298104</td>
</tr>
</tbody>
</table>

All nodes must be up. You cannot use SET_AHM_EPOCH when any node in the cluster is down, except by using the optional true parameter.

When a node is down and you use MAKE_AHM_NOW, the following error is printed to the vertica.log:

```
Some nodes were excluded from setAHM. If their LGE is before the AHM they will perform full recovery.
```

Examples

The following command sets the AHM to a specified epoch of 12:

```
=> SELECT SET_AHM_EPOCH(12);
```

The following command sets the AHM to a specified epoch of 2 and allows the AHM to advance despite a failed node:

```
=> SELECT SET_AHM_EPOCH(2, true);
```

See Also

- MAKE_AHM_NOW
- SET_AHM_TIME
- SYSTEM

SET_AHM_TIME

Sets the Ancient History Mark (AHM) to the epoch corresponding to the specified time on the initiator node. This function allows historical data up to and including the AHM epoch to be purged from physical storage.

Syntax

```
SET_AHM_TIME ( time , [ true ] )
```
Parameters

| time | Is a `TIMESTAMP/TIMESTAMPZ` value that is automatically converted to the appropriate epoch number. |
| true | [Optional] Allows the AHM to advance when nodes are down. Note: If the AHM is advanced after the last good epoch of the failed nodes, those nodes must recover all data from scratch. |

Privileges

Superuser

Notes

- `SET_AHM_TIME` returns a `TIMESTAMP WITH TIME ZONE` value representing the end point of the AHM epoch.
- You cannot change the AHM when any node in the cluster is down, except by using the optional `true` parameter.
- When a node is down and you issue `SELECT MAKE_AHM_NOW()`, the following error is printed to the vertica.log:

```
Some nodes were excluded from setAHM. If their LGE is before the AHM they will perform full recovery.
```

Examples

Epochs depend on a configured epoch advancement interval. If an epoch includes a three-minute range of time, the purge operation is accurate only to within minus three minutes of the specified timestamp:

```sql
=> SELECT SET_AHM_TIME('2008-02-27 18:13');
set_ahm_time
---------------------
AHM set to '2008-02-27 18:11:50-05'
(1 row)
```
Note: The –05 part of the output string is a time zone value, an offset in hours from UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, or GMT).

In the previous example, the actual AHM epoch ends at 18:11:50, roughly one minute before the specified timestamp. This is because SET_AHM_TIME selects the epoch that ends at or before the specified timestamp. It does not select the epoch that ends after the specified timestamp because that would purge data deleted as much as three minutes after the AHM.

For example, using only hours and minutes, suppose that epoch 9000 runs from 08:50 to 11:50 and epoch 9001 runs from 11:50 to 15:50. SET_AHM_TIME( '11:51' ) chooses epoch 9000 because it ends roughly one minute before the specified timestamp.

In the next example, suppose that a node went down at 11:00:00 AM on January 1st 2017. At noon, you want to advance the AHM to 11:15:00, but the node is still down.

Suppose you try to set the AHM using this command:

```sql
=> SELECT SET_AHM_TIME('2017-01-01 11:15:00');
```

Then you will receive an error message. Vertica prevents you from moving the AHM past the point where a node went down. Vertica returns this error to prevent the AHM from advancing past the down node's last good epoch. You can force the AHM to advance by supplying the optional second parameter:

```sql
=> SELECT SET_AHM_TIME('2017-01-01 11:15:00', true);
```

However, if you force the AHM past the last good epoch, the failed node will have to recover from scratch.

**Flex Table Functions**

This section contains helper functions for use in working with flex tables.
**Note:** While the functions are available to all users, they are applicable only to flex table, their associated `flex_table_keys` table and `flex_table_view` views. By computing keys and creating views from flex table data, the functions facilitate SELECT queries. One function restores the original keys table and view that were made when you first created the flex table. For more information, see Using Flex Tables.

**BUILD_FLEXTABLE_VIEW**

Creates, or re-creates, a view for a default or user-defined `_keys` table, ignoring any empty keys.

**Syntax**

```
BUILD_FLEXTABLE_VIEW('[[database.]schema.]flex-table' [,,'view-name'] [,,'user-keys-table'] )
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>flex-table</code></td>
<td>The flex table name. By default, this function builds or rebuilds a view for the input table with the current contents of the associated <code>flex_table_keys</code> table.</td>
</tr>
<tr>
<td><code>view-name</code></td>
<td>A custom view name. Use this option to build a new view for <code>flex-table</code> with the name you specify.</td>
</tr>
<tr>
<td><code>user-keys-table</code></td>
<td>Specifies a keys table from which to create the view. Use this option if you created a custom <code>user-keys</code> table from the flex table map data, rather than from the default <code>flex_table_keys</code> table. The function builds a view from the keys in <code>user-keys</code> table, rather than from the <code>flex_table_keys</code> table.</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to call `build_flextable_view` with 1, 2, or 3 arguments.
Creating a Default View

To create, or re-create, a default view:

1. Call the function with an input flex table, `darkdata`:

```sql
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata');

The view public.darkdata_view is ready for querying
(1 row)
```

The function creates a view with the default name (darkdata_view) from the `darkdata_keys` table.

2. Query a key name (`user.id`) from the new or updated view:

```sql
=> SELECT "user.id" FROM darkdata_view;

user.id
---------
340857907
727774963
390498773
288187825
164464905
125434448
601328899
352494946
(12 rows)
```

Creating a Custom Name View

To create, or re-create, a view with a custom name:

1. Call the function with two arguments, an input flex table, `darkdata`, and the name of the view to create, `dd_view`:

```sql
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view');

The view public.dd_view is ready for querying
(1 row)
```

2. Query a key name (`user.lang`) from the new or updated view (dd_view):

```sql
=> SELECT "user.lang" FROM dd_view;

user.lang
---------
tr
en
es
```
Creating a View from a Custom Keys Table

To create a view from a custom _keys table with build_flextable_view, the custom table must have the same schema and table definition as the default table (darkdata_keys).

Create a custom keys table, using any of these three approaches:

1. Create a columnar table with all keys from the default keys table for a flex table (darkdata_keys):

   ```sql
   => CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys;
   ```

2. Create a columnar table without content (LIMIT 0) from the default keys table for a flex table (darkdata_keys):

   ```sql
   CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys LIMIT 0;
   ```

   ```sql
   kdb=> SELECT * FROM new_darkdata_keys;
   key_name | frequency | data_type_guess
   ===========
   ===========
   (0 rows)
   ```

3. Create a columnar table without content (LIMIT 0) from the default keys table, and insert two values ('user.lang', 'user.name') into the key_name column:

   ```sql
   => CREATE TABLE dd_keys AS SELECT * FROM darkdata_keys LIMIT 0;
   CREATE TABLE
   => INSERT INTO dd_keys (key_name) values ('user.lang');
   OUTPUT
   -------
   1
   (1 row)
   => INSERT INTO dd_keys (key_name) values ('user.name');
   OUTPUT
   -------
   1
   (1 row)
   => SELECT * FROM dd_keys;
   key_name | frequency | data_type_guess
   ===========
   ===========
   user.lang | |
4. After creating a custom keys table, call `build_flextable_view` with all arguments (an input flex table, the new view name, the custom keys table):

```sql
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view', 'dd_keys');
build_flextable_view
---------------------------------------------
The view public.dd_view is ready for querying
(1 row)
```

5. Query the new view:

```sql
=> SELECT * FROM dd_view;
```

See Also

- `COMPUTE_FLEXTABLE_KEYS`
- `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`
- `MATERIALIZE_FLEXTABLE_COLUMNS`
- `RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW`

**COMPUTE_FLEXTABLE_KEYS**

Computes the virtual columns (keys and values) from the flex table VMap data. Use this function to compute keys without creating an associated table view. To also build a view, use `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`.

The function stores its results in the associated flex _keys table, which has the following columns:

- `key_name`
- `frequency`
- `data_type_guess`

For more information, see Computing Flex Table Keys.
Syntax

```
COMPUTE_FLEXTABLE.Keys('[[database.]schema.]flex-table')
```

Arguments

| [database.]schema | Specifies a schema, by default public. If `schema` is any schema other than public, you must supply the schema name. For example:  
| myschema.thisDbObject | If you specify a database, it must be the current database. |

| flex-table | The name of a flex table. |

Using Data Type Guessing

The results of the flex_keys table data_type_guess column depend on the EnableBetterFlexTypeGuessing configuration parameter. By default, the parameter is 1 (ON). This setting results in the function returning all non-string keys in the data_type_guess column as one of the following types (and others listed in SQL Data Types):

- BOOLEAN
- INTEGER
- FLOAT
- TIMESTAMP
- DATE

Setting the configuration parameter to 0 (OFF), results in the function returning only string types ([LONG]VARCHAR) or ([LONG] VARBINARY) for all values in the data_type_guess column of the flex_keys table.

Assigning Flex Key Data Types

Use the sample CSV data in this section to compare the results of using or not using the EnableBetterFlexTypeGuessing configuration parameter. When the parameter is ON,
the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as trees.csv).

2. Create a flex table (trees) and load trees.csv using the fcsvparser:

```
=> CREATE FLEX TABLE trees();
=> COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
```

3. Use COMPUTE_FLEXTABLE_KEYS with the trees flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('trees');
COMPUTE_FLEXTABLE_KEYS
---------------------------------------------
Please see public.trees_keys for updated keys
(1 row)
```

4. Query the trees_keys table output:

```
=> SELECT * FROM trees_keys;
  key_name | frequency | data_type_guess
----------|-----------|------------------
 Year      | 6         | Integer          
 Quarter   | 6         | Integer          
 Region    | 6         | Varchar(66)      
 Available | 6         | Boolean          
 Number of Quotes | 6 | Integer          
 Grade     | 6         | Varchar(20)      
 Species   | 6         | Varchar(22)      
 Pond Value | 6      | Numeric(8,3)     
(8 rows)
```

5. Set the EnableBetterFlexTypeGuessing parameter to 0 (OFF).

6. Call COMPUTE_FLEXTABLE_KEYS with the trees flex table again.

7. Query the trees_keys table to compare the data_type_guess values with the previous results. Without the configuration parameter set, all of the non-string data types are VARCHARS of various lengths:
```sql
SELECT *
FROM trees_keys;
```

<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Quarter</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Region</td>
<td>6</td>
<td>varchar(66)</td>
</tr>
<tr>
<td>Available</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Grade</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Number of Quotes</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Pond Value</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Species</td>
<td>6</td>
<td>varchar(22)</td>
</tr>
</tbody>
</table>

(8 rows)

8. To maintain accurate results for non-string data types, set the EnableBetterFlexTypeGuessing parameter back to 1 (ON).

For more information about setting the EnableBetterFlexTypeGuessing configuration parameter, see Setting Flex Table Configuration Parameters.

See Also

- **BUILD_FLEXTABLE_VIEW**
- **COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW**
- **MATERIALIZE_FLEXTABLE_COLUMNS**
- **RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW**

**COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW**

Combines the functionality of **BUILD_FLEXTABLE_VIEW** and **COMPUTE_FLEXTABLE_KEYS** to compute virtual columns (keys) from the VMap data of a flex table and construct a view. Creating a view with this function ignores empty keys. If you do not need to perform both operations together, use one of the single-operation functions instead.

**Syntax**

```sql
COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW( 'flex_table' )
```

**Arguments**

| flex_table | The name of a flex table. |
Examples

This example shows how to call the function for the darkdata flex table.

```sql
=> SELECT COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('darkdata');
              compute_flextable_keys_and_build_view
-------------------------------------------------------------------
  Please see public.darkdata_keys for updated keys

EMPTYMAP

Constructs a new VMap with one row but without keys or data. Use this transform function to populate a map without using a flex parser. Instead, you use either from SQL queries or from map data present elsewhere in the database.

Syntax

EMPTYMAP()

Arguments

None

Examples

Create an Empty Map

```sql
=> SELECT EMPTYMAP();
  emptymap
-------------------------------------------------------------------
```
Create an Empty Map from an Existing Flex Table

If you create an empty map from an existing flex table, the new map has the same number of rows as the table from which it was created.

This example shows the result if you create an empty map from the `darkdata` table, which has 12 rows of JSON data:

```
=> SELECT EMPTYMAP() FROM darkdata;
emptymap
-----------------------------
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
\01\00\00\00\00\04\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00\00
(12 rows)
```

MAPVALUES

MAPVERSION

MAPAGGREGATE

Returns a LONG VARBINARY VMap with keys and value pairs supplied from two VARCHAR input columns of an existing columnar table. Using this function requires specifying an over() clause for the source table.

Syntax

MAPAGGREGATE(source_column1, source_column2)

Arguments

<table>
<thead>
<tr>
<th>source_column1</th>
<th>Table column with values to use as the keys of the key/value pair of the returned VMap data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_column2</td>
<td>Table column with values to use as the values in the key/value pair of the returned VMap data.</td>
</tr>
</tbody>
</table>

Examples

This example creates a columnar table btest, with two VARCHAR columns, named keys and values, and adds three sets of values:

```sql
=> CREATE TABLE btest(keys varchar(10), values varchar(10));
CREATE TABLE
=> COPY btest FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
   >> one|1
   >> two|2
   >> three|3
   >> \.  
```

After populating the btest table, call mapaggregate(), using the the over (PARTITION BEST) clause. This call returns the raw_map data:

```sql
=> SELECT MAPAGGREGATE(keys, values) OVER(PARTITION BEST) FROM btest;
raw_map
------------------------------------------------------------------------------------------------------------------
```
The next example illustrates using `MAPTOSTRING()` with the returned `raw_map` from `mapaggregate()` to see the values:

```sql
-> SELECT MAPTOSTRING(raw_map) FROM (SELECT MAPAGGREGATE(keys, values) OVER(PARTITION BEST) FROM btest) bit;

 maptostream
------------------------
 {  "one": "1",
    "three": "3",
    "two": "2"
 }
(1 row)
```

- `MAPVERSION`

**MAPCONTAINSKEY**

Determines whether a VMap contains a virtual column (key). This scalar function returns true (t), if the virtual column exists, or false (f) if it does not. Determining that a key exists before
calling maplookup() lets you distinguish between NULL returns. The maplookup() function uses for both a non-existent key and an existing key with a NULL value.

Syntax

MAPCONTAINSKEY(VMap_data, 'virtual_column_name')

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>• Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>• Other database content</td>
</tr>
</tbody>
</table>

| virtual_column_name | The name of the key to check. |

Examples

This example shows how to use the mapcontainskey() functions with maplookup(). View the results returned from both functions. Check whether the empty fields that maplookup() returns indicate a NULL value for the row (t) or no value (f):

You can use mapcontainskey() to determine that a key exists before calling maplookup(). The maplookup() function uses both NULL returns and existing keys with NULL values to indicate a non-existent key.

```
=> SELECT MAPLOOKUP(__raw__, 'user.location'), MAPCONTAINSKEY(__raw__, 'user.location')
FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
-----------+-------------------
   t       |       t           |
   t       |       t           |
   t       |       t           |
   t       |       t           |
    t      |       t           |
    t      |       t           |
    t      |       t           |
    t      |       t           |
    t      |       t           |
```

- MAPVALUES
- MAPVERSION

MAPCONTAINSVALUE

Determines whether a VMap contains a specific value. Use this scalar function to return true (t), if the value exists, or false (f), if it does not.

Syntax

MAPCONTAINSVALUE(VMap_data, 'virtual_column_value')

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>- Data returned from a map function such as maplookup()</td>
</tr>
</tbody>
</table>
Vertica Documentation
SQL Reference Manual

l

virtual_column_value

Other database content

The value whose existence you want to confirm.

Examples
This example shows how to use mapcontainsvalue() to determine whether or not a virtual
column contains a particular value. Create a flex table (ftest), and populate it with some
virtual columns and values. Name both virtual columns one:
=> CREATE FLEX TABLE ftest();
CREATE TABLE
=> copy ftest from stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one":1, "two":2}
>> {"one":"one","2":"2"}
>> \.

Call mapcontainsvalue() on the ftest map data. The query returns false (f) for the first
virtual column, and true (t) for the second , which contains the value one:
=> SELECT MAPCONTAINSVALUE(__raw__, 'one') FROM ftest;
mapcontainsvalue
-----------------f
t
(2 rows)

MAPDELIMITEDEXTRACTOR

Extracts data with a delimiter character, and other optional arguments, returning a single VMap value. The USING PARAMETERS phrase specifies optional parameters for the function.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>VARCHAR</td>
<td>Single delimiter character.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Default value:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>header_names</td>
<td>VARCHAR</td>
<td>[Optional] Specifies header names for columns.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Default value:</strong> ucoln</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Where n is the column offset number, starting with 0 for the first column. The function uses default values if you do not specify values for the header_names parameter.</td>
</tr>
<tr>
<td>trim</td>
<td>BOOLEAN</td>
<td>[Optional] Trims white space from header names and field values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Default value:</strong> true</td>
</tr>
<tr>
<td>treat_empty_val_as_null</td>
<td>BOOLEAN</td>
<td>[Optional] Specifies that empty fields become NULLs, rather than empty strings (' ').</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Default value:</strong> true</td>
</tr>
</tbody>
</table>

Examples

These examples use a short set of delimited data:

<table>
<thead>
<tr>
<th>Name</th>
<th>CITY</th>
<th>New city</th>
<th>State</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tom</td>
<td>BOSTON</td>
<td>boston</td>
<td>MA</td>
<td>01</td>
</tr>
<tr>
<td>Eric</td>
<td>Burlington</td>
<td>BURLINGTON</td>
<td>MA</td>
<td>02</td>
</tr>
<tr>
<td>Jamie</td>
<td>cambridge</td>
<td>CAMBRIDGE</td>
<td>MA</td>
<td>08</td>
</tr>
</tbody>
</table>
To begin, save this data as `delim.dat`.

1. Create a flex table, `dflex`:

```
=> CREATE FLEX TABLE dflex();
```  

2. Use COPY to load the `delim.dat` file. Use the flex tables `fdelimitedparser` with the `header='false'` option:

```
=> COPY dflex FROM '/home/release/kmm/flextables/delim.dat' parser fdelimitedparser (header='false');
  Rows Loaded
  4
  (1 row)
```  

3. Create a columnar table, `dtab`, with an identity `id` column, a `delim` column, and a column to hold a VMap, named `vmap`:

```
=> CREATE TABLE dtab (id IDENTITY(1,1), delim varchar(128), vmap long varbinary(512));
```  

4. Use COPY to load the `delim.dat` file into the `dtab` table. For the `mapdelimitedextractor` function, add a header row with `USING PARAMETERS header_names=` option to specify the header row for the sample data, along with `delimiter '!'`:

```
=> COPY dtab(delim, vmap AS MAPDELIMITEDEXTRACTOR (delim
   USING PARAMETERS header_names='Name|CITY|New City|State|Zip')) FROM
  '/home/dbadmin/data/delim.dat'
  DELIMITER '!';
  Rows Loaded
  4
  (1 row)
```  

5. Use `maptostring` for the flex table `dflex` to view the `__raw__` column contents. Notice the default header names in use (`ucol0 – ucol4`), since you specified `header='false'` when you loaded the flex table:

```
=> SELECT MAPTOSTRING(__raw__) FROM dflex limit 10;
```

```
{  
  "ucol0" : "Jamie",
  "ucol1" : "cambridge",
  "ucol2" : "CAMBRIDGE",
```
6. Use maptostring again, this time with the dtab table's vmap column. Compare the results of this output to those for the flex table. Note that maptostring returns the header_name parameter values you specified when you loaded the data:

```sql
=> SELECT MAPTOSTRING(vmap) FROM dtab;

maptostring

{ "CITY" : "CITY", "Name" : "Name", "New City" : "New city", "State" : "State", "Zip" : "zip" }

{ "CITY" : "BOSTON", "Name" : "Tom", "New City" : "boston", "State" : "MA", "Zip" : "02121" }

(4 rows)
```
7. Query the `delim` column to view the contents differently:

```sql
=> SELECT delim FROM dtab;
      delim
-------------------------------
 Name|CITY|New city|State|zip
-----|-----|--------|-----|-----
Tom  |BOSTON|boston   |MA   |02121
Eric |Burlington|BURLINGTON|MA |02482
Jamie|cambridge|CAMBRIDGE|MA |02811
(4 rows)
```

See Also

- [MAPJSONEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

**MAPITEMS**

Returns information about items in a VMap. Use this transform function with one or more optional arguments to access polystructured values within the VMap data. This function requires an `OVER()` clause.

**Syntax**

```sql
MAPITEMS(VMap_data [, passthrough_arg [,...]] )
```
Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>• Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>• Other database content</td>
</tr>
<tr>
<td>passthrough_</td>
<td>[Optional] One or more arguments indicating keys within the map data</td>
</tr>
<tr>
<td>arg</td>
<td>in VMap_data</td>
</tr>
</tbody>
</table>

Examples

The following examples illustrate using mapItems() with the over(PARTITION BEST) clause.

This example determines the number of virtual columns in the map data using a flex table, labeled darkmountain. Query using the count() function to return the number of virtual columns in the map data:

```
=> SELECT COUNT(keys) FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
  count
-----
   19
(1 row)
```

The next example determines what items exist in the map data:

```
=> SELECT * FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
   keys  |   values
----------|-----------
hike_safety | 50.6      
name       | Mt Washington
height     | 17000
hike_safety | 12.2      
name       | Denali
height     | 29029
hike_safety | 34.1      
name       | Everest
height     | 14000
hike_safety | 22.8      
name       | Kilimanjaro
type       | mountain
```
Directly Query a Key Value in a VMap

Review the following JSON input file, `simple.json`. In particular, notice the array called `three_Array`, and its four values:

```json
{
    "one": "one",
    "two": 2,
    "three_Array": [
        "three_One",
        "three_Two",
        3,
        "three_Four"
    ],
    "four": 4,
    "five_Map": {
        "five_One": 51,
        "five_Two": "Fifty-two",
        "five_Three": "fifty three",
        "five_Four": 54,
        "five_Five": "5 x 5"
    },
    "six": 6
}
```

1. Create a flex table, mapper:

```sql
=> CREATE FLEX TABLE mapper();
CREATE TABLE
```

1. Load `simple.json` into the flex table mapper:

```sql
=> COPY mapper FROM '/home/dbadmin/data/simple.json' parser fjsonparser (flatten_arrays=false, flatten_maps=false);
Rows Loaded
----------
1
(1 row)
```

2. Call `mapkeys` on the flex table's `__raw__` column to see the flex table's keys, but not the key submaps. The return values indicate `three_Array` as one of the virtual columns:

```sql
=> SELECT MAPKEYS(__raw__) OVER() FROM mapper;
keys
----------
```

Vertica Analytic Database (9.0.x)
3. Call `mapitems` on flex table mapper with `three_Array` as a pass-through argument to the function. The call returns these array values:

```
=> SELECT __identity__, mapitems(three_Array) OVER(PARTITION BY __identity__) FROM mapper;

<table>
<thead>
<tr>
<th><strong>identity</strong></th>
<th>keys</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>three_One</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>three_Two</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>three_Four</td>
</tr>
</tbody>
</table>
```

(4 rows)

- `MAPVERSION`
MAPJSONEXTRACTOR

Extracts content of repeated JSON data objects, including nested maps, or data with an outer list of JSON elements. The USING PARAMETERS phrase specifies optional parameters for the function. Empty input does not generate a Warning or Error.

Note: The function fails if the output size of the function is greater than 65000.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flatten_maps</td>
<td>BOOLEAN</td>
<td>[Optional] Flattens sub-maps within the JSON data, separating map levels with a period (.). Default value: true</td>
</tr>
<tr>
<td>flatten_arrays</td>
<td>BOOLEAN</td>
<td>[Optional] Converts lists to sub-maps with integer keys. Lists are not flattened by default. Default value: false</td>
</tr>
<tr>
<td>reject_on_duplicate</td>
<td>BOOLEAN</td>
<td>[Optional] Specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues.  Default value: false</td>
</tr>
<tr>
<td>reject_on_empty_key</td>
<td>BOOLEAN</td>
<td>[Optional] Rejects any row containing a key without a value (reject_on_empty_key=true). Default value: false</td>
</tr>
<tr>
<td>omit_empty_keys</td>
<td>BOOLEAN</td>
<td>[Optional] Omits any key from the load data that does not have a value (omit_empty_keys=true). Default value: false</td>
</tr>
<tr>
<td>start_point</td>
<td>CHAR</td>
<td>[Optional] Specifies the name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the start_point value. The parser processes data after the first instance, and up to the second, ignoring any remaining data. Default value: none</td>
</tr>
</tbody>
</table>
Examples

These examples use the following sample JSON data:

```json
{  "id": "5001",  "type": "None" }
{  "id": "5002",  "type": "Glazed" }
{  "id": "5005",  "type": "Sugar" }
{  "id": "5007",  "type": "Powdered Sugar" }
{  "id": "5004",  "type": "Maple" }
```

Save this example data as `bake_single.json`, and load that file.

1. Create a flex table, `flexjson`:

```sql
=> CREATE FLEX TABLE flexjson();
CREATE TABLE
```

2. Use `COPY` to load the `bake_single.json` file with the `fjsonparser` parser:

```sql
=> COPY flexjson FROM '/home/dbadmin/data/bake_single.json' parser fjsonparser();
Rows Loaded
----------
  5
(1 row)
```

3. Create a columnar table, `coljson`, with an identity column (`id`), a `json` column, and a column to hold a VMap, called `vmap`:

```sql
=> CREATE TABLE coljson(id IDENTITY(1,1), json varchar(128), vmap long varbinary(10000));
CREATE TABLE
```

4. Use `COPY` to load the `bake_single.json` file into the `coljson` table, using the `mapjsonextractor` function:

```sql
=> COPY coljson (json, vmap AS MapJSONExtractor(json)) FROM '/home/dbadmin/data/bake_single.json';
Rows Loaded
----------
  5
(1 row)
```

5. Use the `map tostring` function for the flex table `flexjson` to output the `__raw__` column contents as strings:

```sql
=> SELECT MAPTOSTRING(__raw__) FROM flexjson limit 5;
map tostring
```
6. Use the maptostring function again, this time with the coljson table's vmap column and compare the results. The element order differs:

```sql
=> SELECT MAPTOSTRING(vmap) FROM coljson limit 5;
maptostring

{   
  "id" : "5001",
  "type" : "None"
}

{   
  "id" : "5002",
  "type" : "Glazed"
}

{   
  "id" : "5004",
  "type" : "Maple"
}

{   
  "id" : "5005",
  "type" : "Sugar"
}

{   
  "id" : "5007",
  "type" : "Powdered Sugar"
}
```

(5 rows)
MAPKEYS

Returns the virtual columns (and values) present in any VMap data. This transform function requires an `over(PARTITION BEST)` clause.

Syntax

```
MAPKEYS(VMap_data)
```

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The _raw_ column of a flex table</td>
</tr>
<tr>
<td></td>
<td>Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>Other database content</td>
</tr>
</tbody>
</table>

Examples

**Determine Number of Virtual Columns in Map Data**

This example shows how to create a query, using an `over(PARTITION BEST)` clause with a flex table, `darkdata` to find the number of virtual column in the map data. The table is populated with JSON tweet data.
Query Ordered List of All Virtual Columns in the Map

This example shows a snippet of the return data when you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
      count
-------
      550
(1 row)
```

```
=> SELECT * FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;

MAPKEYSINFO

Returns virtual column information from a given map. This transform function requires an over(PARTITION BEST) clause.

Syntax

MAPKEYSINFO(VMap_data)

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>Other database content</td>
</tr>
</tbody>
</table>

Returns

This function is a superset of the MAPKEYS() function. It returns the following information about each virtual column:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keys</td>
<td>The virtual column names in the raw data.</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>length</td>
<td>The data length of the key name, which can differ from the actual string length.</td>
</tr>
<tr>
<td>type_oid</td>
<td>The OID type into which the value should be converted. Currently, the type is always 116 for a LONG VARCHAR, or 199 for a nested map that is stored as a LONG VARBINARY.</td>
</tr>
<tr>
<td>row_num</td>
<td>The number of rows in which the key was found.</td>
</tr>
<tr>
<td>field_num</td>
<td>The field number in which the key exists.</td>
</tr>
</tbody>
</table>

Examples

This example shows a snippet of the return data you receive if you query an ordered list of all virtual columns in the map data:

```sql
=> SELECT * FROM (SELECT MAPKEYSINFO(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
```

<table>
<thead>
<tr>
<th>keys</th>
<th>length</th>
<th>type_oid</th>
<th>row_num</th>
<th>field_num</th>
</tr>
</thead>
<tbody>
<tr>

- **MAPAGGREGATE**
MAPLOOKUP

Returns single-key values from VMAP data. This scalar function returns a LONG VARCHAR, with values, or NULL if the virtual column does not have a value.

Using maplookup is case insensitive to virtual column names. To avoid loading same-name values, set the fjsonparser parser reject_on_duplicate parameter to true when data loading.

You can control the behavior for non-scalar values in a VMAP (like arrays), when loading data with the fjsonparser or favroparser parsers and its flatten-arrays argument. See Loading JSON Data and the FJSONPARSER reference.

For information about using maplookup() to access nested JSON data, see Querying Nested Data.

Syntax

MAPLOOKUP(VMap_data, 'virtual_column_name' [USING PARAMETERS [case_sensitive={false | true}] [, buffer_size=n] ]

Parameters

| VMap_data     | Any VMap data. The VMap can exist as: |
- The __raw__ column of a flex table
- Data returned from a map function such as maplookup()
- Other database content

<table>
<thead>
<tr>
<th>virtual_column_name</th>
<th>The name of the virtual column whose values this function returns.</th>
</tr>
</thead>
<tbody>
<tr>
<td>buffer_size</td>
<td>[Optional parameter] Specifies the maximum length (in bytes) of each value returned for virtual_column_name. To return all values for virtual_column_name, specify a buffer_size equal to or greater than (=&gt;) the number of bytes for any returned value. Any returned values greater in length than buffer_size are rejected. <strong>Default value:</strong> 0 (No limit on buffer_size)</td>
</tr>
<tr>
<td>case_sensitive</td>
<td>[Optional parameter] Specifies whether to return values for virtual_column_name if keys with different cases exist. <strong>Example:</strong> (...) USING PARAMETERS case_sensitive=true) <strong>Default value:</strong> false</td>
</tr>
</tbody>
</table>

**Examples**

This example returns the values of one virtual column, user.location:

```sql
=> SELECT MAPLOOKUP(__raw__, 'user.location') FROM darkdata ORDER BY 1;
maplookup
----------
Chile
Nesnia
Uptown
.
chicago
(12 rows)
```

**Using maplookup buffer_size**

Use the buffer_size= parameter to indicate the maximum length of any value that maplookup returns for the virtual column you specify. If none of the returned key values can be greater than n bytes, use this parameter to allocate n bytes as the buffer_size.

For the next example, save this JSON data to a file, simple_name.json:
1. Create a flex table, logs.

2. Load the simple_name.json data into logs, using the fjsonparser. Specify the flatten_arrays option as True:

   ```sql
   => COPY logs FROM '/home/dbadmin/data/simple_name.json' 
      PARSER fjsonparser(flatten_arrays=True);
   ```

3. Use maplookup with buffer_size=0 for the logs table name key. This query returns all of the values:

   ```sql
   => SELECT MAPLOOKUP(__raw__, 'name' USING PARAMETERS buffer_size=0) FROM logs;
   MapLookup
   .......... 
   sierra
   ben
   janis
   jen
   (4 rows)
   ```

4. Next, call maplookup() three times, specifying the buffer_size parameter as 3, 5, and 6, respectively. Now, maplookup() returns values with a byte length less than or equal to (=) buffer_size:

   ```sql
   => SELECT MAPLOOKUP(__raw__, 'name' USING PARAMETERS buffer_size=3) FROM logs;
   MapLookup
   .......... 
   ```
Disambiguate Empty Output Rows

This example shows how to interpret empty rows. Using `maplookup` without first checking whether a key exists can be ambiguous. When you review the following output, 12 empty rows, you cannot determine whether a `user.location` key has:

- A non-NULL value
- A NULL value
- No value

```sql
=> SELECT MAPLOOKUP(__raw__, 'user.location') FROM darkdata;
maplookup
---------
(12 rows)
```
To disambiguate empty output rows, use the `mapcontainskey()` function in conjunction with `maplookup()`. When `maplookup` returns an empty field, the corresponding value from `mapcontainskey` indicates `t` for a NULL or other value, or `f` for no value.

The following example output using both functions lists rows with NULL or a name value as `t`, and rows with no value as `f`:

```
=> SELECT MAPLOOKUP(__raw__, 'user.location'), MAPCONTAINSKEY(__raw__, 'user.location')
FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
-----------|---------------------------
        t |                t
        t |                t
        t |                t
        t |                t
Chile   |                t
Nesnia  |                t
Uptown  |                t
chicago |    f >>>>>>>>>No value
|    f >>>>>>>>>No value
|    f >>>>>>>>>No value
|    f >>>>>>>>>No value
(12 rows)
```

**Check for Case-Sensitive Virtual Columns**

You can use `maplookup()` with the `case_sensitive` parameter to return results when key names with different cases exist.

1. Save the following sample content as a JSON file. This example saves the file as `repeated_key_name.json`:

```json
{
    "test": "lower1"
}
{
    "TEST": "upper1"
}
{
    "TEst": "half1"
}
{
    "test": "lower2",
    "TEst": "half2"
}
{
    "TEST": "upper2",
    "TEst": "half3"
}
{
    "test": "lower3",
    "TEST": "upper3"
}
```
2. Create a flex table, dupe, and load the JSON file:

```sql
=> CREATE FLEX TABLE dupe();
CREATE TABLE
dbt=> COPY dupe FROM '/home/release/KData/repeated_key_name.json' parser fjsonparser();
Rows Loaded
-----------------
 8
(1 row)
```

MAPPUT

Accepts a VMap and one or more key/value pairs and returns a new VMap with the key/value pairs added. Keys must be set using the auxiliary function SetMapKeys(), and can only be constant strings. If the VMap has any of the new input keys, then the original values are replaced by the new ones.

Syntax

MAPPUT(VMap_data, value1 [, value2, value3, ...] using parameters keys=SetMapKeys('key1'[, 'key2', 'key3', ...])

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMap_data</td>
<td>Any VMap data. The VMap can exist as:</td>
</tr>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>- Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>- Other database content</td>
</tr>
<tr>
<td>value</td>
<td>One or more values to add to the VMap specified in VMap_data.</td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keys</td>
<td>The keys parameter must be the result of SetMapKeys(). SetMapKeys() simply takes one or more constant strings as arguments.</td>
</tr>
</tbody>
</table>

The following example shows how to create a flex table and use COPY to enter some basic JSON data. After creating a second flex table (vmapdata2), insert the new vmap results from mapput(), with additional key/value pairs.

1. Create sample table:

```sql
=> CREATE FLEX TABLE vmapdata1();
CREATE TABLE
```
2. Load sample JSON data from STDIN:

```sql
=> COPY vmapdata1 FROM stdin parser fjsonparser();
Enter data to be copied followed by a newline. 
End with a backslash and a period on a line by itself. 
>>{"aaa": 1, "bbb": 2, "ccc": 3} 
>> 
```

3. Create another flex table and use the function to insert data into it:

```sql
=> CREATE FLEX TABLE vmapdata2(); 
=> INSERT INTO vmapdata2 SELECT MAPPUT(_raw_, '7','8','9' 
using parameters keys=SetMapKeys('xxx','yyy','zzz')) from vmapdata1; 
```

4. View the difference between the original and the new flex tables:

```sql
=> SELECT MAPTOSTRING(_raw__) FROM vmapdata1; 
maptostring------------------------ 
| { 
| "aaa" : "1", 
| "bbb" : "2", 
| "ccc" : "3" 
| } 
| (1 row) 
=> SELECT MAPTOSTRING(_raw__) FROM vmapdata2; 
maptostring------------------------ 
| { 
| "mapput" : { 
| "aaa" : "1", 
| "bbb" : "2", 
| "ccc" : "3", 
| "xxx" : "7", 
| "yyy" : "8", 
| "zzz" : "9" 
| } 
| }
```

MAPREGEXEXTRACTOR

Extracts data from a regular expression and returns the results as a VMap. Use the USING PARAMETERS pattern= phrase, followed by the regular expression.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern=</td>
<td>VARCHAR</td>
<td>The regular expression as a string. Default value: An empty string (&quot; &quot;).</td>
</tr>
<tr>
<td>record_terminator</td>
<td>VARCHAR</td>
<td>[Optional] The character used to separate input records. Default value: \n.</td>
</tr>
<tr>
<td>logline_column</td>
<td>VARCHAR</td>
<td>[Optional] The destination column containing the full string that the regular expression matched. Default value: An empty string (&quot; &quot;).</td>
</tr>
</tbody>
</table>
Examples

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread_name, and thread_id strings.

Caution: For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, ((thread_id(?:0x)?[0-9a-f]+).

'^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+) (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+) -(?(?<transaction_id>[0-9a-f])?):[\[]<component>\w+\][\[]\w+\]<\(\w+\) @?\(?<enode>\w+\): (?<text>.*'))

The following examples may include newline characters for display purposes.

1. Create a flex table, flogs:

   => CREATE FLEX TABLE flogs();

2. Use COPY to load a sample log file (vertica.log), using the flex table fregexparsel. Note that this example includes added line characters for displaying long text lines.

   => COPY flogs FROM '/home/dbadmin/tempdat/vertica.log' PARSER FREGEXPARSER(pattern='^\(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+) (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+) -(?(?<transaction_id>[0-9a-f])?):[\[]<component>\w+\][\[]\w+\]<\(\w+\) @?\(?<enode>\w+\): (?<text>.*'));

   Rows Loaded
   ------------
   81399
   (1 row)

3. Use MapToString to return the results from calling MapRegexExtractor with a regular expression. The output returns the results of the function in string format.

   => SELECT MAPTOSTRING(MapregexExtractor(E'2014-04-02 04:02:51.011 TM Moveout:0x2aab08008f860-a0000000002067 [Txn] <INFO> Begin Txn: a0000000002067 'Moveout: Tuple Mover' using PARAMETERS pattern='(\(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+) (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+) -(?(?<transaction_id>[0-9a-f])?):[\[]<component>\w+\][\[]\w+\]<\(\w+\) @?\(?<enode>\w+\): (?<text>.*')) FROM flogs where _identity_=13;
See Also

- MAPDELIMITEDEXTRACTOR
- MAPJSONEXTRACTOR

MAPSIZE

Returns the number of virtual columns present in any VMap data. Use this scalar function to determine the size of keys.

Syntax

MAPSIZE(VMap_data)

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The <code>__raw__</code> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>Other database content</td>
</tr>
</tbody>
</table>

```sql
maptostring
-- 
{
  "component": "Txn",
  "level": "INFO",
  "text": "Begin Txn: a0000000002067 'Moveout: Tuple Mover'",
  "thread_id": "0x2aab9000f860",
  "thread_name": "TM Moveout",
  "time": "2014-04-02 04:02:51.011",
  "transaction_id": "a0000000002067"
}
(1 row)
```
Examples

This example shows the returned sizes from the number of keys in the flex table darkmountain:

```sql
=> SELECT MAPSIZE(__raw__) FROM darkmountain;
mapsize
--------
3
4
4
4
4
(5 rows)
```

MAPTOSTRING

Recursively builds a string representation VMap data, including nested JSON maps. Use this transform function to display the VMap contents in a readable LONG VARCHAR format. Use mptostring to see how map data is nested before querying virtual columns with mapvalues().
Syntax

MAPTOSTRING(VMap_data [using parameters canonical_json={true | false}])

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>• Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>• Other database content</td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>canonical_json</th>
<th>=bool</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>[Optional parameter]</td>
</tr>
<tr>
<td></td>
<td>Produces canonical JSON output by default, using the first instance of any duplicate keys in the map data.</td>
</tr>
<tr>
<td></td>
<td>Use this parameter as other UDF parameters, preceded by using parameters, as shown in the examples. Setting this argument to false maintains the previous behavior of mptostring() and returns same-name keys and their values.</td>
</tr>
<tr>
<td></td>
<td><strong>Default value:</strong> canonical-json=true</td>
</tr>
</tbody>
</table>

Examples

The following example shows how to create a sample flex table, darkdata and load JSON data from STDIN. By calling mptostring() twice with both values for the canonical_json parameter, you can see the different results on the flex table __raw__ column data.
1. Create sample table:

```sql
=> CREATE FLEX TABLE darkdata();
CREATE TABLE
```

2. Load sample JSON data from STDIN:

```sql
=> COPY darkdata FROM stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"aaa": 1, "aaa": 2, "AAA": 3, "bbb": "aaa\bbb"
>> \.
```

3. Call mptostring() with its default behavior using canonical JSON output, and then review the flex table contents. The function returns the first duplicate key and its value ("aaa": "1") but omits remaining duplicate keys ("aaa": "2"):

```sql
=> SELECT MAPTOSTRING(__raw__) FROM darkdata;
maptostring
-----------------------------------------------
{  
    "AAA": "3",
    "aaa": "1",
    "bbb": "aaa\bbb"
}
(1 row)
```

4. Next, call mptostring() with using parameters canonical_json=false). This time, the function returns the first duplicate keys and their values:

```sql
=> SELECT MAPTOSTRING(__raw__ using parameters canonical_json=false) FROM darkdata;
maptostring
-----------------------------------------------
{
    "aaa": "1",
    "aaa": "2",
    "AAA": "3",
    "bbb": "aaa\bbb"
}
(1 row)
```

• MAPKEYSINFO
• MAPLOOKUP
• MAPSIZE
• MAPVALUES
• MAPVERSION

MAPVALUES

Returns a string representation of the top-level values from a VMap. This transform function requires an over() clause.

Syntax

MAPVALUES(VMap_data)

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>The VMap from which values should be returned. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>• Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>• Other database content</td>
</tr>
</tbody>
</table>

Examples

The following example shows how to query a darkmountain flex table, using an over() clause (in this case, the over(PARTITION BEST) clause) with mapvalues().
=> SELECT * FROM (SELECT MAPVALUES(darkmountain._raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
values
-------------------
29029
34.1

MAPVERSION

Returns the version or invalidity of any map data. This scalar function returns the map version (such as 1) or -1, if the map data is invalid.

Syntax

MAPVERSION(VMap_data)

Arguments

| VMap_data | The VMap data either from a __raw__ column in a flex table or from the data returned from a map function such as maplookup(). |

Examples

The following example shows how to use mapversion() with the darkmountainflex table, returning mapversion 1 for the flex table map data:

```sql
=> SELECT MAPVERSION(__raw__) FROM darkmountain;
  version
------------
       1
       1
       1
       1
       1
(5 rows)
```

**MATERIALIZE_FLEXTABLE_COLUMNS**

Materializes virtual columns listed as `key_names` in the `flextable_keys` table you compute using either `COMPUTE_FLEXTABLE_KEYS` or `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`.

**Note:** Each column that you materialize with this function counts against the data storage limit of your license. To check your Vertica license compliance, call the `AUDIT()` or `AUDIT_FLEX()` functions.

**Syntax**

```
MATERIALIZE_FLEXTABLE_COLUMNS('[[[database.]schema.]flextable] [, n-columns [, keys-table-name]]
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td><code>flextable</code></td>
<td>The name of the flex table with columns to materialize. Specifying only the flex table name attempts to materialize up to 50 columns of key names in the default <code>flextable_keys</code> table. When you use this argument, the function:</td>
</tr>
<tr>
<td></td>
<td>- Skips any columns already materialized</td>
</tr>
</tbody>
</table>
Ignores any empty keys

To materialize a specific number of columns, use the optional parameter n_columns, described next.

**n-columns**

The number of columns to materialize. The function attempts to materialize the number of columns from the flex_table_keys table, skipping any columns already materialized.

Vertica tables support a total of 1600 columns, which is the largest value you can specify for n-columns. The function orders the materialized results by frequency, descending, key_name when materializing the first n columns.

**keys-table-name**

The name of a flex_keys_table from which to materialize columns. The function:

- Materializes the number of columns (value of n-columns) from keys-table-name
- Skips any columns already materialized
- Orders the materialized results by frequency, descending, key_name when materializing the first n columns.

Examples

The following example shows how to call MATERIALIZE_FLEXTABLE_COLUMNS to materialize columns. First, load a sample file of tweets (tweets_10000.json) into the flex table twitter_r.

After loading data and computing keys for the sample flex table, call materialize_flextable_columns to materialize the first four columns:

```sql
=> COPY twitter_r FROM '/home/release/KData/tweets_10000.json' parser fjsonparser();
Rows Loaded
-------------
10000
(1 row)

=> SELECT compute_flextable_keys ('twitter_r');
compute_flextable_keys
-------------------------------------------------------------------------------
Please see public.twitter_r_keys for updated keys
(1 row)

=> select materialize_flextable_columns('twitter_r', 4);
```
materialize_flextable_columns

The following columns were added to the table public.twitter_r:
  contributors
  entities.hashtags
  entities.urls

For more details, run the following query:
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and table_name = 'twitter_r';

(1 row)

The last message in the example recommends querying system table MATERIALIZE_FLEXTABLE_COLUMNS_RESULTS for the results of materializing the columns, as shown:

```
=> SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and table_name = 'twitter_r';
  table_id | table_schema | table_name | creation_time | key_name
-----------------+-----------------+------------+---------------+----------
      4503599627373 | public | twitter_r | 2013-11-20 17:00:27.945484-05 | contributors
ADDED | Added successfully
      4503599627373 | public | twitter_r | 2013-11-20 17:00:27.94551-05 | entities.hashtags

RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW

Restores the _keys table and the _view. The function also links the _keys table with its associated flex table, in cases where either table is dropped. The function also indicates whether it restored one or both objects.
Syntax

RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('flex_table')

Arguments

| flex_table | The name of a flex table. |

Examples

This example shows how to invoke this function with an existing flex table, restoring both the _keys table and _view:

=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
   RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
-----------------------------
The keys table public.darkdata_keys was restored successfully.
The view public.darkdata_view was restored successfully.
(1 row)

This example illustrates that the function restored darkdata_view, but that darkdata_keys did not need restoring:

=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
   RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
-----------------------------
The keys table public.darkdata_keys already exists and is linked to darkdata.
The view public.darkdata_view was restored successfully.
(1 row)

After restoring the _keys table, there is no content. To populate the flex keys, call the COMPUTE_FLEXTABLE_KEYS meta function.

=> SELECT * FROM darkdata_keys;
   key_name | frequency | data_type_guess
----------|-----------|-----------------|
(0 rows)

Hadoop Functions

This section contains functions to manage interactions with Hadoop.

CLEAR_HDFS_CACHES

Clears the configuration information copied from HDFS and any cached connections.

This function affects reads using the hdfs scheme in the following ways:

- This function flushes information loaded from configuration files copied from Hadoop (such as core-site.xml). These files are found on the path set by the HadoopConfDir configuration parameter.

- This function flushes information about which Name Node is active in a High Availability (HA) Hadoop cluster. Therefore, the first request to Hadoop after calling this function is slower than expected.

Vertica maintains a cache of open connections to name nodes to reduce latency. This function flushes that cache.

Syntax

CLEAR_HDFS_CACHES ( )

Privileges

Superuser

Example

The following example clears the Hadoop configuration information:

```sql
=> SELECT CLEAR_HDFS_CACHES();
CLEARED_HDFS_CACHES
--------------------
Cleared
```
See Also

Apache Hadoop Parameters

**KERBEROS_HDFS_CONFIG_CHECK**

Tests the Kerberos configuration of a Vertica cluster that uses HDFS. This function is a more specific version of **KERBEROS_CONFIG_CHECK**.

You can call this function with arguments to specify an HDFS configuration to test, or without arguments. If you call it with no arguments, this function reads the HDFS configuration files and fails if it does not find them. See Configuring the hdfs Scheme. If it finds configuration files, it tests all configured nameservices.

The function performs the following tests, in order:

- Are Kerberos services available?
- Does a keytab file exist and are the Kerberos and HDFS configuration parameters set in the database?
- Can Vertica read and invoke kinit with the keys to authenticate to HDFS and obtain the database Kerberos ticket?
- Can Vertica perform hdfs and webhdfs operations using both the database Kerberos ticket and user-forwardable tickets?
- Can Vertica make unauthenticated WebHCat calls?

If any test fails, the function returns a descriptive error message.

**Syntax**

```
KERBEROS_HDFS_CONFIG_CHECK( ['hdfsHost:hdfsPort',
   'webhdfsHost:webhdfsPort', 'webhcatHost:webhcatPort'] )
```

**Arguments**

| hdfsHost, hdfsPort | The hostname or IP address and port of the HDFS name node. Vertica uses this server to access data that is specified with hdfs |
URLs. If the value is '', the function skips this part of the check.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>webhdfsHost</code>, <code>webhdfsPort</code></td>
<td>The hostname or IP address and port of the WebHDFS server. Vertica uses this server to access data that is specified with webhdfs URLs. If the value is '', the function skips this part of the check.</td>
</tr>
<tr>
<td><code>webhcatHost</code>, <code>webhcatPort</code></td>
<td>The hostname or IP address and port of the WebHCat server. The HCatalog Connector uses this server to access data through Hive. If the value is '', the function skips this part of the check.</td>
</tr>
</tbody>
</table>

Privileges

This function does not require privileges.

Examples

The following example shows the results when the function infers the configuration from the HDFS configuration files. In this example, the configuration files use HiveServer2, not WebHCat, so the function skips the WebHCat part of the test.

```sql
=> SELECT KERBEROS_HDFS_CONFIG_CHECK();
kerberos_hdfs_config_check
---------------------------------------------
-------- Checking Hadoop Kerberos configuration--------

HadoopFS parameters:
  Principal: [vertica/data.hadoop.com@EXAMPLE.COM]
  Token Refresh Frequency: 0
  Connection Timeout: 60
  Authentication (default): [/scratch_b/user/data/vertica.user.q18v05.keytab]
ok: krb5 exists at [/scratch_b/user/data/q18v05.krb5.conf]
ok: Vertica can kinit using keytab file
ok: User [user_1] has valid client authentication for kerberos principal [user_1@EXAMPLE.COM]

**Inferring HDFS configuration**
  Number of HDFS Clusters: 1
  Cluster 1: Nameservice [ns-q18v05] has [2] Namenodes [q18v05.example.com:8020]

ok: Can make unauthenticated external curl connection
ok: Can make authenticated external curl connection
ok: Can access using ticket for [Vertica]
ok: Can access using ticket for [user_1]

---------- Checking HCatalog ----------
SYNC_WITH_HCATALOG_SCHEMA

Copies the structure of a Hive database schema available through the HCatalog Connector to a Vertica schema.

Syntax

SYNC_WITH_HCATALOG_SCHEMA( local_schema, hcatalog_schema, [drop_tables] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local_schema</td>
<td>The existing Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as hcatalog_schema, or it can be a separate one created using CREATE SCHEMA.</td>
</tr>
<tr>
<td>hcatalog_schema</td>
<td>The HCatalog schema to copy. This is the schema created using CREATE HCATALOG SCHEMA.</td>
</tr>
<tr>
<td>[drop_tables]</td>
<td>If true, drop any tables in local_schema that do not correspond to a table in hcatalog_schema</td>
</tr>
</tbody>
</table>

Notes

The SYNC_WITH_HCATALOG_SCHEMA function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

Hive STRING and BINARY data types are matched, in Vertica, to VARCHAR(65000) and VARBINARY(65000) types. You can use ALTER TABLE to adjust these after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can result in mismatches between the two. Set values in Vertica based on bytes, not characters, to avoid data truncation.
If the data size exceeds the declared size for the column, Vertica logs an event at read time in the QUERYEVENTS system table.

This function can synchronize the HCatalog schema directly, in which case you call it with the same schema name for both parameters. It can also synchronize a different schema to the HCatalog schema.

If you change the settings of any HCatalog Connector configuration parameters (Apache Hadoop Parameters), you must call this function again.

Privileges

The user must have CREATE privileges on Local_schema.

The user also requires access to Hive data in one of the following ways:

- Have USAGE permissions on hcatalog_schema, if Hive does not use an authorization service to manage access.
- Have permission through an authorization service (Sentry or Ranger), and have access to the underlying files in HDFS. (Sentry can provide that access through ACL synchronization.)
- Be the dbadmin user, with or without an authorization service.

Examples

The following example shows using SYNC_WITH_HCATALOG_SCHEMA to synchronize an HCatalog schema named hcat:

```sql
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost' HCATALOG_SCHEMA='default'
    HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema
---------------------------------------------------------------
Schema hcat synchronized with hcat
tables in hcat = 56
tables altered in hcat = 0
tables created in hcat = 56
stale tables in hcat = 0
table changes erred in hcat = 0
(1 row)
=> -- Use vsql's \d command to describe a table in the synced schema
=> \d hcat.messages
List of Fields by Tables
| Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key |
```

Vertica Documentation
SQL Reference Manual
Vertica Analytic Database (9.0.x)
The following example shows using SYNC_WITH_HCATALOG_SCHEMA followed by ALTER TABLE to adjust a column value:

```sql
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost' HCATALOG_SCHEMA='default'
  -> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
...
=> ALTER TABLE hcat.t ALTER COLUMN a1 SET DATA TYPE long varchar(1000000);
=> ALTER TABLE hcat.t ALTER COLUMN a2 SET DATA TYPE long varbinary(1000000);
```

The following example shows using SYNC_WITH_HCATALOG_SCHEMA with a local (non-HCatalog) schema:

```sql
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost' HCATALOG_SCHEMA='default'
  -> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> CREATE SCHEMA hcat_local;
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat_local', 'hcat');
```

**SYNC_WITH_HCATALOG_SCHEMA_TABLE**

Copies the structure of a single table in a Hive database schema available through the HCatalog Connector to a Vertica table.

**Syntax**

```
SYNC_WITH_HCATALOG_SCHEMA_TABLE( local_schema, hcatalog_schema, table_name )
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Local_schema</strong></td>
<td>The existing Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as <strong>hcatalog_schema</strong>, or it can be a separate one created using CREATE SCHEMA.</td>
</tr>
<tr>
<td><strong>hcatalog_schema</strong></td>
<td>The HCatalog schema to copy. This is the schema created using CREATE HCATALOG SCHEMA.</td>
</tr>
</tbody>
</table>
**table_name** The table in **hcatalog_schema** to copy.

---

**Notes**

If **table_name** does not exist in **hcatalog_schema**, this function returns an error.

If **table_name** already exists in **local_schema**, the **SYNC_WITH_HCATALOG_SCHEMA_TABLE** function overwrites it.

Hive STRING and BINARY data types are matched, in Vertica, to VARCHAR(65000) and VARBINARY(65000) types. You can use **ALTER TABLE** to adjust these after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can result in mismatches between the two. Set values in Vertica based on bytes, not characters, to avoid data truncation.

If the data size exceeds the declared size for the column, Vertica logs an event at read time in the **QUERY_EVENTS** system table.

This function can synchronize the HCatalog schema directly, in which case you call it with the same schema name for both of the **local_schema** and **hcatalog_schema** parameters. It can also synchronize a different schema to the HCatalog schema.

---

**Privileges**

The user must have CREATE privileges on **local_schema**.

The user also requires access to Hive data in one of the following ways:

- Have USAGE permissions on **hcatalog_schema**, if Hive does not use an authorization service to manage access.

- Have permission through an authorization service (Sentry or Ranger), and have access to the underlying files in HDFS. (Sentry can provide that access through ACL synchronization.)

- Be the dbadmin user, with or without an authorization service.

---

**Examples**

The following example shows using **SYNC_WITH_HCATALOG_SCHEMA_TABLE** to synchronize the "nation" table:
```sql
=> CREATE SCHEMA 'hcat_local';
CREATE SCHEMA

=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost' HCATALOG_SCHEMA='hcat'
    HCATALOG_USER='hcatuser';
CREATE SCHEMA

=> SELECT sync_with_hcatalog_schema_table('hcat_local', 'hcat', 'nation');
sync_with_hcatalog_schema_table
-------------------------------
    Schema hcat_local synchronized with hcat for table nation
    table nation is created in schema hcat_local
    (1 row)
```

The following example shows the behavior if the "nation" table already exists in the local schema:

```sql
=> SELECT sync_with_hcatalog_schema_table('hcat_local','hcat','nation');
sync_with_hcatalog_schema_table
-------------------------------
    Schema hcat_local synchronized with hcat for table nation
    table nation is altered in schema hcat_local
    (1 row)
```

**VERIFY_HADOOP_CONF_DIR**

Verifies that the Hadoop configuration that is used to access HDFS is valid on all Vertica nodes. The configuration is valid if:

- all required configuration files are found on the path defined by the HadoopConfDir configuration parameter
- all properties needed by Vertica are set in those files

This function does not attempt to validate the settings of those properties; it only verifies that they have values.

It is possible for Hadoop configuration to be valid on some nodes and invalid on others. The function reports a validation failure if the value is invalid on any node; the rest of the output reports the details.

**Syntax**

```sql
VERIFY_HADOOP_CONF_DIR( )
```
Parameters

This function has no parameters.

Privileges

This function does not require privileges.

Examples

The following example shows the results when the Hadoop configuration is valid.

```sql
=> SELECT VERIFY_HADOOP_CONF_DIR();
verify_hadoop_conf_dir

Validation Success
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0002: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0003: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0004: HadoopConfDir [PG_TESTOUT/config] is valid
(1 row)
```

In the following example, the Hadoop configuration is valid on one node, but on other nodes a needed value is missing.

```sql
=> SELECT VERIFY_HADOOP_CONF_DIR();
verify_hadoop_conf_dir

Validation Failure
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/test_configs/config] is valid
v_vmart_node0002: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
v_vmart_node0003: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
v_vmart_node0004: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
(1 row)
```

LDAP Link Functions

This section contains the functions associated with the Vertica LDAP Link function.

In This Section
LDAP_LINK_SYNC_START

Begins the synchronization between the LDAP server and Vertica immediately rather than waiting for the interval set in LDAPLinkInterval.

Syntax

ldap_link_sync_start()

Privileges

You must be a dbadmin user.

Example

=> SELECT ldap_link_sync_start();

See Also

LDAP Link Parameters
License Management Functions

This section contains function that monitor Vertica license status and compliance.

AUDIT

Returns the raw data size (in bytes) of a database, schema, or table as it is counted in an audit of the database size. Unless you specify zero error tolerance and 100 percent confidence level, AUDIT returns only approximate results that can vary over multiple iterations.

AUDIT estimates the size using the same data sampling method as Vertica uses, to determine if a database complies with the licensed database size allowance. Vertica does not use these results to determine whether the size of the database complies with the Vertica license's data allowance. For details, see Auditing Database Size in the Administrator's Guide.

Syntax

AUDIT('[[[database.]schema.]scope ][, 'granularity'[, error-tolerance[, confidence-level]]] )

Parameters

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>myschema.myObject</td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>scope</th>
<th>Specifies the extent of the audit:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Empty string ('') audits the entire database.</td>
</tr>
<tr>
<td></td>
<td>The name of the schema or table to audit.</td>
</tr>
<tr>
<td></td>
<td>The schema or table to audit. To audit the database, set this parameter to an empty string.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>granularity</th>
<th>The level at which the audit reports its results, one of the following strings:</th>
</tr>
</thead>
</table>
*database*  
*schema*  
*table*

The level of granularity must be equal to or less than the granularity of *scope*. If you omit this parameter, granularity is set to the same level as *scope*. Thus, if `online_sales` is a schema, the following statements are identical:

```sql
AUDIT('online_sales', 'schema');
AUDIT('online_sales');
```

If `AUDIT` sets granularity to a level lower than the target object, it returns with a message that refers you to system table `USER_AUDITS`. For details, see Querying `V_CATALOG.USER_AUDITS`, below.

**error-tolerance**

Specifies the percentage margin of error allowed in the audit estimate. Enter the tolerance value as a decimal number, between 0 and 100. The default value is 5, for a 5% margin of error.

Setting this value to 0 results in a full database audit, which is very resource intensive, as `AUDIT` analyzes the entire database. A full database audit significantly impacts performance, so Vertica does not recommend it for a production database.

Caution: Due to the iterative sampling that the auditing process uses, setting the error tolerance to a small fraction of a percent (for example, 0.00001) can cause `AUDIT` to run for a longer period than a full database audit. The lower you specify this value, the more resources the audit uses, as it performs more data sampling.

**confidence-level**

Specifies the statistical confidence level percentage of the estimate. Enter the confidence value as a decimal number, between 0 and 100. The default value is 99, indicating a confidence level of 99%.

The higher the confidence value, the more resources the function uses, as it performs more data sampling. Setting this value to 100 results in a full audit of the database, which is very resource intensive, as the function analyzes all of the database. A full
database audit significantly impacts performance, so Vertica does not recommend it for a production database.

Privileges

Superuser, or one of the following:

- SELECT privilege on the target tables
- USAGE privilege on the target schemas

**Note:** If you audit a schema or the database, Vertica only returns the size of all objects that you have privileges to access within the audited object, as described above.

Querying V_CATALOG.USER_AUDITS

If AUDIT sets granularity to a level lower than the target object, it returns with a message that refers you to system table USER_AUDITS. To obtain audit data on objects of the specified granularity, query this table. For example, the following query seeks to audit all tables in the store schema:

```sql
=> SELECT AUDIT('store', 'table');
AUDIT
See table sizes in v_catalog.user_audits for schema store
(1 row)
```

The next query queries USER_AUDITS and obtains the latest audits on those tables:

```sql
=> SELECT object_name, AVG(size_bytes)::int size_bytes, MAX(audit_start_timestamp::date) audit_start
    FROM user_audits WHERE object_schema='store'
    GROUP BY rollup(object_name) HAVING GROUPING_ID(object_name) < 1 ORDER BY GROUPING_ID();
```

<table>
<thead>
<tr>
<th>object_name</th>
<th>size_bytes</th>
<th>audit_start</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_dimension</td>
<td>22067</td>
<td>2017-10-26</td>
</tr>
<tr>
<td>store_orders_fact</td>
<td>27201312</td>
<td>2017-10-26</td>
</tr>
<tr>
<td>store_sales_fact</td>
<td>301260170</td>
<td>2017-10-26</td>
</tr>
</tbody>
</table>

(3 rows)

Examples

See [Auditing Database Size](#).
AUDIT_FLEX

Returns the estimated ROS size of __raw__ columns, equivalent to the export size of the flex data in the audited objects. You can audit all flex data in the database, or narrow the audit scope to a specific flex table, projection, or schema. Vertica stores the audit results in system table USER_AUDITS.

The audit excludes the following:

- Flex keys
- Other columns in the audited tables.
- Temporary flex tables

Syntax

AUDIT_FLEX ('[scope]')

Parameters

<table>
<thead>
<tr>
<th>scope</th>
<th>Specifies the extent of the audit:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Empty string (' ') audits all flexible tables in the database.</td>
</tr>
<tr>
<td></td>
<td>The name of a schema, projection, or flex table.</td>
</tr>
</tbody>
</table>

Privileges

Superuser, or one of the following:

- SELECT privilege on the target tables
- USAGE privilege on the target schemas

Note: If you audit a schema or the database, Vertica only returns the size of all objects that you have privileges to access within the audited object, as described above.

Examples

Audit all flex tables in the current database:
dbs=> select audit_flex('');
  audit_flex
--------------
  8567679
(1 row)

Audit the flex tables in schema public:

dbs=> select audit_flex('public');
  audit_flex
--------------
  8567679
(1 row)

Audit the flex data in projection bakery_b0:

dbs=> select audit_flex('bakery_b0');
  audit_flex
--------------
  8566723
(1 row)

Audit flex table bakery:

dbs=> select audit_flex('bakery');
  audit_flex
--------------
  8566723
(1 row)

To report the results of all audits saved in the USER_AUDITS, the following shows part of an extended display from the system table showing an audit run on a schema called test, and the entire database, dbs:

dbs=> \x
Expanded display is on.

dbs=> select * from user_audits;
- RECORD 1 ------------------------------------------+
size_bytes | 0
user_id | 45035996273704962
user_name | release
object_id | 45035996273736664

confidence_interval_lower_bound_bytes | 0
confidence_interval_upper_bound_bytes | 0
sample_count | 0
### AUDIT_LICENSE_SIZE

Triggers an immediate audit of the database size to determine if it is in compliance with the raw data storage allowance included in your Vertica licenses.

**Syntax**

```
AUDIT_LICENSE_SIZE()
```

**Privileges**

Superuser

**Example**

```
=> SELECT audit_license_size();
audit_license_size
---------------------
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization : 0%
Audit Time : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.
License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```
AUDIT_LICENSE_TERM

Triggers an immediate audit to determine if the Vertica license has expired.

Syntax

AUDIT_LICENSE_TERM()

Privileges

Superuser

Example

```sql
=> SELECT audit_license_term();
  audit_license_term
----------------------
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization : 0%
Audit Time : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.
License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

DISPLAY_LICENSE

Returns the terms of your Vertica license. The information this function displays is:

- The start and end dates for which the license is valid (or "Perpetual" if the license has no expiration).
- The number of days you are allowed to use Vertica after your license term expires (the grace period)
- The amount of data your database can store, if your license includes a data allowance.

Syntax

DISPLAY_LICENSE()
Privileges
None

Examples

```sql
=> SELECT DISPLAY_LICENSE();
    DISPLAY_LICENSE
---------
Vertica Systems, Inc.
1/1/2011
12/31/2011
30
50TB
(1 row)
```

**GET_AUDIT_TIME**

Reports the time when the automatic audit of database size occurs. Vertica performs this audit if your Vertica license includes a data size allowance. For details of this audit, see Managing Licenses in the Administrator's Guide. To change the time the audit runs, use the SET_AUDIT_TIME function.

Syntax

```
GET_AUDIT_TIME()
```

Privileges
None

Example

```sql
=> SELECT get_audit_time();
get_audit_time
--------------------
The audit is scheduled to run at 11:59 PM each day.
(1 row)
```
GET_COMPLIANCE_STATUS

Displays whether your database is in compliance with your Vertica license agreement. This information includes the results of Vertica's most recent audit of the database size (if your license has a data allowance as part of its terms), the license term (if your license has an end date), and the number of nodes (if your license has a node limit).

GET_COMPLIANCE_STATUS measures data allowance by TBs (where a TB equals $1024^4$ bytes).

The information displayed by GET_COMPLIANCE_STATUS includes:

- The estimated size of the database (see Auditing Database Size in the Administrator's Guide for an explanation of the size estimate).

- The raw data size allowed by your Vertica license.

- The percentage of your allowance that your database is currently using.

- The number of nodes and license limit.

- The date and time of the last audit.

- Whether your database complies with the data allowance terms of your license agreement.

- The end date of your license.

- How many days remain until your license expires.

Note: If your license does not have a data allowance, end date, or node limit, some of the values might not appear in the output for GET_COMPLIANCE_STATUS.

If the audit shows your license is not in compliance with your data allowance, you should either delete data to bring the size of the database under the licensed amount, or upgrade your license. If your license term has expired, you should contact Vertica immediately to renew your license. See Managing Licenses in the Administrator's Guide for further details.

Syntax

GET_COMPLIANCE_STATUS()

Privileges

None
Examples

```sql
=> SELECT GET_COMPLIANCE_STATUS();
get_compliance_status
-----------------------
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization : 0%
Audit Time : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

The following example shows output for a Vertica for SQL on Apache Hadoop cluster.

```sql
=> SELECT GET_COMPLIANCE_STATUS();
get_compliance_status
-----------------------
Node count : 4
License Node limit : 5
No size-compliance concerns for an Unlimited license

No expiration date for a Perpetual license
(1 row)
```

SET_AUDIT_TIME

Sets the time that Vertica performs automatic database size audit to determine if the size of the database is compliant with the raw data allowance in your Vertica license. Use this function if the audits are currently scheduled to occur during your database's peak activity time. This is normally not a concern, since the automatic audit has little impact on database performance.

Audits are scheduled by the preceding audit, so changing the audit time does not affect the next scheduled audit. For example, if your next audit is scheduled to take place at 11:59PM and you use SET_AUDIT_TIME to change the audit schedule 3AM, the previously scheduled 11:59PM audit still runs. As that audit finishes, it schedules the next audit to occur at 3AM.

Vertica always performs the next scheduled audit even where you have changed the audit time using SET_AUDIT_TIME and then triggered an automatic audit by issuing the statement, SELECT AUDIT_LICENSE_SIZE. Only after the next scheduled audit does Vertica begin auditing at the new time you set using SET_AUDIT_TIME. Thereafter, Vertica audits at the new time.

Syntax

```
SET_AUDIT_TIME(time)
```
time | A string containing the time in 'HH:MM AM/PM' format (for example, '1:00 AM') when the audit should run daily.

Privileges
Superuser

Example

```sql
=> SELECT SET_AUDIT_TIME('3:00 AM');

<table>
<thead>
<tr>
<th>set_audit_time</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>----------------</td>
<td>--------</td>
</tr>
</tbody>
</table>
```

The scheduled audit time will be set to 3:00 AM after the next audit.

(1 row)

Multiple Active Result Sets Functions

This section contains the functions associated with the Vertica library for Multiple Active Result Sets (MARS).

CLOSE_ALL_RESULTSETS

Closes all result set sessions within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

Syntax

```sql
SELECT CLOSE_ALL_RESULTSETS ('session_id')
```

Parameters

| session_id | A string that specifies the Multiple Active Result Sets session. |

Privileges

None; however, without superuser privileges, you can only close your own session's results.
Examples

This example shows how you can view a MARS result set, then close the result set, and then confirm that the result set has been closed.

Query the MARS storage table. One session ID is open and three result sets appear in the output.

```sql
SELECT * FROM SESSION_MARS_STORE;
```

| node_name: v_vmart_node0001 | session_id: server1.company.-83046:1y28gu9 | remaining_row_count: 776460 | bytes_used: 89692848 | user_name: dbadmin | resultset_id: 7 | row_count: 777460 |
| node_name: v_vmart_node0001 | session_id: server1.company.-83046:1y28gu9 | remaining_row_count: 323349 | bytes_used: 81862010 | user_name: dbadmin | resultset_id: 8 | row_count: 324349 |
| node_name: v_vmart_node0001 | session_id: server1.company.-83046:1y28gu9 | remaining_row_count: 276947 | bytes_used: 32978280 | user_name: dbadmin | resultset_id: 9 | row_count: 277947 |

(1 row)

Close all result sets for session server1.company.-83046:1y28gu9:

```sql
SELECT CLOSE_ALL_RESULTSETS('server1.company.-83046:1y28gu9');
```

Closing all result sets from server1.company.-83046:1y28gu9

(1 row)

Query the MARS storage table again for the current status. You can see that the session and result sets have been closed:

```sql
SELECT * FROM SESSION_MARS_STORE;
```

| node_name: v_vmart_node0001 | session_id: server1.company.-83046:1y28gu9 | remaining_row_count: 0 | bytes_used: 0 | user_name: dbadmin | resultset_id: 0 | row_count: 0 |

(0 rows)

**CLOSE_RESULTSET**

Closes a specific result set within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.
Syntax

```
SELECT CLOSE_RESULTSET ('session_id', ResultSetID)
```

Parameters

<table>
<thead>
<tr>
<th>session_id</th>
<th>A string that specifies the Multiple Active Result Sets session containing the ResultSetID to close.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResultSetID</td>
<td>An integer that specifies which result set to close.</td>
</tr>
</tbody>
</table>

Privileges

None; however, without superuser privileges, you can only close your own session's results.

Examples

This example shows a MARS storage table opened. One session_id is currently open, and one result set appears in the output.

```
SELECT * FROM SESSION_MARS_STORE;
```

```
<table>
<thead>
<tr>
<th>node_name</th>
<th>session_id</th>
<th>user_name</th>
<th>resultset_id</th>
<th>row_count</th>
<th>remaining_row_count</th>
<th>bytes_used</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>server1.company.-83046:1y28gu9</td>
<td>dbadmin</td>
<td>1</td>
<td>318718</td>
<td>312718</td>
<td>80441904</td>
</tr>
</tbody>
</table>
(1 row)
```

Close user session server1.company.-83046:1y28gu9 and result set 1:

```
SELECT CLOSE_RESULTSET('server1.company.-83046:1y28gu9', 1);
```

```
Closing result set 1 from server1.company.-83046:1y28gu9
(1 row)
```

Query the MARS storage table again for current status. You can see that result set 1 is now closed:

```
SELECT * FROM SESSION_MARS_STORE;
```

```
<table>
<thead>
<tr>
<th>node_name</th>
<th>session_id</th>
<th>user_name</th>
<th>resultset_id</th>
<th>row_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>server1.company.-83046:1y28gu9</td>
<td>dbadmin</td>
<td>1</td>
<td>318718</td>
</tr>
</tbody>
</table>
(1 row)
```
Partition Management Functions

This section contains partition management functions specific to Vertica.

CALENDAR_HIERARCHY_DAY

Specifies to group DATE partition keys into a hierarchy of years, months, and days. The Vertica Tuple Mover regularly evaluates partition keys against the current date, and merges partitions as needed into the appropriate year and month partition groups.

Syntax

CALENDAR_HIERARCHY_DAY( partition-expression[, active-months[, active-years] ] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>partition-expression</td>
<td>The DATE expression on which to group partition keys, which must be identical to the table's PARTITION BY expression.</td>
</tr>
<tr>
<td>active-months</td>
<td>An integer ( \geq 0 ) that specifies how many months preceding ( \text{MONTH(CURRENT_DATE)} ) to store unique partition keys in separate partitions.</td>
</tr>
<tr>
<td></td>
<td>If you specify 1, only partition keys of the current month are stored in separate partitions.</td>
</tr>
<tr>
<td></td>
<td>If you specify 0, all partition keys of the current month are merged into a partition group for that month.</td>
</tr>
<tr>
<td></td>
<td>For details, see Hierarchical Partitioning.</td>
</tr>
<tr>
<td></td>
<td>Default value: 2</td>
</tr>
<tr>
<td>active-years</td>
<td>An integer ( \geq 0 ), specifies how many years preceding ( \text{YEAR(CURRENT_DATE)} ) to partition group keys by month in separate partitions.</td>
</tr>
<tr>
<td></td>
<td>If you specify 1, only partition keys of the current year are stored in month partition groups.</td>
</tr>
<tr>
<td></td>
<td>If you specify 0, all partition keys of the current and previous years are merged into year partition groups.</td>
</tr>
</tbody>
</table>
For details, see Hierarchical Partitioning.
Default value: 2

Important: The CALENDAR_HIERARCHY_DAY algorithm assumes that most table activity is focused on recent dates. Setting active-years and active-months to a low number ≥ 2 serves to isolate merge activity to date-specific containers, and incurs minimal overhead. Vertica recommends that you use the default setting of 2 for active-years and active-months. For most users, these settings achieve an optimal balance between ROS storage and performance.

Usage

Specify this function in a table partition clause, as its GROUP BY expression:

```
PARTITION BY partition-expression
  GROUP BY CALENDAR_HIERARCHY_DAY(
    group-expression
    [, active-months[, active-years] ]
  )
```

For example:

```
=> CREATE TABLE public.store_orders
  (    order_no int,
       order_date timestamp NOT NULL,
       shipper varchar(20),
       ship_date date
  );
...
=> ALTER TABLE public.store_orders
  PARTITION BY order_date::DATE
  GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 3, 2) REORGANIZE;
```

For details on usage, see Hierarchical Partitioning in the Administrator's Guide.

COPY_PARTITIONS_TO_TABLE

Copies partitions from one table to another. This lightweight partition copy increases performance by initially sharing the same storage between two tables. After the copy operation is complete, the tables are independent of each other. Users can perform operations
on one table without impacting the other. These operations can increase the overall storage required for both tables.

Note: Although they share storage space, Vertica considers the partitions as discrete objects for license capacity purposes. For example, copying a one TB partition would only consume one TB of space. Your Vertica license, however, considers them as separate objects consuming two TB of space.

Syntax

COPY_PARTITIONS_TO_TABLE (  
  '[[database.]schema.]source-table',  
  'min-range-value',  
  'max-range-value',  
  '[[database.]schema.]target-table'  
)  

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>source-table</td>
<td>The source table of the partitions to copy.</td>
</tr>
<tr>
<td>min-range-value</td>
<td>The minimum and maximum value of partition keys to copy, where min-range-value must be ≤ max-range-value. To copy one partition, min-range-value and max-range-value must be equal.</td>
</tr>
<tr>
<td>max-range-value</td>
<td></td>
</tr>
<tr>
<td>target-table</td>
<td>The target table of the partitions to copy. If the table does not exist, Vertica creates a table from the source table's definition, by calling CREATE TABLE with LIKE and INCLUDING PROJECTIONS clause. The new table inherits ownership from the source table. For details, see Replicating a Table.</td>
</tr>
<tr>
<td>force-split</td>
<td>Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>true: Split ROS containers as needed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>false (default): Return with an error if ROS containers must be split to implement this operation.</td>
</tr>
</tbody>
</table>

### Privileges

- Ownership or USAGE privileges on the source table.
- CREATE privileges on the target table, if COPY_PARTITIONS_TO_TABLE creates it.

### Table Attribute Requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- Partition clause
- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, refer to Enforcing Primary Key and Foreign Key Constraints.

  Note: If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For MOVE_PARTITIONS_TO_TABLE and COPY_PARTITIONS_TO_TABLE, Vertica enforces enabled check constraints on the target table only. For SWAP_PARTITIONS_BETWEEN_TABLES, Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.
- Number and definitions of text indices.

### Table Restrictions

The following restrictions apply to the source and target tables:
• If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.

• The following tables cannot be used as sources or targets:
  - Temporary tables
  - Virtual tables
  - System tables
  - External tables

Examples

If you call COPY_PARTITIONS_TO_TABLE and the target table does not exist, the function creates the table automatically. In the following example, the target table `partn_backup.trades_200801` does not exist. COPY_PARTITIONS_TO_TABLE creates the table and replicates the partition. Vertica also copies all the constraints associated with the source table except foreign key constraints.

```sql
=> SELECT COPY_PARTITIONS_TO_TABLE ('prod_trades', '200801', '200801', 'partn_backup.trades_200801');
COPY_PARTITIONS_TO_TABLE
----------------------------------------
1 distinct partition values copied at epoch 15.
(1 row)
```

See Also

Archiving Partitions

DROP_PARTITIONS

This function supersedes meta-function DROP_PARTITION. Vertica will continue to support DROP_PARTITION. For information about this function, refer to the Vertica 8.1 documentation.

Drops the specified table partition keys. If the WOS contains table data, DROP_PARTITIONS forces a moveout before it executes the drop operation.
Syntax

DROP_PARTITIONS (  
  '[[database.]schema.]table-name',  
  'min-range-value',  
  'max-range-value'  
  [, 'force-split']  
)

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>table-name</td>
<td>The target table. The table cannot be used as a dimension table in a pre-join projection and cannot have out-of-date (unrefreshed) projections.</td>
</tr>
<tr>
<td>min-range-value</td>
<td>The minimum and maximum value of partition keys to drop, where min-range-value must be ≤ max-range-value. To drop one partition key, min-range-value and max-range-value must be equal.</td>
</tr>
<tr>
<td>max-range-value</td>
<td></td>
</tr>
</tbody>
</table>
| force-split     | Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:  
  • true: Split ROS containers as needed.  
  • false (default): Return with an error if ROS containers must be split to implement this operation. |

Privileges

One of the following:
- DBADMIN
- Table owner
- USAGE privileges on the table schema and TRUNCATE privileges on the table

Examples

See [Dropping Partitions](#) in the Administrator's Guide.

See Also

*PARTITION_TABLE*

## DUMP_PROJECTION_PARTITION_KEYS

Dumps the partition keys of the specified projection.

### Syntax

```
DUMP_PROJECTION_PARTITION_KEYS( '{[database.]schema.]projection-name'}
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td>projection-name</td>
<td>The projection name.</td>
</tr>
</tbody>
</table>

### Privileges

- SELECT privilege on table
- USAGE privileges on schema
Example

The following statements create the table and projection `online_sales.online_sales_fact` and `online_sales.online_sales_fact_unseg_p`, respectively, and partitions table data by the column `call_center_key`:

```sql
=> CREATE TABLE online_sales.online_sales_fact
(
    sale_date_key int NOT NULL,
    ship_date_key int NOT NULL,
    product_key int NOT NULL,
    product_version int NOT NULL,
    customer_key int NOT NULL,
    call_center_key int NOT NULL,
    online_page_key int NOT NULL,
    shipping_key int NOT NULL,
    warehouse_key int NOT NULL,
    promotion_key int NOT NULL,
    pos_transaction_number int NOT NULL,
    sales_quantity int,
    sales_dollar_amount float,
    ship_dollar_amount float,
    net_dollar_amount float,
    cost_dollar_amount float,
    gross_profit_dollar_amount float,
    transaction_type varchar(16)
) PARTITION BY (online_sales_fact.call_center_key);
```

The following `DUMP_PROJECTION_PARTITION_KEYS` statement dumps the partition key from the projection `online_sales.online_sales_fact_unseg_p`:

```sql
=> SELECT DUMP_PROJECTION_PARTITION_KEYS('online_sales.online_sales_fact_unseg_p');
```

Partition keys on node `v_vmart_node0001`
Projection 'online_sales_fact_unseg_p'
Storage [ROS container]
   No of partition keys: 1
   Partition keys: 200
Storage [ROS container]
   No of partition keys: 1
   Partition keys: 199
...  
Storage [ROS container]
   No of partition keys: 1
   Partition keys: 2
Storage [ROS container]
   No of partition keys: 1
   Partition keys: 1

Partition keys on node `v_vmart_node0002`
Projection 'online_sales_fact_unseg_p'

...
See Also

- Partitioning Tables in the Administrator's Guide
- DUMP_PARTITION_KEYS
- DUMP_TABLE_PARTITION_KEYS
- PARTITION_PROJECTION
- PARTITION_TABLE

**DUMP_TABLE_PARTITION_KEYS**

Dumps the partition keys of all projections for the specified table.

**Syntax**

```
DUMP_TABLE_PARTITION_KEYS ( 'table-name' )
```

**Parameters**

<table>
<thead>
<tr>
<th>table-name</th>
<th>The name of the table.</th>
</tr>
</thead>
</table>

**Privilege**

- SELECT privilege on table
- USAGE privileges on schema

**Examples**

The following example creates a simple table called states and partitions the data by state:
Now dump the partition keys of all projections anchored on table `states`:

```sql
=> SELECT DUMP_TABLE_PARTITION_KEYS('states');

Partition keys on node v_vmart_node0001
Projection 'states_p'
  Storage [ROS container]
    No of partition keys: 1
    Partition keys: VT
  Storage [ROS container]
    No of partition keys: 1
    Partition keys: PA
  Storage [ROS container]
    No of partition keys: 1
    Partition keys: NY
  Storage [ROS container]
    No of partition keys: 1
    Partition keys: MA

Partition keys on node v_vmart_node0002
...
(1 row)
```

See Also

- `DUMP_PROJECTION_PARTITION_KEYS`
- `DUMP_TABLE_PARTITION_KEYS`
- `PARTITION_PROJECTION`
- `PARTITION_TABLE`
- `Partitioning Tables` in the Administrator's Guide

**MOVE_PARTITIONS_TO_TABLE**

Moves partitions from one table to another.
Syntax

MOVE_PARTITIONS_TO_TABLE ( 
  '[[database.]schema.]source-table',
  'min-range-value',
  'max-range-value',
  '[[database.]schema.]target-table' 
  [, force-split] 
)

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>source-table</code></td>
<td>The source table of the partitions to move.</td>
</tr>
<tr>
<td><code>min-range-value</code></td>
<td>The minimum and maximum value of partition keys to move, where <code>min-range-value</code> must be (\leq max-range-value). To move one partition, <code>min-range-value</code> and <code>max-range-value</code> must be equal.</td>
</tr>
<tr>
<td><code>max-range-value</code></td>
<td></td>
</tr>
<tr>
<td><code>target-table</code></td>
<td>The target table of the partitions to move. If the table does not exist, Vertica creates a table from the source table's definition, by calling <code>CREATE TABLE</code> with LIKE and INCLUDING PROJECTIONS clause. The new table inherits ownership from the source table. For details, see Replicating a Table.</td>
</tr>
<tr>
<td><code>force-split</code></td>
<td>Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:</td>
</tr>
<tr>
<td></td>
<td>* true: Split ROS containers as needed.</td>
</tr>
<tr>
<td></td>
<td>* false (default): Return with an error if ROS containers must be split to implement this operation.</td>
</tr>
</tbody>
</table>
Privileges

If the target table does not exist, you must have CREATE privileges on the target schema, to enable table creation. One of the following conditions is also required:

- DBADMIN role
- Owner of the source and target tables
- USAGE privileges on source and target schemas, TRUNCATE privileges on the source table, and INSERT privileges on the target table

Table Attribute Requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- Partition clause
- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, refer to Enforcing Primary Key and Foreign Key Constraints.

  Note: If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For MOVE_PARTITIONS_TO_TABLE and COPY_PARTITIONS_TO_TABLE, Vertica enforces enabled check constraints on the target table only. For SWAP_PARTITIONS_BETWEEN_TABLES, Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.

- Number and definitions of text indices.

Table Restrictions

The following restrictions apply to the source and target tables:
If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.

The following tables cannot be used as sources or targets:
- Temporary tables
- Virtual tables
- System tables
- External tables

Examples
See Archiving Partitions.

See Also
- COPY_PARTITIONS_TO_TABLE
- SWAP_PARTITIONS_BETWEEN_TABLES

PARTITION_PROJECTION

Splits ROS containers for a specified projection. PARTITION_PROJECTION also purges data while partitioning ROS containers if deletes were applied before the AHM epoch.

Syntax

```
PARTITION_PROJECTION ( '[[database.]schema.]projection')
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>
projection | The projection to partition.

Privileges

- Table owner
- USAGE privilege on schema

Examples

In this example, PARTITION_PROJECTION forces a split of ROS containers on the `states_p` projection:

```sql
=> SELECT PARTITION_PROJECTION ('states_p');
PARTITION_PROJECTION
------------------------
Projection partitioned
(1 row)
```

See Also

- PARTITION_TABLE
- Partitioning Tables in the Administrator's Guide

PARTITION_TABLE

Invokes the Tuple Mover to reorganize ROS storage containers as needed to conform with the current partitioning policy.

Syntax

```
PARTITION_TABLE ( '[schema.]table-name')
```

Parameters

<table>
<thead>
<tr>
<th><code>[database.]schema</code></th>
<th>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
</table>
If you specify a database, it must be the current database.

| table-name | The table to partition. |

Privileges

- Table owner
- USAGE privilege on schema

Restrictions

You cannot run PARTITION_TABLE on a table that is an anchor table for a live aggregate projection or a Top-K projection.

See Also

- PARTITION_PROJECTION
- Partitioning Existing Table Data

**PURGE_PARTITION**

Purges a table partition of deleted rows. Similar to PURGE and PURGE_PROJECTION, this function removes deleted data from physical storage so you can reuse the disk space. PURGE_PARTITION removes data only from the AHM epoch and earlier.

Syntax

```sql
PURGE_PARTITION ( '[database.]schema.]table', partition-key )
```

Parameters

| [database.]schema | Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: |

If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th>table</th>
<th>The partitioned table to purge.</th>
</tr>
</thead>
<tbody>
<tr>
<td>partition-key</td>
<td>The key of the partition to purge.</td>
</tr>
</tbody>
</table>

**Privileges**

- Table owner
- USAGE privilege on schema

**Example**

The following example lists the count of deleted rows for each partition in a table, then calls PURGE_PARTITION() to purge the deleted rows from the data.

```sql
=> SELECT partition_key, table_schema, projection_name, sum(deleted_row_count)
    AS deleted_row_count FROM partitions
GROUP BY partition_key, table_schema, projection_name
ORDER BY partition_key;
```

<table>
<thead>
<tr>
<th>partition_key</th>
<th>table_schema</th>
<th>projection_name</th>
<th>deleted_row_count</th>

(10 rows)

```sql
=> SELECT PURGE_PARTITION('t',5); -- Purge partition with key 5.
```

**Task:** merge partitions

(Table: public.t) (Projection: public.t_super)
(1 row)

```sql
=> SELECT partition_key, table_schema, projection_name, sum(deleted_row_count)
    AS deleted_row_count FROM partitions
GROUP BY partition_key, table_schema, projection_name
ORDER BY partition_key;
```

<table>
<thead>
<tr>
<th>partition_key</th>
<th>table_schema</th>
<th>projection_name</th>
<th>deleted_row_count</th>

- `STORAGE_CONTAINERS`

**SWAP_PARTITIONS_BETWEEN_TABLES**

Swaps partitions between two tables.

**Syntax**

```
SWAP_PARTITIONS_BETWEEN_TABLES (  
    '[[database.]schema.]staging-table',  
    'min-range-value',  
    'max-range-value',  
    '[[database.]schema.]target-table'  
    [, force-split]  
)
```

**Parameters**

<table>
<thead>
<tr>
<th><code>[[database.]schema]</code></th>
<th>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>myschema.thisDbObject</td>
<td>(Example)</td>
</tr>
</tbody>
</table>
If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>staging-table</td>
<td>The staging table from which to swap partitions.</td>
</tr>
<tr>
<td>min-range-value</td>
<td>The minimum and maximum value of partition keys to swap,</td>
</tr>
<tr>
<td>max-range-value</td>
<td>where min-range-value must be ( \leq ) max-range-value. To swap one partition, min-range-value and max-range-value must be equal.</td>
</tr>
<tr>
<td>target-table</td>
<td>The table to which the partitions are to be swapped. The target table cannot be the same as the staging table.</td>
</tr>
<tr>
<td>force-split</td>
<td>Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:</td>
</tr>
<tr>
<td></td>
<td>- true: Split ROS containers as needed.</td>
</tr>
<tr>
<td></td>
<td>- false (default): Return with an error if ROS containers must be split to implement this operation.</td>
</tr>
</tbody>
</table>

**Privileges**

One of the following:

- DBADMIN role
- Owner of both tables
- USAGE privileges on both schemas, and TRUNCATE and INSERT privileges on both tables.

**Requirements**

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- Partition clause
- Number of projections
- Projection sort order
• Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, refer to Enforcing Primary Key and Foreign Key Constraints.

  Note: If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

• Check constraints. For MOVE_PARTITIONS_TO_TABLE and COPY_PARTITIONS_TO_TABLE, Vertica enforces enabled check constraints on the target table only. For SWAP_PARTITIONS_BETWEEN_TABLES, Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.

• Number and definitions of text indices.

Restrictions

The following restrictions apply to the source and target tables:

• If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.

• The following tables cannot be used as sources or targets:
  - Temporary tables
  - Virtual tables
  - System tables
  - External tables

Examples

See Swapping Partitions.

See Also

MOVE_PARTITIONS_TO_TABLE
Profiling Functions

This section contains profiling functions specific to Vertica.

CLEAR_PROFILING

Clears from memory data for the specified profiling type.

*Note:* Vertica stores profiled data in memory, so profiling can be memory intensive depending on how much data you collect.

Syntax

`CLEAR_PROFILING( 'profiling-type' )`

Parameters

<table>
<thead>
<tr>
<th>profiling-type</th>
<th>The type of profiling data to clear:</th>
</tr>
</thead>
<tbody>
<tr>
<td>session</td>
<td>Clears profiling for basic session parameters and lock time out data.</td>
</tr>
<tr>
<td>query</td>
<td>Clears profiling for general information about queries that ran, such as the query strings used and the duration of queries.</td>
</tr>
<tr>
<td>ee</td>
<td>Clears profiling for information about the execution run of each query.</td>
</tr>
</tbody>
</table>

Example

The following statement clears profiled data for queries:

```
=> SELECT CLEAR_PROFILING('query');
```
See Also

- DISABLE_PROFILING
- ENABLE_PROFILING
- SHOW_PROFILING_CONFIG
- Profiling Database Performance

DISABLE_PROFILING

Disables profiling for the specified profiling type.

Syntax

DISABLE_PROFILING( 'profiling-type' )

Parameters

<table>
<thead>
<tr>
<th>profiling-type</th>
<th>The type of profiling data to disable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>session</td>
<td>Disables profiling for basic session parameters and lock time out data.</td>
</tr>
<tr>
<td>query</td>
<td>Disables profiling for general information about queries that ran, such as the query strings used and the duration of queries.</td>
</tr>
<tr>
<td>ee</td>
<td>Disables profiling for information about the execution run of each query.</td>
</tr>
</tbody>
</table>

Example

The following statement disables profiling on query execution runs:

```sql
=> SELECT DISABLE_PROFILING('ee');
DISABLE_PROFILING
---------------------
EE Profiling Disabled
(1 row)
```
See Also

- CLEAR_PROFILING
- ENABLE_PROFILING
- SHOW_PROFILING_CONFIG
- Profiling Database Performance

ENABLE_PROFILING

Enables profiling for the specified profiling type.

**Note:** Vertica stores profiled data in memory, so profiling can be memory intensive depending on how much data you collect.

Syntax

```
ENABLE_PROFILING( 'profiling-type' )
```

Parameters

<table>
<thead>
<tr>
<th>profiling-type</th>
<th>The type of profiling data to enable:</th>
</tr>
</thead>
<tbody>
<tr>
<td>session</td>
<td>Enables profiling for basic session parameters and lock timeout data.</td>
</tr>
<tr>
<td>query</td>
<td>Enables profiling for general information about queries that ran, such as the query strings used and the duration of queries.</td>
</tr>
<tr>
<td>ee</td>
<td>Enables profiling for information about the execution run of each query.</td>
</tr>
</tbody>
</table>

Example

The following statement enables profiling on query execution runs:

```
=> SELECT ENABLE_PROFILING('ee');
```

Enable PROFILING
SHOW_PROFILING_CONFIG

Shows whether profiling is enabled.

Syntax

SHOW_PROFILING_CONFIG ()

Example

The following statement shows that profiling is enabled globally for all profiling types (session, execution engine, and query):

```sql
=> SELECT SHOW_PROFILING_CONFIG();
SHOW_PROFILING_CONFIG
-----------------------------
Session Profiling: Session off, Global on
EE Profiling: Session off, Global on
Query Profiling: Session off, Global on
(1 row)
```

Projection Management Functions

This section contains projection management functions specific to Vertica.

See Also

- V_CATALOG.PROJECTIONS
- V_CATALOG.PROJECTION_COLUMNS
- V_MONITOR.PROJECTION_REFRESHES
- V_MONITOR.PROJECTION_STORAGE

CLEAR_PROJECTION_REFRESHES

Clears information in system table PROJECTION_REFRESHES of projection refresh history.

System table PROJECTION_REFRESHES records information about refresh operations, successful and unsuccessful. PROJECTION_REFRESHES retains refresh data until one of the following events occurs:

- CLEAR_PROJECTION_REFRESHES is called.
- The table's storage quota is exceeded.

PROJECTION_REFRESHES checks the Boolean column IS_EXECUTING in PROJECTION_REFRESHES to determine whether refresh operations are still running or are complete. The function only removes information for refresh operations that are complete.

Syntax

CLEAR_PROJECTION_REFRESHES()

Privileges

Superuser
Example

```sql
=> SELECT CLEAR_PROJECTION_REFRESHES();
CLEAR_PROJECTION_REFRESHES
-----------------------------
CLEAR
(1 row)
```

See Also

- `REFRESH`
- `START_REFRESH`
- Clearing Projection Refresh History

**EVALUATE_DELETE_PERFORMANCE**

Evaluates projections for potential `DELETE` performance issues. If there are issues found, a warning message is displayed. For steps you can take to resolve delete and update performance issues, see `DELETE` and `UPDATE Optimization` in the Administrator's Guide. This function uses data sampling to determine whether there are any issues with a projection. Therefore, it does not generate false-positives warnings, but it can miss some cases where there are performance issues.

**Note:** Optimizing for delete performance is the same as optimizing for update performance. So, you can use this function to help optimize a projection for updates as well as deletes.

Syntax

`EVALUATE_DELETE_PERFORMANCE ( 'target' )`

Parameters

| `target` | The name of a projection or table. If you supply the name of a projection, only that projection is evaluated for `DELETE` performance issues. If you supply the name of a table, then all of the projections anchored to the table will be evaluated for issues. If you do not provide a projection or table name, `EVALUATE_DELETE_` |
PERFORMANCE examines all of the projections that you can access for DELETE performance issues. Depending on the size you your database, this may take a long time.

Privileges
None

Notes
When evaluating multiple projections, EVALUATE_DELETE_PERFORMANCE reports up to ten projections that have issues, and refers you to a table that contains the full list of issues it has found.

Example
The following example demonstrates how you can use EVALUATE_DELETE_PERFORMANCE to evaluate your projections for slow DELETE performance.

```sql
=> create table example (A int, B int,C int);
CREATE TABLE
=> create projection one_sort (A,B,C) as (select A,B,C from example) order by A;
CREATE PROJECTION
=> create projection two_sort (A,B,C) as (select A,B,C from example) order by A,B;
CREATE PROJECTION
=> select evaluate_delete_performance('one_sort');
   evaluate_delete_performance
No projection delete performance concerns found.
(1 row)
=> select evaluate_delete_performance('two_sort');
   evaluate_delete_performance
No projection delete performance concerns found.
(1 row)
```

The previous example showed that there was no structural issue with the projection that would cause poor DELETE performance. However, the data contained within the projection can create potential delete issues if the sorted columns do not uniquely identify a row or small number of rows. In the following example, Perl is used to populate the table with data using a nested series of loops. The inner loop populates column C, the middle loop populates column B, and the outer loop populates column A. The result is column A contains only three distinct values (0, 1, and 2), while column B slowly varies between 20 and 0 and column C changes in
each row. EVALUATE_DELETE_PERFORMANCE is run against the projections again to see if the data within the projections causes any potential DELETE performance issues.

```plaintext
=> \! perl -e 'for ($i=0; $i<3; $i++) { for ($j=0; $j<21; $j++) { for ($k=0; $k<19; $k++) { printf "%d,%d,%d\n", $i,$j,$k;}}}' | /opt/vertica/bin/vsql -c "copy example from stdin delimiter ',' direct;"
Password:
=> select * from example;
A | B | C
---+---+---
0 | 20 | 18
0 | 20 | 17
0 | 20 | 16
0 | 20 | 15
0 | 20 | 14
0 | 20 | 13
0 | 20 | 12
0 | 20 | 11
0 | 20 | 10
0 | 20 | 9
0 | 20 | 8
0 | 20 | 7
0 | 20 | 6
0 | 20 | 5
0 | 20 | 4
0 | 20 | 3
0 | 20 | 2
0 | 20 | 1
0 | 20 | 0
0 | 19 | 18
1157 rows omitted
2 | 1 | 0
2 | 0 | 18
2 | 0 | 17
2 | 0 | 16
2 | 0 | 15
2 | 0 | 14
2 | 0 | 13
2 | 0 | 12
2 | 0 | 11
2 | 0 | 10
2 | 0 | 9
2 | 0 | 8
2 | 0 | 7
2 | 0 | 6
2 | 0 | 5
2 | 0 | 4
2 | 0 | 3
2 | 0 | 2
2 | 0 | 1
2 | 0 | 0
=> SELECT COUNT (*) FROM example;
COUNT
-------
1197
(1 row)
=> SELECT COUNT (DISTINCT A) FROM example;
COUNT
-------
```
The one_sort projection has potential delete issues since it only sorts on column A which has few distinct values. This means that each value in the sort column corresponds to many rows in the projection, which negatively impacts DELETE performance. Since the two_sort projection is sorted on columns A and B, each combination of values in the two sort columns identifies just a few rows, allowing deletes to be performed faster.

Not supplying a projection name results in all of the projections you can access being evaluated for DELETE performance issues.

GET_PROJECTION_STATUS

Returns information relevant to the status of a projection:

- The current K-safety status of the database
- The number of nodes in the database
- Whether the projection is segmented
- The number and names of buddy projections
- Whether the projection is safe
- Whether the projection is up to date
- Whether statistics have been computed for the projection

Use GET_PROJECTION_STATUS to monitor the progress of a projection data refresh.
Syntax

GET_PROJECTION_STATUS ( '[[database.]schema.]projection' );

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| [database.]schema  | Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: |\
|                    | mysql.schema.thisDbObject                                                   |
| projection         | The projection for which to display status.                                 |

Examples

=> SELECT GET_PROJECTION_STATUS('public.customer_dimension_site01');

---

Current system K is 1.
# of Nodes: 4.
public.customer_dimension_site01 [Segmented: No] [Seg Cols: ] [K: 3] [public.customer_dimension_site04, public.customer_dimension_site03, public.customer_dimension_site02] [Safe: Yes] [UptoDate: Yes] [Stats: Yes]

GET_PROJECTIONS

Returns the following information about projections of the specified anchor table:

<table>
<thead>
<tr>
<th>Contextual information</th>
<th>Projection data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database K-safety</td>
<td>For each projection, specifies:</td>
</tr>
<tr>
<td>Number of database nodes</td>
<td>All buddy projections</td>
</tr>
<tr>
<td>Number of projections for this table</td>
<td>Whether it is segmented</td>
</tr>
<tr>
<td></td>
<td>Whether it is safe</td>
</tr>
<tr>
<td></td>
<td>Whether it is up-to-date.</td>
</tr>
</tbody>
</table>
You can use GET_PROJECTIONS to monitor the progress of a projection data refresh.

Syntax

```
GET_PROJECTIONS ( '[[database.]schema-name.]table' )
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `[database.]schema` | Specifies a schema, by default public. If `schema` is any schema other than public, you must supply the schema name. For example:  

```
myschema.thisDbObject
```

If you specify a database, it must be the current database. |
| `table`         | Anchor table of the projections to list.                                    |

Privileges

None

Examples

The following example gets information about projections for VMart table `store.store_dimension`:

```
=> SELECT GET_PROJECTIONS('store.store_dimension');
-[ RECORD 1 ]-----
GET_PROJECTIONS | Current system K is 1.
# of Nodes: 3. 
Table store.store_dimension has 2 projections.

Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-----------------------------------------------------------------------------------------------
store.store_dimension_b1 [Segmented: Yes] [Seg Cols: "store.store_dimension.store_key"] [K: 1]  
[store.store_dimension_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
store.store_dimension_b0 [Segmented: Yes] [Seg Cols: "store.store_dimension.store_key"] [K: 1]  
[store.store_dimension_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
```

REFRESH

Synchronously refreshes one or more table projections in the foreground, and updates system table `PROJECTION_REFRESHES`. If you run REFRESH with no arguments, it refreshes all
projections that contain stale data.

Syntax

```
REFRESH ( [ '[[database.]schema.]table-name[,...]' ] )
```

Parameters

| `database.]schema` | Specifies a schema, by default public. If `schema` is any schema other than public, you must supply the schema name. For example:
| `myschema.thisDbObject` |

If you specify a database, it must be the current database.

| `table-name` | The anchor table of the projections to refresh. If you specify multiple tables, REFRESH attempts to refresh them in parallel. Such calls are part of the Database Designer deployment (and deployment script). |

Returns

Note: If REFRESH does not refresh any projections, it returns a header string with no results.

<table>
<thead>
<tr>
<th>Column...</th>
<th>Returns...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Projection Name</td>
<td>The projection targeted for refresh.</td>
</tr>
<tr>
<td>Anchor Table</td>
<td>The projection's associated anchor table.</td>
</tr>
<tr>
<td>Status</td>
<td>Projections' refresh status:</td>
</tr>
<tr>
<td></td>
<td>• queued: Queued for refresh.</td>
</tr>
<tr>
<td></td>
<td>• refreshing: Refresh is in process.</td>
</tr>
<tr>
<td></td>
<td>• refreshed: Refresh successfully completed.</td>
</tr>
<tr>
<td></td>
<td>• failed: Refresh did not successfully complete.</td>
</tr>
<tr>
<td>Refresh Method</td>
<td>Method used to refresh the projection.</td>
</tr>
</tbody>
</table>
Privileges

- Superuser
- Owner of the specified tables

Refresh Methods

Vertica can refresh a projection from one of its buddies, if one is available. In this case, the target projection gets the source buddy's historical data. Otherwise, the projection is refreshed from scratch with data of the latest epoch at the time of the refresh operation. In this case, the projection cannot participate in historical queries on any epoch that precedes the refresh operation.

To determine the method used to refresh a given projection, query REFRESH_METHOD from system table PROJECTION_REFRESHES.

Examples

The following example refreshes the projections in tables t1 and t2:

```sql
=> SELECT REFRESH('t1, t2');

REFRESH

Refresh completed with the following outcomes:

Projection Name: [Anchor Table] [Status] [Refresh Method] [Error Count] [Duration (sec)]

"public"."t1_p": [t1] [refreshed] [scratch] [0] [0]"public"."t2_p": [t2] [refreshed] [scratch] [0] [0]
```

This next example shows that only the projection on table t was refreshed:

```sql
=> SELECT REFRESH('allow, public.deny, t');

REFRESH

Refresh completed with the following outcomes:

Projection Name: [Anchor Table] [Status] [Refresh Method] [Error Count] [Duration (sec)]

"n/a"."n/a": [n/a] [failed: insufficient permissions on table "allow"] [0] [1] [0]
```
REFRESH_COLUMNS

Refreshes table columns that are defined with the constraint SET USING. All refresh operations associated with a REFRESH_COLUMNS operation belong to the same transaction. All tables and columns specified by REFRESH_COLUMNS must be refreshed; otherwise, the entire operation is rolled back.

Syntax

```
REFRESH_COLUMNS ( 'tables', ['columns'] [ , 'refresh-mode' ] )
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tables</strong></td>
<td>A comma-delimited list that specifies the tables to refresh:</td>
</tr>
<tr>
<td></td>
<td><code>[[database.]schema.]table[, ...]</code></td>
</tr>
<tr>
<td></td>
<td><strong>Important:</strong> If you specify multiple tables, you must also set parameter <code>refresh-mode</code> to REBUILD.</td>
</tr>
<tr>
<td><strong>columns</strong></td>
<td>Specifies one or more columns to refresh, as follows:</td>
</tr>
<tr>
<td></td>
<td>- '' (empty string)</td>
</tr>
<tr>
<td></td>
<td>Refresh all SET USING/DEFAULT USING columns in the specified tables.</td>
</tr>
<tr>
<td></td>
<td>- <code>[[database.]schema.]table.]column[, ...]</code></td>
</tr>
<tr>
<td></td>
<td>Refresh all columns in the comma-delimited list. The following requirements apply:</td>
</tr>
</tbody>
</table>
|             |     - If REFRESH_COLUMNS specifies multiple tables, all column names must be qualified by their table names. If the target tables span
multiple schemas, all column names must be fully qualified by their schema and table names.

- All specified columns must have a SET USING or DEFAULT USING constraint.

For example:

```
SELECT REFRESH_COLUMNS ('t1, t2', 't1.a, t2.b', 'REBUILD');
```

- `[[database.]schema.]table.*`
  Refresh all SET USING/DEFAULT USING columns in `table`. For example:

```
SELECT REFRESH_COLUMNS ('t1, t2', 't1.*, t2.b', 'REBUILD');
```

If you specify a database, it must be the current database.

**refresh-mode**

Specifies how to refresh SET USING columns:

- **UPDATE**: Marks original rows as deleted and replaces them with new rows. In order to save these updates, you must issue a COMMIT statement.

- **REBUILD**: Replaces all data in the specified columns. The rebuild operation is auto-committed.

If set to an empty string or omitted, REFRESH_COLUMNS executes in UPDATE mode. If you specify multiple tables, you must explicitly specify REBUILD mode.

In both cases, REFRESH_COLUMNS returns an error if any SET USING column is defined as a primary or unique key in a table that enforces those constraints.

See **REBUILD Mode Restrictions** for limitations on using the REBUILD option.

**Privileges**

- MODIFY privilege on the target table, USAGE privilege on its schema

- For each SET USING column to refresh that queries another table or view: SELECT privilege on the queried table/view, USAGE privilege on its schema
REBUILD versus REFRESH Modes

In general, UPDATE is a better choice when changes to SET USING column data are confined to a relatively small number of rows. Use REBUILD when a significant amount of SET USING column data is stale and must be updated. It is generally good practice to call REFRESH_COLUMNS with REBUILD on any new SET USING column—for example, to populate a SET USING column after adding it with ALTER TABLE...ADD COLUMN.

REBUILD Mode Restrictions

If you call REFRESH_COLUMNS on a SET USING column and specify the refresh mode as REBUILD, Vertica returns an error if any of the following conditions is true for that column:

- Specified as a table partition key.
- Included in a live aggregate projection or projection with expressions.
- Included in a projection's sort order or segmentation.
- Included in a projection, and the projection omits an anchor table column that is referenced in the column's SET USING expression.
- Included in a projection's GROUPED clause.

See Also

- Column-Constraint
- Defining Column Values

START_REFRESH

Refreshes projections in the current schema with the latest data of their respective anchor tables. START_REFRESH runs asynchronously in the background, and updates system table PROJECTION_REFRESHES. This function has no effect if a refresh is already running.

To refresh only projections of a specific table, use REFRESH. When you deploy a design through Database Designer, it automatically refreshes its projections.

Syntax

START_REFRESH()
Privileges
None

Requirements
All nodes must be up.

Refresh Methods
Vertica can refresh a projection from one of its buddies, if one is available. In this case, the target projection gets the source buddy's historical data. Otherwise, the projection is refreshed from scratch with data of the latest epoch at the time of the refresh operation. In this case, the projection cannot participate in historical queries on any epoch that precedes the refresh operation.

To determine the method used to refresh a given projection, query REFRESH_METHOD from system table PROJECTION_REFRESHES.

Example

```sql
=> SELECT START_REFRESH();
START_REFRESH
---------------------
Starting refresh background process.
(1 row)
```

See Also

- Refreshing Projections
- CLEAR_PROJECTION_REFRESHES
Purge Functions

This section contains purge functions specific to Vertica.

PURGE

Permanently removes delete vectors from ROS storage containers so disk space can be reused. PURGE removes all historical data up to and including the Ancient History Mark epoch.

PURGE does not delete temporary tables.

Caution: PURGE can temporarily take up significant disk space.

Syntax

PURGE()

Privileges

- Table owner
- USAGE privilege on schema

See Also

- PURGE_PROJECTION
- PURGE_TABLE
- Purging Deleted Data

PURGE_PROJECTION

Permanently removes deleted data from physical storage so disk space can be reused. You can purge historical data up to and including the Ancient History Mark epoch.

Caution: PURGE_PROJECTION can use significant disk space while purging the data.

See PURGE for details about purge operations.
Syntax

PURGE_PROJECTION ( '[[database.]schema.]projection' )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td>projection</td>
<td>The projection to purge.</td>
</tr>
</tbody>
</table>

Privileges

- Table owner
- USAGE privilege on schema

Examples

The following example purges all historical data in projection tbl_p that precedes the Ancient History Mark epoch.

```sql
=> CREATE TABLE tbl (x int, y int);
CREATE TABLE
=> INSERT INTO tbl VALUES(1,2);
  OUTPUT
  -------
  1
  (1 row)
=> INSERT INTO tbl VALUES(3,4);
  OUTPUT
  -------
  1
  (1 row)
dbadmin=> COMMIT;
COMMl
=> CREATE PROJECTION tbl_p AS SELECT x FROM tbl UNSEGMENTED ALL NODES;
WARNING 4468: Projection <public.tbl_p> is not available for query processing.
```
Execute the select start_refresh() function to copy data into this projection. The projection must have a sufficient number of buddy projections and all nodes must be up before starting a refresh.

```sql
CREATE PROJECTION
=> SELECT START_REFRESH();
START_REFRESH

Starting refresh background process.
=> DELETE FROM tbl WHERE x=1;
OUTPUT
-------
 1
(1 row)

=> COMMIT;
COMMIT
=> SELECT MAKE_AHM_NOW();
MAKE_AHM_NOW

AHM set (New AHM Epoch: 9066)
(1 row)

=> SELECT PURGE_PROJECTION ('tbl_p');
PURGE_PROJECTION

Projection purged
(1 row)
```

See Also

- **PURGE_TABLE**
- **STORAGE_CONTAINERS**
- Purging Deleted Data in the Administrator's Guide.

**PURGE_TABLE**

Note: This function was formerly named PURGE_TABLE_PROJECTIONS(). Vertica still supports the former function name.

Permanently removes deleted data from physical storage so disk space can be reused. You can purge historical data up to and including the Ancient History Mark epoch.

Purges all projections of the specified table. You cannot use this function to purge temporary tables.

**Syntax**

```sql
PURGE_TABLE ( '[database.]schema.]table' )
```
Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example: <code>&lt;myschema.thisDbObject&gt;</code></td>
</tr>
<tr>
<td><code>table</code></td>
<td>The table to purge.</td>
</tr>
</tbody>
</table>

Privileges

- Table owner
- USAGE privilege on schema

Caution: PURGE_TABLE could temporarily take up significant disk space while the data is being purged.

Example

The following example purges all projections for the store sales fact table located in the Vmart schema:

```sql
=> SELECT PURGE_TABLE('store.store_sales_fact');
```

See Also

- PURGE
- PURGE_TABLE
- STORAGE_CONTAINERS
- Purging Deleted Data
Session Management Functions

This section contains session management functions specific to Vertica.
See also the SQL system table V_MONITOR.SESSIONS.

CANCEL_REFRESH

Cancels refresh-related internal operations initiated by START_REFRESH and REFRESH.

Syntax

CANCEL_REFRESH()

Privileges

None

Notes

- Refresh tasks run in a background thread in an internal session, so you cannot use INTERRUPT_STATEMENT to cancel those statements. Instead, use CANCEL_REFRESH to cancel statements that are run by refresh-related internal sessions.

- Run CANCEL_REFRESH() on the same node on which START_REFRESH() was initiated.

- CANCEL_REFRESH() cancels the refresh operation running on a node, waits for the cancelation to complete, and returns SUCCESS.

- Only one set of refresh operations runs on a node at any time.

Example

Cancel a refresh operation executing in the background.

```sql
=> SELECT START_REFRESH();
START_REFRESH
-----------------------------------------------
Starting refresh background process.
```
(1 row)
=> SELECT CANCEL_REFRESH();
  CANCEL_REFRESH
-----------------------------------------------
Stopping background refresh process.
(1 row)

See Also

- INTERRUPT_STATEMENT
- SESSIONS
- START_REFRESH
- PROJECTION_REFRESHES

CLOSE_ALL_SESSIONS

Closes all external sessions except the one that issues this function. Use CLOSE_ALL_SESSIONS before shutting down the Vertica database.

Vertica closes sessions asynchronously, so it is possible for another session to open before all previous sessions close. In this case, you must reissue this function before the database can be shut down. To view the status of all open sessions, query the system table SESSIONS.

Query to view all database sessions.

For detailed information about session management options, see Managing Sessions in the Administrator's Guide.

Syntax

CLOSE_ALL_SESSIONS()

Privileges

- Superuser to close all database sessions
- None to close your own session

Examples

Two user sessions are open on separate nodes:
```sql
=> SELECT * FROM sessions;
- [ RECORD 1 ]---------------------------------------------------------------
  node_name   | v_vmartdb_node0001
  user_name   | dbadmin
  client_hostname | 127.0.0.1:52110
  client_pid  | 4554
  login_timestamp | 2011-01-03 14:05:40.252625-05
  session_id  | stress04-4325:0x14
  client_label | |
  transaction_start | 2011-01-03 14:05:44.325781
  transaction_id  | 45035996273728326
  transaction_description | user dbadmin (select * from sessions);
  statement_start | 2011-01-03 15:36:13.896288
  statement_id  | 10
  last_statement_duration_us | 14978
  current_statement | select * from sessions;
  ssl_state  | None
  authentication_method | Trust
- [ RECORD 2 ]---------------------------------------------------------------
  node_name   | v_vmartdb_node0002
  user_name   | dbadmin
  client_hostname | 127.0.0.1:57174
  client_pid  | 30117
  login_timestamp | 2011-01-03 15:33:00.842021-05
  session_id  | stress05-27944:0xc1a
  client_label | |
  transaction_start | 2011-01-03 15:34:46.538102
  transaction_id  | -1
  transaction_description | user dbadmin (COPY Mart_Fact FROM '/data/mart_Fact.tbl'
                        DELIMITER '|' NULL '\n';)
  statement_start | 2011-01-03 15:34:46.538862
  statement_id  | |
  last_statement_duration_us | 26250
  current_statement | COPY Mart_Fact FROM '/data/Mart_Fact.tbl' DELIMITER '|
                     NULL '\n';
  ssl_state  | None
  authentication_method | Trust
- [ RECORD 3 ]---------------------------------------------------------------
  node_name   | v_vmartdb_node0003
  user_name   | dbadmin
  client_hostname | 127.0.0.1:56367
  client_pid  | 1191
  login_timestamp | 2011-01-03 15:31:44.93902-05
  session_id  | stress06-25663:0xbec
  client_label | |
  transaction_start | 2011-01-03 15:34:51.05939
  transaction_id  | 54043195528458775
  transaction_description | user dbadmin (COPY Mart_Fact FROM '/data/Mart_Fact.tbl'
                        DELIMITER '|' NULL '\n' DIRECT;)
  statement_start | 2011-01-03 15:34:51.05939
  statement_id  | |
  last_statement_duration_us | 1591403
  current_statement | COPY Mart_Fact FROM '/data/Mart_Fact.tbl' DELIMITER '|
                     NULL '\n' DIRECT;
  ssl_state  | None
  authentication_method | Trust
```

Close all sessions:
Expanded display is off.

`SELECT CLOSE_ALL_SESSIONS();
CLOSE_ALL_SESSIONS
------------------------------------------`

Close all sessions command sent. Check `v_monitor.sessions` for progress.
(1 row)

**Session contents after issuing CLOSE_ALL_SESSIONS:**

`=> SELECT * FROM SESSIONS;
- [ RECORD 1 ]------------------------------------------
nodename | v_vmartdb_node001
user_name | dbadmin
client_hostname | 127.0.0.1:52110
client_pid | 4554
login_timestamp | 2011-01-03 14:05:40.252625-05
session_id | stress04-4325:0x14
client_label | 
transaction_start | 2011-01-03 14:05:44.325781
transaction_id | 45035996273728326
transaction_description | user dbadmin (SELECT * FROM sessions;)
statement_start | 2011-01-03 16:19:56.720071
statement_id | 25
last_statement_duration_us | 15605
current_statement | SELECT * FROM SESSIONS;
ssl_state | None
authentication_method | Trust`

See Also

- `< Cue Mark>` CLOSE_SESSION
- `< Cue Mark>` CLOSE_USER_SESSIONS
- `< Cue Mark>` SHUTDOWN

**CLOSE_SESSION**

Interrupts the specified external session, rolls back the current transaction if any, and closes the socket. You can only close your own session.

It might take some time before a session is closed. To view the status of all open sessions, query the system table `SESSIONS`.

For detailed information about session management options, see Managing Sessions in the Administrator's Guide.
Syntax

CLOSE_SESSION ( 'sessionid')

Parameters

| sessionid       | A string that specifies the session to close. This identifier is unique within the cluster at any point in time but can be reused when the session closes. |

Privileges

None

Examples

User session opened. Record 2 shows the user session running a COPY DIRECT statement.

```
=> SELECT * FROM sessions;
-[ RECORD 1 ]---------------------------
node_name       | v_vmartdb_node001
user_name       | dbadmin
client_hostname | 127.0.0.1:52110
client_pid      | 4554
login_timestamp | 2011-01-03 14:05:40.252625-05
session_id      | stress04-4325:0x14
client_label    | 
transaction_start | 2011-01-03 14:05:44.325781
transaction_id  | 45035996273728326
transaction_description | user dbadmin (SELECT * FROM sessions;)
statement_start | 2011-01-03 15:36:13.096288
statement_id    | 10
last_statement_duration_us | 14978
current_statement | select * from sessions;
ssl_state       | None
authentication_method | Trust

-[ RECORD 2 ]---------------------------
node_name       | v_vmartdb_node002
user_name       | dbadmin
client_hostname | 127.0.0.1:57174
client_pid      | 30117
login_timestamp | 2011-01-03 15:33:00.842021-05
session_id      | stress05-27944:0xc1a
client_label    | 
transaction_start | 2011-01-03 15:34:46.538102
transaction_id  | -1
transaction_description | user dbadmin (COPY ClickStream_Fact FROM '/data/clickstream/1g/ClickStream_Fact.tbl' DELIMITER '|' NULL '\n' DIRECT;)
statement_start | 2011-01-03 15:34:46.538862
```
Close user session stress05-27944:0xc1a

=> \x
Expanded display is off.
=> SELECT CLOSE_SESSION('stress05-27944:0xc1a');
CLOSE_SESSION
------------------------------------------
Session close command sent. Check v_monitor.sessions for progress.
(1 row)

Query the sessions table again for current status, and you can see that the second session has been closed:

=> SELECT * FROM SESSIONS;
-[ RECORD 1 ]------------------------------------------
node_name | v_vmartdb_node0001
user_name | dbadmin
client_hostname | 127.0.0.1:52110
client_pid | 4554
login_timestamp | 2011-01-03 14:05:40.252625-05
session_id | stress04-4325:0x14
client_label |
transaction_start | 2011-01-03 14:05:44.325781
transaction_id | 4503596273728326
transaction_description | user dbadmin (select * from SESSIONS;)
statement_start | 2011-01-03 16:12:07.841298
statement_id | 20
last_statement_duration_us | 2099
current_statement | SELECT * FROM SESSIONS;
ssl_state | None
authentication_method | Trust

See Also

- CLOSE_ALL_SESSIONS
- SHUTDOWN

CLOSE_USER_SESSIONS

Stops the session for a user, rolls back any transaction currently running, and closes the connection. To determine the status of the sessions to close, query the SESSIONS table.
### CLOSE_USER_SESSIONS

#### Syntax

```sql
CLOSE_USER_SESSIONS ( 'user-name' )
```

#### Parameters

| **user-name** | Specifies the user whose sessions are to be closed. If you specify your own user name, Vertica closes all sessions except the one in which you issue this function. |

#### Privileges

**DBADMIN**

#### Examples

This example closes all active session for user u1:

```sql
=> SELECT close_user_sessions('u1');
```

### See Also

- CLOSE_ALL_SESSIONS
- CLOSE_SESSION
- SHUTDOWN

### GET_NUM_ACCEPTED_ROWS

Returns the number of rows loaded into the database for the last completed load for the current session. **GET_NUM_ACCEPTED_ROWS** is a meta-function. Do not use it as a value in an INSERT query.

The number of accepted rows is not available for a load that is currently in process. Check the **LOAD_STREAMS** system table for its status.
This meta-function supports loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use GET_NUM_ACCEPTED_ROWS for multi-node loads.

Syntax

```
GET_NUM_ACCEPTED_ROWS();
```

Privileges

None

Note: The data regarding accepted rows from the last load during the current session does not persist, and is lost when you initiate a new load.

Examples

This examples shows the number of accepted rows from the vmart_load_data.sql meta-command.

```
=> \\i vmart_load_data.sql;
=> SELECT GET_NUM_ACCEPTED_ROWS ();
GET_NUM_ACCEPTED_ROWS
-----------------------
300000
(1 row)
```

See Also

- `GET_NUM_REJECTED_ROWS`

GET_NUM_REJECTED_ROWS

Returns the number of rows that were rejected during the last completed load for the current session. GET_NUM_REJECTED_ROWS is a meta-function. Do not use it as a value in an INSERT query.

Rejected row information is unavailable for a load that is currently running. The number of rejected rows is not available for a load that is currently in process. Check the LOAD_STREAMS system table for its status.

This meta-function supports loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use GET_NUM_REJECTED_ROWS for multi-node loads.
Syntax

GET_NUM_REJECTED_ROWS();

Privileges

None

Note: The data regarding rejected rows from the last load during the current session does not persist, and is dropped when you initiate a new load.

Examples

This example shows the number of rejected rows from the vmart_load_data.sql meta-command.

```
=> \i vmart_load_data.sql
=> SELECT GET_NUM_REJECTED_ROWS();
GET_NUM_REJECTED_ROWS
-----------------------
0
(1 row)
```

See Also

- GET_NUM_ACCEPTED_ROWS

**INTERRUPT_STATEMENT**

Interrupts the specified statement in a user session, rolls back the current transaction, and writes a success or failure message to the log file.

Sessions can be interrupted during statement execution. Only statements run by user sessions can be interrupted.

Syntax

INTERRUPT_STATEMENT( 'session-id', statement-id )
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session-id</td>
<td>Identifies the session to interrupt. This identifier is unique within the</td>
</tr>
<tr>
<td></td>
<td>cluster at any point in time.</td>
</tr>
<tr>
<td>statement-id</td>
<td>Identifies the statement to interrupt. If the statement-id is valid, the</td>
</tr>
<tr>
<td></td>
<td>statement can be interrupted and INTERRUPT_STATEMENT returns a success</td>
</tr>
<tr>
<td></td>
<td>message. Otherwise the system returns an error.</td>
</tr>
</tbody>
</table>

Privileges

Superuser

Messages

The following list describes messages you might encounter:

<table>
<thead>
<tr>
<th>Message</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statement interrupt sent. Check SESSIONS for progress.</td>
<td>This message indicates success.</td>
</tr>
<tr>
<td>Session &lt;id&gt; could not be successfully interrupted: session not found.</td>
<td>The session ID argument to the interrupt command does not match a running session.</td>
</tr>
<tr>
<td>Session &lt;id&gt; could not be successfully interrupted: statement not found.</td>
<td>The statement ID does not match (or no longer matches) the ID of a running statement (if any).</td>
</tr>
<tr>
<td>No interruptible statement running</td>
<td>The statement is DDL or otherwise non-interruptible.</td>
</tr>
<tr>
<td>Internal (system) sessions cannot be interrupted.</td>
<td>The session is internal, and only statements run by external</td>
</tr>
</tbody>
</table>
Message | Meaning
--- | ---
| | sessions can be interrupted.

Examples

Two user sessions are open. RECORD 1 shows user session running `SELECT FROM SESSION`, and RECORD 2 shows user session running `COPY DIRECT`:

```sql
=> SELECT * FROM SESSIONS;

[-[ RECORD 1 ]-----------------------------------------------
node_name | v_vmartdb_node0001
user_name | dbadmin
client_hostname | 127.0.0.1:52110
client_pid | 4554
login_timestamp | 2011-01-03 14:05:40.252625-05
session_id | stress04-4325:0x14
client_label | |
transaction_start | 2011-01-03 14:05:44.325781
transaction_id | 45035996273728326
transaction_description | user dbadmin (select * from sessions;)
statement_start | 2011-01-03 15:36:13.896288
statement_id | 10
last_statement_duration_us | 14978
current_statement | select * from sessions;
ssl_state | None
authentication_method | Trust

[-[ RECORD 2 ]-----------------------------------------------
node_name | v_vmartdb_node0003
user_name | dbadmin
client_hostname | 127.0.0.1:56367
client_pid | 1191
login_timestamp | 2011-01-03 15:31:44.939302-05
session_id | stress06-25663:0xbec
client_label | |
transaction_start | 2011-01-03 15:34:51.05939
transaction_id | 54043195528458775
transaction_description | user dbadmin (COPY Mart_Fact FROM '/data/Mart_Fact.tbl'
| | DELIMITER '|' NULL '\n' DIRECT;)
statement_start | 2011-01-03 15:35:46.436748
statement_id | 5
last_statement_duration_us | 1591403
current_statement | COPY Mart_Fact FROM '/data/Mart_Fact.tbl' DELIMITER '|' NULL '\n' DIRECT;
ssl_state | None
authentication_method | Trust
```

Interrupt the COPY DIRECT statement running in session `stress06-25663:0xbec`:

```sql
=> \x
Expanded display is off.
=> SELECT INTERRUPT_STATEMENT('stress06-25663:0x1537', 5);
```

Vertica Analytic Database (9.0.x)
Verify that the interrupted statement is no longer active by looking at the `current_statement` column in the `SESSIONS` system table. This column becomes blank when the statement is interrupted:

```sql
=> SELECT * FROM SESSIONS;

node_name          | v_vmartdb_node0001
user_name           | dbadmin
client_hostname     | 127.0.0.1:52110
client_pid          | 4554
login_timestamp     | 2011-01-03 14:05:40.252625-05
session_id          | stress04-4325:8x14
client_label        | transaction_start | 2011-01-03 14:05:44.325781
transaction_id      | 45035996273728326
transaction_description | user dbadmin (select * from sessions;)
statement_start     | 2011-01-03 15:36:14.896208
statement_id        | 10
last_statement_duration_us | 14978
current_statement   | select * from sessions;
ssl_state           | None
authentication_method | Trust
```

**See Also**

- [SESSIONS](#)
- Managing Sessions
- Configuration Parameters
RELEASE_ALL_JVM_MEMORY

Forces all sessions to release the memory consumed by their Java Virtual Machines (JVM).

Syntax

```
RELEASE_ALL_JVM_MEMORY();
```

Privileges

Must be a superuser.

Example

The following example demonstrates viewing the JVM memory use in all open sessions, then calling RELEASE_ALL_JVM_MEMORY() to release the memory:

```
=> select user_name, external_memory_kb FROM V_MONITOR_SESSIONS;
  user_name | external_memory_kb
-------------
  dbadmin    | 79705
(1 row)

=> SELECT RELEASE_ALL_JVM_MEMORY();
RELEASE_ALL_JVM_MEMORY

Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

=> SELECT user_name, external_memory_kb FROM V_MONITOR_SESSIONS;
  user_name | external_memory_kb
-------------
  dbadmin    | 0
(1 row)
```

See Also

- RELEASE_JVM_MEMORY

RELEASE_JVM_MEMORY

Terminates a Java Virtual Machine (JVM), making available the memory the JVM was using.
Syntax

RELEASE_JVM_MEMORY();

Privileges

None.

Examples

User session opened. RECORD 2 shows the user session running COPY DIRECT statement.

```
=> SELECT RELEASE_JVM_MEMORY();
    release_jvm_memory
-----------------------------
Java process killed and memory released
(1 row)
```

See Also

- RELEASE_ALL_JVM_MEMORY

RESERVE_SESSION_RESOURCE

Reserves memory resources from the general resource pool for the exclusive use of the Vertica backup and restore process. No other Vertica process can access reserved resources. If insufficient resources are available, Vertica queues the reservation request.

This metafunction is a session level reservation. When a session ends Vertica automatically releases any resources reserved in that session. Because the metafunction operates at the session level, the resource name does not need to be unique across multiple sessions.

You can view reserved resources by querying the SESSIONS table.

Syntax

RESERVE_SESSION_RESOURCE ( 'name', memory)
Parameters

<table>
<thead>
<tr>
<th>name</th>
<th>The name of the resource to reserve.</th>
</tr>
</thead>
<tbody>
<tr>
<td>memory</td>
<td>The amount of memory in kilobytes to allocate to the resource.</td>
</tr>
</tbody>
</table>

Privileges

None

Example

Reserve 1024 kilobytes of memory for the backup and restore process:

```
=> SELECT reserve_session_resource('VBR_RESERVE',1024);
- [ RECORD 1 ]-----------------------------------------------
             reserve_session_resource | Grant succeed
```

RESET_SESSION

Applies your default connection string configuration settings to your current session.

Syntax

```
RESET_SESSION()
```

Examples

The following example shows how you use RESET_SESSION.

Resets the current client connection string to the default connection string settings:

```
=> SELECT RESET_SESSION();
  RESET_SESSION
------------------
  Reset session: done.
(1 row)
```
Statistic Management Functions

This section contains statistic management functions specific to Vertica.

ANALYZE_EXTERNAL_ROW_COUNT

Calculates the exact number of rows in an external table. ANALYZE_EXTERNAL_ROW_COUNT runs in the background.

**Note:** You cannot calculate row counts on external tables with \texttt{DO_TM_TASK}.

**Syntax**

\begin{verbatim}
ANALYZE_EXTERNAL_ROW_COUNT ('[[\{database\}\{.\}\{schema\}\{.\}\{table-name\} \}]')
\end{verbatim}

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{database}{.}\texttt{schema}</td>
<td>Specifies a schema, by default public. If \texttt{schema} is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code> If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>\texttt{table-name}</td>
<td>Specifies the name of the external table for which to calculate the exact row count. If you supply an empty string, Vertica calculate the exact number of rows for all external tables.</td>
</tr>
</tbody>
</table>

**Privileges**

Any \texttt{INSERT/UPDATE/DELETE} privilege on the external table

**Examples**

Calculate the exact row count for all external tables:

```
=> SELECT ANALYZE_EXTERNAL_ROW_COUNT('');
```

Calculate the exact row count for table \texttt{loader_rejects}:
=> SELECT ANALYZE_EXTERNAL_ROW_COUNT('loader_rejects');

See Also

- Collecting Database Statistics
- DROP_EXTERNAL_ROW_COUNT

ANALYZE_STATISTICS

Note: ANALYZE_STATISTICS is an alias of the function ANALYZE_HISTOGRAM, which is no longer documented.

Collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table. By default, Vertica analyzes multiple columns in a single-query execution plan, depending on resource limits. Such multi-column analysis facilitates the following objectives:

- Reduce plan execution latency.
- Speed up analysis of relatively small tables with many columns.

Vertica writes statistics to the database catalog. The query optimizer uses this collected data to create query plans. Without this data, the query optimizer assumes uniform distribution of data values and equal storage usage for all projections.

You can cancel statistics collection with CTRL+C or by calling INTERRUPT_STATEMENT.

Syntax

ANALYZE_STATISTICS ('[ scope ]' [, 'column[,...]' ] [, percent ] )

Returns

0—Success

If an error occurs, refer to vertica.log for details.
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>scope</strong></td>
<td>Specifies the table on which to collect data, as follows: <code>[[database.]schema.]table</code> If set to an empty string, Vertica collects statistics for all database tables and their projections. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><strong>column</strong></td>
<td>The name of a column in <em>table</em>, typically a predicate column. You can specify multiple comma-delimited columns. Vertica narrows the scope of the data collection to the specified columns. If you alter a table to add a column and populate its contents with either default or other values, call <code>ANALYZE_STATISTICS</code> on this column to get the most current statistics.</td>
</tr>
<tr>
<td><strong>percent</strong></td>
<td>A float value between 0 and 100 that specifies what percentage of data to read from disk (not the amount of data to analyze). If you omit this argument, Vertica sets the percentage to 10. Analyzing more than 10 percent disk space takes proportionally longer to process, but produces a higher level of sampling accuracy.</td>
</tr>
</tbody>
</table>

Privileges

- Any INSERT/UPDATE/DELETE privilege on the specified table.
- USAGE privilege on schema that contains the table

Restrictions

- Vertica collects no statistics on live aggregate and Top-K projections that are anchored to the specified table.
- If you include a SQL function within an expression when you create a projection, Vertica collects no statistics for that projection.
- Vertica supports `ANALYZE_STATISTICS` on local temporary tables but not on global temporary tables. To obtain statistics on a temporary table, create the table with the option...
ON COMMIT PRESERVE ROWS. Otherwise, Vertica deletes the table content when it commits the current transaction, so no table data is available for analysis.

See Also

- Getting Statistics
- DROP_STATISTICS
- EXPORT_STATISTICS
- IMPORT_STATISTICS
- VALIDATE_STATISTICS

DROP_EXTERNAL_ROW_COUNT

Removes external table row count statistics compiled by ANALYZEEXTERNAL_ROW_COUNT. DROPEXTERNAL_ROW_COUNT runs in the background.

Caution: Statistics can be time consuming to regenerate.

Syntax

DROP_EXTERNAL_ROW_COUNT ('[[[database.]schema.]table-name ]');

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>schema</strong></td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><strong>table-name</strong></td>
<td>The external table for which to remove the exact row count. If you specify an empty string, Vertica drops the exact row count statistic for all external tables.</td>
</tr>
</tbody>
</table>
Privileges

- INSERT/UPDATE/DELETE privilege on table
- USAGE privilege on schema that contains the table

Examples

Drop row count statistics for external table `loader_rejects`:

```sql
=> SELECT DROP_EXTERNAL_ROW_COUNT('loader_rejects');
```

See Also

Collecting Database Statistics

DROP_STATISTICS

Removes statistical data on database projections previously generated by `ANALYZE_STATISTICS`. When you drop this data, the Vertica optimizer uses default statistics to create query plans.

**Caution:** Before you drop statistics, be aware that statistics can be time consuming to regenerate.

Syntax

`DROP_STATISTICS ('[ scope ][, 'category'][ , 'column[,...]'] )`

Parameters

<table>
<thead>
<tr>
<th><strong>scope</strong></th>
<th>Specifies the target table as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>[[database.]schema.]table</code></td>
</tr>
<tr>
<td></td>
<td>If set to an empty string, Vertica drops statistics for projections of all database tables.</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><strong>category</strong></td>
<td>The category of statistics to drop for the named table, one of the</td>
</tr>
</tbody>
</table>
following:

- BASE (default) drops histograms and row counts (min/max column values, histogram).
- HISTOGRAMS drops only histograms. Row counts statistics remain.
- ALL drops all statistics.

| column | The name of a column in table, typically a predicate column. You can specify multiple comma-delimited columns. Vertica narrows the scope of dropped statistics to the specified columns only. |

Privileges

- INSERT/UPDATE/DELETE privilege on table
- USAGE privilege on schema that contains the table

Examples

Drop all base statistics for the table store.store_sales_fact:

```
=> SELECT DROP_STATISTICS('store.store_sales_fact');
DROP_STATISTICS
------------------
  0
(1 row)
```

Drop statistics for all table projections:

```
=> SELECT DROP_STATISTICS ('');
DROP_STATISTICS
------------------
  0
(1 row)
```

See Also

- ANALYZE_STATISTICS
- EXPORT_STATISTICS
- **IMPORT_STATISTICS**
- **VALIDATE_STATISTICS**

**EXPORT_STATISTICS**

Generates database statistics in XML format from data previously collected by `ANALYZE_STATISTICS`. Before you export statistics, collect the latest data by calling `ANALYZE_STATISTICS`.

**Syntax**

`EXPORT_STATISTICS ('[filename][, scope][, column[,...]]')`

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>filename</code></td>
<td>Specifies where to write the generated XML. If <code>filename</code> already exists, <code>EXPORT_STATISTICS</code> overwrites it. If you supply an empty string, <code>EXPORT_STATISTICS</code> writes the XML to standard output.</td>
</tr>
</tbody>
</table>
| `scope` | Specifies the target table as follows:  
`[[database.]schema.]table`  
If you specify a table, Vertica exports statistics for its projections. If you supply an empty string, Vertica exports all statistics for the database.  
If you specify a database, it must be the current database. |
| `column` | The name of a column in `table`, typically a predicate column. You can specify multiple comma-delimited columns. Vertica narrows the scope of exported statistics to the specified columns only. |

**Privileges**

Superuser

**Restrictions**

`EXPORT_STATISTICS` does not export statistics for LONG data type columns.
Examples

The following statement exports statistics on the VMart example database to a file:

```sql
=> SELECT EXPORT_STATISTICS('/opt/vertica/examples/VMart_Schema/vmart_stats.xml');
EXPORT_STATISTICS
------------------------------------------
Statistics exported successfully
(1 row)
```

The next statement exports statistics on a single column (price) from a table named food:

```sql
=> SELECT EXPORT_STATISTICS('/opt/vertica/examples/VMart_Schema/price.xml', 'food.price');
EXPORT_STATISTICS
------------------------------------------
Statistics exported successfully
(1 row)
```

See Also

- `ANALYZE_STATISTICS`
- `DROP_STATISTICS`
- `IMPORT_STATISTICS`
- `VALIDATE_STATISTICS`
- Collecting Database Statistics
- Best Practices For Statistics Collection

**IMPORT_STATISTICS**

Imports statistics from the XML file that was generated by `EXPORT_STATISTICS`. Imported statistics override existing statistics for all projections of the table referenced in the XML file.

**Syntax**

```sql
IMPORT_STATISTICS ('filename')
```
Parameters

| filename | The path and name of an XML input file that was generated by \texttt{EXPORT\_STATISTICS}. |

Privileges

Superuser

Restrictions

- \texttt{IMPORT\_STATISTICS} imports only valid statistics. If the source XML file has invalid statistics for a specific column, those statistics are not imported and Vertica throws a warning. If the statistics file has an invalid structure, the import operation fails. To check a statistics file for validity, run \texttt{VALIDATE\_STATISTICS}.

- \texttt{IMPORT\_STATISTICS} returns warnings for LONG data type columns, as the source XML file generated by \texttt{EXPORT\_STATISTICS} contains no statistics for columns of that type.

Example

Import the statistics for the VMart database that \texttt{EXPORT\_STATISTICS} saved.

```sql
=> SELECT IMPORT\_STATISTICS('/opt/vertica/examples/VMart_\_Schema/vmart_stats.xml');

IMPORT\_STATISTICS

-------------------------------------------------------------
Importing statistics for projection date\_dimension\_super column date\_key failure (stats did not contain row counts)
Importing statistics for projection date\_dimension\_super column date failure (stats did not contain row counts)
Importing statistics for projection date\_dimension\_super column full\_date\_description failure (stats did not contain row counts)
...
(1 row)
```

See Also

- \texttt{ANALYZE\_STATISTICS}
- \texttt{DROP\_STATISTICS}
**EXPORT_STATISTICS**

- Collecting Statistics in the Administrator's Guide

**VALIDATE_STATISTICS**

Validates statistics in the XML file generated by the EXPORT_STATISTICS command.

**Syntax**

```sql
VALIDATE_STATISTICS ( 'XML_statistics_file' )
```

**Parameters**

<table>
<thead>
<tr>
<th>XML_statistics_file</th>
<th>Specifies the path and name of the XML file that contains the statistics you want to validate, type VARCHAR.</th>
</tr>
</thead>
</table>

**Privileges**

Superuser

**Usage Considerations**

- **IMPORT_STATISTICS** imports only valid statistics. If the source file has invalid statistics for a specific column, those statistics are not imported and a warning occurs. To identify the invalid statistics, run VALIDATE_STATISTICS.

**Example: Valid Statistics**

The following example shows the results when the statistics are valid:

```sql
=> SELECT EXPORT_STATISTICS('cust_dim_stats.xml','customer_dimension');
EXPORT_STATISTICS
--------------------------
Statistics exported successfully
(1 row)
=> SELECT VALIDATE_STATISTICS('cust_dim_stats.xml');
VALIDATE_STATISTICS
----------------------
(1 row)
```
Example: Invalid Statistics File

The following example shows the results when some of the statistics are invalid. For example, the 'distinct', 'buckets', 'rows', 'count', and 'distinctCount' attributes cannot be negative numbers. Vertica recommends that you rerun `ANALYZE_STATISTICS` on this table to create valid statistics:

```sql
=> SELECT VALIDATE_STATISTICS('/stats.xml');
WARNING 0: Invalid value '-1' for attribute 'distinct' under column 'public.t.x'.
  Please use a positive value.
WARNING 0: Invalid value '-1' for attribute 'buckets' under column 'public.t.x'.
  Please use a positive value.
WARNING 0: Invalid value '-1' for attribute 'rows' under column 'public.t.x'.
  Please use a positive value.
WARNING 0: Invalid value '-1' for attribute 'count' under bound '1', column 'public.t.x'.
  Please use a positive value.
WARNING 0: Invalid value '-1' for attribute 'distinctCount' under bound '1', column 'public.t.x'.
  Please use a positive value.
VALIDATE_STATISTICS
```

Example: Invalid Statistics File

The following example shows the result when the statistics file is invalid:

```sql
=> SELECT VALIDATE_STATISTICS('/home/dbadmin/stats.xml');
    
VALIDATE_STATISTICS
```

Error validating statistics file: At line 1:1. Invalid document structure

(1 row)

Storage Management Functions

This section contains storage management functions specific to Vertica.

**ALTER_LOCATION_LABEL**

Alters the location label. Use this function to add, change, or remove a location label. You change a location label only if it is not currently in use as part of a storage policy.

You can use this function to remove a location label. However, you cannot remove a location label if the name being removed is used in a storage policy, and the location from which you are removing the label is the last available storage for its associated objects.

*Note:* If you label an existing storage location that already contains data, and then include the labeled location in one or more storage policies, existing data could be moved. If the ATM determines data stored on a labeled location does not comply with a storage policy, the ATM moves the data elsewhere.

**Syntax**

```
ALTER_LOCATION_LABEL ('path', 'node', 'location_label')
```

**Parameters**

- **path**
  Specifies the path of the storage location.

- **node**
  The Vertica node for the storage location.
  If you enter node as an empty string (''), the function performs a cluster-wide label change to all nodes. Any node that is unavailable generates an error.

- **location_label**
  Specifies a storage label as a string, for instance SSD. You can change an existing label assigned to a storage location, or add a new label. Specifying an empty string ('') removes an existing label.

**Privileges**

Superuser
Example

The following example alters (or adds) the label SSD to the storage location at the given path on all cluster nodes:

```sql
=> SELECT alter_location_label('/home/dbadmin/SSD/tables','','SSD');
alter_location_label
------------------------------------------
/home/dbadmin/SSD/tables label changed.
(1 row)
```

See Also

- Altering Location Labels
- CLEAR_OBJECT_STORAGE_POLICY
- SET_OBJECT_STORAGE_POLICY

ALTER_LOCATION_USE

Alters the type of files that can be stored at the specified storage location.

Syntax

```sql
ALTER_LOCATION_USE ( 'path' , 'node' , 'usage' )
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>path</code></td>
<td>Specifies where the storage location is mounted.</td>
</tr>
<tr>
<td><code>node</code></td>
<td>[Optional] The Vertica node with the storage location. Specifying the <code>node</code> parameter as an empty string (' ') alters the location across all cluster nodes in a single transaction.</td>
</tr>
<tr>
<td><code>usage</code></td>
<td>Is one of the following:</td>
</tr>
<tr>
<td></td>
<td>- DATA: The storage location stores only data files. This is the supported use for both a USER storage location, and a labeled storage location.</td>
</tr>
<tr>
<td></td>
<td>- TEMP: The location stores only temporary files that are created during loads or</td>
</tr>
</tbody>
</table>
queries.

- DATA, TEMP: The location can store both types of files.

Privileges

Superuser

USER Storage Location Restrictions

You cannot change a storage location from a USER usage type if you created the location that way, or to a USER type if you did not. You can change a USER storage location to specify DATA (storing TEMP files is not supported). However, doing so does not affect the primary objective of a USER storage location, to be accessible by non-dbadmin users with assigned privileges.

Monitoring Storage Locations

Disk storage information that the database uses on each node appears in the V_MONITOR.DISK_STORAGe system table.

Example

The following example alters the storage location across all cluster nodes to store only data:

```sql
=> SELECT ALTER_LOCATION_USE ('/thirdVerticaStorageLocation/', '', 'DATA');
```

See Also

- Altering Location Use
- DROP_LOCATION
- RESTORE_LOCATION
- RETIRE_LOCATION
- GRANT (Storage Location)
- REVOKE (Storage Location)
CLEAR_CACHES

Clears the Vertica internal cache files.

Syntax

CLEAR_CACHES ( )

 Privileges

Superuser

Notes

If you want to run benchmark tests for your queries, in addition to clearing the internal Vertica cache files, clear the Linux file system cache. The kernel uses unallocated memory as a cache to hold clean disk blocks. If you are running version 2.6.16 or later of Linux and you have root access, you can clear the kernel filesystem cache as follows:

1. Make sure that all data in the cache is written to disk:

   # sync

2. Writing to the drop_caches file causes the kernel to drop clean caches, entries, and inodes from memory, causing that memory to become free, as follows:

   - To clear the page cache:

     # echo 1 > /proc/sys/vm/drop_caches

   - To clear the entries and inodes:

     # echo 2 > /proc/sys/vm/drop_caches

   - To clear the page cache, entries, and inodes:

     # echo 3 > /proc/sys/vm/drop_caches
Example

The following example clears the Vertica internal cache files:

```sql
=> SELECT CLEAR_CACHES();
CLEAR_CACHES
------------
Cleared
(1 row)
```

**CLEAR_OBJECT_STORAGE_POLICY**

Removes an existing storage policy. The specified object will no longer use a user-created storage location. Any existing data stored currently at the labeled location in the object's storage policy is moved to default storage during the next TM moveout operation.

**Syntax**

```sql
CLEAR_OBJECT_STORAGE_POLICY ( '[database.]schema.object-name' [, 'key-min', 'key-max'] [, 'enforce-storage-move' ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td><code>object-name</code></td>
<td>Identifies the database object whose storage policies are to be cleared. The <code>object_name</code> parameter can resolve to a database, schema, or table.</td>
</tr>
<tr>
<td><code>key-min</code> <code>key-max</code></td>
<td>Specifies the table partition key value ranges stored at the labeled location. These parameters are applicable only when <code>object_name</code> is a table.</td>
</tr>
<tr>
<td><code>enforce-storage-move</code></td>
<td>If <code>true</code>, moves the storage containers that belong to this object to the new location immediately. If <code>false</code> (the default), this move occurs automatically sometime after the</td>
</tr>
</tbody>
</table>
Privileges

Superuser

Examples

This example shows how to clear the storage policy for the object `lineorder`. Changes take effect after the next moveout:

```sql
=> select clear_object_storage_policy('lineorder');
       clear_object_storage_policy
----------------------------
 Default storage policy cleared.
(1 row)
```

See Also

- Clearing Storage Policies
- `ALTER_LOCATION_LABEL`
- `SET_OBJECT_STORAGE_POLICY`
- `ENFORCE_OBJECT_STORAGE_POLICY`

COMPACT_STORAGE

Bundles existing data (.fdb) and index (.pidx) files into the .gt file format. The .gt format was introduced in Vertica 7.2 and is enabled by default for any data files created version 7.2 or later. If you have a database from an earlier version, you can use COMPACT_STORAGET to upgrade existing storage files to the new format. Your database can continue to operate with a mix of file storage formats.

If the settings you specify for COMPACT_STORAGE vary from the limit specified in configuration parameter `MaxBundleableROSSizeKB`, Vertica does not change the size of the automatically created bundles. You can use this function even if storage bundling is not enabled on your database.

Note: Run this function during periods of low demand.
Syntax

SELECT COMPACT_STORAGE ('[[database.]schema.]object-name', min-ros-filesize-kb, 'small-or-all-files', 'simulate');

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>object-name</td>
<td>Specifies the table or projection to bundle.</td>
</tr>
<tr>
<td>min-ros-filesize-kb</td>
<td>Specifies the minimum size, in kilobytes, of an independent ROS file. Vertica bundles storage container ROS files below this size into a single file. If set to 0, Vertica bundles the data and index files of an individual column, but not with other columns in that storage container.</td>
</tr>
<tr>
<td>small-or-all-files</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>small: Bundles only files smaller than the limit specified in min-ros-filesize-kb</td>
</tr>
<tr>
<td></td>
<td>all: Bundles files smaller than the limit specified in min-ros-filesize-kb and bundles the .fdb and .pidx files for larger storage containers.</td>
</tr>
<tr>
<td>simulate</td>
<td>Specifies whether to simulate the storage settings and produce a report describing the impact of those settings.</td>
</tr>
<tr>
<td></td>
<td>true: Produces a report on the impact of the specified bundle settings without actually bundling storage files.</td>
</tr>
<tr>
<td></td>
<td>false: Vertica performs the bundling according to the settings you specified.</td>
</tr>
</tbody>
</table>
Privileges
Superuser

Storage and Performance Impact

Bundling reduces the number of files in your file system by at least fifty percent and improves the performance of file-intensive operations. Improved operations include backups, restores, mergeouts and moveouts.

Vertica creates small files for the following reasons:

- Tables contain hundreds of columns.
- Partition ranges are small (partition by minute).
- Local segmentation is enabled and your factor is set to a high value.

Evaluating the Benefits of Bundled Storage

You can determine whether bundling existing storage can provide a significant benefit, as follows:

**View the median file size of a projection on a node**

Run the following query:

```sql
SELECT MEDIAN(size) OVER() AS median_fsize
FROM vs_ros AS ros, storage_containers AS cont
WHERE ros.delid=cont.storage_oid
AND cont.node_name='node-name'
AND cont.projection_name='proj-name' LIMIT 1;
```

If many files are smaller than 1mb, bundling storage is likely to provide significant performance benefits.

**Run COMPACT_STORAGE in simulation mode**

The simulate parameter produces a report that shows the number of affected files and the change in file storage.

**Example**

The following example describes the impact of bundling the table EMPLOYEES:
DROP_LOCATION

Removes the specified storage location. Dropping a storage location is a permanent operation and cannot be undone. Therefore, you must retire a storage location before dropping it.

Syntax

DROP_LOCATION ( 'path', 'node' )

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Specifies where the storage location to drop is mounted.</td>
</tr>
<tr>
<td>node</td>
<td>The Vertica node where the location is available. A value of &quot; (an empty string) means to perform this operation on all nodes.</td>
</tr>
</tbody>
</table>
Privileges
Superuser

Retiring a Storage Location
Retiring a storage location lets you verify that you do not need the storage before dropping it. You can also restore a retired storage location if you determine it is still in use.

Dropping a Shared Location
When a storage location is created in a shared location, such as HDFS, Vertica creates subdirectories for each node to prevent conflicts. For example, suppose you create a shared storage location in /data. The location for v_vmart_node0001 is /data/v_vmart_node0001, the location for v_vmart_node0002 is /data/v_vmart_node0002, and so on. To drop a location on only one node, use the node-specific path such as /data/v_vmart_node0002. To drop a location on all nodes, use the same path that you used to create it (/data in this example).

Storage Locations with Temp and Data Files
If you use a storage location to store data and then alter it to store only temp files, the location can still contain data files. Vertica does not let you drop a storage location containing data files. You can use the function MOVE_RETIRED_LOCATION_DATA to manually merge out the data files from the storage location, or you can drop partitions. Deleting data files does not work.

Examples
The following example shows how to drop a previously retired storage location on v_vmart_node0003:

```sql
=> SELECT DROP_LOCATION('/data', 'v_vmart_node003');
```

See Also
- Dropping Storage Locations
- Retiring Storage Locations
- ALTER_LOCATION_USE
• **RESTORE_LOCATION**

• **RETIRE_LOCATION**

• **GRANT (Storage Location)**

• **REVOKE (Storage Location)**

**ENFORCE_OBJECT_STORAGE_POLICY**

Applies object storage policies immediately, instead of waiting for the Tuple Mover to perform the next moveout. Calling this function is equivalent to setting the `enforce_storage_move` parameter on related meta-functions. You typically use this function as the last step before dropping a storage location.

This function invokes the Tuple Mover on a one-time basis.

**Syntax**

```
ENFORCE_OBJECT_STORAGE_POLICY ( 'object_name', [', 'key_min', ', 'key_max'] )
```

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>object_name</code></td>
<td>Identifies the database object whose storage policies are to be applied. The <code>object_name</code> parameter can resolve to a database, schema, or table.</td>
</tr>
<tr>
<td><code>key_min, key_max</code></td>
<td>Applicable only when <code>object_name</code> is a table, <code>key_min</code> and <code>key_max</code> specify the table partition key value range over which to perform the moves.</td>
</tr>
</tbody>
</table>

**Privileges**

Must be the object owner to enforce the storage policy and have access to the storage location.

**Examples**

This example shows how to apply storage-policy updates to the `test` table:

```
=> select enforce_object_storage_policy('test');
```
See Also

- **CLEAR_OBJECT_STORAGE_POLICY**
- **RETIRE_LOCATION**
- **DROP_LOCATION**
- Managing Storage Locations

**MEASURE_LOCATION_PERFORMANCE**

Measures disk performance for the location specified.

**Syntax**

```sql
MEASURE_LOCATION_PERFORMANCE ( 'path', 'node' )
```

**Parameters**

<table>
<thead>
<tr>
<th>path</th>
<th>Specifies where the storage location to measure is mounted.</th>
</tr>
</thead>
<tbody>
<tr>
<td>node</td>
<td>Is the Vertica node where the location to be measured is available.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**Notes**

- To get a list of all node names on your cluster, query the `V_MONITOR.DISK_STORAGE` system table:

```sql
=> SELECT node_name from DISK_STORAGE;
node_name
---------
v_vmartdb_node0004
v_vmartdb_node0004
v_vmartdb_node0005
```
If you intend to create a tiered disk architecture in which projections, columns, and partitions are stored on different disks based on predicted or measured access patterns, you need to measure storage location performance for each location in which data is stored. You do not need to measure storage location performance for temp data storage locations because temporary files are stored based on available space.

The method of measuring storage location performance applies only to configured clusters. If you want to measure a disk before configuring a cluster see Measuring Storage Performance.

Storage location performance equates to the amount of time it takes to read and write 1MB of data from the disk. This time equates to:

\[ \text{IO time} = \text{Time to read/write 1MB} + \text{Time to seek} = 1/\text{Throughput} + 1/\text{Latency} \]

Throughput is the average throughput of sequential reads/writes (units in MB per second)

Latency is for random reads only in seeks (units in seeks per second)

**Note:** The IO time of a faster storage location is less than a slower storage location.

**Example**

The following example measures the performance of a storage location on v_vmartdb_node0004:

```sql
=> SELECT MEASURE_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/', 'v_vmartdb_node0004');
WARNING: measure_location_performance can take a long time. Please check logs for progress
                        measure_location_performance
Throughput : 122 MB/sec. Latency : 140 seeks/sec
```

**See Also**

- **CREATE LOCATION**
- **ALTER_LOCATION_USE**
• **RESTORE_LOCATION**

• **RETIRE_LOCATION**

• **Measuring Storage Performance**

**MOVE RETIRED LOCATION DATA**

Moves all data from either a single retired storage location or all retired storage locations in the database. This function migrates the data to non-retired storage locations based on the storage policies of the objects whose data is stored in the location.

**Syntax**

```sql
MOVE RETIRED LOCATION DATA(['location_path'] ['node'])
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>['location_path']</td>
<td>The path of the storage location as listed in the LOCATION_PATH column of the STORAGE_LOCATIONS system table. You must have previously marked this storage location as retired.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> If you do not supply a storage location path, this function moves data from all retired storage locations.</td>
</tr>
<tr>
<td>['node']</td>
<td>A specific node on which to move the retired storage location's data.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> If you do not specify a node, all nodes in the cluster move data from the retired location or locations. If a node does not define the storage location, this function returns an error.</td>
</tr>
</tbody>
</table>

**Privileges**

The user must be a superuser.

**Usage Considerations**

This function forces the Tuple Mover to move data out of the retired location or locations. Normally, the Tuple Mover only migrates data out of retired storage locations as it consolidates data into larger ROS containers. This function does not return until all of the data has moved off of the retired storage location or locations.
Examples

The following example:

1. Queries the STORAGE_LOCATIONS system table to show which storage locations are retired.

2. Queries the STORAGE_CONTAINERS system table to show the current location of the messages table, which is currently stored in the retired storage location named ssd.

3. Calls MOVE_RETIREDLOCATION_DATA to move the data off of the ssd storage location.

4. Repeats the previous query to show the storage location of the messages table.

```sql
=> SELECT node_name, location_path, location_label, is_retired FROM STORAGE_LOCATIONS
   WHERE is_retired = 't';
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>location_path</th>
<th>location_label</th>
<th>is_retired</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>/home/dbadmin/SSDLoc</td>
<td>ssd</td>
<td>t</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>/home/dbadmin/SSDLoc</td>
<td>ssd</td>
<td>t</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>/home/dbadmin/SSDLoc</td>
<td>ssd</td>
<td>t</td>
</tr>
</tbody>
</table>

(3 rows)

```sql
=> SELECT node_name, total_row_count, storage_type, location_label FROM STORAGE_CONTAINERS
   WHERE projection_name ILIKE 'messages%';
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>total_row_count</th>
<th>storage_type</th>
<th>location_label</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>333514</td>
<td>ROS</td>
<td>ssd</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>333255</td>
<td>ROS</td>
<td>ssd</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>333255</td>
<td>ROS</td>
<td>ssd</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>333231</td>
<td>ROS</td>
<td>ssd</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>333231</td>
<td>ROS</td>
<td>ssd</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>333514</td>
<td>ROS</td>
<td>ssd</td>
</tr>
</tbody>
</table>

(6 rows)

```sql
=> SELECT MOVE_RETIREDLOCATION_DATA('/home/dbadmin/SSDLoc');
```

MOVE_RETIREDLOCATION_DATA

Move data off retired storage locations done

(1 row)

```sql
=> SELECT node_name, total_row_count, storage_type, location_label FROM storage_containers
   WHERE projection_name ILIKE 'messages%';
```

<table>

- `RETIRE_LOCATION`
- `RESTORE_LOCATION`
- `Managing Storage Locations` in the Administrator's Guide.

**RESTORE_LOCATION**

Restores a storage location that was previously retired with `RETIRE_LOCATION`.

**Syntax**

```sql
RESTORE_LOCATION ( 'path', 'node' )
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>path</code></td>
<td>Specifies where the retired storage location is mounted.</td>
</tr>
<tr>
<td><code>node</code></td>
<td>The Vertica node where the retired location is available. A value of '' (an empty string) means to perform this operation on all nodes. The operation fails if you have dropped any locations.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**Effects of Restoring a Previously Retired Location**

After restoring a storage location, Vertica re-ranks all of the cluster storage locations. It uses the newly restored location to process queries as determined by its rank.

**Monitoring Storage Locations**

Disk storage information that the database uses on each node appears in the `V_MONITOR.DISK_STORAGE` system table.
Examples

The following example shows how to restore the retired storage location on node3:

```
=> SELECT RESTORE_LOCATION ('/thirdVerticaStorageLocation/', 'v_vmartdb_node0004');
```

See Also

- Altering Location Use
- CREATE LOCATION
- ALTER_LOCATION_USE
- DROP_LOCATION
- RETIRE_LOCATION
- GRANT (Storage Location)
- REVOKE (Storage Location)

**RETIRE_LOCATION**

Makes the specified storage location inactive. To see a list of all of the storage locations in Vertica, refer to **STORAGE_LOCATIONS**.

Syntax

```
RETIRE_LOCATION ( 'path', 'node' [, enforce_storage_move ] )
```

Parameters

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Specifies where the storage location to retire resides.</td>
</tr>
<tr>
<td>node</td>
<td>The Vertica node where the location is available. A value of &quot;&quot; (an empty string) means to perform this operation on all nodes.</td>
</tr>
<tr>
<td>enforce_storage_move</td>
<td>[Optional] Use this to expedite dropping a location. If you set this argument to true, the location label is set to the empty string, and</td>
</tr>
</tbody>
</table>
the data is moved elsewhere. The location can then be dropped without errors or warnings.

Privileges
Superuser

Retiring a Shared Location

When you create a storage location in a shared HDFS location, Vertica creates subdirectories for each node to prevent conflicts. For example, suppose you create a shared storage location in /data. The location for v_vmartdb_node0001 is /data/v_vmartdb_node0001, the location for v_vmartdb_node0002 is /data/v_vmartdb_node0002, and so on. To retire a location on only one node, use the node-specific path such as /data/v_vmartdb_node0002. To retire a location on all nodes, use the same path that you used to create it (/data in this example).

Note: Vertica does not identify NFS as a shared file system.

Effects of Retiring a Storage Location

When you use this function, Vertica checks that the location is not the only storage for data and temp files. At least one location must exist on each node to store data and temp files. However, you can store both sorts of files in either the same location or separate locations.

Note: If a location is the last available storage for its associated objects, you cannot retire it unless you set enforce_storage_move to true

When you retire a storage location:

- No new data is stored at the retired location, unless you first restore it with the RESTORE_LOCATION() function.

- By default, if the storage location being retired contains stored data, the data is not moved. Thus, you cannot drop the storage location. Instead, Vertica removes the stored data through one or more mergeouts. If you want to drop the location immediately after retiring it, add the enforce_storage_move parameter, using a value of true.

- If the storage location being retired is used only for temp files or you use enforce_storage_move, you can drop the location. See Dropping Storage Locations in the Administrators Guide and the DROP_LOCATION() function.
Monitoring Storage Locations

Disk storage information that the database uses on each node appears in the V_MONITOR.DISK_STORAGE system table.

Examples

The following examples show two approaches to retiring a storage location.

You can specify that a storage location be dropped automatically at a future time:

```
=> SELECT RETIRE_LOCATION ('/data', 'v_vmartdb_node0004');
```

You can also specify that a storage location be dropped immediately:

```
=> SELECT RETIRE_LOCATION ('/data', 'v_vmartdb_node0004', true);
```

See Also

- Retiring Storage Locations
- CREATE LOCATION
- ALTER_LOCATION_USE
- DROP_LOCATION
- RESTORE_LOCATION
- GRANT (Storage Location)
- REVOKE (Storage Location)

SET_LOCATION_PERFORMANCE

Sets disk performance for the location specified.

Syntax

```
SET_LOCATION_PERFORMANCE ('path', 'node', 'throughput', 'average_latency')
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Specifies where the storage location to set is mounted.</td>
</tr>
<tr>
<td>node</td>
<td>Is the Vertica node where the location to be set is available. If this parameter is omitted, node defaults to the initiator.</td>
</tr>
<tr>
<td>throughput</td>
<td>Specifies the throughput for the location, which must be 1 or more.</td>
</tr>
<tr>
<td>average_latency</td>
<td>Specifies the average latency for the location. The average_latency must be 1 or more.</td>
</tr>
</tbody>
</table>

Privileges

Superuser

Notes

To obtain the throughput and average latency for the location, run the MEASURE_LOCATION_PERFORMANCE() function before you attempt to set the location's performance.

Example

The following example sets the performance of a storage location on node2 to a throughput of 122 megabytes per second and a latency of 140 seeks per second.

```sql
=> SELECT SET_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/','node2','122','140');
```

See Also

- CREATE LOCATION
- MEASURE_LOCATION_PERFORMANCE
- Measuring Storage Performance
- Setting Storage Performance
SET_OBJECT_STORAGE_POLICY

Creates or changes an object storage policy by associating a database object with a labeled storage location.

Note: You cannot create a storage policy on a USER type storage location.

Syntax

```
SET_OBJECT_STORAGE_POLICY (
    '[[database.]schema.]object-name', 'location-Label'
    [, 'key-min', 'key-max'] [, 'enforce-storage-move']
)
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code> If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>object-name</td>
<td>Identifies the database object assigned to a labeled storage location. The <code>object-name</code> can resolve to a database, schema, or table.</td>
</tr>
<tr>
<td>location-Label</td>
<td>The label of the storage location with which <code>object-name</code> is being associated.</td>
</tr>
<tr>
<td>key-min</td>
<td>Applicable only when <code>object-name</code> is a table, <code>key-min</code> and <code>key-max</code> specify the table partition key value range to be stored at the location.</td>
</tr>
<tr>
<td>key-max</td>
<td></td>
</tr>
<tr>
<td>enforce-storage-move</td>
<td>Specify this parameter as true to move all existing storage data to the target location within this function’s transaction. By default, data move the next time the Tuple Mover runs on the affected data.</td>
</tr>
</tbody>
</table>

Privileges

Must be the object owner to set the storage policy and have access to the storage location.
New Storage Policy

If an object does not have a storage policy, this function creates a new policy. The labeled location is then used as the default storage location during TM operations, such as moveout and mergeout.

Existing Storage Policy

If the object already has an active storage policy, calling this function changes the default storage for the object to the new labeled location. Any existing data stored on the previous storage location is marked to move to the new location during the next TM moveout operations. To move the data immediately, use the `enforce-storage-move` argument.

Forcing Existing Data Storage to a New Storage Location

You can optionally use this function to move existing data storage to a new location as part of completing the current transaction. To do so, set parameter `enforce-storage-move` to `true`. You might want to force a move, even though it means waiting for the operation to complete before continuing, if the data being moved is old. The Tuple Mover runs less frequently on older data.

To move existing data as part of the next TM moveout, either omit the parameter, or specify its value as `false`.

Note: Specifying the parameter as `true` performs a cluster-wide operation. If an error occurs on any node, the function displays a warning message and skips the node where the error occurs. It then continues executing the operation on the remaining nodes.

Examples

This example shows how to set a storage policy for the table `test` to use the storage labeled SSD as its default location:

```sql
=> select set_object_storage_policy('test','ssd', true);
set_object_storage_policy
-----------------------------
Object storage policy set.
Task: moving storages
(Table: public.test) (Projection: public.test_b0)
(Table: public.test) (Projection: public.test_b1)
(1 row)
```

System Table Restriction Functions

This section contains the functions associated with the System Table Restriction and Access functionality.

In This Section

RELEASE_SYSTEM_TABLES_ACCESS

Opens access to non-superuser-only tables that are not accessible during lockdown.

Syntax

`RELEASE_SYSTEM_TABLES_ACCESS()`

Privileges

Superuser

Determine if a Table is Restricted

Query the `SYSTEM_TABLES` table to determine if a table is accessible. The table contains a column called `is_accessible_during_lockdown`. This flag indicates if a table is accessible. Valid values are:

- `t` — A table is accessible
f — A table is not accessible

Examples

The following examples show how to open access to system tables:

```sql
=> SELECT RELEASE_SYSTEM_TABLES_ACCESS();
RELEASE_SYSTEM_TABLES_ACCESS
---------------------------------------
Granted SELECT privileges on system tables to public.
(1 row)
```

See Also

- `RESTRICT_SYSTEM_TABLES_ACCESS`
- System Table Restriction and Access

**RESTRICT_SYSTEM_TABLES_ACCESS**

Restricts access to non-superuser-only tables that are not accessible during lockdown.

Syntax

```sql
RESTRICT_SYSTEM_TABLES_ACCESS()
```

Privileges

Superuser

Determine if a Table is Restricted

Query the `SYSTEM_TABLES` table to determine if a table is accessible. The table contains a column called `is_accessible_during_lockdown`. This flag indicates if a table is accessible. Valid values are:

- `t` — A table is accessible
- `f` — A table is not accessible

Examples

The following examples show how to restrict system table access:
See Also

- RELEASE_SYSTEM_TABLES_ACCESS
- System Table Restriction and Access

Text Search Functions

This section contains text search functions specific to Vertica.

DELETE_TOKENIZER_CONFIG_FILE

Deletes a tokenizer configuration file.

Syntax

```sql
SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE (USING PARAMETERS proc_oid='proc_oid', confirm={true | false});
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>confirm</td>
<td>Boolean flag. Indicates that the configuration file should be removed even if the tokenizer is still in use. True — Force deletion of the tokenizer when the used parameter value is True. False — Delete tokenizer if the used parameter value is False. Default: False</td>
</tr>
<tr>
<td>proc_oid</td>
<td>A unique identifier assigned to a tokenizer when it is created. Users must query the system table vs_procedures to get the proc_oid for a given tokenizer name. See Configuring a Tokenizer for more information.</td>
</tr>
</tbody>
</table>
Examples

The following example shows how you can use `DELETE_TOKENIZER_CONFIG_FILE` to delete the tokenizer configuration file:

```sql
=> SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE (USING PARAMETERS proc_oid='45035996274126984');
DELETE_TOKENIZER_CONFIG_FILE
---------
t
(1 row)
```

GET_TOKENIZER_PARAMETER

Returns the configuration parameter for a given tokenizer.

Syntax

```sql
SELECT v_txtindex.GET_TOKENIZER_PARAMETER(parameter_name USING PARAMETERS proc_oid='proc_oid');
```

Parameters

<table>
<thead>
<tr>
<th>parameter_name</th>
<th>Name of the parameter to be returned. One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>stopWordsCaseInsensitive</td>
<td></td>
</tr>
<tr>
<td>minorSeparators</td>
<td></td>
</tr>
<tr>
<td>majorSeparators</td>
<td></td>
</tr>
<tr>
<td>minLength</td>
<td></td>
</tr>
<tr>
<td>maxLength</td>
<td></td>
</tr>
<tr>
<td>ngramsSize</td>
<td></td>
</tr>
<tr>
<td>used</td>
<td></td>
</tr>
</tbody>
</table>

| proc_oid | A unique identifier assigned to a tokenizer when it is created. Users must query the system table vs_procedures to get the proc_oid for a given tokenizer name. See Configuring a Tokenizer for more information. |
**Examples**

The following examples show how you can use `GET_TOKENIZER_PARAMETER`.

**Return the stop words used in a tokenizer:**

```sql
=> SELECT v_txtindex.GET_TOKENIZER_PARAMETER('stopwordcaseinsensitive' USING PARAMETERS proc_oid='45035996274126984');
getTokenizerParameter
------------------------
devil,TODAY,the,fox
(1 row)
```

**Return the major separators used in a tokenizer:**

```sql
=> SELECT v_txtindex.GET_TOKENIZER_PARAMETER('majorseparators' USING PARAMETERS proc_oid='45035996274126984');
getTokenizerParameter
------------------------
{}[]&[]
(1 row)
```

**READ_CONFIG_FILE**

Reads and returns the key-value pairs of all the parameters of a given tokenizer.

You must use the OVER() clause with this function.

**Syntax**

```sql
SELECT v_txtindex.READ_CONFIG_FILE(USING PARAMETERS proc_oid='proc_oid') OVER ()
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>proc_oid</code></td>
<td>A unique identifier assigned to a tokenizer when it is created. Users must query the system table <code>vs_procedures</code> to get the proc_oid for a given tokenizer name. See <a href="#">Configuring a Tokenizer</a> for more information.</td>
</tr>
</tbody>
</table>

**Examples**

The following example shows how you can use `READ_CONFIG_FILE` to return the parameters associated with a tokenizer:
SELECT v_txtindex.READ_CONFIG_FILE(USING PARAMETERS proc_oid='45035996274126984') OVER()

<table>
<thead>
<tr>
<th>config_key</th>
<th>config_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorseparators</td>
<td>{ }&amp;[ ]()</td>
</tr>
<tr>
<td>stopwordsCaseInsensitive</td>
<td>devil,TODAY,the,fox</td>
</tr>
</tbody>
</table>

(2 rows)

**SET_TOKENIZER_PARAMETER**

Configures the tokenizer parameters.

**Important:** \n, \t, \r  must be entered as Unicode using Vertica notation, U&’\00D’, or using Vertica escaping notation, E’\r’. Otherwise, they are taken literally as two separate characters. For example, "\" & "\r".

**Syntax**

SELECT v_txtindex.SET_TOKENIZER_PARAMETER (parameter_name, parameter_value USING PARAMETERS proc_oid='proc_oid')

**Parameters**

<table>
<thead>
<tr>
<th>parameter_name</th>
<th>Name of the parameter to be configured.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Use one of the following:</td>
</tr>
<tr>
<td>stopwordsCaseInsensitive</td>
<td>List of stop words. All the tokens</td>
</tr>
<tr>
<td></td>
<td>that belong to the list are ignored. Vertica supports separators and stop words up to the first 256 Unicode characters.</td>
</tr>
<tr>
<td></td>
<td>If you want to define a stop word that contains a comma or a backslash, then it needs to be escaped.</td>
</tr>
<tr>
<td></td>
<td>For example: &quot;Dear Jack,&quot; &quot;Dear Jack&quot;</td>
</tr>
<tr>
<td>Default:</td>
<td>' ' (empty list)</td>
</tr>
<tr>
<td>majorSeparators</td>
<td>List of major separators. Enclose in quotes with no spaces between.</td>
</tr>
<tr>
<td>Default:</td>
<td>E' [ ]&lt;&gt;(){}</td>
</tr>
<tr>
<td>minorSeparators</td>
<td>List of minor separators. Enclose in quotes with no spaces between.</td>
</tr>
</tbody>
</table>
Default: `E'/:=@.-#$%\_`

- **minLength** — Minimum length a token can have, type Integer. Must be greater than 0.
  
  Default: `'2'`

- **maxLength** — Maximum length a token can be. Type Integer. Cannot be greater than 1024 bytes. For information about increasing the token size, see Text Search Parameters.
  
  Default: `'128'`

- **ngramsSize** — Integer value greater than zero. Use only with ngram tokenizers.
  
  Default: `'3'`

- **used** — Indicates when a tokenizer configuration cannot be changed. Type Boolean. After you set used to True, any calls to setTokenizerParameter fail.

  You must set the parameter used to True before using the configured tokenizer. Doing so prevents the configuration from being modified after being used to create a text index.

  Default: `False`

<table>
<thead>
<tr>
<th>parameter_value</th>
<th>The value of a configuration parameter.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If you want to disable minorSeperators or stopWordsCaseInsensitive, then set their values to `''.</td>
</tr>
</tbody>
</table>

| proc_oid | A unique identifier assigned to a tokenizer when it is created. Users must query the system table vs_procedures to get the proc_oid for a given tokenizer name. See Configuring a Tokenizer for more information. |

**Examples**

The following examples show how you can use `SET_TOKENIZER_PARAMETER` to configure stop words and separators.

Configure the stop words of a tokenizer:
Configure the major separators of a tokenizer:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('stopwordsCaseInsensitive', 'devil,TODAY,the,fox' USING PARAMETERS proc_oid='45035996274126984');

```

```
SELECT v_txtindex.SET_TOKENIZER_PARAMETER('majorSeparators',E'{}()&[]' USING PARAMETERS proc_oid='45035996274126984');

```

Table Management Functions

This section contains the functions associated with the Vertica library table management.

**COPY_TABLE**

Copies one table to another. This lightweight, in-memory copy increases performance by initially sharing the same storage between two tables. The copied table includes copies of any explicitly created projections from the source table. Once copied, the source and copy tables are independent of each other. Users can perform operations on one table without impacting the other. These operations can increase the overall storage required for both tables.

Creating multiple, concurrent copies of the same table may cause some of the copies to fail. To ensure success, copy tables sequentially.

**Note:** Although they share storage space, Vertica considers the tables as discrete objects for license capacity purposes. For example, copying a one TB table would only consume one TB of space. Your Vertica license, however, considers them as separate objects consuming two TB of space.

**Syntax**

```
COPY_TABLE (  
    '[[database.]schema.]source-table',  
    '[[database.]schema.]target-table'  
)
```
Parameters

| [database.]schema | Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:
|                  | myschema.thisDbObject |
| source-table     | The source table to copy. Vertica copies all data from this table to the target table. |
| target-table     | The target table of the source table. If the target table already exists, Vertica appends the source to the existing table. If the table does not exist, Vertica creates a table from the source table's definition, by calling CREATE TABLE with LIKE and INCLUDING PROJECTIONS clause. The new table inherits ownership from the source table. For details, see Replicating a Table. |

Privileges

- User must have INSERT, UPDATE, DELETE and SELECT privileges on the source table.
- User must have CREATE privileges on the target table and target table schema if COPY_TABLE is creating a new table.
- User must have INSERT privileges on the target table if COPY_TABLE is adding to an existing table.

Table Attribute Requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- Partitioning expression
- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled.

  Note: If the target table has primary or unique key constraints enabled and moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation. Enforcing constraints requires disk reads and can slow the copy process.

- Number and definitions of text indices.

Table Restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.

- If the source table contains a sequence, Vertica converts the sequence to an integer before copying it to the target table. If the target table contains auto-increment, identity, or named sequence columns, Vertica cancels the copy and displays an error message.

- The following tables cannot be used as sources or targets:
  - Temporary tables
  - Virtual tables
  - System tables
  - External tables

Examples

If you call COPY_TABLE and the target table does not exist, the function creates the table automatically. In the following example, the target table `public.newtable` does not exist. COPY_TABLE creates the table and replicates the source table. Vertica also copies all the constraints associated with the source table except foreign key constraints.

```sql
=> SELECT COPY_TABLE(
  'public.product_dimension',
  'public.newtable');
```
REBALANCE_TABLE

Synchronously rebalances data in the specified table.

A rebalance operation performs the following tasks:

- Distributes data based on:
  - User-defined fault groups, if specified
  - Large cluster automatic fault groups
- Redistributes database projection data across all nodes.

Syntax

REBALANCE_TABLE('[[database.]schema.]table-name')

Parameters

<table>
<thead>
<tr>
<th>schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>

| table-name | The table to rebalance.                                                                                               |

Privileges

Superuser

When to Rebalance

Rebalancing is useful or even necessary after you perform the following tasks:
- Mark one or more nodes as ephemeral in preparation of removing them from the cluster.
- Add one or more nodes to the cluster so that Vertica can populate the empty nodes with data.
- Change the scaling factor of an elastic cluster, which determines the number of storage containers used to store a projection across the database.
- Set the control node size or realign control nodes on a large cluster layout
- Add nodes to or remove nodes from a fault group.

Tip: By default, before performing a rebalance, Vertica queries system tables to compute the size of all projections involved in the rebalance task. This query can add significant overhead to the rebalance operation. To disable this query, set projection configuration parameter RebalanceQueryStorageContainers to 0.

Example

The following command shows how to rebalance data on the specified table.

```sql
=> SELECT REBALANCE_TABLE('online_sales.online_sales_fact');
REBALANCE_TABLE
---------------------
REBALANCED
(1 row)
```

See Also

- REBALANCE_CLUSTER
- Rebalancing Data Across Nodes
- NODES
Tuple Mover Functions

This section contains tuple mover functions specific to Vertica.

DO_TM_TASK

Runs a Tuple Mover operation on the specified table or projection and commits any current transaction.

Tip: Running this function does not require you to stop the tuple mover.

Syntax

DO_TM_TASK('task', '[database.]schema.]table | projection')

Parameters

<table>
<thead>
<tr>
<th>task</th>
<th>Specifies one of the following tuple mover operations:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- moveout: Moves out data from WOS to ROS. For details, see Moveout in the Administrator's Guide.</td>
</tr>
<tr>
<td></td>
<td>- mergeout: Consolidates ROS containers and purges deleted records. For details, see Mergeout in the Administrator's Guide.</td>
</tr>
<tr>
<td></td>
<td>- analyze_row_count: Collects the number of rows in the specified projection. If you specify a table name, DO_TM_TASK returns the row counts for all projections of that table. Vertica automatically analyzes all projection row counts at the time intervals specified by configuration parameter AnalyzeRowCountInterval.</td>
</tr>
<tr>
<td></td>
<td>DO_TM_TASK aggregates row counts calculated during loads. It commits this data to the catalog when the percentage of WOS to ROS equals the setting in configuration parameter ARCCommitPercentage.</td>
</tr>
</tbody>
</table>
analyze_row_count analyzes the row count of Vertica projections. To calculate row counts for external tables, use **ANALYZE_EXTERNAL_ROW_COUNT**.

[database.]schema

Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:

```sql
myschema.thisDbObject
```

If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th>table</th>
<th>projection</th>
</tr>
</thead>
</table>

Applies task to the specified table or projection. If you specify a projection and it is not found, DO_TM_TASK looks for a table with that name and, if found, applies the task to it and all projections associated with it.

If no table or projection is specified, the task is applied to all tables and projections in the database.

Privileges

- Any INSERT/UPDATE/DELETE privilege on table
- USAGE privileges on schema

Examples

The following example performs a moveout of all projections for the t1 table:

```sql
=> SELECT DO_TM_TASK('moveout', 't1');
```

The following example performs a moveout for the t1_proj projection:

```sql
=> SELECT DO_TM_TASK('moveout', 't1_proj');
```
Workload Management Functions

This section contains workload management functions specific to Vertica.

**ANALYZE_WORKLOAD**

Runs the Workload Analyzer (WLA), a utility that analyzes system information held in system tables.

WLA intelligently monitors the performance of SQL queries and workload history, resources, and configurations to identify the root causes for poor query performance. ANALYZE_WORKLOAD returns tuning recommendations for all events within the scope and time that you specify, from system table TUNING_RECOMMENDATIONS.

Tuning recommendations are based on a combination of statistics, system and data collector events, and database-table-projection design. WLA recommendations can help you quickly and easily tune query performance.

See Understanding WLA Triggering Conditions in the Administrator's Guide for the common triggering conditions and recommendations.

**Syntax**

```
ANALYZE_WORKLOAD ( '[ scope ]' [, 'since-time' | save-data ] );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| **scope** | Specifies the catalog objects to analyze, as follows:  
```
[[database.]schema.]table
```
If set to an empty string, Vertica returns recommendations for all database objects.
If you specify a database, it must be the current database. |
| **since-time** | Specifies the start time for the analysis time span, which continues up to the current system status, inclusive. If you omit this parameter, ANALYZE_WORKLOAD returns recommendations on events since the last time you called this function. |

**Note:** You must explicitly cast strings to TIMESTAMP or TIMESTAMPZ.
For example:

```
SELECT ANALYZE_WORKLOAD('T1', '2010-10-04 11:18:15':TIMESTAMPZ);
SELECT ANALYZE_WORKLOAD('T1', TIMESTAMP '2010-10-04 11:18:15');
```

### save-data

Specifies whether to save returned values from `ANALYZE_WORKLOAD`:

- **false** (default): Results are discarded.
- **true**: Saves the results returned by `ANALYZE_WORKLOAD`. Subsequent calls to `ANALYZE_WORKLOAD` return results that start from the last invocation when results were saved. Object events preceding that invocation are ignored.

### Return Values

Returns aggregated tuning recommendations from `TUNING_RECOMMENDATIONS`.

### Privileges

Superuser

### Examples

See [Getting Tuning Recommendations](#) in the Administrator's Guide.

### See Also

- Analyzing Workloads
- Understanding WLA Triggering Conditions

---

**CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY**

Changes the run-time priority of an active query.

**Note:** This function replaces deprecated function `CHANGE_RUNTIME_PRIORITY`.

### Syntax

```
CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY(transaction-id, 'value')
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>transaction-id</strong></td>
<td>Identifies the transaction, obtained from the system table <strong>SESSIONS</strong>.</td>
</tr>
<tr>
<td><strong>value</strong></td>
<td>The RUNTIMEPRIORITY value: HIGH, MEDIUM, or LOW.</td>
</tr>
</tbody>
</table>

Privileges

- Superuser: None
- Non-superusers can only change the runtime priority of their own queries, and cannot raise the runtime priority of a query to a level higher than that of the resource pool.

Example

See Changing Runtime Priority of a Running Query.

**CHANGE_RUNTIME_PRIORITY**

Changes the run-time priority of a query that is actively running. Note that, while this function is still valid, you should instead use CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY to change run-time priority. CHANGE_RUNTIME_PRIORITY will be deprecated in a future release of Vertica.

Syntax

```
CHANGE_RUNTIME_PRIORITY(TRANSACTION_ID, STATEMENT_ID, 'value')
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRANSACTION_ID</td>
<td>An identifier for the transaction within the session.</td>
</tr>
<tr>
<td></td>
<td>TRANSACTION_ID cannot be NULL.</td>
</tr>
<tr>
<td></td>
<td>You can find the transaction ID in the Sessions table.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the currently executing statement.</td>
</tr>
</tbody>
</table>
You can find the statement ID in the Sessions table.
You can specify NULL to change the run-time priority of the currently running query within the transaction.

| 'value' | The RUNTIMEPRIORITY value. Can be HIGH, MEDIUM, or LOW. |

privileges

No special privileges required. However, non-superusers can change the run-time priority of their own queries only. In addition, non-superusers can never raise the run-time priority of a query to a level higher than that of the resource pool.

Example

```sql
==> SELECT CHANGE_RUNTIME_PRIORITY(45035996273705748, NULL, 'low');
```

**MOVE_STATEMENT_TO_RESOURCE_POOL**

Attempts to move the specified query to the specified target pool.

Syntax

```
MOVE_STATEMENT_TO_RESOURCE_POOL (session_id, transaction_id, statement_id, target_resource_pool_name)
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session_id</td>
<td>Identifier for the session where the query you want to move is currently executing.</td>
</tr>
<tr>
<td>transaction_id</td>
<td>Identifier for the transaction within the session.</td>
</tr>
<tr>
<td>statement_id</td>
<td>Unique numeric ID for the statement you want to move.</td>
</tr>
<tr>
<td>target_resource_pool_name</td>
<td>Name of the existing resource pool to which you want to move the specified query.</td>
</tr>
</tbody>
</table>

Outputs

The function may return the following results:
MOV_REPLAN: Target pool does not have sufficient resources. See v_monitor.resource_pool_move for details. Vertica will attempt to replan the statement on target pool.

MOV_REPLAN: Target pool has priority HOLD. Vertica will attempt to replan the statement on target pool.

MOV_FAILED: Statement not found.

MOV_NO_OP: Statement already on target pool.

MOV_REPLAN: Statement is in queue. Vertica will attempt to replan the statement on target pool.

MOV_SUCCEED: Statement successfully moved to target pool.

Privileges
Superuser

Examples

The following example shows how you can move a specific statement to a resource pool called my_target_pool:

```sql
=> SELECT MOVE_STATEMENT_TO_RESOURCE_POOL ('v_vmart_node0001.example.-31427:0x82fbm', 45035996273711993, 1, 'my_target_pool');
```

See Also:
- Manually Moving Queries to Different Resource Pools
- RESOURCE_POOL_MOVE

SLEEP

Waits a specified number of seconds before executing another statement or command.

Syntax

```sql
SLEEP( seconds )
```
Parameters

| seconds | The wait time, specified in one or more seconds (0 or higher) expressed as a positive integer. Single quotes are optional; for example, SLEEP(3) is the same as SLEEP(’3’). |

Notes

- This function returns value 0 when successful; otherwise it returns an error message due to syntax errors.
- You cannot cancel a sleep operation.
- Be cautious when using SLEEP() in an environment with shared resources, such as in combination with transactions that take exclusive locks.

Example

The following command suspends execution for 100 seconds:

```sql
=> SELECT SLEEP(100);
sleep
-----
 0
(1 row)
```
SQL Statements

The primary structure of a SQL query is its statement. Multiple statements are separated by semicolons. The following example contains four common SQL statements—CREATE TABLE, INSERT, SELECT, and COMMIT:

```sql
=> CREATE TABLE comments (id INT, comment VARCHAR);
CREATE TABLE
=> INSERT INTO comments VALUES (1, 'Hello World');
OUTPUT
-------
1
(1 row)
=> SELECT * FROM comments;
id | comment
------------
1 | Hello World
(1 row)
=> COMMIT;
COMMIT
=>
```

ALTER ACCESS POLICY

The ALTER ACCESS POLICY statement:

- Enables and disables individual access policies in a table.
- Copies an access policy from one table to another.

Important: When you copy or rename a table, access policies associated with the original table are not included in the copied table. You must use ALTER ACCESS POLICY to copy the access policies to the new table.

Syntax

```
ALTER ACCESS POLICY ON [schema.]tablename
    | FOR COLUMN { columnname expression }
    | FOR ROWS WHERE expression
    [ENABLE | DISABLE | COPY TO TABLE tablename];
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tablename</td>
<td>The name of the table that contains the access policy you want to enable, disable, or copy.</td>
</tr>
<tr>
<td>columnname</td>
<td>Either of the following values:</td>
</tr>
<tr>
<td></td>
<td>• The name of the column on which to enable or disable the access policy</td>
</tr>
<tr>
<td></td>
<td>• The name of the column you want to copy</td>
</tr>
<tr>
<td>expression</td>
<td>An expression that provides further information to limit column or row access.</td>
</tr>
<tr>
<td></td>
<td>• In a column access policy the expression is the transformation of the column.</td>
</tr>
<tr>
<td></td>
<td>• In a row access policy the expressions is the content of the WHERE clause.</td>
</tr>
<tr>
<td></td>
<td>For example, the expression:</td>
</tr>
<tr>
<td></td>
<td>=&gt; ALTER ACCESS POLICY ON customer_dimension FOR COLUMN customer_key length ('xxxxx') enable;</td>
</tr>
<tr>
<td></td>
<td>limits access to strings in the customer_key column to a specific length.</td>
</tr>
<tr>
<td>ENABLE</td>
<td>DISABLE</td>
</tr>
<tr>
<td>COPY TO TABLE tablename</td>
<td>Copies the existing access policy to the specified table. Do not use an expression when performing a COPY TO function.</td>
</tr>
</tbody>
</table>

Privileges

You must be a dbadmin user to alter an access policy.
Examples

Copy Access Policy from Table to Table

=> ALTER ACCESS POLICY ON customer FOR COLUMN customer_number COPY TO TABLE customer_old;

Enable Access Policy

=> ALTER ACCESS POLICY ON customer FOR ROWS WHERE cid1>1 ENABLE;

ALTER AUTHENTICATION

Modifies the settings for a specified authentication method.

Syntax

ALTER AUTHENTICATION auth_method_name {
    |   { ENABLE | DISABLE }
    |   { LOCAL | HOST [ { TLS | NO TLS } ] host_ip_address }
    |   RENAME TO new_auth_method_name
    |   METHOD value
    |   SET param=value[, ...]
    |   PRIORITY value
}

Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth_method_name</td>
<td>Name of the authentication method that you want to create.</td>
</tr>
<tr>
<td></td>
<td><strong>Type:</strong> VARCHAR</td>
</tr>
<tr>
<td>ENABLE</td>
<td>DISABLE</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> Enabled</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE:</strong> When you perform an upgrade and use Kerberos authentication, you must manually set the authentication to ENABLE as it is disabled by default.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>LOCAL</td>
<td>HOST [ { TLS</td>
</tr>
<tr>
<td>RENAME TO new_auth_method_name</td>
<td>Rename the authentication record. <strong>Type</strong>: VARCHAR</td>
</tr>
<tr>
<td>METHOD value</td>
<td>The authentication method you are altering.</td>
</tr>
<tr>
<td>SET param=value</td>
<td>Set a parameter name and value for the authentication method that you are creating. Required only for LDAP and Ident authentication. ALTER AUTHENTICATION validates the parameters you enter. See parameters for specific authentication types in Client Authentication.</td>
</tr>
<tr>
<td>PRIORITY value</td>
<td>If the user is associated with multiple authentication methods, the priority value specifies which authentication method Vertica tries first. <strong>Default</strong>: 0 <strong>Type</strong>: INTEGER Higher values indicate higher priorities. For example, a priority of 10 is higher than a priority of 5; priority 0 is the lowest possible value. For details, see Priorities for Client Authentication Methods.</td>
</tr>
</tbody>
</table>

**Privileges**

Must have DBADMIN privileges.
Examples

Enabling and Disabling Authentication Methods

This example uses ALTER AUTHENTICATION to disable the v_ldap authentication method and then enable it again:

```
=> ALTER AUTHENTICATION v_ldap DISABLE;
=> ALTER AUTHENTICATION v_ldap ENABLE;
```

Renaming Authentication Methods

This example renames the v_kerberos authentication method to K5 and enables it. All users who have been granted the v_kerberos authentication method now have the K5 method granted instead.

```
=> ALTER AUTHENTICATION v_kerberos RENAME TO K5 ENABLE;
```

Modifying Authentication Parameters

This example sets the system user for ident1 authentication to user1:

```
=> CREATE AUTHENTICATION ident1 METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION ident1 SET system_users='user1';
```

When you set or modify LDAP or Ident parameters using ALTER AUTHENTICATION, Vertica validates them.

This example changes the IP address and specifies the parameters for an LDAP authentication method named Ldap1. Specify the bind parameters for the LDAP server. Vertica connects to the LDAP server, which authenticates the database client. If authentication succeeds, Vertica authenticates any users who have been associated with (granted) the Ldap1 authentication method on the designated LDAP server:

```
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
   binddn_prefix='cn=', binddn_suffix=',dc=qa_domain,dc=com';
```

The next example specifies the parameters for an LDAP authentication method named Ldap2. Specify the LDAP search and bind parameters. Sometimes, Vertica does not have enough information to create the distinguished name (DN) for a user attempting to authenticate. In such cases, you must specify to use LDAP search and bind:

```
=> CREATE AUTHENTICATION Ldap2 METHOD 'ldap' HOST '172.16.65.196';
```
=> ALTER AUTHENTICATION Ldap2 SET basedn='dc=qa_domain,dc=com', binddn='cn=Manager,dc=qa_domain, dc=com', search_attribute='cn', bind_password='secret';

### Changing the Authentication Method

This example changes the `localpwd` authentication from hash to trust:

```sql
=> CREATE AUTHENTICATION localpwd METHOD 'hash' LOCAL;
=> ALTER AUTHENTICATION localpwd METHOD 'trust';
```

### Set Multiple Realms

This example sets another realm for the authentication method `krb_local`:

```sql
=> ALTER AUTHENTICATION krb_local set realm = 'COMPANY.COM';
```

### See Also

- `CREATE AUTHENTICATION`
- `DROP AUTHENTICATION`
- `GRANT (Authentication)`
- `REVOKE (Authentication)`

### ALTER DATABASE

Use `ALTER DATABASE` to perform the following tasks:

- Set and clear database configuration parameters.
- Drop all fault groups and their child fault groups from a database.
- Specify the subnet name of a public network to use for import/export.
- Restore down nodes, and revert active standby nodes to standby status.
Syntax

```
ALTER DATABASE db-spec {
    DROP ALL FAULT GROUP
    | EXPORT ON { subnet-name | DEFAULT }
    | RESET STANDBY
    | SET [PARAMETER] parameter=value [,...]
    | CLEAR [PARAMETER] parameter[,...]
}
```

Parameters

<table>
<thead>
<tr>
<th>db-spec</th>
<th>Specifies the database to alter, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• The database name</td>
</tr>
<tr>
<td></td>
<td>• DEFAULT: The current database</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>DROP ALL FAULT GROUP</th>
<th>Drops all fault groups defined on the specified database. The syntax for DROP ALL FAULT GROUP is singular for GROUP.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>EXPORT ON</th>
<th>Specifies the network to use for importing and exporting data, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• subnet-name: A subnet of the public network.</td>
</tr>
<tr>
<td></td>
<td>• DEFAULT: Specifies to use a private network.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>RESET STANDBY</th>
<th>Restores any replaced nodes and reverts all active standby nodes to standby status. If any replaced nodes cannot resume activity, Vertica leaves the standby nodes in place.</th>
</tr>
</thead>
</table>

<p>| SET [PARAMETER]      | Sets one or more configuration parameters to the specified value at the database level.                        |</p>
<table>
<thead>
<tr>
<th>parameter=value</th>
<th></th>
</tr>
</thead>
</table>

| CLEAR [PARAMETER]    | Clears one or more specified configuration parameters at the database level.                                   |
| parameter             |                                                                                                               |

Privileges

Superuser
Examples

Drop and restore all default groups:

```sql
=> ALTER DATABASE exampledb DROP ALL FAULT GROUP;
ALTER DATABASE
```

Restore down nodes and revert all active standby nodes:

```sql
=> ALTER DATABASE exampledb RESET STANDBY;
ALTER DATABASE
```

Set multiple configuration parameters:

```sql
=> ALTER DATABASE exampledb SET
   AnalyzeRowCountInterval = 3600,
   DBDCorrelationSampleRowCount = 3000,
   ActivePartitionCount = 2;
```

Clear configuration parameters:

```sql
=> ALTER DATABASE exampledb CLEAR
   AnalyzeRowCountInterval, DBDCorrelationSampleRowCount, ActivePartitionCount;
```

**ALTER FAULT GROUP**

Modifies an existing fault group. For example, use the ALTER FAULT GROUP statement to:

- Add a node to or drop a node from an existing fault group
- Add a child fault group to or drop a child fault group from a parent fault group
- Rename a fault group

**Syntax**

```
ALTER FAULT GROUP fault-group-name
   [ ADD NODE node-name ]
   [ DROP NODE node-name ]
   [ ADD FAULT GROUP child-fault-group-name ]
   [ DROP FAULT GROUP child-fault-group-name ]
   [ RENAME TO new-fault-group-name ]
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fault-group-name</td>
<td>The existing fault group name you want to modify.</td>
</tr>
<tr>
<td></td>
<td>Tip: For a list of all fault groups defined in the cluster, query the V_CATALOG.FAULT_GROUPS system table.</td>
</tr>
<tr>
<td>node-name</td>
<td>The node name you want to add to or drop from the existing (parent) fault group.</td>
</tr>
<tr>
<td>child-fault-group-name</td>
<td>The name of the child fault group you want to add to or remove from an existing parent fault group.</td>
</tr>
<tr>
<td>new-fault-group-name</td>
<td>The new name for the fault group you want to rename.</td>
</tr>
</tbody>
</table>

Privileges

Must be a superuser to alter a fault group.

Example

This example renames the parent0 fault group to parent100:

```
=> ALTER FAULT GROUP parent0 RENAME TO parent100;
ALTER FAULT GROUP
```

You can verify the change by querying the V_CATALOG.FAULT_GROUPS system table:

```
=> SELECT member_name FROM fault_groups;
   member_name
------------------------
   v_exampledb_node0003
   parent100
   mygroup
(3 rows)
```
See Also

- CREATE FAULT GROUP
- V_CATALOG.FAULT_GROUPS
- V_CATALOG.CLUSTER_LAYOUT
- Fault Groups
- High Availability With Fault Groups

ALTER FUNCTION (SQL)

Alters a user-defined SQL function.

Syntax

ALTER FUNCTION [[db-name.]schema.]function-name([arg-type1], ...) {SET SCHEMA new_schema
  | RENAME TO new_name
  | OWNER TO new_owner}

Parameters

<table>
<thead>
<tr>
<th>[db-name.]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>function-name</td>
<td>The name of the SQL function to alter. Each function requires an accompanying argument, so you must specify the argument type for each function.</td>
</tr>
<tr>
<td>RENAME TO new_name</td>
<td>Specifies the new name of the function</td>
</tr>
<tr>
<td>SET SCHEMA new_schema</td>
<td>Specifies the new schema name where the function resides.</td>
</tr>
</tbody>
</table>
OWNER TO new_owner

Specifies the new owner of the function.

Privileges

- Only a superuser or owner can alter a function.

- To rename a function (ALTER FUNCTION RENAME TO) the user must have USAGE and CREATE privilege on schema that contains the function.

- To specify a new schema (ALTER FUNCTION SET SCHEMA), the user must have USAGE privilege on schema that currently contains the function (old schema) and CREATE privilege on the schema to which the function will be moved (new schema).

Examples

This example renames a function called SQL_one to SQL_two:

```sql
=> ALTER FUNCTION SQL_one (int,int) RENAME TO SQL_two;
```

This example moves the SQL_two function to a new schema called macros:

```sql
=> ALTER FUNCTION SQL_two (int) SET SCHEMA macros;
```

This example assigns a new owner to SQL_two:

```sql
=> ALTER FUNCTION SQL_two (int, int) OWNER TO user1;
```

See Also

- CREATE FUNCTION (SQL Functions)
- DROP FUNCTION
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
**USER_FUNCTIONS**

**Using User-Defined SQL Functions**

**ALTER FUNCTION (UDF)**

Alters a user defined function (UDF).

**Syntax**

```
ALTER FUNCTION [[db-name.]schema.]function-name([arg-type1,] ...) 
  { SET SCHEMA new_schema 
  | RENAME TO new_name 
  | SET FENCED bool_val 
  | OWNER TO new_owner }
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[db-name.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code> If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>function-name</code></td>
<td>The name of the UDF to alter. You must specify the argument type list, which may be empty.</td>
</tr>
<tr>
<td>RENAME TO <code>new_name</code></td>
<td>Specifies the new name of the function</td>
</tr>
<tr>
<td>SET SCHEMA <code>new_schema</code></td>
<td>Specifies the new schema name where the function resides.</td>
</tr>
<tr>
<td>OWNER TO <code>new_owner</code></td>
<td>Specifies the new owner of the function.</td>
</tr>
</tbody>
</table>
| SET FENCED `bool_val`      | A boolean value that specifies if Fenced Mode is enabled for this function. Valid values are: true - enables Fenced Mode  
false - disables Fenced Mode  
Fenced Mode is not available for User Defined Aggregates or User
Privileges

- Only a superuser or owner can alter a function.
- To rename a function (ALTER FUNCTION RENAME TO) the user must have USAGE and CREATE privilege on schema that contains the function.
- To specify a new schema (ALTER FUNCTION SET SCHEMA), the user must have USAGE privilege on the schema that currently contains the function (old schema) and CREATE privilege on the schema to which the function will be moved (new schema).

Examples

This example renames a function called UDF_one to UDF_two:

```sql
=> ALTER FUNCTION UDF_one (int,int) RENAME TO UDF_two;
```

This example moves the UDF_two function to a new schema called macros:

```sql
=> ALTER FUNCTION UDF_two (int) SET SCHEMA macros;
```

This example disables Fenced Mode for the UDF_two function:

```sql
=> ALTER FUNCTION UDF_two (int, int) SET FENCED false;
```

- CREATE FUNCTION (UDF)
- DROP FUNCTION
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
- USER_FUNCTIONS
ALTER HCATALOG SCHEMA

Alters parameter values on a schema that was created with CREATE HCATALOG SCHEMA. HCatalog schemas are used by the HCatalog Connector to access data stored in a Hive data warehouse. For more information, see Using the HCatalog Connector in Integrating with Apache Hadoop.

Some parameters cannot be altered after creation. If you need to change one of those values, delete and recreate the schema instead. You can use ALTER HCATALOG SCHEMA to change the following parameters:

- HOSTNAME
- PORT
- HIVESERVER2_HOSTNAME
- WEBSERVICE_HOSTNAME
- WEBSERVICE_PORT
- WEBHDFS_ADDRESS
- HCATALOG_CONNECTION_TIMEOUT
- HCATALOG_SLOW_TRANSFER_LIMIT
- HCATALOG_SLOW_TRANSFER_TIME
- SSL_CONFIG

Syntax

ALTER HCATALOG SCHEMA schema-name SET [param=value]+;

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.0.x)
### ALTER HCATALOG SCHEMA

The name of the schema in the Vertica catalog to alter. The tables in the Hive database are available through this schema.

<table>
<thead>
<tr>
<th>param</th>
<th>The name of the parameter to alter.</th>
</tr>
</thead>
</table>
| value       | The new value for the parameter. You must specify a value; this statement does not read default values from configuration files like CREATE HCATALOG SCHEMA.

### Privileges

One of the following:

- Superuser
- Schema owner

### Examples

The following example shows how to change the Hive metastore hostname and port for the "hcat" schema. In this example, Hive uses High Availability metastore.

```sql
=> ALTER HCATALOG SCHEMA hcat SET HOSTNAME='thrift://ms1.example.com:9083,thrift://ms2.example.com:9083';
```

The following example shows the error you receive if you try to set an unalterable parameter.

```sql
=> ALTER HCATALOG SCHEMA hcat SET HCATALOG_USER='admin';
ERROR 4856: Syntax error at or near "HCATALOG_USER" at character 39
```

### ALTER LIBRARY

Replaces the library file (C++ .so file, Java JAR file, or R source file) associated with a UDx library that is defined in the Vertica catalog. Vertica automatically distributes copies of the updated file throughout the cluster. UDxs defined in the catalog that reference the updated library automatically start using the updated library file. Nodes that are down or added to the cluster also receive a copy of the updated library file as soon as they join the cluster.
Syntax

ALTER LIBRARY [[database.]schema.]library-name [DEPENDS 'support-path'] AS 'library-path';

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>library-name</td>
<td>The library to alter. You can only alter an existing library.</td>
</tr>
</tbody>
</table>
| DEPENDS 'support-path' | Indicates that the UDx library depends on one or more support libraries, where support-path specifies one or more absolute paths to the support libraries files, located in the initiator node's file system. You can specify multiple support paths as follows:  
  - Separate multiple paths with colons (:).  
  - Specify a directory that contains multiple libraries with an asterisk wildcard (*). For example: /home/mydir/mylibs/* |
| library-path   | The absolute path in the initiator node file system to the replacement library file.                                                            |
Requirements

- The new library must be developed in the same programming language as the library file being replaced. For example, you cannot use this statement to replace a C++ library file with an R library file.

- Vertica does not compare the functions defined in the new library to ensure they match any currently-defined functions in the catalog. If you change the signature of a function in the library (for example, if you change the number and data types accepted by a UDSF defined in the library), calls to that function will likely generate errors. If your new library file changes the definition of a function, you must remove the function using DROP FUNCTION before using ALTER LIBRARY to load the new library. You can then recreate the function using its new signature.

Examples

This example shows how to update an already-defined library myFunctions with a new file.

```sql
=> ALTER LIBRARY myFunctions AS '/home/dbadmin/my_new_functions.so';
```

See Also

Developing User-Defined Extensions (UDxs)

**ALTER MODEL**

Allows users to rename an existing model, change owner parameters, and set schema to the model.

Syntax

```
ALTER MODEL [[db-name.]schema.]model-name
  [ OWNER TO owner-name
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$db-name.schema$</td>
<td>Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td>$myschema$</td>
</tr>
<tr>
<td>$model-name$</td>
<td>The model to alter.</td>
</tr>
<tr>
<td>$OWNER TO $owner-name$</td>
<td>Changes the model owner.</td>
</tr>
<tr>
<td>$RENAME TO$</td>
<td>Renames the model.</td>
</tr>
<tr>
<td>$SET SCHEMA$</td>
<td>Moves the model from one schema to another.</td>
</tr>
</tbody>
</table>

Privileges

Any user who creates a model can drop or alter his or her own model. If you are the dbadmin user, you can drop or alter any model in the database.

Examples

This example shows how you can alter an existing model to rename the model.

```sql
=> ALTER MODEL mymodel RENAME to mykmeansmodel;
ALTER MODEL
```

This example shows how you can alter an existing model to change the owner.

```sql
=> ALTER MODEL mykmeansmodel OWNER TO user1;
ALTER MODEL
```

This example shows how you can alter an existing model to rename the model.

```sql
=> ALTER MODEL mykmeansmodel SET SCHEMA public;
ALTER MODEL
```
See Also

- Altering Models

**ALTER NETWORK INTERFACE**

Lets you rename a network interface.

**Syntax**

```
ALTER NETWORK INTERFACE network-interface-name RENAME TO new-network-interface-name
```

**Parameters**

<table>
<thead>
<tr>
<th>network-interface-name</th>
<th>The name of the existing network interface.</th>
</tr>
</thead>
<tbody>
<tr>
<td>new-network-interface-name</td>
<td>The new name for the network interface.</td>
</tr>
</tbody>
</table>

**Privileges**

Must be a superuser to alter a network interface.

**Examples**

This example shows how to rename a network interface.

```
=> ALTER NETWORK INTERFACE myNetwork RENAME TO myNewNetwork;
```
ALTER NODE

Sets and clears node-level configuration parameters on the specified node. ALTER NODE also performs the following management tasks:

- Changes the node type.
- Specifies the network interface of the public network on individual nodes that are used for import and export.
- Replaces a down node.

Syntax

ALTER NODE node-name {
  EXPORT ON { network-interface | DEFAULT }
  [ IS ] node-type
  REPLACE [ WITH standby-node ]
  RESET
  SET [PARAMETER] parameter=value[,...]
  CLEAR [PARAMETER] parameter[,...]
}

Parameters

<table>
<thead>
<tr>
<th>node-name</th>
<th>The name of the node to alter.</th>
</tr>
</thead>
<tbody>
<tr>
<td>[IS] node-type</td>
<td>Changes the node type, where node-type is one of the following:</td>
</tr>
<tr>
<td></td>
<td>- PERMANENT (default): A node that is used to store data.</td>
</tr>
<tr>
<td></td>
<td>- EPHEMERAL: A node that is in transition from one type to another—typically, from PERMANENT to either STANDBY or EXECUTE.</td>
</tr>
<tr>
<td></td>
<td>- STANDBY: A node that is reserved to replace any node when it goes down. When used as a replacement node, Vertica changes its type to PERMANENT. A standby node stores no segments or data until it is called to replace a down node. At</td>
</tr>
</tbody>
</table>
that time, Vertica changes its type to PERMANENT. For more information, see *Active Standby Nodes*.

- **EXECUTE**: A node that is reserved for computation purposes only. An execute node contains no segments or data.

<table>
<thead>
<tr>
<th>EXPORT ON</th>
<th>Specifies the network to use for importing and exporting data, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- <em>network-interface</em>: The name of a network interface of the public network.</td>
</tr>
<tr>
<td></td>
<td>- DEFAULT: Use the default network interface of the public network, as specified by <em>ALTER DATABASE</em>.</td>
</tr>
</tbody>
</table>

| REPLACE [WITH *standby-node*] | Replaces the specified node with an available active standby node. If you omit the WITH clause, Vertica tries to find a replacement node from the same fault group as the down node. If you specify a node that is not down, Vertica ignores this statement. |

| RESET | Restores the specified down node and returns its replacement to standby status. If the down node is unable to resume activity, Vertica ignores this statement and leaves the standby node in place. |

| SET [PARAMETER] *parameter=value* | Sets one or more configuration parameters to the specified value at the node level. |

| CLEAR [PARAMETER] *parameter* | Clears one or more specified configuration parameters. |

**Privileges**

Superuser
Examples

Specify to use the default network interface of public network on v_vmart_node0001 for import/export operations:

```sql
=> ALTER NODE v_vmart_node0001 EXPORT ON DEFAULT;
```

Replace down node v_vmart_node0001 with an active standby node, then restore it:

```sql
=> ALTER NODE v_vmart_node0001 REPLACE WITH standby1;
...  
=> ALTER NODE v_vmart_node0001 RESET;
```

Set and clear configuration parameter `MaxClientSessions`:

```sql
=> ALTER NODE v_vmart_node0001 SET MaxClientSessions = 0;
...  
=> ALTER NODE v_vmart_node0001 CLEAR MaxClientSessions;
```

Set the node type as `EPHEMERAL`:

```sql
=> ALTER NODE v_vmart_node0001 IS EPHEMERAL;
```

**ALTER NOTIFIER**

Updates an existing notifier.

**Note:** To change the action URL associated with an existing identifier, drop the notifier and re-create it.

**Syntax**

```
ALTER NOTIFIER notifier-name parameter[...]
```

*parameter*

- [NO] CHECK COMMITTED
- ENABLE | DISABLE
- IDENTIFIED BY uuid
- MAXMEMORYSIZE `max-memory-size`
- MAXPAYLOAD `max-payload-size`
- PARAMETERS `adapter-params`
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>notifier-name</td>
<td>Specifies the notifier to update.</td>
</tr>
<tr>
<td>[NO] CHECK COMMITTED</td>
<td>Specifies to wait for delivery confirmation before sending the next message in the queue. Not all messaging systems support delivery confirmation.</td>
</tr>
<tr>
<td>ENABLE</td>
<td>DISABLE</td>
</tr>
<tr>
<td>IDENTIFIED BY uuid</td>
<td>Specifies the notifier's unique identifier. If set, all the messages published by this notifier have this attribute.</td>
</tr>
<tr>
<td>MAXMEMORYSIZE</td>
<td>The maximum size of the internal notifier, up to 2 TB, specified in kilobytes, megabytes, gigabytes, or terabytes as follows:</td>
</tr>
<tr>
<td></td>
<td>[\text{MAXMEMORYSIZE} \text{integer}{K</td>
</tr>
<tr>
<td></td>
<td>If the queue exceeds this size, the notifier drops excess messages.</td>
</tr>
<tr>
<td>MAXPAYLOAD</td>
<td>The maximum size of the message, up to 2 TB, specified in kilobytes, megabytes, gigabytes, or terabytes as follows:</td>
</tr>
<tr>
<td></td>
<td>[\text{MAXPAYLOAD} \text{integer}{K</td>
</tr>
<tr>
<td></td>
<td>The default setting is adapter-specific—for example, 1 M for Kafka.</td>
</tr>
<tr>
<td>PARAMETERS 'adapter-params'</td>
<td>Specifies one or more optional adapter parameters that are passed as a string to the adapter. Adapter parameters apply only to the adapter associated with the notifier.</td>
</tr>
<tr>
<td></td>
<td>For Kafka notifiers, refer to Kafka and Vertica Configuration Settings.</td>
</tr>
</tbody>
</table>

Privileges

Database Administrator
Examples

Update the settings on an existing notifier:

```sql
=> ALTER NOTIFIER my_dc_notifier
   ENABLE
   MAXMEMORYSIZE '2G'
   IDENTIFIED BY 'f8b0278a-3282-4e1a-9c86-e0f3f042a971'
   CHECK COMMITTED;
```

See Also

- CREATE NOTIFIER
- DROP NOTIFIER

**ALTER PROJECTION RENAME**

Initiates a rename operation on the specified projection.

**Syntax**

```sql
ALTER PROJECTION [[database.]schema.]projection RENAME TO new-name
```

**Parameters**

<table>
<thead>
<tr>
<th><strong>schema</strong></th>
<th>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>
### projection

The projection to change. See Projection Naming for projection name conventions.

### new-name

The new projection name.

---

**Privileges**

Superuser, or the following:

- Anchor table owner
- CREATE privilege on the schema

---

**Examples**

This example shows how to rename a projection.

```sql
=> CREATE TABLE tbl (x integer, y integer); CREATE TABLE

=> CREATE PROJECTION tbl_p AS SELECT x from tbl; CREATE PROJECTION

=> ALTER PROJECTION tbl_p RENAME to new_tbl_p; ALTER PROJECTION
```

---

**See Also**

CREATE PROJECTION

---

**ALTER PROFILE**

Changes a profile. All parameters that are not set in a profile inherit their setting from the default profile. You can use ALTER PROFILE to change the default profile.

---

**Syntax**

```sql
CREATE PROFILE name LIMIT [ password-parameter setting ]...
```
**password-parameter**

PASSWORD_LIFE_TIME
PASSWORD_GRACE_TIME
FAILED_LOGIN_ATTEMPTS
PASSWORD_LOCK_TIME
PASSWORD_REUSE_MAX
PASSWORD_REUSE_TIME
PASSWORD_MAX_LENGTH
PASSWORD_MIN_LENGTH
PASSWORD_MIN_UPPERCASE_LETTERS
PASSWORD_MIN_LOWERCASE_LETTERS
PASSWORD_MIN_DIGITS
PASSWORD_MIN_SYMBOLS

## Parameters

**Note:** To reset a parameter to inherit from the default profile, set its value to `default`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong></td>
<td>The name of the profile to create, where <code>name</code> conforms to conventions described in Identifiers. To modify the default profile, set <code>name</code> to <code>default</code>. For example:</td>
</tr>
<tr>
<td></td>
<td><code>ALTER PROFILE DEFAULT LIMIT PASSWORD_MIN_SYMBOLS 1;</code></td>
</tr>
<tr>
<td><strong>PASSWORD_LIFE_TIME</strong></td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>- ≥ 1: The number of days a password remains valid.</td>
</tr>
<tr>
<td></td>
<td>- UNLIMITED: Password remains valid indefinitely.</td>
</tr>
<tr>
<td></td>
<td>After your password's lifetime and grace period expire, you must change your password on your next login, if you have not done so already.</td>
</tr>
<tr>
<td><strong>PASSWORD_GRACE_TIME</strong></td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>- ≥ 1: The number of days a password can be used after it expires.</td>
</tr>
<tr>
<td></td>
<td>- UNLIMITED: No grace period.</td>
</tr>
<tr>
<td><strong>FAILED_LOGIN_ATTEMPTS</strong></td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>- ≥ 1: The number of days a password remains valid.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>● ≥ 1: The number of consecutive failed login attempts Vertica allows before locking your account.</td>
</tr>
<tr>
<td></td>
<td>● UNLIMITED: Vertica allows an unlimited number of failed login attempts.</td>
</tr>
<tr>
<td>PASSWORD_LOCK_TIME</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td>● ≥ 1: The number of days your account is locked after too many failed login attempts. The account is automatically unlocked when the lock time elapses.</td>
</tr>
<tr>
<td></td>
<td>● UNLIMITED: Account remains indefinitely inaccessible until a superuser manually unlocks it.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_MAX</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td>● ≥ 1: The number of times you must change your password before you can reuse an earlier password.</td>
</tr>
<tr>
<td></td>
<td>● UNLIMITED: You can reuse an earlier password without any intervening changes.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_TIME</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td>● ≥ 1: The number of days that must pass after a password is set before you can reuse it.</td>
</tr>
<tr>
<td></td>
<td>● UNLIMITED: You can reuse an earlier password immediately.</td>
</tr>
<tr>
<td>PASSWORD_MAX_LENGTH</td>
<td>The maximum number of characters allowed in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>● Integer between 8 and 100, inclusive</td>
</tr>
<tr>
<td></td>
<td>● UNLIMITED: Maximum of 100 characters</td>
</tr>
<tr>
<td>PASSWORD_MIN_LENGTH</td>
<td>The minimum number of characters required in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>● 0 to PASSWORD_MAX_LENGTH</td>
</tr>
<tr>
<td></td>
<td>● UNLIMITED: Minimum of PASSWORD_MAX_LENGTH</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PASSWORD_MIN_LETTERS</td>
<td>Minimum number of letters (a-z and A-Z) that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
<tr>
<td>PASSWORD_MIN_UPPERCASE_LETTERS</td>
<td>Minimum number of uppercase letters (A-Z) that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
<tr>
<td>PASSWORD_MIN_LOWERCASE_LETTERS</td>
<td>Minimum number of lowercase letters (a-z) that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
<tr>
<td>PASSWORD_MIN_DIGITS</td>
<td>Minimum number of digits (0-9) that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
<tr>
<td>PASSWORD_MIN_SYMBOLS</td>
<td>Minimum number of symbols— printable non-letter and non-digit characters such as $, #, @— that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser
Profile Settings and Client Authentication

The following profile settings affect client authentication methods, such as LDAP or GSS:

- FAILED_LOGIN_ATTEMPTS
- PASSWORD_LOCK_TIME

All other profile settings are used only by Vertica to manage its passwords.

Example

```sql
ALTER PROFILE sample_profile LIMIT FAILED_LOGIN_ATTEMPTS 3;
```

See Also

- CREATE PROFILE
- DROP PROFILE
- Creating a Database Name and Password

**ALTER PROFILE RENAME**

Rename an existing profile.

**Syntax**

```
ALTER PROFILE name RENAME TO newname;
```

**Parameters**

| name     | The current name of the profile. |
The new name for the profile.

Privileges

Must be a superuser to alter a profile.

Examples

This example shows how to rename an existing profile.

```
ALTER PROFILE sample_profile RENAME TO new_sample_profile;
```

See Also

- ALTER PROFILE
- CREATE PROFILE
- DROP PROFILE

**ALTER RESOURCE POOL**

Modifies an existing resource pool by setting one or more parameters.

Syntax

```
ALTER RESOURCE POOL pool-name [ parameter-name setting ]...
```

Parameters

Note: You can set all resource pool parameters to their DEFAULT value. The `V_CATALOG RESOURCE_POOL_DEFAULTS` system table contains default parameter values. Query this table to determine default settings for all resource pools.
Default values specified in this table pertain only to user-defined resource pools. For built-in pool default values, see Built-In Pool Configuration.

<table>
<thead>
<tr>
<th>pool-name</th>
<th>The name of the resource pool. Built-in pool names cannot be used for user-defined pools.</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameter-name</td>
<td>The parameter to set, listed below.</td>
</tr>
<tr>
<td>CASCADE TO</td>
<td>Specifies a secondary resource pool for executing queries that exceed the RUNTIMECAP setting of their assigned resource pool:</td>
</tr>
<tr>
<td></td>
<td>CASCADE TO secondary-pool</td>
</tr>
<tr>
<td>CPUAFFINITYMODE</td>
<td>Specifies whether the resource pool has exclusive or shared use of the CPUs specified in CPUAFFINITYSET:</td>
</tr>
<tr>
<td></td>
<td>CPUAFFINITYMODE {</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>• SHAREAD: Queries that run in this pool share its CPUAFFINITYSET CPUs with other Vertica resource pools.</td>
</tr>
<tr>
<td></td>
<td>• EXCLUSIVE: Duplicates CPUAFFINITYSET CPUs to this resource pool only, and excludes other Vertica resource pools. If CPUAFFINITYSET is set as a percentage, then that percentage of CPU resources available to Vertica is assigned solely for this resource pool.</td>
</tr>
<tr>
<td></td>
<td>• ANY (default): Queries in this resource pool can run on any CPU, invalid if CPUAFFINITYSET designates CPU resources.</td>
</tr>
<tr>
<td>CPUAFFINITYSET</td>
<td>Specifies which CPUs are available to this resource pool. All cluster nodes must have the same number of CPUs. The CPU resources assigned to this set are unavailable to general resource pools.</td>
</tr>
<tr>
<td></td>
<td>CPUAFFINITYSET {</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
- `cpu-index[, ...]`: Dedicates one or more comma-delimited CPUs to this pool.

- `cpu-index_i-cpu-index_n`: Dedicates a range of contiguous CPU indexes to this pool.

- `integer%`: Percentage of all available CPUs to use for this pool. Vertica rounds this percentage down to include whole CPU units.

- `NONE` (default): No affinity set is assigned to this resource pool. The queries associated with this pool are executed on any CPU.

**EXECUTIONPARALLELISM**

Limits the number of threads used to process any single query issued in this resource pool.

**EXECUTIONPARALLELISM { integer | AUTO }**

- `integer`: A value between 1 and the number of cores. Setting this parameter to a reduced value increases throughput of short queries issued in the pool, especially if the queries are executed concurrently.

- `AUTO` (default): Vertica sets this value based on the number of cores, available memory, and amount of data in the system. Unless memory is limited, or the amount of data is very small, Vertica sets this value to the number of cores on the node.

**MAXCONCURRENCY**

Sets the maximum number of concurrent execution slots available to the resource pool, across the cluster:

**MAXCONCURRENCY { integer | NONE }**

`NONE` (default) specifies unlimited number of concurrent execution slots.

**MAXMEMORYSIZE**

The maximum size per node the resource pool can grow by borrowing memory from the **GENERAL** pool:

**MAXMEMORYSIZE**

```
(integer%)
(integer{K|M|G|T})
NONE
```
<table>
<thead>
<tr>
<th>MEMORYSIZE</th>
<th>The amount of total memory available to the Vertica resource manager that is allocated to this pool per node:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>MEMORYSIZE {</td>
</tr>
<tr>
<td></td>
<td>'integer%': Percentage of total memory</td>
</tr>
<tr>
<td></td>
<td>'integer{K</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: 0%. No memory allocated, the resource pool borrows memory from the <strong>GENERAL</strong> pool.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>PLANNEDCONCURRENCY</th>
<th>Specifies the preferred number queries to execute concurrently in the resource pool. This setting applies to the entire cluster:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PLANNEDCONCURRENCY { integer</td>
</tr>
<tr>
<td></td>
<td><strong>integer</strong>: The preferred number of concurrently executing queries. When possible, query resource budgets are limited to allow this level of concurrent execution.</td>
</tr>
<tr>
<td></td>
<td>AUTO (default): Value is calculated automatically at query runtime. Vertica sets this parameter to the lower of these two calculations, but never less than 4:</td>
</tr>
<tr>
<td></td>
<td>- Number of logical cores</td>
</tr>
<tr>
<td></td>
<td>- Memory divided by 2GB</td>
</tr>
</tbody>
</table>

For clusters where the number of logical cores differs
on different nodes, AUTO can apply differently on each node. Distributed queries run like the minimal effective planned concurrency. Single node queries run with the planned concurrency of the initiator.

Tip: Change this parameter only after evaluating performance over a period of time.

<table>
<thead>
<tr>
<th>PRIORITY</th>
<th>Specifies priority of queries in this pool when they compete for resources in the <strong>GENERAL</strong> pool:</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIORITY { integer</td>
<td>HOLD }</td>
</tr>
<tr>
<td>integer: A negative or positive integer value, where higher numbers denote higher priority:</td>
<td></td>
</tr>
<tr>
<td>User-defined pools: -100 to 100</td>
<td></td>
</tr>
<tr>
<td>Built-in pools <em>SYSQUERY</em>, <em>RECOVERY</em>, and <em>TM</em>: -110 to 110</td>
<td></td>
</tr>
<tr>
<td>HOLD: Sets priority to -999. Queries in this pool are queued until <strong>QUEUETIMEOUT</strong> is reached.</td>
<td></td>
</tr>
<tr>
<td>Default: 0</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>QUEUETIMEOUT</th>
<th>Specifies how long a request can wait for pool resources before it is rejected:</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUEUETIMEOUT { integer</td>
<td>NONE }</td>
</tr>
<tr>
<td>integer: Maximum wait time in seconds</td>
<td></td>
</tr>
<tr>
<td>NONE: No maximum wait time, request can be queued indefinitely.</td>
<td></td>
</tr>
<tr>
<td>Default: 300 seconds</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>RUNTIMECAP</th>
<th>Prevents runaway queries by setting the maximum time a query in the pool can execute. If a query exceeds this setting, it tries to cascade to a secondary pool:</th>
</tr>
</thead>
<tbody>
<tr>
<td>RUNTIMECAP { interval</td>
<td>NONE }</td>
</tr>
<tr>
<td>interval: An interval of 1 minute or 100 seconds; should not exceed one year.</td>
<td></td>
</tr>
<tr>
<td>NONE: No time limit on queries running in this pool.</td>
<td></td>
</tr>
</tbody>
</table>
To specify a value in days, provide an integer value. To provide a value less than one day, provide the interval in the format hours:minutes:seconds. For example a value of 1:30:00 would equal 90 minutes. If the user or session also has a RUNTIMECAP, the shorter limit applies.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>RUNTIMEPRIORITY</td>
<td>Determines how the resource manager should prioritize dedication of run-time resources (CPU, I/O bandwidth) to queries already running in this resource pool:</td>
<td>MEDIUM</td>
</tr>
<tr>
<td>RUNTIMEPRIORITYTHRESHOLD</td>
<td>Specifies in seconds a time limit in which a query must finish before the resource manager assigns to it the resource pool's RUNTIMEPRIORITY. All queries begin running at a HIGH priority. When a query's duration exceeds this threshold, it is assigned the RUNTIMEPRIORITY of the resource pool.</td>
<td>2 seconds</td>
</tr>
</tbody>
</table>

### Privileges

The following parameters require superuser privileges on the resource pool:

- CASCADE TO
- CPUAFFINITYSET
- CPUAFFINITYMODE
- MAXMEMORYSIZE
- PRIORITY
- QUEUETIMEOUT

The following parameters require UPDATE privileges on the resource pool:
Examples

This example shows how to alter resource pool ceo_pool by setting the priority to 5.

```sql
=> ALTER RESOURCE POOL ceo_pool PRIORITY 5;
```

This example shows how to designate a secondary pool for the ceo_pool.

```sql
=> CREATE RESOURCE POOL second_pool;
=> ALTER RESOURCE POOL ceo_pool CASCADE TO second_pool;
```

See Also

- CREATE RESOURCE POOL
- CREATE USER
- DROP RESOURCE POOL
- RESOURCE_POOL_STATUS
- SET SESSION RESOURCE_POOL
- SET SESSION MEMORYCAP
- Managing Workloads

**ALTER ROLE RENAME**

Rename an existing role.
NOTE: You cannot use the ALTER ROLE RENAME command on a role added to the Vertica database with the LDAPLink service.

Syntax

```
ALTER ROLE name RENAME TO new_name;
```

Parameters

<table>
<thead>
<tr>
<th>name</th>
<th>The current name of the role that you want to rename.</th>
</tr>
</thead>
<tbody>
<tr>
<td>new_name</td>
<td>The new name for the role.</td>
</tr>
</tbody>
</table>

Privileges

Must be a superuser to rename a role.

Example

```
=> ALTER ROLE applicationadministrator RENAME TO appadmin;
ALTER ROLE
```

See Also

- CREATE ROLE
- DROP ROLE

**ALTER SCHEMA**

Changes one or more schemas in one of the following ways:
• Enables or disables inheritance of schema privileges by tables created in the schemas.

• Renames schemas.

Syntax

Set inheritance of schema privileges

ALTER SCHEMA [database.]schema[,...] DEFAULT {INCLUDE | EXCLUDE} SCHEMA PRIVILEGES

Rename schemas

ALTER SCHEMA [database.]schema[,...] RENAME TO new-schema-name[,...]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema to modify. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>DEFAULT {INCLUDE</td>
<td>EXCLUDE} SCHEMA PRIVILEGES</td>
</tr>
<tr>
<td>RENAME TO</td>
<td>Renames one or more schemas: RENAME TO new-schema-name[,...] The following requirements apply:</td>
</tr>
<tr>
<td></td>
<td>• The new schema name conforms to conventions described in Identifiers. It must also be unique among all names of sequences, tables, projections, views, models, and schemas in the database.</td>
</tr>
<tr>
<td></td>
<td>• If you specify multiple schemas to rename, the source and target lists must have the same number of names.</td>
</tr>
</tbody>
</table>
Caution: Renaming a schema referenced by a view causes the view to fail unless another schema is created to replace it.

Privileges

Superuser, or one of the following:

- To modify inheritance of privileges, schema owner or USAGE privilege on the schema
- To rename a schema, owner of the schema and CREATE privilege on the database

Swapping Schemas

Renaming schemas is useful for swapping schemas without actually moving data. To facilitate the swap, enter a non-existent, temporary placeholder schema. For example, the following ALTER SCHEMA statement uses the temporary schema temps to facilitate swapping schema S1 with schema S2. In this example, S1 is renamed to temps. Then S2 is renamed to S1. Finally, temps is renamed to S2.

```
ALTER SCHEMA S1, S2, temps RENAME TO temps, S1, S2;
```

Examples

The following example renames schemas S1 and S2 to S3 and S4, respectively:

```
=> ALTER SCHEMA S1, S2 RENAME TO S3, S4;
```

This example sets the default behavior for new table t2 to automatically inherit the schema's privileges:

```
=> ALTER SCHEMA s1 DEFAULT INCLUDE SCHEMA PRIVILEGES;
=> CREATE TABLE s1.t2 (i, int);
```

This example sets the default for new tables to not automatically inherit privileges from the schema:

```
=> ALTER SCHEMA s1 DEFAULT EXCLUDE SCHEMA PRIVILEGES;
```
See Also

- CREATE SCHEMA
- DROP SCHEMA

**ALTER SEQUENCE**

Changes a named sequence in two ways:

- Sets parameters that control sequence behavior—for example, its start value, and range of minimum and maximum values. These changes take effect only when you start a new database session.

- Sets sequence name, schema, or ownership. These changes take effect immediately.

Note: You can only modify a named sequence—that is, a sequence that was defined by CREATE SEQUENCE. AUTO_INCREMENT and IDENTITY sequences are owned by the table where they were created, and cannot be changed independently of that table.

**Syntax**

Change sequence behavior:

```sql
ALTER SEQUENCE [[database.]schema.]sequence
... [ INCREMENT [ BY ] integer ]
... [ MINVALUE integer | NO MINVALUE ]
... [ MAXVALUE integer | NO MAXVALUE ]
... [ RESTART [ WITH ] integer ]
... [ CACHE integer | NO CACHE ]
... [ CYCLE | NO CYCLE ]
```

Change sequence name, schema, or ownership:

```sql
ALTER SEQUENCE [schema.]sequence-name {
... RENAME TO seq-name
... | SET SCHEMA schema-name
... | OWNER TO owner-name
}
```
### Parameters

<table>
<thead>
<tr>
<th><strong>schema</strong></th>
<th>Specifies a schema, by default public. If <em>schema</em> is any schema other than public, you must supply the schema name. For example:</th>
<th></th>
</tr>
</thead>
</table>
| myschema.thisDbObject | If you specify a database, it must be the current database.  
If you do not specify a schema, the table is created in the default schema. |  |

<table>
<thead>
<tr>
<th><strong>sequence</strong></th>
<th>The name of the sequence to alter.</th>
<th></th>
</tr>
</thead>
</table>

| **INCREMENT [BY] integer** | A positive or negative integer that specifies how much to increment or decrement the sequence on each call to `NEXTVAL`, by default set to 1.  
**Note:** Setting this parameter to `integer` guarantees that column values always increment by at least `integer`. However, column values can sometimes increment by more than `integer` unless you also set the `NO CACHE` parameter. |  |

| **MINVALUE integer** (default) | Modifies the minimum value a sequence can generate. If you change this value and the current value exceeds the range, the current value is changed to the minimum value if increment is greater than zero, or to the maximum value if increment is less than zero.  
**NO MINVALUE** |  |

| **MAXVALUE integer** (default) | Modifies the maximum value for the sequence. If you change this value and the current value exceeds the range, the current value is changed to the minimum value if increment is greater than zero, or to the maximum value if increment is less than zero. |  |

| **RESTART [WITH] integer** | Changes the current value of the sequence to `integer`. The next call to `NEXTVAL` returns `integer`.  
**Caution:** Using `ALTER SEQUENCE` to set a sequence start value below its current value can result in duplicate keys. |  |

| **CACHE integer** (default) | Specifies how many sequence numbers are pre-allocated and stored in memory for faster access. Vertica sets up caching for each session, and distributes it across all nodes. By default, the sequence cache is |  |
set to 250,000.
For details, see Distributing Named Sequences in the Administrator's Guide.

<table>
<thead>
<tr>
<th>CYCLE</th>
<th>NO CYCLE (default)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Specifies whether the sequence can wrap when its minimum or maximum values are reached:</td>
</tr>
<tr>
<td></td>
<td>• CYCLE: The sequence wraps as follows:</td>
</tr>
<tr>
<td></td>
<td>■ When an incrementing sequence reaches its upper limit, it is reset to its minimum value.</td>
</tr>
<tr>
<td></td>
<td>■ When an decrementing sequence reaches its lower limit, it is reset to its maximum value.</td>
</tr>
<tr>
<td></td>
<td>• NO CYCLE (default): Calls to NEXTVAL return an error after the sequence reaches its maximum or minimum value.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>RENAME TO</th>
<th>seq-name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Renames a sequence within the current schema, where seq-name conforms to conventions described in Identifiers. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>SET SCHEMA</th>
<th>schema-name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Moves the sequence to schema schema-name.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>OWNER TO</th>
<th>owner-name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Reassigns the current sequence owner to the specified owner.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser, or sequence owner with the following privileges:

- Rename sequence: USAGE and CREATE privileges on sequence.
- Move to another schema: USAGE privileges on current schema, and CREATE privilege on destination schema.
- Reassign ownership: Current sequence owner.

**Examples**

See Altering Sequences in the Administrator's Guide.
See Also

**CREATE SEQUENCE**

**ALTER SESSION**

Use `ALTER SESSION` to set and clear session-level configuration parameter values for the current session.

**Syntax**

```
ALTER SESSION {
    SET [PARAMETER] parameter-name=value [, ...]
    | CLEAR [PARAMETER] parameter-name[, ...]
    | SET UDPARAMETER [ FOR { namespace | libname } ] key=value [, ...]
    | CLEAR UDPARAMETER [ FOR { namespace | libname } ] key [, ...]
}
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET [PARAMETER]</td>
<td>Sets one or more configuration parameters to the specified value.</td>
</tr>
<tr>
<td>CLEAR [PARAMETER]</td>
<td>Clears one or more specified configuration parameters.</td>
</tr>
<tr>
<td>SET UDPARAMETER</td>
<td>Sets a user-defined session parameter, can be used in combination with a UDx. If omit a name space, Vertica uses the PUBLIC name space.</td>
</tr>
<tr>
<td></td>
<td><strong>Key size values:</strong></td>
</tr>
<tr>
<td></td>
<td>• Set from client side: 128 characters</td>
</tr>
<tr>
<td></td>
<td>• Set from UDx side: Unlimited</td>
</tr>
<tr>
<td>CLEAR UDPARAMETER</td>
<td>Clears one or more user-defined session parameters.</td>
</tr>
</tbody>
</table>
Privileges

None

Examples

Set and clear a parameter

- Force all UDxes that support fenced mode to run in fenced mode, even if their definition specified is NOT FENCED:

  => ALTER SESSION SET ForceUDxFencedMode = 1;

- Clear ForceUDxFencedMode at the session level. The value now reflects the default value (0).

  => ALTER SESSION CLEAR ForceUDxFencedMode;

Set and clear a user-defined parameter

- Set the value of RowCount, in the MyLibrary library and PUBLIC namespace, to 25.

  => ALTER SESSION SET UDPARAMETER FOR MyLibrary RowCount = 25;

- Clear RowCount at the session level. The value now reflects the default value (0).

  => ALTER SESSION CLEAR UDPARAMETER FOR MyLibrary RowCount;

See Also

SESSION_PARAMETERS
**ALTER SUBNET**

Renames an existing subnet.

**Syntax**

```
ALTER SUBNET subnet-name RENAME TO new-subnet-name
```

**Parameters**

<table>
<thead>
<tr>
<th>subnet-name</th>
<th>The name of the existing subnet.</th>
</tr>
</thead>
<tbody>
<tr>
<td>new-subnet-name</td>
<td>The new name for the subnet.</td>
</tr>
</tbody>
</table>

**Privileges**

Must be a superuser to alter a subnet.

**Examples**

This example renames a subnet.

```
=> ALTER SUBNET mysubnet RENAME TO myNewSubnet;
```

**ALTER TABLE**

Modifies the metadata of an existing table. The changes are auto-committed.

You cannot modify the metadata of an anchor table for a live aggregate projection or Top-K projection.
General Usage

ALTER TABLE [[database.]schema.]table {
  ... ADD COLUMN column data-type
      [ column-constraint ]
      [ ENCODING encoding-type ]
      [ RESTRICT | CASCADE ]
      [ PROJECTIONS (projection [, ...]) ]
  ... | ADD table-constraint
  ... | ALTER COLUMN column column-setting
  ... | ALTER CONSTRAINT constraint-name { ENABLED | DISABLED }
  ... | DROP CONSTRAINT constraint-name [ CASCADE | RESTRICT ]
  ... | DROP [ COLUMN ] column [ CASCADE | RESTRICT ]
  ... | FORCE OUTER integer
  ... | { INCLUDE | EXCLUDE | MATERIALIZE } [ SCHEMA ] PRIVILEGES
  ... | OWNER TO owner
  ... | partition-clause
  ... | REMOVE PARTITIONING
  ... | RENAME [ COLUMN ] name TO new-name
  ... | REORGANIZE
  ... | SET DATA TYPE datatype
  ... | SET SCHEMA schema
  ... | SET STORAGE load-option
}

Table Renaming

ALTER TABLE [[database.]schema.]table[,]... RENAME TO new-table-name[,]...

Parameters

<table>
<thead>
<tr>
<th>[ database .]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>

| table               | The table to alter.                                                                                                                                                                             |

<table>
<thead>
<tr>
<th>ADD COLUMN</th>
<th>Adds a column to the table and to its superprojections:</th>
</tr>
</thead>
</table>
|                     | ADD COLUMN column-name datatype
      [column-constraint]
      [ENCODING encoding-type]
      [RESTRICT | CASCADE]
      [PROJECTIONS (projection [, ...]) ]

You can qualify the new column definition with one of these options:

- column-constraint specifies a column constraint as follows:
<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD table-constraint</td>
<td>Adds a constraint to a table that does not have any associated projections. See About Constraints in the Administrator's Guide.</td>
</tr>
</tbody>
</table>
| ALTER COLUMN | Alters a setting for column:  
| column-setting | column-setting can be one of the following:  
| SET DEFAULT expression | sets column values to the specified expression.  
| DROP DEFAULT | drops the DEFAULT setting.  
| SET USING expression | specifies to set this column's values from the result set returned by expression. When you make this change, Vertica automatically calls the function REFRESH_COLUMNS, which populates the column from the result set |

**ENCODING** specifies the column's encoding type, by default set to AUTO.

**RESTRICT** (default) adds the new column to pre-join projections only if they are anchored to the updated table. **CASCADE** updates all pre-join projections where the table is specified, regardless of whether they are anchored to it.

**PROJECTIONS** specifies to add the new column to one or more projections, where projection is the projection base name and is not a superprojection. Vertica adds the column to all buddies of each projection.

Note: Altering an existing table column to specify a DEFAULT expression has no effect on existing values in that column. Vertica applies the DEFAULT expression only on new rows when they are added to the table, through load operations such as INSERT and COPY. To refresh the entire column with its DEFAULT expression, update the column as follows:

```
UPDATE table-name SET column-name=DEFAULT;
```
<table>
<thead>
<tr>
<th><strong>ALTER CONSTRAINT</strong></th>
<th>Applies to automatic enforcement of primary key, unique key, and check constraints:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER CONSTRAINT <strong>constraint-name</strong> {ENABLED</td>
<td>DISABLED}</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>DROP CONSTRAINT</strong></th>
<th>Drops the specified table constraint from the table:</th>
</tr>
</thead>
<tbody>
<tr>
<td>DROP CONSTRAINT <strong>constraint-name</strong> [CASCADE</td>
<td>RESTRICT]</td>
</tr>
</tbody>
</table>

You can qualify DROP CONSTRAINT with one of these options:

- **CASCADE**: Drops a constraint and all dependencies in other tables.
- **RESTRICT**: Does not drop a constraint if there are dependent objects. Same as the default behavior.

Dropping a table constraint has no effect on views that reference the table.

<table>
<thead>
<tr>
<th><strong>DROP [COLUMN]</strong></th>
<th>Drops the specified column from the table and that column's ROS containers:</th>
</tr>
</thead>
<tbody>
<tr>
<td>DROP [COLUMN] <strong>column</strong> [CASCADE</td>
<td>RESTRICT]</td>
</tr>
</tbody>
</table>
You can qualify `DROP COLUMN` with one of these options:

- **CASCADE** is required if the table column to drop has dependencies.
- **RESTRICT** drops the column only from the given table.

See [Dropping Table Columns](#) in the Administrator's Guide.

<table>
<thead>
<tr>
<th>FORCE OUTER integer</th>
<th>Specifies whether a table is joined to another as an inner or outer input. For details, see <a href="#">Controlling Join Inputs</a> in Analyzing Data.</th>
</tr>
</thead>
</table>
| `{ INCLUDE | EXCLUDE | MATERIALIZE } [SCHEMA] PRIVILEGES` | Specifies default inheritance of schema privileges for this table:  
  
  - **EXCLUDE [SCHEMA] PRIVILEGES** (default) disables inheritance of privileges from the schema.  
  
  - **INCLUDE [SCHEMA] PRIVILEGES** grants the table the same privileges granted to its schema.  
  
  - **MATERIALIZE**: Copies grants to the table and creates a GRANT object on the table. This disables the inherited privileges flag on the table, so you can:  
    - Grant more specific privileges at the table level  
    - Use schema-level privileges as a template  
    - Move the table to a different schema  
    - Change schema privileges without affecting the table  

  **Note:** If inherited privileges are disabled at the database level, schema privileges can still be materialized.

  For more information see [Grant Inherited Privileges](#) in the Administrator's Guide.

<table>
<thead>
<tr>
<th>OWNER TO owner</th>
<th>Changes the table owner. See <a href="#">Changing Table Ownership</a> in the Administrator's Guide.</th>
</tr>
</thead>
</table>
| partition-clause | Invalid for external tables, specifies how to repartition table data storage as follows:  

  ```sql  
  PARTITION BY partition-expression [ GROUP BY group-expression ] [ REORGANIZE ]  
  ```  

  For more information see [Controlling Partitioning](#) in the Administrator's Guide.
For details about partition and group expressions, see [Partition Clause](#).

If the partition clause includes REORGANIZE and the table previously specified no partitioning, the VerticaTuple Mover immediately implements the partition clause. If the table previously specified partitioning, Vertica compares the new and previous partition clauses:

- If the clauses are identical, Vertica ignores the REORGANIZE keyword.
- If the clauses are different, Vertica immediately implements the new partition clause: the Tuple Mover evaluates current partitioning and reorganizes ROS storage containers as needed to conform with the new partitioning policy.

<table>
<thead>
<tr>
<th>REMOVE PARTITIONING</th>
<th>Specifies to remove partitioning from a table definition. The Tuple Mover subsequently removes existing partitions from ROS containers.</th>
</tr>
</thead>
<tbody>
<tr>
<td>RENAME [COLUMN]</td>
<td>Renames the specified column within the table. See <a href="#">Renaming Columns</a> in the Administrator's Guide.</td>
</tr>
<tr>
<td>REORGANIZE</td>
<td>If used alone with ALTER TABLE, REORGANIZE invokes the Tuple Mover to reorganize ROS storage containers as needed to conform with the table’s current partitioning policy. ALTER TABLE...REORGANIZE and Vertica meta-function PARTITION_TABLE operate identically. REORGANIZE can also qualify a new partition clause.</td>
</tr>
<tr>
<td>SET DATA TYPE <em>datatype</em></td>
<td>Changes the column's data type to any type whose conversion does not require storage reorganization. See <a href="#">Changing a Column Data Type</a> in the Administrator's Guide.</td>
</tr>
<tr>
<td>SET SCHEMA</td>
<td>Moves the table from one schema to another. Vertica automatically moves all projections that are anchored to the source table to the destination schema. It also moves all IDENTITY and AUTO_INCREMENT columns to the destination schema. For details, see <a href="#">Moving Tables to Another Schema</a> in the Administrator's Guide.</td>
</tr>
<tr>
<td>SET STORAGE <em>Load-method</em></td>
<td>Specifies default load behavior for all DML operations on this table, such as INSERT and COPY, one of the following:</td>
</tr>
</tbody>
</table>
- **AUTO (default):** Initially loads data into WOS, suitable for smaller bulk loads.
- **DIRECT:** Loads data directly into ROS containers, suitable for large (>100 MB) bulk loads.
- **TRICKLE:** Loads data only into WOS, suitable for frequent incremental loads.

For details, see [Choosing a Load Method](#) in the Administrator's Guide.

<table>
<thead>
<tr>
<th>RENAME TO</th>
</tr>
</thead>
<tbody>
<tr>
<td>Renames one or more tables:</td>
</tr>
<tr>
<td>RENAME TO new-table-name[, ...]</td>
</tr>
</tbody>
</table>

The following requirements apply:

- The new table name conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.
- If you specify multiple tables to rename, the source and target lists must have the same number of names.
- Renaming a table requires USAGE and CREATE privileges on the schema that contains it.

**Privileges**

The following privileges are required:

- Table owner or superuser, and USAGE privileges on the table schema to make the following changes:
  - Add, drop, rename, or alter column.
  - Add or drop a constraint.
  - Partition or repartition the table.

Renaming a table requires USAGE and CREATE privilege on the table schema.

Moving a table to a new schema requires:
• USAGE privilege on the old schema

• CREATE privilege on new schema

Locked Tables

If the operation cannot obtain an O lock on the target table, Vertica tries to close any internal Tuple Mover sessions that are running on that table. If successful, the operation can proceed. Explicit Tuple Mover operations that are running in user sessions do not close. If an explicit Tuple Mover operation is running on the table, the operation proceeds only when the operation is complete.

See Also

• Managing Tables

• Altering Table Definitions

• Adding Table Columns

Table-Constraint

Adds a constraint to table metadata. You can specify table constraints with CREATE TABLE, or add a constraint to an existing table with ALTER TABLE. For details, see Adding Constraints in the Administrator's Guide.

Note: Adding a constraint to a table that is referenced in a view does not affect the view.

Syntax

[ CONSTRAINT constraint-name ]
{
  ... PRIMARY KEY (column[,...]) [ ENABLED | DISABLED ]
  ... FOREIGN KEY (column[,...]) REFERENCES table [ (column[,...]) ]
  ... UNIQUE (column[,...]) [ ENABLED | DISABLED ]
  ... CHECK (expression) [ ENABLED | DISABLED ]
}
## Parameters

<table>
<thead>
<tr>
<th><strong>CONSTRAINT</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>constraint-name</strong></td>
</tr>
<tr>
<td>Assigns a name to the constraint. Vertica recommends that you name all constraints.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>PRIMARY KEY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defines one or more NOT NULL columns as the primary key as follows:</td>
</tr>
<tr>
<td>PRIMARY KEY (<em>column[,...]</em>) [ ENABLED</td>
</tr>
<tr>
<td>You can qualify this constraint with the keyword ENABLED or DISABLED. See <strong>Enforcing Constraints</strong> below.</td>
</tr>
<tr>
<td>If you do not name a primary key constraint, Vertica assigns the name <strong>C_PRIMARY</strong>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>FOREIGN KEY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adds a referential integrity constraint defining one or more columns as foreign keys as follows:</td>
</tr>
<tr>
<td>FOREIGN KEY (<em>column[,...]</em>) REFERENCES <em>table</em> [(column[,...])]</td>
</tr>
<tr>
<td>If you omit <em>column</em> references, If you omit <em>column</em>, Vertica references the primary key in <em>table</em>.</td>
</tr>
<tr>
<td>If you do not name a foreign key constraint, Vertica assigns the name <strong>C_FOREIGN</strong>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>UNIQUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies that the data in a column or group of columns is unique with respect to all table rows, as follows:</td>
</tr>
<tr>
<td>UNIQUE (<em>column[,...]</em>) [ENABLED</td>
</tr>
<tr>
<td>You can qualify this constraint with the keyword ENABLED or DISABLED. See <strong>Enforcing Constraints</strong> below.</td>
</tr>
<tr>
<td>If you do not name a unique constraint, Vertica assigns the name <strong>C_UNIQUE</strong>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CHECK</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies a check condition as an expression that returns a Boolean value, as follows:</td>
</tr>
<tr>
<td>CHECK (<em>expression</em>) [ENABLED</td>
</tr>
<tr>
<td>You can qualify this constraint with the keyword ENABLED or DISABLED. See <strong>Enforcing Constraints</strong> below.</td>
</tr>
</tbody>
</table>
If you do not name a check constraint, Vertica assigns the name C_CHECK.

Privileges

Table owner or user WITH GRANT OPTION is grantor.

- REFERENCES privilege on table to create foreign key constraints that reference this table
- USAGE privilege on schema that contains the table

Enforcing Constraints

A table can specify whether Vertica automatically enforces a primary key, unique key or check constraint with the keyword ENABLED or DISABLED. If you omit ENABLED or DISABLED, Vertica determines whether to enable the constraint automatically by checking the appropriate configuration parameter:

- EnableNewPrimaryKeysByDefault
- EnableNewUniqueKeysByDefault
- EnableNewCheckConstraintsByDefault

For details, see Enforcing Primary Key, Unique Key, and Check Constraints Automatically.

Examples

The following example creates a table (t01) with a primary key constraint.

```
CREATE TABLE t01 (id int CONSTRAINT sampleconstraint PRIMARY KEY);
```

This example creates the same table without the constraint, and then adds the constraint with

```
ALTER TABLE t01 ADD CONSTRAINT
```

```
CREATE TABLE t01 (id int);
CREATE TABLE
```

```
ALTER TABLE t01 ADD CONSTRAINT sampleconstraint PRIMARY KEY(id);
WARNING 2623: Column "id" definition changed to NOT NULL
```
The following example creates a table (addapk) with two columns, adds a third column to the table, and then adds a primary key constraint on the third column.

```sql
=> CREATE TABLE addapk (col1 INT, col2 INT);
CREATE TABLE

=> ALTER TABLE addapk ADD COLUMN col3 INT;
ALTER TABLE

=> ALTER TABLE addapk ADD CONSTRAINT col3constraint PRIMARY KEY (col3) ENABLED;
WARNING 2623: Column "col3" definition changed to NOT NULL
ALTER TABLE
```

Using the sample table addapk, check that the primary key constraint is enabled (is_enabled is t).

```sql
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_name IN ('addapk');

<table>
<thead>
<tr>
<th>constraint_name</th>
<th>column_name</th>
<th>constraint_type</th>
<th>is_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>col3constraint</td>
<td>col3</td>
<td>p</td>
<td>t</td>
</tr>
</tbody>
</table>
(1 row)
```

This example disables the constraint using ALTER TABLE ALTER CONSTRAINT.

```sql
=> ALTER TABLE addapk ALTER CONSTRAINT col3constraint DISABLED;
```

Check that the primary key is now disabled (is_enabled is f).

```sql
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_name IN ('addapk');

<table>
<thead>
<tr>
<th>constraint_name</th>
<th>column_name</th>
<th>constraint_type</th>
<th>is_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>col3constraint</td>
<td>col3</td>
<td>p</td>
<td>f</td>
</tr>
</tbody>
</table>
(1 row)
```

For a general discussion of constraints, see About Constraints. For additional examples of creating and naming constraints, see Naming Constraints.

---

**ALTER USER**

Changes a database user account. Changes that you make to a user account affect only future user sessions.
Important: The following ALTER USER parameters are invalid for a user who is added to the Vertica database with the LDAPLink service:

- IDENTIFIED BY
- PROFILE
- SECURITY ALGORITHM

Syntax

ALTER USER name user-parameter setting[, ...]

user-parameter

ACCOUNT
DEFAULT ROLE*
GRACEPERIOD
IDENTIFIED BY
IDLESESSIONTIMEOUT
MAXCONNECTIONS
MEMORYCAP
PASSWORD EXPIRE
PROFILE
RENAME TO*
RESOURCE POOL
RUNTIMECAP
SEARCH_PATH
SECURITY_ALGORITHM
TEMPSPACECAP

* Cannot be used in combination with other parameters

Parameters

<table>
<thead>
<tr>
<th>name</th>
<th>Specifies the name of the new user. Names that contain special characters must be double-quoted. To enforce case-sensitivity, use double-quotes. For details on name requirements, see Creating a Database Name and Password.</th>
</tr>
</thead>
</table>
| ACCOUNT { LOCK | UNLOCK } | Locks or unlocks a user's access to the database:  
- UNLOCK (default)  
- LOCK prevents a new user from logging in. This can be useful |
when creating an account for a user who does not need immediate access.

Tip: To automate account locking, set a maximum number of failed login attempts with `CREATE PROFILE`.

| **DEFAULT ROLE**<br>`roles-expression` | Specifies what roles are the default roles for this user, with one of the following expressions:
| | - **NONE** (default): Removes all default roles.
| | - A comma-delimited list of roles.
| | - **ALL**: Sets as default all user roles.
| | - **ALL EXCEPT** `role[, ...]`: A comma-delimited list of roles to exclude as default roles.
| | Default roles are automatically activated when a user logs in. The roles specified by this parameter supersede any roles assigned earlier.
| | **Note:** `DEFAULT ROLE` cannot be specified in combination with other `ALTER USER` parameters.

| **GRACEPERIOD**<br>`limit` | Specifies how long a user query can block on any session socket, where `limit` is one of the following:
| | - **NONE** (default): Removes any grace period previously set on session queries.
| | - `'interval'`: Specifies as an `interval` the maximum grace period for current session queries, up to 20 days.
| | For details, see [Handling Session Socket Blocking](#).

| **IDENTIFIED BY**<br>`'[new-password]'`<br>[REPLACE `'current-password'`] | Sets a new password for the user, where `new-password` must conform to the password complexity policy set by the user's profile.
| | Superusers can change the password for any user, and are not required to specify the `REPLACE` clause. Non-superusers can only change their own password, and must supply their current password with the `REPLACE` clause.
If you supply an empty string, the user's current password is removed, and the user is no longer prompted for a password when starting a new session.

For details, see Password Guidelines and Creating a Database Name and Password.

**IDLESESSIONTIMEOUT**

The length of time the system waits before disconnecting an idle session, where `limit` is one of the following:

- NONE (default): No limit set for this user. If you omit this parameter, no limit is set for this user.
- `'interval'`: An interval value, up to one year.

For details, see Managing Client Connections.

**MAXCONNECTIONS**

Indicates the maximum number of connections the user can have to the server, where `limit` is one of the following:

- NONE (default): No limit set. If you omit this parameter, the user can have an unlimited number of connections.
- `'integer'` ON NODE: Sets the maximum number of connections to each node to `integer`.
- `'integer'` ON DATABASE: Sets the maximum number of connections across the database cluster to `integer`.

For details, see Managing Client Connections.

**MEMORYCAP**

Specifies how much memory can be allocated to user requests, where `limit` is specified in this format:

- NONE (default): No limit
- `'max-expression'`: A string value that specifies the memory limit, one of the following:
  - `int%` — Expresses the maximum as a percentage of total memory available to the Resource Manager, where `int` is an integer value between 0 and 100. For example:
    
    MEMORYCAP '40%'
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`int{K</td>
<td>M</td>
</tr>
<tr>
<td>PASSWORD EXPIRE</td>
<td>Forces immediate expiration of the user's password. The user must change the password on the next login.</td>
</tr>
<tr>
<td><code>password</code></td>
<td>Forc sức immediate expiration of the user's password. The user must change the password on the next login.</td>
</tr>
<tr>
<td>Note: PASSWORD EXPIRE has no effect when using external password authentication methods such as LDAP or Kerberos.</td>
<td></td>
</tr>
<tr>
<td>PROFILE <code>profile</code></td>
<td>Assigns a profile that controls password requirements for this user, where <code>profile</code> is one of the following:</td>
</tr>
<tr>
<td><code>DEFAULT</code> (default): Assigns the default database profile to this user.</td>
<td></td>
</tr>
<tr>
<td><code>profile-name</code>: A profile that is defined by CREATE PROFILE.</td>
<td></td>
</tr>
<tr>
<td>RENAME TO <code>new-user-name</code></td>
<td>Assigns the user a new user name. All privileges assigned to the user remain unchanged.</td>
</tr>
<tr>
<td>Note: RENAME TO cannot be specified in combination with other ALTER USER parameters.</td>
<td></td>
</tr>
<tr>
<td>RESOURCE POOL <code>pool-name</code></td>
<td>Assigns a default resource pool to this user. The user must also be granted privileges to this pool, unless privileges to the pool are set to PUBLIC.</td>
</tr>
<tr>
<td>RUNTIMECAP <code>limit</code></td>
<td>Specifies how long this user's queries can execute, where <code>limit</code> is one of the following:</td>
</tr>
<tr>
<td>NONE (default): No limit set for this user. If you omit this parameter, no limit is set for this user.</td>
<td></td>
</tr>
<tr>
<td>'interval' An interval value, up to one year.</td>
<td></td>
</tr>
<tr>
<td>A query's runtime limit can be set at three levels: the user's runtime limit, the user's resource pool, and the session setting. For more information, see Setting a Runtime Limit for Queries in the Administrator's Guide.</td>
<td></td>
</tr>
</tbody>
</table>
### SEARCH_PATH `path`

Specifies the user's default search path that tells Vertica which schemas to search for unqualified references to tables and UDFs, where `path` is one of the following:

- **DEFAULT** (default): Sets the search path as follows:
  
  ```
  "$user", public, v_catalog, v_monitor, v_internal
  ```

- A comma-delimited list of schemas.

For details, see [Setting Search Paths](#) in the Administrator's Guide.

### SECURITY_ALGORITHM `'algorithm'`

Set the user-level security algorithm for hash authentication, where `algorithm` is one of the following:

- **NONE** (default): Uses the MD5 algorithm for hash authentication.
- **MD5**
- **SHA512**

The user's password expires when you change the `SECURITY_ALGORITHM` value, and must be reset.

### TEMPSPACECAP `limit`

Limits how much temporary file storage is available for user requests, where `limit` is one of the following:

- **NONE** (default): No limit

- **`max-expression`**: A string value that specifies the storage limit, one of the following:
  
  - `int%` — Expresses storage as a percentage of total file space is available, where `int` is an integer value between 0 and 100. For example:
    
    ```
    TEMPSPACECAP '40%'
    ```

  - `int{K|M|G|T}` — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:
    
    ```
    TEMPSPACECAP '10G'
    ```
Privileges

- Superuser

- Non-superusers can change their own user accounts with these options:
  - IDENTIFIED BY
  - RESOURCE POOL
  - SEARCH_PATH
  - SECURITY_ALGORITHM

Examples

Change the user password

```
=> CREATE USER user1;
=> ALTER USER user1 IDENTIFIED BY 'newpassword';
```

Change the security algorithm and password

This example changes the user's hash authentication and password to SHA-512 and newpassword, respectively. When you execute the ALTER USER statement, Vertica hashes the password, using the SHA-512 algorithm, and saves the hashed version:

```
=> CREATE USER user1;
=> ALTER USER user1 SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword'
```

Assign user default roles

This example makes a user's assigned roles the user's default roles. The first ALTER USER statement makes role1 the default role. The second ALTER USER statement makes role1, role2, and role3 the user's default roles.

```
=> CREATE USER user1;
CREATE USER
=> GRANT role1, role2, role3 to user1;
=> ALTER USER user1 default role role1;
=> ALTER USER user1 default role ALL;
```

Assign user default roles with EXCEPT

This example makes all the user's assigned roles default roles with the exception of role1.

```
=> CREATE USER user1;
CREATE USER
=> GRANT role1, role2, role3 to user1;
=> ALTER USER user1 default role role1;
=> ALTER USER user1 default role ALL;
```
See Also

- **CREATE USER**
- **DROP USER**

**ALTER VIEW**

Modifies the metadata of an existing view. The changes are auto-committed.

**Syntax**

**General Usage**

```
ALTER VIEW [database.]schema.]view {
... | OWNER TO owner
... | SET SCHEMA schema
... | { INCLUDE | EXCLUDE | MATERIALIZE } [ SCHEMA ] PRIVILEGES
```

**View Renaming**

```
ALTER VIEW [database.]schema.]view[,...] RENAME TO new-view-name[,,...]
```

**Parameters**

<table>
<thead>
<tr>
<th><strong>[database.]schema</strong></th>
<th>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>myschema.thisDbObject</code></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>view</strong></th>
<th>The view to alter.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET SCHEMA schema</strong></td>
<td>Moves the view from one schema to another.</td>
</tr>
<tr>
<td>OWNER TO owner</td>
<td>Changes the view owner.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>{ INCLUDE</td>
<td>EXCLUDE</td>
</tr>
<tr>
<td>MATERIALIZE }</td>
<td>[SCHEMA] PRIVILEGES</td>
</tr>
</tbody>
</table>

Specifies default inheritance of schema privileges for this view:

- **EXCLUDE [SCHEMA] PRIVILEGES** (default) disables inheritance of privileges from the schema.

- **INCLUDE [SCHEMA] PRIVILEGES** grants the view the same privileges granted to its schema.

- **MATERIALIZE**: Copies grants to the view and creates a GRANT object on the view. This disables the inherited privileges flag on the view, so you can:
  - Grant more specific privileges at the view level
  - Use schema-level privileges as a template
  - Move the view to a different schema
  - Change schema privileges without affecting the view

**Note:** If inherited privileges are disabled at the database level, schema privileges can still be materialized.

For more information see [Grant Inherited Privileges](#).

<table>
<thead>
<tr>
<th>RENAME TO</th>
<th>Renames one or more views:</th>
</tr>
</thead>
<tbody>
<tr>
<td>RENAME TO new-view-name[,...]</td>
<td>The following requirements apply:</td>
</tr>
</tbody>
</table>

- The new view name conforms to conventions described in Identifiers. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

- If you specify multiple views to rename, the source and target lists must have the same number of names.

- Renaming a view requires USAGE and CREATE privileges on the schema that contains the view.
Privileges
Changing a view requires the following privileges:

- Superuser
- If renaming a view, CREATE privileges on the schema in which the view is renamed.

Example
The following command renames view1 to view2:

```sql
=> CREATE VIEW view1 AS SELECT * FROM t;
CREATE VIEW
=> ALTER VIEW view1 RENAME TO view2;
ALTER VIEW
```

BEGIN
Starts a transaction block. BEGIN is a synonym for START TRANSACTION.

Syntax
BEGIN [ WORK | TRANSACTION ] [ isolation-level ] [ transaction-mode]
and where transaction_mode is one of:
READ { ONLY | WRITE }

Parameters

<table>
<thead>
<tr>
<th>WORK</th>
<th>TRANSACTION</th>
<th>Optional keywords for readability purposes only.</th>
</tr>
</thead>
<tbody>
<tr>
<td>isolation-level</td>
<td>Specifies the transaction's isolation level, which determines what data the transaction can access when other transactions are running concurrently. You can set isolation-level to one of the following:</td>
<td></td>
</tr>
</tbody>
</table>

- **READ COMMITTED** (default)
- **SERIALIZABLE**
- **REPEATABLE READ** (automatically converted to SERIALIZABLE)
- **READ UNCOMMITTED** (automatically converted to READ COMMITTED)

For detailed information, see Transactions in Vertica Concepts.

<table>
<thead>
<tr>
<th>transaction-mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ { ONLY</td>
</tr>
<tr>
<td>Transaction mode can be one of the following:</td>
</tr>
<tr>
<td>- READ WRITE—(default) The transaction is read/write.</td>
</tr>
<tr>
<td>- READ ONLY—The transaction is read-only.</td>
</tr>
</tbody>
</table>

Setting the transaction session mode to read-only disallows the following SQL commands, but does not prevent all disk write operations:

- INSERT, UPDATE, DELETE, and COPY if the table they would write to is not a temporary table
- All CREATE, ALTER, and DROP commands
- GRANT, REVOKE, and EXPLAIN if the command it would run is among those listed.

**Privileges**

None

**Examples**

This example shows how to begin a transaction and set the isolation level.
=> BEGIN TRANSACTION ISOLATION LEVEL READ COMMITTED READ WRITE;
BEGIN
=> CREATE TABLE sample_table (a INT);
CREATE TABLE
=> INSERT INTO sample_table (a) VALUES (1);
OUTPUT
--------
1
(1 row)

COMMENT ON Statements

The following functions allow you to create comments associated with Vertica database objects:

- COMMENT ON COLUMN
- COMMENT ON CONSTRAINT
- COMMENT ON FUNCTION
- COMMENT ON LIBRARY
- COMMENT ON NODE
- COMMENT ON PROJECTION
- COMMENT ON SCHEMA
- COMMENT ON SEQUENCE
- COMMENT ON TABLE
- COMMENT ON TRANSFORM FUNCTION
- COMMENT ON VIEW

COMMENT ON COLUMN

Adds, revises, or removes a projection column comment. You can only add comments to projection columns, not to table columns. Each object can have one comment. Comments are stored in the system table COMMENTS.

Syntax

```
COMMENT ON COLUMN [[database.]schema.]projection.column IS {'comment' | NULL}
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code>&lt;br&gt; If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>projection.column</code></td>
<td>The name of the projection and column with which to associate the comment.</td>
</tr>
<tr>
<td><code>comment</code></td>
<td>Specifies the comment text to add. If a comment already exists for this column, this comment overwrites the previous comment. Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message. You can enclose a blank value within single quotes to remove an existing comment.</td>
</tr>
<tr>
<td><code>NULL</code></td>
<td>Removes an existing comment.</td>
</tr>
</tbody>
</table>

Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

Example

The following example adds a comment to the `customer_name` column in the `customer_dimension` projection:

```
=> COMMENT ON COLUMN customer_dimension_vmart_node01.customer_name IS 'Last name only';
```
The following examples remove a comment from the customer_name column in the customer_dimension projection in two ways, using the NULL option, or specifying a blank string:

```sql
=> COMMENT ON COLUMN customer_dimension_vmart_node01.customer_name IS NULL;
=> COMMENT ON COLUMN customer_dimension_vmart_node01.customer_name IS ';
```

### COMMENT ON CONSTRAINT

Adds, revises, or removes a comment on a constraint. Each object can have one comment. Comments are stored in the system table `COMMENTS`.

#### Syntax

```
COMMENT ON CONSTRAINT constraint ON [[database.]schema.]table IS ... {'comment' | NULL};
```

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>constraint</code></td>
<td>The name of the constraint associated with the comment.</td>
</tr>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example: <code>myschema&gt;thisDbObject</code></td>
</tr>
<tr>
<td><code>table</code></td>
<td>The name of the table constraint with which to associate a comment.</td>
</tr>
<tr>
<td><code>comment</code></td>
<td>Specifies the comment text to add. If a comment already exists for this constraint, this comment overwrites the previous one. Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message. You can enclose a blank value within single quotes to remove an existing comment.</td>
</tr>
<tr>
<td><code>NULL</code></td>
<td>Removes an existing comment.</td>
</tr>
</tbody>
</table>
Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

Example

The following example adds a comment to the constraint_x constraint on the promotion_dimension table:

```
=> COMMENT ON CONSTRAINT constraint_x ON promotion_dimension IS 'Primary key';
```

The following examples remove a comment from the constraint_x constraint on the promotion_dimension table:

```
=> COMMENT ON CONSTRAINT constraint_x ON promotion_dimension IS NULL;
=> COMMENT ON CONSTRAINT constraint_x ON promotion_dimension IS '';
```

COMMENT ON FUNCTION

Adds, revises, or removes a comment on a function. Each object can have one comment. Comments are stored in the system table COMMENTS.

Syntax

```
COMMENT ON FUNCTION [[database.]schema.]function (function-args) IS { 'comment' | NULL };
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject</td>
</tr>
</tbody>
</table>
If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th>function</th>
<th>The name of the function with which to associate the comment.</th>
</tr>
</thead>
<tbody>
<tr>
<td>function-args</td>
<td>The function arguments.</td>
</tr>
<tr>
<td>comment</td>
<td>Specifies the comment text to add. If a comment already exists for this function, this overwrites the previous one. Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message. Enclose a blank value within single quotes to remove an existing comment.</td>
</tr>
<tr>
<td>NULL</td>
<td>Removes an existing comment.</td>
</tr>
</tbody>
</table>

**Privileges**

- **Superuser**: View and add comments to all objects.
- **Object owner**: Add or edit comments for the object.
- **User**: VIEW privileges on an object to view its comments.

**Examples**

The following example adds a comment to the `macros.zerowhennull (x INT)` function:

```sql
=> COMMENT ON FUNCTION macros.zerowhennull(x INT) IS 'Returns a 0 if not NULL';
```

The following examples remove a comment from the `macros.zerowhennull (x INT)` function in two ways by using the NULL option, or specifying a blank string:

```sql
=> COMMENT ON FUNCTION macros.zerowhennull(x INT) IS NULL;
=> COMMENT ON FUNCTION macros.zerowhennull(x INT) IS '';
```

**COMMENT ON LIBRARY**

Adds, revises, or removes a comment on a library. Each object can have one comment. Comments are stored in the system table `COMMENTS`. 
Syntax

```
COMMENT ON LIBRARY [[database.]schema.]library IS {'comment' | NULL}
```

Parameters

| [database.]schema | Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:
|                   | myschema.thisDbObject |
| library           | The name of the library associated with the comment. |
| comment            | Specifies the comment text to add. If a comment already exists for this library, this comment overwrites the previous one. Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message. Enclose a blank value within single quotes to remove an existing comment. |
| NULL               | Removes an existing comment. |

Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

Examples

The following example adds a comment to the library MyFunctions:
The following examples remove a comment from the library MyFunctions:

```
=> COMMENT ON LIBRARY MyFunctions IS NULL;
=> COMMENT ON LIBRARY MyFunctions IS '';
```

See Also

- COMMENTS

**COMMENT ON NODE**

Adds, revises, or removes a comment on a node. Each object can have one comment. Comments are stored in the system table COMMENTS.

Dropping an object drops all comments associated with the object.

**Syntax**

```
COMMENT ON NODE node-name IS { 'comment' | NULL }
```

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>node-name</code></td>
<td>The name of the node associated with the comment.</td>
</tr>
<tr>
<td><code>comment</code></td>
<td>Specifies the comment text to add. If a comment already exists for this node, this comment overwrites the previous one. Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message. Enclose a blank value within single quotes to remove an existing comment.</td>
</tr>
<tr>
<td><code>NULL</code></td>
<td>Removes an existing comment.</td>
</tr>
</tbody>
</table>
Privileges

- **Superuser**: View and add comments to all objects.
- **Object owner**: Add or edit comments for the object.
- **User**: VIEW privileges on an object to view its comments.

Examples

The following example adds a comment for the `initiator` node:

```sql
=> COMMENT ON NODE initiator IS 'Initiator node';
```

The following examples removes a comment from the `initiator` node.

```sql
=> COMMENT ON NODE initiator IS NULL;
=> COMMENT ON NODE initiator IS '';
```

See Also

`COMMENTS`

**COMMENT ON PROJECTION**

Adds, revises, or removes a comment on a projection. Each object can have one comment. Comments are stored in the system table `COMMENTS`.

Dropping an object drops all comments associated with the object.

Syntax

```sql
COMMENT ON PROJECTION [[database.]schema.]projection IS { 'comment' | NULL }
```

Parameters

|   | Specifies a schema, by default public. If `schema` is any schema |
For example:

```
myschema.thisDbObject
```

If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th><strong>database.[schema</strong></th>
<th>other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>projection</strong></td>
<td>The name of the projection associated with the comment.</td>
</tr>
<tr>
<td><strong>comment</strong></td>
<td>Specifies the text of the comment to add. If a comment already exists for this projection, the comment you enter here overwrites the previous comment. Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message. Enclose a blank value within single quotes to remove an existing comment.</td>
</tr>
<tr>
<td><strong>NULL</strong></td>
<td>Removes an existing comment.</td>
</tr>
</tbody>
</table>

**Privileges**

- **Superuser:** View and add comments to all objects.
- **Object owner:** Add or edit comments for the object.
- **User:** VIEW privileges on an object to view its comments.

**Examples**

The following example adds a comment to the `customer_dimension_vmart_node01` projection:

```
=> COMMENT ON PROJECTION customer_dimension_vmart_node01 IS 'Test data';
```

The following examples remove a comment from the `customer_dimension_vmart_node01` projection:

```
=> COMMENT ON PROJECTION customer_dimension_vmart_node01 IS NULL;
=> COMMENT ON PROJECTION customer_dimension_vmart_node01 IS '';
```
See Also

COMMENTS

COMMENT ON SCHEMA

Adds, revises, or removes a comment on a schema. Each object can have one comment. Comments are stored in the system table COMMENTS.

Syntax

COMMENT ON SCHEMA schema-name IS ('comment' | NULL)

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema-name</td>
<td>The schema associated with the comment.</td>
</tr>
<tr>
<td>comment</td>
<td>Text of the comment to add. If a comment already exists for this schema, the comment you enter here overwrites the previous comment. Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message. You can enclose a blank value within single quotes to remove an existing comment.</td>
</tr>
<tr>
<td>NULL</td>
<td>Removes an existing comment.</td>
</tr>
</tbody>
</table>

Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.
Examples

The following example adds a comment to the public schema:

```sql
=> COMMENT ON SCHEMA public IS 'All users can access this schema';
```

The following examples remove a comment from the public schema.

```sql
=> COMMENT ON SCHEMA public IS NULL;
=> COMMENT ON SCHEMA public IS '';
```

**COMMENT ON SEQUENCE**

Adds, revises, or removes a comment on a sequence. Each object can have one comment. Comments are stored in the system table `COMMENTS`.

**Syntax**

```
COMMENT ON SEQUENCE [[database.]schema.]sequence IS { 'comment' | NULL }
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td><code>sequence</code></td>
<td>The name of the sequence associated with the comment.</td>
</tr>
</tbody>
</table>
| `comment` | Specifies the text of the comment to add. If a comment already exists for this sequence, this comment overwrites the previous one. Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message. You can enclose a blank value within single quotes to remove an
existing comment.
NULL    Removes an existing comment.

Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

Examples

The following example adds a comment to the sequence called prom_seq.

```=> COMMENT ON SEQUENCE prom_seq IS 'Promotion codes';```

The following examples remove a comment from the prom_seq sequence.

```=> COMMENT ON SEQUENCE prom_seq IS NULL;
=> COMMENT ON SEQUENCE prom_seq IS '';```

COMMENT ON TABLE

Adds, revises, or removes a comment on a table. Each object can have one comment. Comments are stored in the system table COMMENTS.

Syntax

```COMMENT ON TABLE [[database.]schema.]table IS { 'comment' | NULL }```

Parameters

```
[ database.]schema Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:
```
If you specify a database, it must be the current database.

**table**
The name of the table with which to associate the comment.

**comment**
Specifies the text of the comment to add. Enclose the text of the comment within single-quotes. If a comment already exists for this table, the comment you enter here overwrites the previous comment.

Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.

You can enclose a blank value within single quotes to remove an existing comment.

**NULL**
Removes a previously added comment.

**Privileges**

- **Superuser**: View and add comments to all objects.
- **Object owner**: Add or edit comments for the object.
- **User**: VIEW privileges on an object to view its comments

**Examples**

The following example adds a comment to the promotion_dimension table:

```sql
=> COMMENT ON TABLE promotion_dimension IS '2011 Promotions';
```

The following examples remove a comment from the promotion_dimension table:

```sql
=> COMMENT ON TABLE promotion_dimension IS NULL;
=> COMMENT ON TABLE promotion_dimension IS '';
```
COMMENT ON TRANSFORM FUNCTION

Adds, revises, or removes a comment on a user-defined transform function. Each object can have one comment. Comments are stored in the system table COMMENTS.

Syntax

```
COMMENT ON TRANSFORM FUNCTION [[database.]schema.]tfunction
...( [ tfunction-arg-name tfunction-arg-type ][,...] ) IS ('comment' | NULL)
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>tfunction</code></td>
<td>The name of the transform function with which to associate the comment.</td>
</tr>
<tr>
<td><code>tfunction-arg-name</code></td>
<td>The names and data types of one or more transform function arguments. If you supply argument names and types, each type must match the type specified in the library used to create the original transform function.</td>
</tr>
<tr>
<td><code>tfunction-arg-type</code></td>
<td></td>
</tr>
<tr>
<td><code>comment</code></td>
<td>Specifies the comment text to add. If a comment already exists for this transform function, this comment overwrites the previous one.</td>
</tr>
<tr>
<td></td>
<td>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</td>
</tr>
<tr>
<td></td>
<td>Enclose a blank value within single quotes to remove an existing comment.</td>
</tr>
<tr>
<td><code>NULL</code></td>
<td>Removes an existing comment.</td>
</tr>
</tbody>
</table>
Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

Examples

The following example adds a comment to the `macros.zerowhennull (x INT) UTF` function:

```sql
=> COMMENT ON TRANSFORM FUNCTION macros.zerowhennull(x INT) IS 'Returns a 0 if not NULL';
```

The following example removes a comment from the `acros.zerowhennull (x INT)` function by using the NULL option:

```sql
=> COMMENT ON TRANSFORM FUNCTION macros.zerowhennull(x INT) IS NULL;
```

COMMENT ON VIEW

Adds, revises, or removes a comment on a view. Each object can have one comment. Comments are stored in the system table `COMMENTS`.

Syntax

```
COMMENT ON VIEW [[database.]schema.]view IS { 'comment' | NULL }
```

Parameters

```
[ database.]schema

Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:

```
myschema.thisDbObject
```

If you specify a database, it must be the current database.
```
**view**  | The name of the view with which to associate the comment.
---|---
**comment**  | Specifies the text of the comment to add. If a comment already exists for this view, this comment overwrites the previous one.
  Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.
  Enclose a blank value in single quotes to remove an existing comment.
**NULL**  | Removes an existing comment.

### Privileges

- **Superuser**: View and add comments to all objects.
- **Object owner**: Add or edit comments for the object.
- **User**: VIEW privileges on an object to view its comments.

### Examples

The following example adds a comment to a view called `curr_month_ship`:

```sql
=> COMMENT ON VIEW curr_month_ship IS 'Shipping data for the current month';
```

The following example removes a comment from the `curr_month_ship` view:

```sql
=> COMMENT ON VIEW curr_month_ship IS NULL;
```

### COMMIT

Ends the current transaction and makes all changes that occurred during the transaction permanent and visible to other users.

COMMIT is a synonym for **END**
Syntax

`COMMIT [ WORK | TRANSACTION ]`

Parameters

| WORK   | TRANSACTION   | Optional keywords for readability only. |

Privileges

None

Examples

This example shows how to commit an insert.

```sql
=> CREATE TABLE sample_table (a INT);
=> INSERT INTO sample_table (a) VALUES (1);
OUTPUT
-------
1
=> COMMIT;
```

See Also

- Transactions
- Creating Transactions
- BEGIN
- ROLLBACK
- START TRANSACTION
CONNECT

Connects to another Vertica database to enable data import (using the COPY FROM VERTICA statement) or export (using the EXPORT statement). By default, invoking CONNECT occurs over the Vertica private network. Creating a connection over a public network requires some configuration. For information about using CONNECT to export data to or import data over a public network, see Using Public and Private IP Networks.

When importing from or exporting to a Vertica database, you can connect only to a database that uses trusted- (username-only) or password-based authentication, as described in Security and Authentication. SSL authentication is not supported.

Syntax

CONNECT TO VERTICA database USER username PASSWORD 'password' ON 'host',port

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>The connection target database name.</td>
</tr>
<tr>
<td>username</td>
<td>The username to use when connecting to the other database.</td>
</tr>
<tr>
<td>password</td>
<td>A string containing the password to use to connect to the other database.</td>
</tr>
<tr>
<td>host</td>
<td>A string containing the host name of one of the nodes in the other database.</td>
</tr>
<tr>
<td>port</td>
<td>The port number of the other database as an integer.</td>
</tr>
</tbody>
</table>

Privileges

None

Connection Details

After you establish a connection to another database, the connection remains open for the current session. To disconnect a connection, use the DISCONNECT statement.
You can have only one connection to another database at a time. However, you can create connections to multiple different databases in the same session.

If the target database does not have a password, and you specify a password in the CONNECT statement, the connection succeeds, but does not give any indication that you supplied an incorrect password.

**Example**

```sql
=> CONNECT TO VERTICA ExampleDB USER dbadmin PASSWORD 'Password123' ON 'VerticaHost01',5433;
CONNECT
```

**See Also**

- COPY FROM VERTICA
- EXPORT TO VERTICA

**COPY**

COPY bulk-loads data into a Vertica database. By default, COPY automatically commits itself and any current transaction except when loading temporary tables. If COPY is terminated or interrupted Vertica rolls it back.

COPY reads data as UTF-8 encoding.

For information on loading one or more files or pipes on a cluster host or on a client system, see COPY LOCAL.

**Syntax**

```sql
COPY [[schema-name.]]target-table
  ...
  [ ( { column-as-expression | column } ]
  ....... [ DELEMITER [ AS ] 'char' ]
  ....... [ ENCLOSED [ BY ] 'char' ]
  ....... [ ENFORCELENGTH ]
  ....... [ ESCAPE [ AS ] 'char' | NO ESCAPE ]
  ....... [ FILLER datatype]
  ....... [ FORMAT 'format' ]
  ....... [ NULL [ AS ] 'string' ]
  ....... [ TRIM 'byte' ]
  ...
) ]
```
... [ COLUMN OPTION ( column
...... [ DELIMITER [ AS ] 'char' ]
...... [ ENCLOSED [ BY ] 'char' ]
...... [ ENFORCELENGTH ]
...... [ ESCAPE [ AS ] 'char' | NO ESCAPE ]
...... [ FORMAT 'format' ]
...... [ NULL [ AS ] 'string' ]
...... [ TRIM 'byte' ]
... ([,...] ) ]
 [ FROM {
STDIN [ input-format ]
[ 'path-to-data' [ ON { nodename | (nodeset) | ANY NODE } ] [ input-format ] ] [,...]
[ LOCAL {STDIN | 'path-to-data'} [ input-format ] [,...]
 [ VERTICA source-database.[source-schema.]source-table[(source-column [,...])]
} ]
...[ [ WITH ] PARSER parser ( [ arg=value[,...] ] ) ]
...[ [ WITH ] UDL-clause[,...] ]
...[ DELIMITER [ AS ] 'char' ]
...[ TRAILING NULLCOLS ]
...[ NULL [ AS ] 'string' ]
...[ ESCAPE [ AS ] 'char' | NO ESCAPE ]
...[ ENCLOSED [ BY ] 'char' ]
...[ RECORD TERMINATOR 'string' ]
...[ SKIP records ]
...[ SKIP BYTES integer ]
...[ TRIM 'byte' ]
...[ REJECTMAX integer ]
...[ REJECTED DATA ( [path' [ ON nodename ] [,...] | AS TABLE reject-table] ]
...[ EXCEPTIONS 'path' [ ON nodename ] [,...] ]
...[ ENFORCELENGTH ]
...[ ERROR TOLERANCE ]
...[ ABORT ON ERROR ]
...[ [ STORAGE ] load-method ]
...[ STREAM NAME 'streamName']
...[ NO COMMIT ]

Parameters
See COPY Parameters

Privileges

General

Superusers have full COPY privileges. The following requirements apply to non-superusers:

- USER-accessible storage location

- Applicable READ or WRITE privileges granted to the storage location where files are read or written
COPY LOCAL

- INSERT privileges to copy data from the STDIN pipe
- USAGE privileges on the schema

COPY FROM STDIN

- INSERT privilege on table
- USAGE privilege on schema

File Paths for Rejected Data and Exceptions

COPY can specify a path to store rejected data and exceptions. If the path resolves to a storage location, the following privileges apply to non-superusers:

- The storage location was created with the USER option (see CREATE LOCATION).
- The user must have READ access to the storage location, as described in GRANT (Storage Location)

COPY Topics

COPY Option Parser Dependencies
COPY Restrictions
Setting vsql Variables
See Also

COPY Parameters

Note: For details on which COPY parameters are valid for specific parsers, see COPY Option Parser Dependencies.

| database | schema | Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject |
If you specify a database, it must be the current database. COPY ignores `schema-name` when used in `CREATE EXTERNAL TABLE` or `CREATE FLEX EXTERNAL TABLE` statements.

<table>
<thead>
<tr>
<th><strong>target-table</strong></th>
<th>The target columnar or flexible table for loading new data. Vertica loads the data into all projections that include columns from the schema table.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>column-as-expression</strong></td>
<td>Specifies the expression used to compute values for the target column. For example: <code>COPY t(year AS TO_CHAR(k, 'YYY')) FROM 'myfile.dat'</code> Use this option to transform data when it is loaded into the target database. For details about:</td>
</tr>
<tr>
<td><strong>column</strong></td>
<td>Restricts the load to one or more specified columns in the table. If you do not specify any columns, COPY loads all columns by default. Table columns that you do not specify in the column list are assigned their default values. If a column had no defined default value, COPY inserts NULL. If you leave the column parameter blank to load all columns in the table, you can use the optional parameter <code>COLUMN OPTION</code> to specify parsing options for specific columns. The data file must contain the same number of columns as the COPY command's column list. For example, in a table T1 with nine columns (C1 through C9), the following statement loads the three columns of data in each record to columns C1, C6, and C9, respectively: <code>COPY T1 (C1, C6, C9);</code></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### FILLER `datatype`

Specifies not to load the column and its fields into the destination table. Use this option to omit columns that you do not want to transfer into a table.

This parameter also transforms data from a source column and loads the transformed data to the destination table, rather than loading the original, untransformed source column (parsed column).

**Note:** If `datatype` is VARCHAR, set the VARCHAR length (VARCHAR(`n`)) so the combined length of all FILLER source fields does not exceed the target column's defined length. Otherwise, the COPY command can return with an error.

For more information, see Manipulating Source Data Columns in the Administrator's Guide.

### FORMAT `'format'`

Specifies the input formats to use when loading `date/time` and `binary` columns, where `format` can be one of the following:

These are the valid input formats when loading binary columns:

- octal
- hex
- bitstream

See Loading Binary (Native) Data to learn more about these formats.

When loading `date/time` columns, using FORMAT significantly improves load performance. COPY supports the same formats as the TO_DATE function.

See the following topics for additional information:

- Template Patterns for Date/Time Formatting
- Template Pattern Modifiers for Date/Time Formatting

If you specify invalid format strings, the COPY operation returns an error.
**path-to-data**

Specifies the absolute path of the file (or files) containing the data, which can be from multiple input sources. If the file is stored in HDFS, *path-to-data* is a URL in the hdfs scheme, typically hdfs:///path/to/file. See [Reading Directly from HDFS](#).

For Parquet, ORC, text, and delimited files only, *path-to-data* can be the URL of an S3 bucket in the format 's3://bucket/path'.

*path-to-data* can optionally contain wildcards to match more than one file. The file or files must be accessible to the local client or the host on which the COPY statement runs. COPY skips empty files in the file list. A file list that includes directories causes the query to fail. See [Specifying COPY FROM Options](#).

The supported patterns for wildcards are specified in the [Linux Manual Page for Glob (7)](#), and for ADO.net platforms, through the .NET [Directory.GetFiles Method](#).

You can use variables to construct the pathname as described in [Using Load Scripts](#).

If *path* resolves to a storage location on a local file system, and the user invoking COPY is not a superuser, the following privileges apply:

- The storage location must have been created with the USER option (see [CREATE LOCATION](#)).

- The user must already have been granted READ access to the file storage location, as described in [GRANT (Storage Location)](#).

Further, if a user has privileges but is not a superuser, and invokes COPY from that storage location, Vertica ensures that symbolic links do not result in unauthorized access.

**ON nodename**

Specifies the node on which the data to copy resides and the node that should parse the load file. If you omit *nodename*, the location of the input file defaults to the COPY initiator node. Use *nodename* to copy and parse a load file from a node other than the COPY initiator node.

**Note:** *nodename* is invalid with STDIN and LOCAL: STDIN
<table>
<thead>
<tr>
<th>Clause</th>
<th>Description</th>
</tr>
</thead>
</table>
| **ON** **(`nodeset`)** | Specifies a set of nodes on which to perform the load. The same data must be available for load on all named nodes. `nodeset` is a comma-separated list of node names in parentheses. For example:  
   
   ```sql
   => COPY t FROM 'file1.txt' ON (v_vmart_node0001, v_vmart_node0002);
   ```  
   Vertica apportions the load among all of the specified nodes. If you also specify `ERROR TOLERANCE` or `REJECTMAX`, Vertica instead chooses a single node on which to perform the load.  
   
   If the data is available on all nodes, you usually use `ON ANY NODE`. However, you can use `nodeset` to do manual load-balancing among concurrent loads. |
| **ON ANY NODE** | Specifies that the source file to load is available on all of the nodes, so `COPY` opens the file and parses it from any node(s) in the cluster.  
   
   **Caution:** The file must be the same on all nodes. If the file differs on two nodes, an incorrect or incomplete result is returned, with no error or warning.  
   
   Vertica attempts to apportion the load among several nodes if the file is large enough to benefit from apportioning. It chooses a single node if `ERROR TOLERANCE` or `REJECTMAX` is specified.  
   
   You can use a wildcard or glob (such as `*.dat`) to load multiple input files, combined with the `ON ANY NODE` clause. If you use a glob, `COPY` distributes the list of files to all cluster nodes and spreads the workload.  
   
   `ON ANY NODE` is invalid with `STDIN` and `LOCAL`: `STDIN` can only use the initiator node, and `LOCAL` indicates a client node.  
   
   `ON ANY NODE` is the default for HDFS and S3 paths and does not need to be specified. |
| **STDIN**     | Reads from the client a standard input instead of a file. `STDIN` is read on the initiator node only, and `LOCAL` indicates a client node. |
takes one input source only and is read on the initiator node. To load multiple input sources, use path-to-data.

User must have INSERT privileges on the table and USAGE privileges on its schema.

| LOCAL | \{STDIN | 'path-to-data'\} |
|-------|--------------------------|
|       | Specifies that all paths for the COPY statement are on the client system and that all COPY variants are initiated from a client. You can use LOCAL and path-to-data (see above), to specify a relative path. For details, see COPY LOCAL. |

<table>
<thead>
<tr>
<th>input-format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the input format, one of the following:</td>
</tr>
<tr>
<td>- UNCOMPRESSED (default)</td>
</tr>
<tr>
<td>- BZIP</td>
</tr>
<tr>
<td>- GZIP</td>
</tr>
<tr>
<td>- LZO</td>
</tr>
</tbody>
</table>

Input files can be of any format. If you use wildcards, all qualifying input files must be in the same format. To load different file formats, specify the format types specifically.

The following requirements and restrictions apply:

- When using concatenated BZIP or GZIP files, verify that all source files terminate with a record terminator before concatenating them.

- Concatenated BZIP and GZIP files are not supported for NATIVE (binary) and NATIVE VARCHAR formats.

- LZO files are assumed to be compressed with lzop. Vertica supports the following lzop arguments:
  --no-checksum / -F
  --crc32
  --adler32
  --no-name / -n
  --name / -N
  --no-mode
  --no-time

</tr>
</tbody>
</table>

By default, COPY uses the DELIMITER parser for UTF-8 format, delimited text input data.

To use a flex table parser for column tables, use the PARSER parameter followed by a flex table parser argument. For parser descriptions, see Flex Parsers Reference.

**Note:** You do not specify the DELIMITER parser directly; absence of a specific parser indicates the default.

For more information, see Specifying a COPY Parser in the Administrator's Guide.

The following restrictions apply:

- These parsers are not applicable when loading flexible tables.
- The ORC and PARQUET parsers are for use with Hadoop files in those formats. The files do not need to be stored in HDFS. For details, see Reading Hadoop Columnar File Formats.
- COPY LOCAL does not support NATIVE and NATIVE VARCHAR parsers.
<table>
<thead>
<tr>
<th><strong>[WITH]</strong> <strong>UDL-clause[...]</strong></th>
<th>Specifies one or more user-defined load functions—one source, one or more filters, and one parser, as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>SOURCE</strong> source( [arg=value[,..] ] )</td>
<td></td>
</tr>
<tr>
<td>• <strong>FILTER</strong> filter( [arg=value[,..] ] )</td>
<td></td>
</tr>
<tr>
<td>• <strong>PARSER</strong> parser( [arg=value[,..] ] )</td>
<td></td>
</tr>
</tbody>
</table>

To use a flex table parser for column tables, use the PARSER parameter followed by a flex table parser argument. For supported flex table parsers, see [Bulk Loading Data into Flex Tables](#).

<table>
<thead>
<tr>
<th><strong>COLUMN OPTION</strong></th>
<th>Specifies load metadata for one or more columns declared in the table column list. For example, you can specify that a column has its own DELIMITER, ENCLOSED BY, NULL as 'NULL' expression, and so on. You do not have to specify every column name explicitly in the COLUMN OPTION list, but each column you specify must correspond to a column in the table column list.</th>
</tr>
</thead>
</table>

| **COLSIZES** (**integer [,...]**)) | Specifies column widths when loading fixed-width data. COPY requires that you specify the COLSIZES when using the FIXEDWIDTH parser. COLSIZES and the list of integers must correspond to the columns listed in the table column list. For more information, see [Loading Fixed-Width Format Data](#) in the Administrator's Guide. |

| **DELMITER** | Indicates the single ASCII character used to separate columns within each record of a file. You can use any ASCII value in the range E'\000' to E'\177', inclusive. You cannot use the same character for both the DELIMITER and NULL parameters. For more information, see [Loading Delimited Data](#) in the Administrator's Guide. |

**Default:** Vertical bar (|).
| **TRAILING NULLCOLS** | Specifies that if Vertica encounters a record with insufficient data to match the columns in the table column list, COPY inserts the missing columns with NULLs. For other information and examples, see [Loading Fixed-Width Format Data](#) in the Administrator's Guide.  
This option is not available for ORC or Parquet data. |
| **ESCAPE [AS]** | Sets the escape character. Once set, the character following the escape character is interpreted literally, rather than as a special character. You can define an escape character using any ASCII value in the range `E'\001'` to `E'\177'`, inclusive (any ASCII character except NULL: `E'\000'`). Note that the backslash character (`\`) is the default escape character.  
The COPY statement does not interpret the data it reads in as [String Literals](#). It also does not follow the same escape rules as other SQL statements (including the COPY parameters). When reading in data, COPY interprets only the characters defined by these options as special values:  
- ESCAPE [AS]  
- DELIMITER  
- ENCLOSED [BY]  
- RECORD TERMINATOR |
| **NO ESCAPE** | Eliminates escape character handling. Use this option if you do not need any escape character and you want to prevent characters in your data from being interpreted as escape sequences. |
| **ENCLOSED [BY]** | Sets the quote character within which to enclose data, allowing delimiter characters to be embedded in string values. You can choose any ASCII value in the range `E'\001'` to `E'\177'` inclusive (any ASCII character except NULL: `E'\000'`). By default, ENCLOSED BY has no value, meaning data is not enclosed by any sort of quote character. |
| **NULL** | The string representing a null value. The default is an empty string (`''`). You can specify a null value as any ASCII value in the range `E'\001'` to `E'\177'` inclusive (any ASCII character
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RECORD TERMINATOR</td>
<td>Specifies the literal character string indicating the end of a data file record. For more information about using this parameter, see Loading Delimited Data. This option is not available for ORC or Parquet data.</td>
</tr>
<tr>
<td>SKIP records</td>
<td>Indicates the number (integer) of records to skip in a load file. For example, you can use the SKIP option to omit table header information. This option is not available for ORC or Parquet data.</td>
</tr>
<tr>
<td>SKIP BYTES total</td>
<td>Indicates the total number (integer) of bytes in a record to skip. This option is only available when loading fixed-width data. This option is not available for ORC or Parquet data.</td>
</tr>
<tr>
<td>TRIM</td>
<td>Trims the number of bytes you specify from a column. This option is only available when loading fixed-width data. You can set TRIM at the table level for a column, or as part of the COLUMN OPTION parameter. This option is not available for ORC or Parquet data.</td>
</tr>
<tr>
<td>REJECTMAX</td>
<td>Specifies a maximum number of logical records that can be rejected before a load fails. For details, see Capturing Load Rejections and Exceptions. REJECTMAX disables apportioned load.</td>
</tr>
<tr>
<td>REJECTED DATA</td>
<td>Specifies where to write each row that failed to load. If this parameter is specified, records that failed due to parsing errors are always written. Records that failed due to an error during a transformation are written only if the CopyFaultTolerantExpressions configuration parameter is set. (See General Parameters.) The syntax for this parameter is:</td>
</tr>
</tbody>
</table>

```sql
REJECTED_DATA
{ 'path' [ ON nodename ] [,..] | AS TABLE reject-table }
```

Vertica can write rejected data to the specified path or to a
### table:

- `'path' [ ON nodename ]`: Copies the rejected row data to the specified path on the node executing the load. If qualified by ON `nodename`, Vertica moves existing rejected data files on `nodename` to `path` on the same node.

The value of `path` can be a directory or a file prefix. If there are multiple load sources, `path` is always treated as a directory. If there are not multiple load sources but `path` ends with `/`, or if a directory of that name already exists, it is also treated as a directory. Otherwise, `path` is treated as a file prefix.

- `REJECTED DATA AS TABLE reject-table`: Saves rejected rows to columnar table `reject-table`.

When this parameter is used with COPY...ON ANY NODE, rejected data processed by each node is written to `path` on that node. To collect all rejected data in one place regardless of how the load is distributed, use a table.

For details about both options, see Capturing Load Rejections and Exceptions in the Administrator's Guide.

### EXCEPTIONS

Specifies the file name or absolute path of the file in which to write exceptions, as follows:

```
EXCEPTIONS 'path' [ ON nodename[, ...] ]
```

Files are written on the node or nodes executing the load.

Exceptions describe why each rejected row was rejected. Each exception describes the corresponding record in the file specified by the REJECTED DATA option.

If `path` resolves to a storage location, the following privileges apply to non-superusers:

- The storage location must be created with the USER option (see CREATE LOCATION).

- The user must have READ access to the storage location where the files exist, as described in GRANT (Storage Location).
The **ON nodename** clause moves existing exceptions files on `nodename` to the indicated **path** on the same node. For details, see Saving Load Exceptions (EXCEPTIONS) in the Administrator's Guide.

When this parameter is used with **COPY...ON ANY NODE**, exceptions processed by each node are written to **path** on that node.

Specifying an exceptions file name is incompatible with the **REJECTED DATA AS TABLE** clause. Exceptions are listed in the table's rejected_reason column.

| **ENFORCELENGTH** | Determines whether **COPY** truncates or rejects data rows of type char, varchar, binary, and varbinary if they do not fit the target table. Specifying the optional ENFORCELENGTH parameter rejects rows.  
You can set ENFORCELENGTH at the table level for a column, or as part of the COLUMN OPTION parameter.  
**Default**: **COPY** truncates offending rows of these data types, but does not reject them. For more details, see Tracking Load Exceptions and Rejections Status in the Administrator's Guide. |
|-------------------|---------------------------------------------------------------------------------------------------------------|
| **ERROR TOLERANCE** | Specifies that **COPY** treats each source during execution independently when loading data. The statement is not rolled back if a single source is invalid. The invalid source is skipped and the load continues.  
This option is not available for ORC or Parquet data.  
Using this parameter disables apportioned load. |
| **ABORT ON ERROR** | Specifies that **COPY** stops if any row is rejected. The statement is rolled back and no data is loaded. |

**[STORAGE]**

**Load-method**

Specifies how to load data into the database, one of the following:

- **AUTO** (default): Initially loads data into WOS, suitable for smaller bulk loads.

- **DIRECT**: Loads data directly into ROS containers, suitable for large (>100 MB) bulk loads.
TRICKLE: Loads data only into WOS, suitable for frequent incremental loads.

This option is invalid for external tables.

For details, see Choosing a Load Method in the Administrator's Guide.

| STREAM NAME | [Optional] Supplies a COPY load stream identifier. Using a stream name helps to quickly identify a particular load. The STREAM_NAME value that you supply in the load statement appears in the stream column of the LOAD_STREAMS system table.

A valid stream name can contain any combination of alphanumeric or special characters up to 128 bytes in length.

By default, Vertica names streams by table and file name. For example, if you are loading two files (f1, f2) into TableA, their default stream names are TableA-f1, TableA-f2, respectively.

To name a stream:
=> COPY mytable FROM myfile DELIMITER '|' DIRECT STREAM_NAME 'My stream name'; |

| NO COMMIT | Prevents the COPY statement from committing its transaction automatically when it finishes copying data.

The following requirements and restrictions apply:

- This option must be the last COPY statement parameter.

- CREATE EXTERNAL TABLE AS COPY ignores this option.

For more information, see Overriding COPY Auto Commit.

This option is not available for ORC or Parquet data.

COPY Option Parser Dependencies

The following table summarizes which COPY parameters are available when loading data using the default (DELIMITER), NATIVE (binary), NATIVE VARCHAR, and FIXEDWIDTH parsers:

</tbody>
</table>
**COPY Restrictions**

### Invalid Data

COPY considers the following data invalid:

- **Missing columns** (an input line has fewer columns than the recipient table).
- **Extra columns** (an input line has more columns than the recipient table).
- **Empty columns** for an INTEGER or DATE/TIME data type. If a column is empty for either of these types, COPY does not use the default value that was defined by `CREATE TABLE`. However, if you do not supply a column option as part of the COPY statement, the default value is used.
- **Incorrect representation** of a data type. For example, trying to load a non-numeric value into an INTEGER column is invalid.

### Constraint Violations

If any primary key, unique key, or check constraints are enabled for automatic enforcement, Vertica enforces those constraints when you insert values into a table. If a violation occurs, Vertica rolls back the SQL statement and returns an error. This behavior occurs for INSERT, UPDATE, COPY, and MERGE SQL statements.

**Note:** Automatic constraint enforcement requires that you have SELECT privileges on the table containing the constraint.
Empty Line Handling

When COPY encounters an empty line while loading data, the line is neither inserted nor rejected, but COPY increments the line record number. Consider this behavior when evaluating rejected records. If you return a list of rejected records and COPY encountered an empty row while loading data, the position of rejected records is incremented by one.

Compressed File Errors

When loading compressed files, COPY might abort and report an error, if the file seems to be corrupted. For example, this behavior can occur if reading the header block fails.

COPY Examples

The following examples show how to load data with the COPY statement using various string options.

The FORMAT, DELIMITER, NULL, and ENCLOSED BY options:

```sql
=> COPY public.customer_dimension (customer_since FORMAT 'YYYY')
   FROM STDIN
   DELIMITER ','
   NULL AS 'null'
   ENCLOSED BY '"';
```

The DELIMITER, NULL, and DIRECT options:

```sql
=> COPY a
   FROM STDIN
   DELIMITER '__,__'
   NULL E'\N'
   DIRECT;
```

The DELIMITER and NULL options:

```sql
=> COPY store.store_dimension
   FROM :input_file
   DELIMITER '|' 
   NULL ''
   RECORD TERMINATOR E'\f';
```
Setting vsql Variables

The first two examples load data from STDIN. The last example uses a vsql variable (`input_file`). You can set a vsql variable as follows:

```sql
=> \set input_file ../myCopyFromLocal/large_table.gzip
```

Including Multiple Source Files

COPY supports the inclusion of multiple source files in a single COPY statement.

The following example creates a table named 'sampletab.' It then copies multiple source files to the table using a single COPY statement.

```sql
=> CREATE TABLE sampletab (a int);
CREATE TABLE
=> COPY sampletab FROM '/home/dbadmin/one.dat', 'home/dbadmin/two.dat';
Rows Loaded
--------------
 2
(1 row)
```

You can use wildcards to indicate a group of files:

```sql
=> COPY myTable FROM 'hdfs:///mydirectory/ofmanyfiles/*.dat';
```

Wildcards can include regular expressions:

```sql
=> COPY myTable FROM 'hdfs:///mydirectory/*_[0-9]';
```

You can use multiple paths in a single COPY statement:

```sql
=> COPY myTable FROM 'hdfs:///data/sales/01/*.dat', 'hdfs:///data/sales/02/*.dat', 'hdfs:///data/sales/historical.dat';
```

Distributing a Load

The following example shows how you can load data that is shared across all nodes. Vertica distributes the load across all nodes, if possible.

```sql
=> COPY sampletab FROM '/data/file.dat' ON ANY NODE;
```
This example shows how to load data from two files. Because the first load file does not specify nodes (or ON ANY NODE), the initiator performs the load. Loading the second file is distributed across all nodes.

```
=> COPY samplertab FROM '/data/file1.dat', '/data/file2.dat' ON ANY NODE;
```

This example shows how to specify different nodes for each load file. Vertica distributes the load of file1.dat across v_vmart_node0001 and v_vmart_node0002 and distributes the load of file2.dat across v_vmart_node0003 and v_vmart_node0004.

```
=> COPY samplertab FROM '/data/file1.dat' ON (v_vmart_node0001, v_vmart_node0002),
    '/data/file2.dat' ON (v_vmart_node0003, v_vmart_node0004);
```

ON ANY NODE is the default for loads from HDFS. You do not need to specify it.

### Loading Data from Shared Storage

To load data from HDFS or S3, use URLs in the corresponding schemes—hdfs:///path or s3://bucket/path. Loads from HDFS and S3 default to ON ANY NODE; you do not need to specify it.

This example shows how you can load a file stored in HDFS using the default name node or name service. See [Reading Directly from HDFS](#) for more information about HDFS URLs.

```
=> COPY t FROM 'hdfs:///opt/data/file1.dat';
```

This example shows how you can load data from a particular HDFS name service (testNS). You specify a name service if your database is configured to read from more than one HDFS cluster.

```
=> COPY t FROM 'hdfs://testNS/opt/data/file2.csv';
```

This example shows how you can load data from an S3 bucket. See [Loading from an S3 Bucket](#) for more information.

```
=> COPY t FROM 's3://AWS_DataLake/*' ORC;
```

### Loading Hadoop Native Formats

This example shows how you can load data in the ORC format from HDFS.

```
=> COPY t FROM 'hdfs:///opt/data/sales.orc' ORC;
```

This example shows how you can load Parquet data from an S3 bucket.
Loading Data into a Flex Table

This statement creates a Flex table, and copies JSON data into the table, using the flex table parser, \texttt{fjsonparser}:

\begin{verbatim}
=> CREATE FLEX TABLE darkdata();
CREATE TABLE
=> COPY tweets FROM '/myTest/Flexible/DATA/tweets_12.json' parser fjsonparser(); Rows Loaded
------------------
  12
(1 row)
\end{verbatim}

Using Named Pipes

COPY supports named pipes that follow the same naming conventions as file names on the given file system. Permissions are open, write, and close.

This statement creates the named pipe, \texttt{pipe1}, and sets two vsql variables, \texttt{dir} and \texttt{file}:

\begin{verbatim}
=> \! mkfifo pipe1
=> \set dir `pwd`/
=> \set file `''dir''pipe1''`
\end{verbatim}

This statement copies an uncompressed file from the named pipe:

\begin{verbatim}
=> \! cat pf1.dat > pipe1 &
=> COPY large_tbl FROM :file delimiter '|';
=> SELECT * FROM large_tbl;
=> COMMIT;
\end{verbatim}

Loading Compressed Data

This statement copies a GZIP file from a named pipe and uncompresses it:

\begin{verbatim}
=> \! gzip pf1.dat
=> \! cat pf1.dat.gz > pipe1 &
=> COPY large_tbl FROM :file ON site01 GZIP delimiter '|';
=> SELECT * FROM large_tbl;
=> COMMIT;
=> \! gunzip pf1.dat.gz
\end{verbatim}

This statement copies a BZIP file from a named pipe and then uncompresses it:
This statement copies an LZO file from a named pipe and then uncompresses it:

```bash
=> \! bzip2 pf1.dat
=> \! cat pf1.dat.bz2 > pipe1 &
=> COPY large_tbl FROM :file ON site01 BZIP delimiter '|';
=> SELECT * FROM large_tbl;
=> COMMIT;
=> \! bunzip2 pf1.dat.bz2
```

```bash
=> \! lzop pf1.dat
=> \! cat pf1.dat.lzo > pipe1 &
=> COPY large_tbl FROM :file ON site01 LZO delimiter '|';
=> SELECT * FROM large_tbl;
=> COMMIT;
=> \! lzop -d pf1.dat.lzo
```

COPY LOCAL

Using the COPY statement with its LOCAL option lets you load a data file on a client system, rather than on a cluster host. COPY LOCAL supports the STDIN and 'pathToData' parameters, but not the [ON nodename] clause. COPY LOCAL does not support multiple file batches in NATIVE or NATIVE VARCHAR formats. COPY LOCAL does not support reading ORC or Parquet files; use ON NODE instead. COPY LOCAL does not support CURRENT_LOAD_SOURCE().

The COPY LOCAL option is platform-independent. The statement works in the same way across all supported Vertica platforms and drivers. For more details about using COPY LOCAL with supported drivers, see the Connecting to Vertica section for your platform.

Note: On Windows clients, the path you supply for the COPY LOCAL file is limited to 216 characters due to limitations in the Windows API.

COPY LOCAL does not automatically create exceptions and rejections files, even if exceptions occur. You cannot save exceptions and rejections to a table with the rejected data as table parameter. For information about saving such files, see Capturing Load Rejections and Exceptions in the Administrator's Guide.

Privileges

User must have INSERT privilege on the table and USAGE privilege on the schema.

How Copy Local Works

COPY LOCAL loads data in a platform-neutral way. The COPY LOCAL statement loads all files from a local client system to the Vertica host, where the server processes the files. You can copy files in various formats: uncompressed, compressed, fixed-width format, in bzip or gzip format, or specified as a bash glob. Files of a single format (such as all bzip, or gzip) can be comma-separated in the list of input files. You can also use any of the applicable COPY statement options (as long as the data format supports the option). For instance, you can define a specific delimiter character, or how to handle NULLs, and so forth.

Note: The Linux glob command returns files that match the pattern you enter, as specified in the Linux Manual Page for Glob (7). For ADO.net platforms, specify patterns and wildcards as described in the .NET Directory.GetFiles Method.
For more information about using the COPY LOCAL option to load data, see COPY for syntactical descriptions, and Using COPY and COPY LOCAL for detailed examples.

The Vertica host uncompresses and processes the files as necessary, regardless of file format or the client platform from which you load the files. Once the server has the copied files, Vertica maintains performance by distributing file parsing tasks, such as encoding, compressing, uncompressing, across nodes.

**Viewing Copy Local Operations in a Query Plan**

When you use the COPY LOCAL option, the GraphViz query plan includes a label for Load-Client-File, rather than Load-File. Following is a section from a sample query plan:

```
PLAN:  BASE BULKLOAD PLAN  (GraphViz Format)

digraph G {
  graph [rankdir=BT, label = " BASE BULKLOAD PLAN \nAll Nodes Vector: \n\n node[0]=initiator (initiator) Up\n", labelloc=t, labeljust=1 ordering=out]
  .
  .
  10[label = "Load-Client-File(/tmp/diff) \nOutBlk=[UncTuple]", color = "green", shape = "ellipse"];```

**Examples**

The following example shows a load from a local file.

```
$ cat > t.dat
12
17
9
^C

=> CREATE TABLE numbers (value INT);
CREATE TABLE

=> COPY numbers FROM LOCAL 't.dat';
Rows Loaded
----------
3
(1 row)

=> SELECT * FROM numbers;
value
-----
12
17```
**COPY FROM VERTICA**

Imports data from another Vertica database. COPY FROM VERTICA is similar to COPY, but accepts only a subset of its parameters.

**Important:** The source database can be one major release behind the target database.

**Syntax**

```
COPY [[database.]schema.]target-table
... [[ target-column[,...]]]
... FROM VERTICA database.[schema.]source-table
... [[source-column[,...]]]
... [load-method]
... [STREAM NAME 'stream name']
... [NO COMMIT]
```

**Parameters**

<table>
<thead>
<tr>
<th><strong>[database.]schema</strong></th>
<th>The table in the local database to store the copied data.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>target-column</strong></td>
<td>A target table column to store the copied data. If you specify target columns, COPY FROM VERTICA writes only to those columns. If you omit specifying target columns, Vertica writes to target table columns as described below, in Source and Target Column Mapping.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> You cannot use column fillers as part of the column definition.</td>
</tr>
<tr>
<td><strong>database</strong></td>
<td>The source database of the data to copy. A connection to this database must already exist in the current session.</td>
</tr>
<tr>
<td><strong>[schema.]source-table</strong></td>
<td>The table that is the source of the copied data.</td>
</tr>
<tr>
<td>source-column</td>
<td>A source table column to copy. If you specify source columns, only these columns are copied from the source table. If you omit specifying source columns, Vertica copies columns from the source table, as described below in Source and Target Column Mapping.</td>
</tr>
<tr>
<td>Load-method</td>
<td>Specifies how to load data into the database, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• AUTO (default): Initially loads data into WOS, suitable for smaller bulk loads.</td>
</tr>
<tr>
<td></td>
<td>• DIRECT: Loads data directly into ROS containers, suitable for large (&gt;100 MB) bulk loads.</td>
</tr>
<tr>
<td></td>
<td>• TRICKLE: Loads data only into WOS, suitable for frequent incremental loads.</td>
</tr>
<tr>
<td></td>
<td>This option is invalid for external tables.</td>
</tr>
<tr>
<td></td>
<td>For details, see Choosing a Load Method in the Administrator’s Guide.</td>
</tr>
<tr>
<td>STREAM NAME</td>
<td>Specifies a COPY load stream identifier. Using a stream name helps to quickly identify a particular load. The STREAM_NAME value that you specify in the load statement appears in the stream column of the LOADSTREAMS system table.</td>
</tr>
<tr>
<td>NO COMMIT</td>
<td>Prevents COPY from committing its transaction automatically when it finishes copying data. For details, see Overriding COPY Auto Commit in the Administrator's Guide.</td>
</tr>
</tbody>
</table>

### Privileges

- SELECT privileges on the source table
- USAGE privilege on source table schema
- INSERT privileges for the destination table in target database
- USAGE privilege on destination table schema
Connecting to the Source Database

Before you can import data from another database, you must establish a connection to the source database with `CONNECT`. See Copying Data from Another Vertica Database for details.

By default, `COPY FROM VERTICA` copies or imports data over the Vertica private network. Connecting to a public network requires some configuration. For information about using this statement to copy data across a public network, see Using Public and Private IP Networks.

The copy operation fails if either side of the connection is a single-node cluster installed to localhost, or you do not specify a host name or IP address.

Source and Target Column Mapping

You can optionally name a subset of source and target columns to participate in the copy operation. `COPY FROM VERTICA` attempts to match columns in the source table with corresponding columns in the destination table.

The following table compares the different combinations of naming source and target columns, and the requirements that pertain to each option.

<table>
<thead>
<tr>
<th></th>
<th>Omit source columns</th>
<th>Specify source columns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Omit target columns</strong></td>
<td>Match all columns in source table to columns in target table.</td>
<td>Match named source table columns to target table columns.</td>
</tr>
<tr>
<td></td>
<td>The number of columns in the two tables can differ, but the target table must have at least as many columns as the source table.</td>
<td>The number of columns in the two tables can differ, but the target table must have at least as many columns as the number of specified source columns.</td>
</tr>
<tr>
<td><strong>Specify target columns</strong></td>
<td>Match source columns to the named target columns.</td>
<td>Match named source columns to named target columns.</td>
</tr>
<tr>
<td></td>
<td>The number of named target columns must equal the number of columns in the source table.</td>
<td>The number of source and target columns must be equal.</td>
</tr>
</tbody>
</table>
Node Failure During COPY

See Handling Node Failure During Copy/Export in the Administrator's Guide.

Examples

This example demonstrates connecting to another database, copying the contents of an entire table from the source database to an identically-defined table in the current database directly into ROS, and then closing the connection:

```sql
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD 'myPassword' ON 'VertTest01',5433;
CONNECT
=> COPY customer_dimension FROM VERTICA vmart.customer_dimension DIRECT;
Rows Loaded
----------
500000
(1 row)
=> DISCONNECT vmart;
DISCONNECT
```

For more examples, see Copying Data from Another Vertica Database in the Administrator's Guide.

EXPORT TO VERTICA

CREATE ACCESS POLICY

Creates a secure access policy to prevent unauthorized users from accessing potentially sensitive information. You can create access policies for table rows and columns. Access policies are a technique of on-the-fly query modification in which the query excludes rows or modifies data from a column in the results returned to the user running the query. Access policies allow different users to run the same query and receive different results.

Column access policies limit access to specific column in a table. Creating a column access policy depends on the expressions specified when creating the policy. The expression is substituted for the column's actual value in any data fetched from the table.
Row access policies limit access to a specific row in a table. You must use a WHERE clause to set the access policy's condition. Only rows that satisfy the WHERE clause are fetched from the table.

For information on how implementing access policies affects how you manage data, see Working With Access Policies in the Administrator's Guide.

Syntax

```
CREATE ACCESS POLICY ON [database.]schema.]table... { FOR COLUMN column | FOR ROWS WHERE } expression
ENABLE
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| ![database.].schema | Specifies a schema, by default public. If `schema` is any schema other than public, you must supply the schema name. For example:  

```
myschema.thisDbObject
```

If you specify a database, it must be the current database. |
| table              | The table that contains the target column.                                  |
| column             | The column on which to apply an access policy.                              |
| expression         | An SQL expression that specifies conditions for column or row access:       |
|                    | - In a column access policy, the expression defines what value is returned when this column is fetched. The expression can contain conditions such as a role to determine what value to return. The expression might return null if no data is returned for this column. |
|                    | - In a row access policy, only rows for which the expression is true are returned. |

The expression in the example below shows the first 5 characters of the key in the `customer_key` column:  

```
=> CREATE ACCESS POLICY ON customer_dimension  
   FOR COLUMN customer_key substr(customer_key, 1, 5) ENABLE;
```

| ENABLE             | Enables the access policy. Always add this to end of the statement when creating an access policy. |
Privileges

One of the following:

- dbadmin
- Superuser

Examples

Create access policy per role on column

Add an expression to the policy to specify the access each role receives. A manager can access the complete customer number, while an operator can only see a portion of the number:

```sql
=> CREATE ACCESS POLICY on customer FOR column customer_number
    CASE
    WHEN enabled_role ('manager') then customer_number
    WHEN enabled_role ('operator') then substr (customer_number, 8,2)
    ELSE NULL
    END
    ENABLE;
```

Create access policy for rows

```sql
=> CREATE ACCESS POLICY ON customer FOR ROWS WHERE cid1>1 ENABLE;
```

See Also

In the Administrator’s Guide:

- Access Policies
- Column Access Policy
- Row Access Policy
CREATE AUTHENTICATION

Creates and enables an authentication method associated with users or roles. Vertica enables the authentication method automatically.

Syntax

```
CREATE AUTHENTICATION auth-method-name METHOD 'auth-type' acess-method
```

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth-method-name</td>
<td>Name of the authentication method to create, where <code>auth-method-name</code> conforms to conventions described in Identifiers.</td>
</tr>
<tr>
<td>auth-type</td>
<td>Name of the authentication method to use, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• gss</td>
</tr>
<tr>
<td></td>
<td>• ident</td>
</tr>
<tr>
<td></td>
<td>• ldap</td>
</tr>
<tr>
<td></td>
<td>• hash</td>
</tr>
<tr>
<td></td>
<td>• reject</td>
</tr>
<tr>
<td></td>
<td>• trust</td>
</tr>
<tr>
<td></td>
<td>• tls</td>
</tr>
<tr>
<td>acess-method</td>
<td>The access method the client uses to connect, specified in one of the following ways:</td>
</tr>
<tr>
<td></td>
<td>• LOCAL</td>
</tr>
<tr>
<td></td>
<td>Matches connection attempts made using local domain sockets.</td>
</tr>
<tr>
<td></td>
<td>• HOST [ TLS</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Matches connection attempts made using TCP/IP, where <code>host-ip-address</code> can be an IPv4 or IPv6 address. You can qualify HOST with one of the following options</td>
</tr>
<tr>
<td></td>
<td>- NO TLS: Match a plain (non-SSL/TLS) socket only.</td>
</tr>
</tbody>
</table>

**Privileges**

DBADMIN

**Examples**

See Creating Authentication Records.

**See Also**

- ALTER AUTHENTICATION
- DROP AUTHENTICATION
- GRANT (Authentication)
- REVOKE (Authentication)

**CREATE EXTERNAL TABLE AS COPY**

The CREATE EXTERNAL TABLE AS COPY statement creates a query definition for a table external to your Vertica database. This statement is a combination of the CREATE TABLE and COPY statements, supporting a subset of each statement's parameters, noted below. You can also use user-defined load extension functions (UDLs) to create external tables. For more information about UDL syntax, see User Defined Load (UDL).

You might discover that you need to change a column data type. For example, a VARCHAR might have longer data values than you anticipated at table-creation time. You can
use `ALTER TABLE` to change the data types of columns instead of dropping and recreating the table.

You can use `CREATE EXTERNAL TABLE AS COPY` with any types except types from the Place package.

**Note:** Vertica does not create superprojections for external tables, since external tables are not stored in the database.

### Syntax

```
CREATE EXTERNAL TABLE [ IF NOT EXISTS ] [[`database`.]`schema.`]`table-name`
... ( [ Column-Definition [ , ... ] )
[[INCLUDE | EXCLUDE] [SCHEMA] PRIVILEGES]
AS COPY
... [ { `column-as-expression` | `column` }
... [ { `DELIMITER` [ AS ] `char` ]
... [ { `ENCLOSED` [ BY ] `char` ]
... [ `ENFORCELENGTH` ]
... [ { `ESCAPE` [ AS ] `char` | NO ESCAPE ]
... [ { `FILLER` `datatype` ]
... [ { `FORMAT` `format` ]
... [ { `NULL` [ AS ] `string` ]
... [ { `TRIM` `byte` ]
... [ , ] ) }
... [ COLUMN OPTION ( `column` ]
... [ { `DELIMITER` [ AS ] `char` ]
... [ { `ENCLOSED` [ BY ] `char` ]
... [ `ENFORCELENGTH` ]
... [ { `ESCAPE` [ AS ] `char` | NO ESCAPE ]
... [ { `FORMAT` `format` ]
... [ { `NULL` [ AS ] `string` ]
... [ { `TRIM` `byte` ]
... [ , ] ) ]
{ FROM
... `pathToData` [ , ... ] [ ON `nodename` | ON ANY NODE | ON (nodeset) ]
... [ WITH ] SOURCE `source`([`arg=value` [, ... ] )
... [ `BZIP` | `GZIP` | `LZO` | UNCOMPRESSED ] [ , ... ]
... [ `NATIVE` ]
... [ `FIXEDWIDTH COLSIZES` `{ ( `integer` ) ,...,}` ]
... [ `NATIVE VARCHAR` ]
... [ ORC ]
... [ PARQUET ]
... ]
... [ `ABORT ON ERROR` ]
... [ `DELIMITER` [ AS ] `char` ]
... [ `ENCLOSED` BY `char` [ AND `char` ] ]
... [ `ENFORCELENGTH` ]
... [ `ERROR TOLERANCE` ]
... [ `ESCAPE` AS `char` | NO ESCAPE ]
... [ `EXCEPTIONS` `path` [ ON `nodename` ] [ , ... ] ]
... [ WITH ] [... [ FILTER `filter`([`arg=value` [, ... ] ) ] [ ... ]]
... [ NULL [ AS ] `string` ]
... [ WITH ] [ PARSER `parser`([`arg=value` [, ... ] ) ]
... [ RECORD TERMINATOR `string` ]
```
Parameters

For all supported parameters, see the CREATE TABLE and COPY statements. For information on using this statement with UDLs see Load (UDLs).

Privileges

You must be a database superuser to create external tables, unless you have created a user-accessible storage location to which the COPY refers, see CREATE LOCATION. If external tables exist, you must also be a database superuser to access them through a select statement.

You must have full access (including SELECT) to an external table that a user has privileges to create. The database superuser must also grant READ access to the USER-accessible storage location, see GRANT (Storage Location).

Examples

Examples of external table definitions:

```sql
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM '/tmp/ext1.dat' DELIMITER ',';
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM 'hdfs:///dat/ext1.dat';
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM '/tmp/ext1.dat.bz2' BZIP DELIMITER ',';
=> CREATE EXTERNAL TABLE ext2 (x integer, y integer) AS COPY (x as '5', y) FROM '/tmp/ext1.dat.bz2'
   BZIP DELIMITER ',';
=> CREATE EXTERNAL TABLE sales (itemID INT, date DATE, price FLOAT)
   AS COPY FROM 's3://datalake/sales/*.parquet' PARQUET;
```

To allow users without superuser access to use these tables, create a location for 'user' usage and grant access to it. This example shows granting access to a user named Bob to any external table whose data is located under /tmp (including in subdirectories to any depth):

```sql
=> CREATE LOCATION '/tmp' ALL NODES USAGE 'user';
=> GRANT ALL ON LOCATION '/tmp' to Bob;
```

The following example shows CREATE EXTERNAL TABLE using a source:
CREATE SOURCE curl AS LANGUAGE 'C++' NAME 'CurlSourceFactory' LIBRARY curllib;
CREATE EXTERNAL TABLE curl_table1 as COPY SOURCE CurlSourceFactory;

See Also
Creating External Tables in the Administrator's Guide

CREATE FAULT GROUP

Creates a fault group, which can contain the following:

- One or more nodes
- One or more child fault groups
- One or more nodes and one or more child fault groups

The CREATE FAULT GROUP statement creates an empty fault group. You must run the ALTER FAULT GROUP statement to add nodes or other fault groups to an existing fault group.

Syntax

CREATE FAULT GROUP name

Parameters

| name | The name of the fault group to create, unique among all fault groups, where name conforms to conventions described in Identifiers. |

Privileges

Superuser
Example

The following command creates a fault group called parent0:

```sql
=> CREATE FAULT GROUP parent0;
CREATE FAULT GROUP
```

To add nodes or other fault groups to the parent0 fault group, run the `ALTER FAULT GROUP` statement.

See Also

- `V_CATALOG.FAULT_GROUPS`
- `V_CATALOG.CLUSTER_LAYOUT`
- `Fault Groups`
- `High Availability With Fault Groups`

CREATE FLEX TABLE

Creates a flex table in the logical schema. Declaring columns (or other supported parameters) is optional. If you do not declare any column definitions, the statement creates two columns automatically:

- `__raw__` : A LONG VARBINARY type column to store any unstructured data you load. This column has a NOT NULL constraint by default.
- `__identity__` : An IDENTITY column. Flex tables use this value for segmentation and sorting, when no other column definition exists.

Additionally, creating any flex table results in three associated objects:

- A flex table (`flex_table`) named in this statement
- A related keys table, called `flex_table_keys`
- A related view, called `flex_table_view`
Both the flex table and its associated _keys table are required to use flex tables successfully. The _keys table and _view are subservient objects of the flex table. Neither can exist without the flex table.

For more details about creating and using flex tables, see Creating Flex Tables and other sections in Using Flex Tables.

CREATE FLEX TABLE supports many of the parameters available when creating columnar tables, but not all. This section presents the optional use of column definitions, and the subset of supported parameters.

You can also create flex external tables, with some syntactical variations, as described in CREATE FLEX EXTERNAL TABLE AS COPY.

You cannot partition a flex table on any virtual column (key).

**Note:** Vertica does not support flexible global temporary tables.

### Syntax

```
CREATE {FLEX | FLEXIBLE} TABLE [ IF NOT EXISTS ] [[database.]schema.]table-name {
... ( [ column-definition [ , ... ] ] )
... | [ table-constraint ( column_name, ... )]
... | [ column-name-list (create table) ]
}
...
[ INCLUDE | EXCLUDE] [SCHEMA] PRIVILEGES ]
...
[ ORDER BY table-column [ , ... ] ]
...
[ ENCODED BY column-definition [ , ... ] ]
...
[ hash-segmentation-clause ]
..... | UNSEGMENTED [ NODE node | ALL NODES ]
...
[ KSAFE [k_num] ]
...
[ PARTITION BY partition-expression]
...
[ AS SELECT (column-name-list) FROM (table-name) ]
```

### Parameters

See the CREATE TABLE statement for all parameter descriptions.

### Unsupported CREATE Flex Table Option

You cannot use the following options when creating a flex table:

```
... AS [COPY] [ [ AT EPOCH LATEST ] ... | [ AT TIME 'timestamp' ] ]
.....[/*+ direct */] query
... | [ LIKE [schema.]existing-table [ INCLUDING PROJECTIONS | EXCLUDING PROJECTIONS ] ]
```
Default Flex Table and Keys Table Projections

Vertica automatically creates superprojections for both the flex table and keys tables when you create them.

If you create a flex table with one or more of the ORDER BY, ENCODED BY, SEGMENTED BY, or KS/SAFE clauses, the clause information is used to create projections. If no clauses are in use, Vertica uses the following defaults for unspecified aspects:

<table>
<thead>
<tr>
<th>Table</th>
<th>order_by</th>
<th>encoded_by</th>
<th>Segmentation</th>
<th>Ksafe</th>
</tr>
</thead>
<tbody>
<tr>
<td>flexible table</td>
<td><strong>identity</strong></td>
<td>none</td>
<td>by hash <strong>identity</strong></td>
<td>1</td>
</tr>
<tr>
<td>keys_table</td>
<td>frequency</td>
<td>none</td>
<td>replicated/unsegmented all nodes</td>
<td>1</td>
</tr>
</tbody>
</table>

Note: When you build a view for a flex table (see `BUILD_FLEXTABLE_VIEW`), the view is ordered by frequency, desc, and key_name.

Privileges

CREATE privileges on the table schema.

Examples

The following example creates a flex table named darkdata without specifying any column information. Vertica creates a default superprojection and buddy projection as part of creating the table:

```sql
=> CREATE FLEXIBLE TABLE darkdata();
CREATE TABLE
```

The following example creates a table called darkdata1 with one column definition (date_col). The statement specifies the partition by clause to partition the data by year. Vertica creates a default superprojection and buddy projections as part of creating the table:

```sql
=> CREATE FLEX TABLE darkdata1 (date_col date NOT NULL) partition by extract('year' from date_col);
CREATE TABLE
```
CREATE FLEX EXTERNAL TABLE AS COPY

The CREATE FLEX EXTERNAL TABLE AS COPY statement creates a flexible external table. This statement is a combination of the CREATE FLEX TABLE and COPY statements, supporting a subset of each statement's parameters, as noted below. You can also use user-defined load extension functions (UDLs) to create external flex tables. For more information about UDL syntax, see User Defined Load (UDL) and COPY. For more details about creating and using flex tables, see Using Flex Tables.

Note: Vertica does not create a superprojection for an external table when you create it.

For details about creating and using flex tables, see Creating Flex Tables in Using Flex Tables.

Syntax

CREATE {FLEX | FLEXIBLE} EXTERNAL TABLE [ IF NOT EXISTS ] [[database.]schema.]table-name 
... ( [ Column-Definition [ , ... ] ] )
) [ INCLUDE | EXCLUDE [SCHEMA] PRIVILEGES]
... AS COPY ... [ ( { column-as-expression | column } ......[ FILLER datatype ] ]
FROM ...
'pathToData' [ ON nodename | ON ANY NODE | ON (nodeset) ]
...... [ BZIP | GZIP | LZO | UNCOMPRESSED ] [, ...]
...[ WITH ]
...[ SOURCE source(arg='value')]
...[ FILTER filter(arg='value') ]
...[ PARSER flexparser(arg='value') ]
...[ DELIMITER [ AS ] 'char' ]
...[ TRAILING NULLCOLS ]
...[ NULL [ AS ] 'string' ]
...[ ESCAPE [ AS ] 'char' | NO ESCAPE ]
...[ ENCLOSED [ BY ] 'char' ]
...[ RECORD TERMINATOR 'string' ]
...[ SKIP integer ]
...[ SKIP BYTES integer ]
...[ TRIM 'byte' ]
...[ REJECTMAX integer ]
...[ EXCEPTIONS 'path' [ ON nodename ] [, ... ]]
...[ REJECTED DATA 'path' [ ON nodename ] [, ... ]]
Parameters

The following parameters from the parent statements are not supported in the CREATE FLEXIBLE EXTERNAL TABLE AS COPY statement:

<table>
<thead>
<tr>
<th>CREATE TABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>AS AT EPOCH LAST</td>
</tr>
<tr>
<td>AT TIME 'timestamp'</td>
</tr>
<tr>
<td>ORDER BY table-column [,... ]</td>
</tr>
<tr>
<td>ENCODED BY hash-segmentation-clause</td>
</tr>
<tr>
<td>UNSEGMENTED (node</td>
</tr>
<tr>
<td>KSAFE [k_num]</td>
</tr>
<tr>
<td>PARTITION BY partition-clause</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>COPY</th>
</tr>
</thead>
<tbody>
<tr>
<td>FROM STDIN</td>
</tr>
<tr>
<td>FROM LOCAL</td>
</tr>
<tr>
<td>DIRECT</td>
</tr>
<tr>
<td>TRICKLE</td>
</tr>
<tr>
<td>NO COMMIT</td>
</tr>
</tbody>
</table>

For all supported parameters, see the CREATE TABLE and COPY statements.

Privileges

Must be a database superuser to create external tables, unless the superuser has created a user-accessible storage location to which the COPY refers, as described in CREATE LOCATION. If external tables exist, you must also be a database superuser to access them through a select statement.

Permission requirements for flex external tables differ from other flex tables. You must have full access (including SELECT) to an external table that a user has privileges to create. The
database superuser must also grant READ access to the USER-accessible storage location, see **GRANT (Storage Location)**.

**Notes**

Canceling a CREATE FLEX EXTERNAL TABLE AS COPY statement can cause unpredictable results. Vertica recommends that you allow the statement to finish, then use **DROP TABLE** once the table exists.

**Examples**

To create an external flex table:

```sql
=> CREATE flex external table mountains() AS COPY FROM 'home/release/KData/kmm_-mountains.json' PARSER fjsonparser();
CREATE TABLE
```

As with other flex tables, creating an external flex table produces two regular tables: the named table and its associated _keys table. The keys table is not an external table:

```sql
=> \dt mountains
List of tables
  Schema | Name    | Kind | Owner | Comment
---------|---------|------|-------|---------
  public | mountains| table | release|         
(1 row)
```

You can use the helper function, **COMPUTE_FLEXTABLE KEYS_AND_BUILD VIEW**, to compute keys and create a view for the external table:

```sql
=> SELECT compute_flextable_keys_and_build_view ('appLog');

<table>
<thead>
<tr>
<th>compute_flextable_keys_and_build_view</th>
</tr>
</thead>
<tbody>
<tr>
<td>Please see public.appLog_keys for updated keys</td>
</tr>
<tr>
<td>The view public.appLog_view is ready for querying</td>
</tr>
</tbody>
</table>
(1 row)
```

1. Check the keys from the _keys table for the results of running the helper application:

```sql
=> SELECT * FROM appLog_keys;

<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>contributors</td>
<td>8</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>coordinates</td>
<td>8</td>
<td>varchar(20)</td>
</tr>
</tbody>
</table>
```
2. Query from the external flex table view:

```sql
=> SELECT "user.lang" FROM appLog_view;
user.lang  
----------
it  
en  
es  
en  
es  
tr  
en  
(12 rows)
```

- CREATE FLEX TABLE
- SELECT

CREATE FUNCTION Statements

CREATE FUNCTION statements can create two different kinds of functions:

- User defined SQL functions let you define and store commonly-used SQL expressions as a function. User defined SQL functions are useful for executing complex queries and
combining Vertica built-in functions. You simply call the function name you assigned in your query.

- User defined scalar functions (UDSFs) take in a single row of data and return a single value. These functions can be used anywhere a native Vertica function or statement can be used, except CREATE TABLE with its PARTITION BY or any segmentation clause.

While you use CREATE FUNCTION to create both SQL and scalar functions, you use a different syntax for each function type. For more information, see:

- CREATE FUNCTION (SQL Functions)
- CREATE FUNCTION (UDF)

About Creating User Defined Transform Functions (UDTFs)

You can use a similar SQL statement to create user-defined transform functions. User defined transform functions (UDTFs) operate on table segments and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, including having its own ordering and segmentation expressions. They can only be used in a query’s SELECT list. For details about creating a UDTF, see CREATE TRANSFORM FUNCTION.

CREATE AGGREGATE FUNCTION

Adds a user-defined aggregate function (UDAF) stored in a shared Linux library to the catalog. You must have already loaded this library using the CREATE LIBRARY statement. When you call the SQL function, Vertica passes data values to the code in the library to process it.

Syntax

```
CREATE [ OR REPLACE ] AGGREGATE FUNCTION [[database.]schema.]function
  ... AS [LANGUAGE 'language'] NAME 'factory' LIBRARY library;
```

Parameters

| OR REPLACE | If you do not supply this parameter, CREATE AGGREGATE |
FUNCTION fails if an existing function matches the name and parameters of the function you are trying to define. If you do supply this parameter, the new function definition overwrites the old.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>function</td>
<td>Identifies the function to create, where function conforms to conventions described in Identifiers. Tip: This name does not need to match the name of the factory, but it is less confusing if they are the same or similar.</td>
</tr>
<tr>
<td>LANGUAGE 'Language'</td>
<td>The language used to develop this function, currently C++ only. Default value: C++</td>
</tr>
<tr>
<td>NAME 'factory'</td>
<td>The name of the factory class in the shared library that generates the object to handle the function's processing.</td>
</tr>
<tr>
<td>LIBRARY Library</td>
<td>The name of the shared library that contains the C++ object to perform the processing for this function. This library must have been previously loaded using the CREATE LIBRARY statement.</td>
</tr>
</tbody>
</table>

Notes

- The parameters and return value for the function are automatically determined by the CREATE AGGREGATE FUNCTION statement, based on data supplied by the factory class.

- When a User Defined Aggregate function that is defined multiple times with arguments of different data types is called, Vertica selects the function whose input parameters match the parameters in the function call to perform the processing.

- You can return a list of all SQL functions and User Defined Functions (including aggregates) by querying the system table V_CATALOG.USER_FUNCTIONS or executing the vsql meta-command df. Users see only the functions on which they have EXECUTE privileges.
Privileges

- Only a superuser can create or drop a User Defined Aggregate library.

- To create a User Defined Aggregate function, the user must have CREATE and USAGE privileges on the schema and USAGE privileges on the library.

- To use a User Defined Aggregate, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function. See GRANT (User Defined Extension) and REVOKE (User Defined Extension).

Examples

The following example demonstrates loading a library named AggregateFunctions then defining a function named ag_avg and ag_cat that are mapped to the ag_cat AverageFactory and ConcatenateFactory classes in the library:

```sql
=> CREATE LIBRARY AggregateFunctions AS '/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE AGGREGATE FUNCTION ag_avg AS LANGUAGE 'C++' NAME 'AverageFactory'
   library AggregateFunctions;
CREATE AGGREGATE FUNCTION
=> CREATE AGGREGATE FUNCTION ag_cat AS LANGUAGE 'C++' NAME 'ConcatenateFactory'
   library AggregateFunctions;
CREATE AGGREGATE FUNCTION
=> \x
Expanded display is on.
select * from user_functions;
-[
RECORD 1 ]-----------------------------------------------
schema_name | public
function_name | ag_avg
procedure_type | User Defined Aggregate
function_return_type | Numeric
function_argument_type | Numeric
function_definition | Class 'AverageFactory' in Library 'public.AggregateFunctions'
v volatility | |
isStrict | f
isFenced | f
comment | |
-[
RECORD 2 ]-----------------------------------------------
schema_name | public
function_name | ag_cat
procedure_type | User Defined Aggregate
function_return_type | Varchar
function_argument_type | Varchar
function_definition | Class 'ConcatenateFactory' in Library 'public.AggregateFunctions'
v volatility | |
isStrict | f
isFenced | f
```
CREATE ANALYTIC FUNCTION

Associates a User Defined Analytic Function (UDAnF) stored in a shared Linux library with a SQL function name. You must have already loaded the library containing the UDAnF using the CREATE LIBRARY statement. When you call the SQL function, Vertica passes the arguments to the analytic function in the library to process.

Syntax

```
CREATE [ OR REPLACE ] ANALYTIC FUNCTION function-name
... AS [ LANGUAGE 'language' ] NAME 'factory'
... LIBRARY library_name
... [ FENCED | NOT FENCED ];
```

Parameters

<table>
<thead>
<tr>
<th>function-name</th>
<th>The name to assign to the UDAnF. This is the name you use in your SQL statements to call the function.</th>
</tr>
</thead>
<tbody>
<tr>
<td>LANGUAGE 'language'</td>
<td>The language used to develop this function, one of the following:</td>
</tr>
</tbody>
</table>
### NAME 'factory'

The name of the C++ factory class in the shared library that generates the object to handle the function's processing.

### LIBRARY library-name

The name of the shared library that contains the C++ object to perform the processing for this function. This library must have been previously loaded using the CREATE LIBRARY statement.

### FENCED | NOT FENCED

Enables or disables Fenced Mode for this function.

**Default Value:** FENCED

### Privileges

- To create a function, the user must have CREATE privilege on the schema to contain the function and USAGE privilege on the library containing the function.

- To use a function, the user must have USAGE privilege on the schema that contains the function and EXECUTE privileges on the function.

- To drop a function, the user must either be a superuser, the owner of the function, or the owner of the schema which contains the function.

### Usage Considerations

- The parameters and return value for the function are automatically determined by the CREATE ANALYTIC FUNCTION statement, based on data supplied by the factory class.

- You can assign multiple functions the same name if they accept different sets of arguments. See Overloading Your UDX in Extending Vertica for more information.

- You can return a list of all UDFs by querying the system table V_CATALOG.USER_FUNCTIONS. Users see only the functions on which they have EXECUTE privileges.
Examples

This example shows how to create an analytic function named `an_rank` based on the factory class named `RankFactory` in the `AnalyticFunctions` library..

```sql
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
    NAME 'RankFactory' LIBRARY AnalyticFunctions;
```

See Also

Analytic Functions (UDAnFs)

CREATE FILTER

Adds a user-defined load filter function. You must have already loaded this library using the `CREATE LIBRARY` statement. When you call the SQL function, Vertica passes the parameters to the function in the library to process it.

Syntax

```sql
CREATE [ OR REPLACE ] FILTER [[database.]schema.]function
... AS [LANGUAGE 'language'] NAME 'factory' LIBRARY library
... [ FENCED | NOT FENCED ];
```

Parameters

<table>
<thead>
<tr>
<th>OR REPLACE</th>
<th>If you do not supply this parameter, the CREATE FILTER statement fails if an existing function matches the name and parameters of the filter function you are trying to define. If you do supply this parameter, the new filter function definition overwrites the old.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than <code>public</code>, you must supply the schema name. For example: <code>myschema.thisDbObject</code></td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.0.x)  Page 3375 of 6180
If you specify a database, it must be the current database.

**function**

The name of the filter function to create. If the filter function name is schema-qualified (as above), the function is created in the specified schema. This name does not need to match the name of the factory, but it is less confusing if they are the same or similar.

**LANGUAGE 'Language'**

The language used to develop this function, one of the following:

- C++ (default)
- Java

**NAME 'factory'**

The name of the factory class in the shared library that generates the object to handle the filter function's processing. This is the same name used by the RegisterFactory class.

**LIBRARY Library**

The name of the shared library that contains the C++ object to perform the processing for this filter function. This library must have been previously loaded using the CREATE LIBRARY statement.

**FENCED | NOT FENCED**

Enables or disables Fenced Mode for this function. Fenced mode is enabled by default.

### Privileges

- Only a superuser can create or drop a function that uses a U Dx library.

- To use a User Defined Filter, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined filter function. See GRANT (User Defined Extension) and REVOKE (User Defined Extension).

**Important:** Installing an untrusted UDL function can compromise the security of the server. U Dx's can contain arbitrary code. In particular, UD Source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to U Dx's to untrusted users.
Notes

- The parameters and return value for the filter function are automatically determined by the CREATE FILTER statement, based on data supplied by the factory class.

- You can return a list of all SQL functions and User Defined Functions by querying the system table V_CATALOG.USER_FUNCTIONs or executing the vsql meta-command `\df`. Users see only the functions on which they have EXECUTE privileges.

Example

The following example demonstrates loading a library named iConverterLib, then defining a function named Iconverter that is mapped to the iConverterFactory factory class in the library:

```
=> CREATE LIBRARY iConverterLib as '/opt/vertica/sdk/examples/build/IconverterLib.so';
CREATE LIBRARY
=> CREATE FILTER Iconverter AS LANGUAGE 'C++' NAME 'IconverterFactory' LIBRARY IconverterLib;
CREATE FILTER FUNCTION
=> \x
Expanded display is on.
=> SELECT * FROM user_functions;
-[ RECORD 1 ]-----------------------------
schema_name | public
function_name | Iconverter
procedure_type | User Defined Filter
function_return_type |
function_argument_type |
function_definition |
v volatility |
is_strict | f
is_fenced | f
comment | |
```

Load (UDLs)

CREATE FUNCTION (SQL Functions)

Lets you store SQL expressions as functions in Vertica for use in queries. These functions are useful for executing complex queries or combining Vertica built-in functions. You simply call the function name you assigned.

Note: This topic describes how to use CREATE FUNCTION to create a SQL function. If you want to create a user-defined scalar function (UDSF), see CREATE FUNCTION (UDF).

In addition, if you want to see how to create a user-defined transform function (UDTF), see CREATE TRANSFORM FUNCTION.

Syntax

CREATE [ OR REPLACE ] FUNCTION
... [[database.]schema.]function( [ argname argtype [, ...] ] )
... RETURN rettype
... AS
... BEGIN
...... RETURN expression;
... END;

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>function</td>
<td>Specifies a name for the SQL function to create, where function conforms to conventions described in Identifiers. When using more than one schema, specify the schema that contains the function, as noted above.</td>
</tr>
<tr>
<td>argname</td>
<td>Specifies the name of the argument.</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td>argtype</td>
<td>Specifies the data type for argument that is passed to the function. Argument types must match Vertica type names. See SQL Data Types.</td>
</tr>
<tr>
<td>rettype</td>
<td>Specifies the data type to be returned by the function.</td>
</tr>
<tr>
<td>RETURN expression;</td>
<td>Specifies the SQL function (function body), which must be in the form of ‘RETURN expression.’ expression can contain built-in functions, operators, and argument names specified in the CREATE FUNCTION statement. A semicolon at the end of the expression is required.</td>
</tr>
</tbody>
</table>

**Note:** Only one RETURN expression is allowed in the CREATE FUNCTION definition. FROM, WHERE, GROUP BY, ORDER BY, LIMIT, aggregation, analytics, and meta function are not allowed.

### Privileges

- To create a function, the user must have CREATE privilege on the schema to contain the function and USAGE privilege on the library containing the function.

- To use a function, the user must have USAGE privilege on the schema that contains the function and EXECUTE privileges on the function.

- To drop a function, the user must either be a superuser, the owner of the function, or the owner of the schema which contains the function.

See [GRANT (User Defined Extension)] and [REVOKE (User Defined Extension)].

### Notes

- A SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

- SQL Macros are flattened in all cases, including DDL.
You can **create views** on the queries that use SQL functions and then query the views. When you create a view, a SQL function replaces a call to the user-defined function with the function body in a view definition. Therefore, when the body of the user-defined function is replaced, the view should also be replaced.

If you want to change the body of a SQL function, use the CREATE OR REPLACE syntax. The command replaces the function with the new definition. If you change only the argument name or argument type, the system maintains both versions under the same function name. See Examples section below.

If multiple SQL functions with same name and argument type are in the search path, the first match is used when the function is called.

The strictness and volatility (stable, immutable, or volatile) of a SQL Macro are automatically inferred from the function's definition. Vertica then determines the correctness of usage, such as where an immutable function is expected but a volatile function is provided.

You can return a list of all SQL functions by querying the system table `V_CATALOG.USER_FUNCTIONS` and executing the vsql meta-command `\df`. Users see only the functions on which they have EXECUTE privileges.

**Example**

This following statement creates a SQL function called `myzeroifnull` that accepts an INTEGER argument and returns an INTEGER result.

```sql
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
       RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
   END;
```

You can use the new SQL function (`myzeroifnull`) anywhere you use an ordinary SQL expression. For example, create a simple table:

```sql
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
```

```
---
1
0
(3 rows)
```
Use the myzeroifnull function in a SELECT statement, where the function calls col1 from table tabwnulls:

```sql
=> SELECT myzeroifnull(col1) FROM tabwnulls;
myzeroifnull
-------
 1
 0
 0
(3 rows)
```

Use the myzeroifnull function in the GROUP BY clause:

```sql
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
count
-------
 2
 1
(2 rows)
```

If you want to change a SQL function's body, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```sql
=> CREATE OR REPLACE FUNCTION zerowhennull(x INT) RETURN INT AS BEGIN
  RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
END;
```

To see how this information is stored in the Vertica catalog, see Viewing Information About SQL Functions in Extending Vertica.

See Also

- ALTER FUNCTION (UDF)
- DROP FUNCTION
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
- USER_FUNCTIONS
- Using User-Defined SQL Functions
CREATE FUNCTION (UDF)

Adds a user-defined function (UDF) to the catalog. You must have already loaded this library using the CREATE LIBRARY statement. When you call the SQL function, Vertica passes the parameters to the function in the library to process it.

Note: This topic describes how to use CREATE FUNCTION to create a User Defined Function. If you want to create a SQL function, see CREATE FUNCTION (SQL Function).

In addition, if you want to create a user-defined transform function (UDTF), see CREATE TRANSFORM FUNCTION.

Syntax

```
CREATE [ OR REPLACE ] FUNCTION [[database.]schema.]function
... AS [ LANGUAGE 'Language' ] NAME 'factory' LIBRARY Library
[ FENCED | NOT FENCED ];
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR REPLACE</td>
<td>If you do not supply this parameter, the CREATE FUNCTION statement fails if an existing function matches the name and parameters of the function you are trying to define. If you do supply this parameter, the new function definition overwrites the old.</td>
</tr>
<tr>
<td>database</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td>schema</td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td>function</td>
<td>The name of the function to create, where function conforms to conventions described in Identifiers. If the function name is schema-qualified (as above), the function is created in the specified schema. This name does not need to match the name of the factory, but it is less confusing if they</td>
</tr>
</tbody>
</table>
are the same or similar.

**LANGUAGE 'Language'**
The language used to develop this function, one of the following:
- C++
- Python
- Java
- R

**NAME 'factory'**
The name of the factory class in the shared library that generates the object to handle the function's processing.

**LIBRARY Library**
The name of the file that contains the C++ library, Python file, Java Jar file, or R functions file to perform the processing for this function. This library must have been previously loaded using the CREATE LIBRARY statement.

**FENCED | NOT FENCED**
Enables or disables Fenced Mode for this function. Fenced mode is enabled by default. Functions written in Java and R always run in fenced mode.

### Privileges

- To create a function, the user must have CREATE privilege on the schema to contain the function and USAGE privilege on the library containing the function.

- To use a function, the user must have USAGE privilege on the schema that contains the function and EXECUTE privileges on the function.

- To drop a function, the user must either be a superuser, the owner of the function, or the owner of the schema which contains the function.

### Notes

- The parameters and return value for the function are automatically determined by the CREATE FUNCTION statement, based on data supplied by the factory class.
Multiple functions can share the same name if they have different parameters. When you call a multiply-defined function, Vertica selects the UDF function whose input parameters match the parameters in the function call to perform the processing. This behavior is similar to having multiple signatures for a method or function in other programming languages.

You can return a list of all SQL functions and UDFs by querying the system table `V_CATALOG.USER_FUNCTIONS` or executing the `vsql` meta-command `\df`. Users see only the functions on which they have EXECUTE privileges.

Examples

The following example demonstrates loading a library named scalarfunctions, then defining a function named Add2ints that is mapped to the Add2intsFactory factory class in the library:

```
=> CREATE LIBRARY ScalarFunctions AS '/opt/vertica/sdk/examples/build/ScalarFunctions.so';
CREATE LIBRARY

=> CREATE FUNCTION Add2Ints AS 'C++' NAME 'Add2IntsFactory' LIBRARY ScalarFunctions;
CREATE FUNCTION

=> \x
Expanded display is on.
=> SELECT * FROM USER_FUNCTIONS;

- [ RECORD 1 ]-+-----------------------------------------------+
  | schema_name | public |
  | function_name | Add2Ints |
  | procedure_type | User Defined Function |
  | function_return_type | Integer |
  | function_argument_type | Integer, Integer |
  | function_definition | Class 'Add2IntsFactory' in Library 'public.ScalarFunctions' |
  | volatility | volatile |
  | is_strict | f |
  | is_fenced | t |
  | comment | |

=> \x
Expanded display is off.
=> -- Try a simple call to the function
=> SELECT Add2Ints(23,19);
  Add2Ints
  --------
  42
(1 row)
```

- Developing User-Defined Extensions (UDxs)

CREATE PARSER

Adds a user-defined load parser function. You must have already loaded this library using the CREATE LIBRARY statement. When you call the SQL function, Vertica passes the parameters to the function in the library to process it.

Syntax

```
CREATE [ OR REPLACE ] PARSER [[database.]schema.]function
... AS [ LANGUAGE 'language' ] NAME 'factory' LIBRARY library
... [ FENCED | NOT FENCED ];
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR REPLACE</td>
<td>If you do not supply this parameter, the CREATE PARSER statement fails if an existing function matches the name and parameters of the parser function you are trying to define. If you do supply this parameter, the new parser function definition overwrites the old.</td>
</tr>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject</td>
</tr>
</tbody>
</table>
If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th>function</th>
<th>The name of the parser function to create. If the parser function name is schema-qualified (as above), the function is created in the specified schema. This name does not need to match the name of the factory, but it is less confusing if they are the same or similar.</th>
</tr>
</thead>
</table>
| LANGUAGE 'Language' | The language used to develop this function, one of the following:  
  * C++ (default)  
  * Java |
| NAME 'factory' | The name of the factory class in the shared library that generates the object to handle the parser function's processing. This is the same name used by the RegisterFactory class. |
| LIBRARY Library | The name of the shared library that contains the C++ object to perform the processing for this parser function. This library must have been previously loaded using the CREATE LIBRARY statement. |
| FENCED | NOT FENCED | Enables or disables Fenced Mode for this function.  
**Default Value:** FENCED |

### Privileges

- Only a superuser can create or drop a function that uses a UDx library.

- To use a User Defined Parser, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined parser function. See [GRANT (User Defined Extension)](User Defined Extension) and [REVOKE (User Defined Extension)](User Defined Extension).

---

**Important:** Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD Source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDx's to untrusted users.
Notes

- The parameters and return value for the parser function are automatically determined by the CREATE PARSER statement, based on data supplied by the factory class.

- You can return a list of all SQL functions and User Defined Functions by querying the system table V_CATALOG.USER_FUNCTIONS or executing the vsq1 meta-command \df. Users see only the functions on which they have EXECUTE privileges.

Example

The following example demonstrates loading a library named BasicIntegrerParserLib, then defining a function named BasicIntegerParser that is mapped to the BasicIntegerParserFactory factory class in the library:

```
=> CREATE LIBRARY BasicIntegerParserLib as '/opt/vertica/sdk/examples/build/BasicIntegerParser.so';
CREATE LIBRARY
=> CREATE PARSER BasicIntegerParser AS LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;
CREATE PARSER FUNCTION
=> \x
Expanded display is on.
=> SELECT * FROM user_functions;
-[ RECORD 1 ]------------------------
schema_name | public
function_name | BasicIntegerParser
procedure_type | User Defined Parser
function_return_type | 
function_argument_type |
function_definition |
v volatility |
is_strict | f
is_fenced | f
comment |
```

USER_FUNCTIONS

Load (UDLs)

CREATE SOURCE

Adds a user-defined load source function. You must have already loaded this library using the CREATE LIBRARY statement. When you call the SQL function, Vertica passes the parameters to the function in the library to process it.

Syntax

```
CREATE [ OR REPLACE ] SOURCE [[database.]schema.]function ...
    AS LANGUAGE 'language' NAME 'factory' LIBRARY library ...
    [ FENCED | NOT FENCED ];
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR REPLACE</td>
<td>If you do not supply this parameter, the CREATE SOURCE statement fails if an existing function matches the name and parameters of the source function you are trying to define. If you do supply this parameter, the new source function definition overwrites the old.</td>
</tr>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td>function</td>
<td>The name of the source function to create. If the source function name is schema-qualified (as above), the function is created in the specified schema. This name does not need to match the name of the factory, but it is less confusing if they are the same or similar.</td>
</tr>
<tr>
<td>LANGUAGE 'language'</td>
<td>The language used to develop this function, one of the following:</td>
</tr>
</tbody>
</table>
### NAME 'factory'

The name of the factory class in the shared library that generates the object to handle the source function's processing.

This is the same name used by the RegisterFactory class.

### LIBRARY Library

The name of the shared library that contains the C++ object to perform the processing for this source function. This library must have been previously loaded using the `CREATE LIBRARY` statement.

### FENCED | NOT FENCED

Enables or disables Fenced Mode for this function.

**Default Value:** FENCED

---

**Privileges**

- Only a superuser can create or drop a function that uses a UDx library.

- To use a User Defined Source, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined source function. See [GRANT (User Defined Extension)](https://docs.vertica.com/vertica-analytic-database-manual/latest/functions/user-defined-source-create.html) and [REVOKE (User Defined Extension)](https://docs.vertica.com/vertica-analytic-database-manual/latest/functions/user-defined-source-create.html).

---

**Important:** Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD Source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDx's to untrusted users.

---

**Notes**

- The parameters and return value for the source function are automatically determined by the `CREATE SOURCE` statement, based on data supplied by the factory class.

- You can return a list of all SQL functions and User Defined Functions by querying the system table `V_CATALOG.USER_FUNCTIONS` or executing the `vsql` meta-command `\df`. Users see only the functions on which they have EXECUTE privileges.
Example

The following example demonstrates loading a library named curlib, then defining a function named curl that is mapped to the CurlSourceFactory factory class in the library:

```sql
=> CREATE LIBRARY curlib as '/opt/vertica/sdk/examples/build/cURLLib.so';
CREATE LIBRARY
=> CREATE SOURCE curl AS LANGUAGE 'C++' NAME 'CurlSourceFactory' LIBRARY curlib;
CREATE SOURCE
=> \x
Expanded display is on.
=> SELECT * FROM user_functions;
- [ RECORD 1 ]- ---------------------------
   schema_name | public
   function_name | curl
   procedure_type | User Defined Source
   function_return_type | |
   function_argument_type | |
   function_definition | |
   volatility | |
   is_strict | f
   is_fenced | f
   comment | |
```

CREATE TRANSFORM FUNCTION

Adds a user-defined transform function (UDTF) stored in a shared Linux library to the catalog. You must have already loaded this library using the CREATE LIBRARY statement. When you call the SQL function, Vertica passes the input table to the transform function in the library to process.
Note: This topic describes how to create a UDTF. To create a user-defined function (UDF), see CREATE FUNCTION (UDF). To create a SQL function, see CREATE FUNCTION (SQL).

Syntax

CREATE [OR REPLACE] TRANSFORM FUNCTION function-name
AS [LANGUAGE 'language'] NAME 'factory'
LIBRARY library-name
[FENCED | NOT FENCED]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR REPLACE</td>
<td>If you omit this parameter, the CREATE TRANSFORM FUNCTION statement fails if an existing function matches the name and parameters of the function you are trying to define. If you supply this parameter, the new function definition overwrites the old one.</td>
</tr>
<tr>
<td>function-name</td>
<td>The name to assign to the UDTF. This is the name you use in your SQL statements to call the function.</td>
</tr>
<tr>
<td>LANGUAGE 'language'</td>
<td>The language used to develop this function, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• C++ (default)</td>
</tr>
<tr>
<td></td>
<td>• Java</td>
</tr>
<tr>
<td></td>
<td>• R</td>
</tr>
<tr>
<td></td>
<td>• PYTHON</td>
</tr>
<tr>
<td>NAME 'factory'</td>
<td>The name of the factory class or R factory function in the shared library that generates the object to handle the function's processing.</td>
</tr>
<tr>
<td>LIBRARY library-name</td>
<td>The name of the shared library that contains the object to perform the processing for this function. This library must have been previously loaded using the CREATE LIBRARY statement.</td>
</tr>
<tr>
<td>FENCED</td>
<td>NOT FENCED</td>
</tr>
</tbody>
</table>
written in R always run in fenced mode.

**Default Value:** FENCED

### Privileges

- To create a function, the user must have CREATE privilege on the schema to contain the function and USAGE privilege on the library containing the function.

- To use a function, the user must have USAGE privilege on the schema that contains the function and EXECUTE privileges on the function.

- To drop a function, the user must either be a superuser, the owner of the function, or the owner of the schema which contains the function.

### UDTF Query Restrictions

A query that includes a UDTF cannot contain:

- Any statements other than the `SELECT` statement containing the call to the UDTF and a `PARTITION BY` expression

- Any other analytic function

- A call to another UDTF

- A `TIMESERIES` clause

- A pattern matching clause

- A gap filling and interpolation clause

### Notes

- The parameters and return values for the function are automatically determined by the `CREATE TRANSFORM FUNCTION` statement, based on data supplied by the factory class.

- You can assign multiple functions the same name if they have different parameters. When you call a multiply-defined function, Vertica selects the UDTF function whose input parameters match the parameters in the function call to perform the processing. This
behavior is similar to having multiple signatures for a method or function in other programming languages.

- You can return a list of all UDTFs by querying the system table `V_CATALOG.USER_FUNCTIONS`. You can only see functions for which you have EXECUTE privileges.

Examples

This example shows how to add a UDTF to the catalog.

```sql
=> CREATE TRANSFORM FUNCTION transFunct AS LANGUAGE 'C++' NAME 'myFactory' LIBRARY myFunction;
```

CREATE HCATALOG SCHEMA

Define a schema for data stored in a Hive data warehouse using the HCatalog Connector. For more information, see Using the HCatalog Connector in Integrating with Apache Hadoop.

Most of the optional parameters are read out of Hadoop configuration files if available. If you copied the Hadoop configuration files as described in Configuring Vertica for HCatalog, you can omit most parameters. By default this statement uses the values specified in those configuration files. If the configuration files are complete, the following is a valid statement:

```sql
=> CREATE HCATALOG SCHEMA hcat;
```

If a value is not specified in the configuration files and a default is shown in the parameter list, then that default value is used.
Some parameters apply only if you are using HiveServer2 (the default). Others apply only if you are using WebHCat, a legacy Hadoop service. When using HiveServer2, use HIVESERVER2_HOSTNAME to specify the server host. When using WebHCat, use WEBSERVICE_HOSTNAME to specify the server host.

If you need to use WebHCat you must also set the HCatalogConnectorUseHiveServer2 configuration parameter to 0. See Apache Hadoop Parameters.

After creating the schema, you can change many (but not all) parameters using ALTER HCATALOG SCHEMA.

Syntax

```sql
CREATE HCATALOG SCHEMA [IF NOT EXISTS] schemaName
  [AUTHORIZATION user-id]
  [WITH [param=value [, ...] ] ]
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[IF NOT EXISTS]</td>
<td>If given, the statement exits without an error when the schema named in <code>schemaName</code> already exists.</td>
</tr>
<tr>
<td><code>schemaName</code></td>
<td>The name of the schema to create in the Vertica catalog. The tables in the Hive database will be available through this schema.</td>
</tr>
<tr>
<td>AUTHORIZATION</td>
<td>The name of a Vertica account to own the schema being created. This parameter is ignored if Kerberos authentication is being used; in that case the current vsql user is used.</td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| HOSTNAME   | The hostname, IP address, or URI of the database server that stores the Hive data warehouse's metastore information.  
If you specify this parameter and do not also specify PORT, then this value must be in the URI format used for hive.metastore.uris in hive- |
site.xml.
If the Hive metastore supports High Availability, you can specify a comma-separated list of URIs for this value.
If this value is not specified, hive-site.xml must be available.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PORT</td>
<td>The port number on which the metastore database is running. If you specify this parameter, you must also specify HOSTNAME and it must be a name or IP address (not a URI).</td>
</tr>
</tbody>
</table>
| HIVESERVER2_HOSTNAME          | The hostname or IP address of the HiveServer2 service. This parameter is optional if in hive-site.xml you set one of the following properties:  
                                 | - hive.server2.thrift.bind.host to a valid host  
                                 | - hive.server2.support.dynamic.service.discovery to true  
                                 | This parameter is ignored if you are using WebHCat. |
| WEBSERVICE_HOSTNAME           | The hostname or IP address of the WebHCat service, if using WebHCat instead of HiveServer2. If this value is not specified, webhcat-site.xml must be available. |
| WEBSERVICE_PORT               | The port number on which the WebHCat service is running, if using WebHCat instead of HiveServer2. If this value is not specified, webhcat-site.xml must be available. |
| WEBHDFS_ADDRESS               | The host and port ("host:port") for the WebHDFS service. This parameter is used only for reading ORC and Parquet files. If this value is not set, hdfs-site.xml must be available to read these file types through the HCatalog Connector. |
| HCATALOG_SCHEMA               | The name of the Hive schema or database that the Vertica schema is being mapped to. The default is `schemaName`. |
| HCATALOG_USER                 | The username of the HCatalog user to use when making calls to the HiveServer2 or WebHCat server. The default is the current database user. |
| HCATALOG_CONNECTION_TIMEOUT   | The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer or WebHCat server. A value of 0 means wait indefinitely. |
| HCATALOG_                      | The lowest data transfer rate (in bytes per second) from the |
**SLOW_TRANSFER_LIMIT**
HiveServer2 or WebHCat server that the HCatalog Connector accepts. See HCATALOG_SLOW_TRANSFER_TIME for details.

**HCATALOG_SLOWTRANSFER_TIME**
The number of seconds the HCatalog Connector waits before enforcing the data transfer rate lower limit. After this time has passed, the HCatalog Connector tests whether the data transfer rate is at least as fast as the value set in HCATALOG_SLOW_TRANSFER_LIMIT. If it is not, then the HCatalog Connector breaks the connection and terminates the query.

**SSL_CONFIG**
The path of the Hadoop ssl-client.xml configuration file. This parameter is required if you are using HiveServer2 and it uses SSL wire encryption. This parameter is ignored if you are using WebHCat.

The default values for HCATALOG_CONNECTOR_TIMEOUT, HCATALOG_SLOW_TRANSFER_LIMIT, and HCATALOG_SLOW_TRANSFER_TIME are set by the database configuration parameters HCatConnectionTimeout, HCatSlowTransferLimit, and HCatSlowTransferTime. See Apache Hadoop Parameters in the Administrator's Guide for more information.

### Configuration Files
The HCatalog Connector uses the following values from the Hadoop configuration files if you do not override them when creating the schema.

<table>
<thead>
<tr>
<th>File</th>
<th>Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>hive-site.xml</td>
<td>hive.server2.thrift.bind.host (used for HIVESERVER2_HOSTNAME)</td>
</tr>
<tr>
<td></td>
<td>hive.server2.thrift.port</td>
</tr>
<tr>
<td></td>
<td>hive.server2.transport.mode</td>
</tr>
<tr>
<td></td>
<td>hive.server2.authentication</td>
</tr>
<tr>
<td></td>
<td>hive.server2.authentication.kerberos.principal</td>
</tr>
<tr>
<td></td>
<td>hive.server2.support.dynamic.service.discovery</td>
</tr>
<tr>
<td></td>
<td>hive.zookeeper.quorum (used as HIVESERVER2_HOSTNAME if dynamic service discovery is enabled)</td>
</tr>
<tr>
<td>File</td>
<td>Properties</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>hive.zookeeper.client.port</td>
<td></td>
</tr>
<tr>
<td>hive.server2.zookeeper.namespace</td>
<td></td>
</tr>
<tr>
<td>hive.metastore.uris (used for HOSTNAME and PORT)</td>
<td></td>
</tr>
<tr>
<td>ssl-client.xml</td>
<td>ssl.client.truststore.location</td>
</tr>
<tr>
<td></td>
<td>ssl.client.truststore.password</td>
</tr>
</tbody>
</table>

**Privileges**

The user must be a superuser or be granted all permissions on the database to use this statement.

The user also requires access to Hive data in one of the following ways:

- Have USAGE permissions on `hcatalog_schema`, if Hive does not use an authorization service (Sentry or Ranger) to manage access.

- Have permission through an authorization service, if Hive uses it to manage access. In this case you must either set `EnableHCatImpersonation` to 0, to access data as the Vertica principal, or grant users access to the HDFS data. For Sentry, you can use ACL synchronization to manage HDFS access.

- Be the dbadmin user, with or without an authorization service.

**Examples**

The following example shows how to use CREATE HCATALOG SCHEMA to define a new schema for tables stored in a Hive database and then query the system tables that contain information about those tables:

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
   HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
   SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin';
CREATE SCHEMA
=> \\x
Expanded display is on.
```
The following example shows how to specify more than one metastore host.

```sql
=> CREATE HCATALOG SCHEMA hcat
    WITH HOSTNAME='thrift://node1.example.com:9083,thrift://node2.example.com:9083';
```
CREATE LIBRARY

Loads a library containing user defined extensions (UDxs) into the Vertica catalog. Vertica automatically distributes copies of the library file and any supporting libraries to all cluster nodes. UDxs defined in the catalog that reference the updated library automatically start using the new library file. Nodes that are down or added to the cluster also receive a copy of the updated library file as soon as they join the cluster.

Because libraries are added to the database catalog, they persist across database restarts. After loading a library in the catalog, you can use statements such as CREATE FUNCTION to define the extensions contained in the library. See Developing User-Defined Extensions (UDxs) in Extending Vertica for details.

Syntax

CREATE [OR REPLACE] LIBRARY
   [[database.]schema.]library
AS 'library-path'
   [ DEPENDS 'support-path' ]
   [ LANGUAGE 'language' ]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR REPLACE</td>
<td>Replaces the old library with the new one. If you do not supply this parameter, the CREATE LIBRARY statement fails when an existing library matches the name the library you are trying to define.</td>
</tr>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td>library</td>
<td>A name to assign to this library, where library conforms to conventions described in Identifiers. Use this name in a CREATE FUNCTION statement to enable user defined functions stored in</td>
</tr>
</tbody>
</table>
the library.

Tip: While not required, it is good practice to match *Library* to the library file name.

<table>
<thead>
<tr>
<th><strong>Library-path</strong></th>
<th>The absolute path and file name of the library to load. This file must be located in the initiator node file system.</th>
</tr>
</thead>
</table>
| **DEPENDS 'support-path'** | Indicates that the UDx library depends on one or more support libraries, where *support-path* specifies one or more absolute paths to the support libraries files, located in the initiator node's file system. You can specify multiple support paths as follows:  
   - Separate multiple paths with colons (:).  
   - Specify a directory that contains multiple libraries with an asterisk wildcard (*). For example: /home/mydir/mylibs/*  
   If your Java library depends on native libraries (SO files), use DEPENDS to specify the path and call `System.loadLibrary()` in your UDx to load the native libraries from that path. |
| **LANGUAGE 'Language'** | The programming language used to develop the function, where *Language* is one of the following:  
   - C++  
   - Python  
   - Java  
   - R |

**Privileges**

Superuser
Requirements

- Vertica makes its own copies of the library files. Later modification or deletion of the original files specified in the statement does not affect the library defined in the catalog. To update the library, use `ALTER LIBRARY`.

- Loading a library is no guarantee that it functions correctly. `CREATE LIBRARY` performs some basic checks on the library file to verify it is compatible with Vertica. The statement fails if it detects that the library was not correctly compiled or it finds other basic incompatibilities. However, `CREATE LIBRARY` cannot detect many other issues in shared libraries.

- You can choose to run UDxs developed in C++ in unfenced mode. Unfenced UDxs run directly in the Vertica process. If the U Dx you run in unfenced mode has bugs, it can negatively impact the database, causing instability or even crashes. To avoid these issues, run your U Dx only in fenced mode. A few U Dx types can only be run in unfenced mode.

Examples

To load a library in the home directory of the dbadmin account with the name MyFunctions:

```sql
=> CREATE LIBRARY MyFunctions AS 'home/dbadmin/my_functions.so';
```

To load a library located in the directory where you started `vsql`:

```sql
=> \set libfile '\''pwd'\''/MyOtherFunctions.so'';
=> CREATE LIBRARY MyOtherFunctions AS :libfile;
```

To load a Java library named `JavaLib.jar` that depends on multiple support JAR files in the `/home/dbadmin/mylibs` subdirectory:

```sql
=> CREATE LIBRARY DeleteVowelsLib AS `/home/dbadmin/JavaLib.jar`
   DEPENDS `'/home/dbadmin/mylibs/*' LANGUAGE 'JAVA';
```

See Also

- `DROP LIBRARY`
CREATE LOCAL TEMPORARY VIEW

Creates or replaces a local temporary view. Views are read only, so they do not support insert, update, delete, or copy operations. Local temporary views are session-scoped, so they are visible only to their creator in the current session. Vertica drops the view when the session ends.

**Note:** Vertica does not support global temporary views.

**Syntax**

```
CREATE [OR REPLACE] LOCAL TEMP[ORARY] VIEW view [ (column[, ...]) ] AS query
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>OR REPLACE</strong></td>
<td>Specifies to overwrite the existing view <code>view-name</code>. If you omit this option and <code>view-name</code> already exists, <code>CREATE VIEW</code> returns an error.</td>
</tr>
<tr>
<td><strong>view</strong></td>
<td>Identifies the view to create, where <code>view-name</code> conforms to conventions described in <code>Identifiers</code>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</td>
</tr>
<tr>
<td><strong>column [ , ...]</strong></td>
<td>A list of names to use as view column names. Vertica maps view column names to query columns according to the order of their respective lists. By default, the view uses column names as they are specified in the query. Each view can contain up to 1600 columns.</td>
</tr>
<tr>
<td><strong>AS query</strong></td>
<td>A <code>SELECT</code> statement that the temporary view executes. The <code>SELECT</code> statement can reference tables, temporary tables, and other views.</td>
</tr>
</tbody>
</table>

**Privileges**

See **Creating Views**
Example

The following CREATE LOCAL TEMPORARY VIEW statement creates the temporary view myview. This view sums all individual incomes of customers listed in the store.store_sales_fact table, and groups results by state:

```sql
=> CREATE LOCAL TEMP VIEW myview AS
    SELECT SUM(annual_income), customer_state FROM public.customer_dimension
    WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact)
    GROUP BY customer_state
    ORDER BY customer_state ASC;
```

The following example uses the temporary view myview with a WHERE clause that limits the results to combined salaries greater than $2 billion:

```sql
=> SELECT * FROM myview WHERE SUM > 200000000;
```

<table>
<thead>
<tr>
<th>SUM</th>
<th>customer_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>2723441590</td>
<td>AZ</td>
</tr>
<tr>
<td>29253817091</td>
<td>CA</td>
</tr>
<tr>
<td>4907216137</td>
<td>CO</td>
</tr>
<tr>
<td>3769455689</td>
<td>CT</td>
</tr>
<tr>
<td>3330524215</td>
<td>FL</td>
</tr>
<tr>
<td>4581840709</td>
<td>IL</td>
</tr>
<tr>
<td>3310667307</td>
<td>IN</td>
</tr>
<tr>
<td>2793284639</td>
<td>MA</td>
</tr>
<tr>
<td>5225333668</td>
<td>MI</td>
</tr>
<tr>
<td>2128169759</td>
<td>NV</td>
</tr>
<tr>
<td>2886158503</td>
<td>PA</td>
</tr>
<tr>
<td>2832710696</td>
<td>TN</td>
</tr>
<tr>
<td>14215397659</td>
<td>TX</td>
</tr>
<tr>
<td>2642551509</td>
<td>UT</td>
</tr>
</tbody>
</table>

- CREATE VIEW
- Creating Views
CREATE LOCATION

Creates a new storage location where Vertica can store data. After you create the location, you create storage policies that assign the storage location to the database objects that will store data in the location.

Cautions

While no technical issue prevents you from using CREATE LOCATION to add one or more Network File System (NFS) storage locations, Vertica does not support NFS data or catalog storage except for MapR mount points. You will be unable to run queries against any other NFS data. When creating locations on MapR file systems, you must specify ALL NODES SHARED.

If you use any HDFS storage locations, the HDFS data must be available at the time you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you have moved data files, or if they have become corrupted, or if your HDFS cluster is not responsive, Vertica cannot start.

Syntax

CREATE LOCATION 'path'
   [NODE 'nodename' | ALL NODES]
   [SHARED]
   [USAGE 'usertype']
   [LABEL 'labelname']

Arguments

<table>
<thead>
<tr>
<th><strong>path</strong></th>
<th>Where Vertica will store this location's data. The type of filesystem on which the location is based determines the format of this argument:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- For storage locations on the Linux filesystem, <em>path</em> must be an absolute path to the directory where Vertica can write the storage location's data.</td>
</tr>
<tr>
<td></td>
<td>- For storage locations on HDFS, <em>path</em> must be an HDFS URL where</td>
</tr>
</tbody>
</table>
Vertica can write the storage location's data. See more information below.

- For USER storage locations on S3 in Eon Mode Beta only, *path* must be a URL of the form 's3://bucket/path'.

| **NODE 'nodename'** <br>**ALL NODES** | The node or nodes on which the storage location is defined.  
- **NODE**: Use this keyword to create the storage location on a single node. Specify the node using its name as it appears in the NODES system table.  
- **ALL NODES**: Use this keyword to create the storage location on all nodes  
  **Default Value**: ALL NODES |
| **SHARED** | Indicates the location set by the *path* is shared (used by all of the nodes) rather than local to each node. See below for details. |
| **USAGE 'use-type'** | The type of data the storage location can hold, where *use-type* is one of the following:  
- **TEMP**: Vertica uses the location to store temporary files it creates while processing queries.  
- **DATA**: The storage location can only store data.  
- **TEMP,DATA (default)**: The storage location can store both temporary files and data.  
- **USER**: Users who have been granted access to the storage location can read and store data there (see GRANT (Storage Location)). This usage type can be used with external tables (see CREATE EXTERNAL TABLE AS COPY), which by default are readable only by administrators.  
  **Default Value**: 'TEMP,DATA' |
| **LABEL 'Labelname'** | A label for the storage location. You use this name later when assigning the storage location to data objects. |
Privileges

Superuser

The Vertica process must also have read and write permissions to the location where date will be stored. Each type of filesystem has its own requirements:

- **Linux**: The database administrator account (usually named dbadmin) must have full read and write access to the directory in the *path* argument.

- **HDFS without Kerberos**: Requires a Hadoop user whose username matches the Vertica database administrator username (usually dbadmin). This Hadoop user must have read and write access to the HDFS directory specified in the *path* argument.

- **HDFS with Kerberos**: Requires a Hadoop user whose username matches the principal in the keytab file on each Vertica node. This is not the same as the database administrator username. This Hadoop user must have read and write access to the HDFS directory stored in the *path* argument.

Shared Versus Local Storage

The *shared* keyword indicates that the location set by the *path* argument is shared by all nodes. Most remote filesystems (such as HDFS) are shared. For these filesystems, the *path* argument represents a single location where all of the nodes store data. Each node creates its own subdirectory to hold its own files in a shared storage location. These subdirectories prevent the nodes from overwriting each other's files. Even if your cluster has only one node, you must include the *shared* keyword if you are using a remote filesystem. If the location is declared as USER Vertica does not create sub directories for each node. The setting of USER takes precedence over *shared*.

If you do not supply this keyword, the new storage location is local. The *path* argument specifies a location that is unique for each node in the cluster. This location is usually a path in the node's own filesystem. Storage locations contained in filesystems that are local to each node (such as the Linux filesystem) are always local.

HDFS URLs

To specify a path for a location on HDFS, use URLs in the *hdfs* scheme. In most cases you can use *hdfs://* (three slashes) followed by the HDFS path. To use HDFS URLs you must give
Vertica access to some HDFS configuration files. For more information, see Reading Directly from HDFS and Configuring the hdfs Scheme.

- Vertica node. This is not the same as the database administrator username. This Hadoop user must have read and write access to the HDFS directory stored in the path argument.

Examples

The following example shows how to create a storage location in the local Linux filesystem for temporary data storage.

```sql
=> CREATE LOCATION '/home/dbadmin/testloc' USAGE 'TEMP' LABEL 'tempfiles';
```

The following example shows how to create a storage location on HDFS in the /user/dbadmin directory. The HDFS cluster does not use Kerberos.

```sql
=> CREATE LOCATION 'hdfs:///user/dbadmin' ALL NODES SHARED
   USAGE 'data' LABEL 'coldstorage';
```

The following example shows how to create the same storage location, but on a Hadoop cluster that uses Kerberos. Note the output that reports the principal being used.

```sql
=> CREATE LOCATION 'hdfs:///user/dbadmin' ALL NODES SHARED
   USAGE 'data' LABEL 'coldstorage';
NOTICE 0: Performing HDFS operations using kerberos principal [vertica/hadoop.example.com]
CREATE LOCATION
```

The following example shows how to create a location for user data, grant access to it, and use it to create an external table.

```sql
=> CREATE LOCATION '/tmp' ALL NODES USAGE 'user';
CREATE LOCATION
=> GRANT ALL ON LOCATION '/tmp' to Bob;
GRANT PRIVILEGE
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM '/tmp/data/ext1.dat' DELIMITER ',';
CREATE TABLE
```

For an example of a USER storage location using S3, see Browsing S3 Data Using External Tables in Using Eon Mode Beta.

See Also

- Managing Storage Locations in the Administrator's Guide
- Vertica Storage Location for HDFS in Integrating with Apache Hadoop.
CREATE NETWORK INTERFACE

Identifies a network interface to which a node belongs. Use this statement when you want to configure import/export operations from individual nodes to other Vertica clusters.

Syntax

```sql
CREATE NETWORK INTERFACE network-interface-name ON node-name WITH 'node-IP-address'
```

<table>
<thead>
<tr>
<th>network-interface-name</th>
<th>The name you assign to the network interface, where network-interface-name conforms to conventions described in Identifiers.</th>
</tr>
</thead>
<tbody>
<tr>
<td>node-name</td>
<td>The name of the node.</td>
</tr>
<tr>
<td>node-IP-address</td>
<td>The node's IP address, either a public or private IP address. For more information, see Using Public and Private IP Networks.</td>
</tr>
</tbody>
</table>

Privileges

Superuser

Examples

Create a network interface:

```sql
=> CREATE NETWORK INTERFACE mynetwork ON v_vmart_node0001 WITH '123.4.5.6';
```
CREATE NOTIFIER

Creates a push-based notifier to send event notifications and messages out of Vertica.

Syntax

```
CREATE NOTIFIER notifier-name ACTION action-url MAXMEMORYSIZE max-memory-size
... [ [NO] CHECK COMMITTED ]
... [ ENABLE | DISABLE ]
... [ IDENTIFIED BY uuid ]
... [ MAXPAYLOAD max-payload-size ]
... [ PARAMETERS 'adapter-params' ]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>notifier-name</code></td>
<td>This notifier's unique identifier.</td>
</tr>
<tr>
<td><strong>ACTION action-url</strong></td>
<td>Identifies the target Kafka server, where <code>action-url</code> has the following format:</td>
</tr>
<tr>
<td></td>
<td>kafka://kafka-server-ip-address:port-number</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td></td>
<td>kafka://127.0.0.1:9092</td>
</tr>
<tr>
<td><strong>MAXMEMORYSIZE</strong></td>
<td>The maximum size of the internal notifier, up to 2 TB, specified in kilobytes, megabytes,</td>
</tr>
<tr>
<td></td>
<td>gigabytes, or terabytes as follows:</td>
</tr>
<tr>
<td></td>
<td>MAXMEMORYSIZE integer(K</td>
</tr>
<tr>
<td></td>
<td>If the queue exceeds this size, the notifier drops excess messages.</td>
</tr>
<tr>
<td><strong>[NO] CHECK COMMITTED</strong></td>
<td>Specifies to wait for delivery confirmation before sending the next message in the queue.</td>
</tr>
<tr>
<td></td>
<td>Not all messaging systems support delivery confirmation.</td>
</tr>
<tr>
<td>**ENABLE</td>
<td>DISABLE**</td>
</tr>
<tr>
<td></td>
<td>this notifier to ENABLE.</td>
</tr>
<tr>
<td><strong>IDENTIFIED BY uuid</strong></td>
<td>Specifies the notifier's unique identifier. If set, all the</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| MAXPAYLOAD | The maximum size of the message, up to 2 TB, specified in kilobytes, megabytes, gigabytes, or terabytes as follows:
|            | MAXPAYLOAD integer{K|M|G|T}
|            | The default setting is adapter-specific—for example, 1 M for Kafka.
| PARAMETERS 'adapter-params' | Specifies one or more optional adapter parameters that are passed as a string to the adapter. Adapter parameters apply only to the adapter associated with the notifier.
|            | For Kafka notifiers, refer to Kafka and Vertica Configuration Settings.

**Privileges**

Database Administrator

**Examples**

Create a Kafka notifier:

```sql
=> CREATE NOTIFIER my_dc_notifier
    ACTION 'kafka://172.16.20.10:9092'
    MAXMEMORYSIZE '1G'
    IDENTIFIED BY 'f8b0278a-3282-4e1a-9c86-e0f3f042a971'
    NO CHECK COMMITTED;
```

Create a notifier with an adapter-specific parameter:

```sql
=> CREATE NOTIFIER my_notifier
    ACTION 'kafka://127.0.0.1:9092'
    MAXMEMORYSIZE '10M'
    PARAMETERS 'queue.buffering.max.ms=1000';
```

**See Also**

- ALTER NOTIFIER
- DROP NOTIFIER
• Monitoring Vertica Using Notifiers in the Administrator's Guide.

**CREATE PROCEDURE**

Adds an external procedure to Vertica. See Implementing External Procedures in Extending Vertica for more information about external procedures.

**Syntax**

```sql
CREATE PROCEDURE [[database.]schema.]procedure( 
  ... [ argname ] [ argtype [, ... ] ] ) 
  AS 'executable' 
  ... LANGUAGE 'language' 
  ... USER 'OS-user'
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `[database.]schema` | Specifies a schema, by default public. If `schema` is any schema other than public, you must supply the schema name. For example:  
  ```sql
  myschema.thisDbObject
  ```  
  If you specify a database, it must be the current database. |
| `procedure`     | Specifies a name for the external procedure, where `procedure-name` conforms to conventions described in Identifiers. |
| `argname`       | Presents a descriptive argument name to provide a cue to procedure callers. |
| `argtype`       | Specifies the data type for argument(s) that will be passed to the procedure. Argument types must be one of the following Vertica type names: BIGINT, BOOLEAN, DECIMAL, DOUBLE PRECISION, FLOAT, FLOAT8, INT, INT8, INTEGER, MONEY, NUMBER, NUMERIC, REAL, SMALLINT, TINYINT, VARCHAR. |
| `executable`   | Specifies the executable program in the procedures directory. |
### Language

<table>
<thead>
<tr>
<th>Language</th>
<th>Specifies the procedure language. This parameter must be set to EXTERNAL.</th>
</tr>
</thead>
</table>

| USER | Specifies the user executed as. The user is the owner of the file. The external program must allow execute privileges for this user. The user cannot be root. |

### Privileges

CREATE privilege on the schema to contain the procedure.

### System Security

- A procedure file must be owned by the database administrator (OS account) or by a user in the same group as the administrator. (The procedure file owner cannot be root.) The procedure file must also have the set UID attribute enabled, and allow read and execute permission for the group.

- External procedures that you create with `CREATE PROCEDURE` are always run with Linux dbadmin privileges. If a dbadmin or pseudosuperuser grants a non-dbadmin permission to run a procedure using `GRANT (Procedure)`, be aware that the non-dbadmin user runs the procedure with full Linux dbadmin privileges.

### Examples

The following example shows how to create procedure `helloplanet` for external procedure file `helloplanet.sh`. This file accepts one varchar argument.

Create the file:

```bash
#!/bin/bash
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

Create the procedure with the following SQL:

```sql
=> CREATE PROCEDURE helloplanet(arg1 varchar) AS 'helloplanet.sh' LANGUAGE 'external' USER 'dbadmin';
```
CREATE PROFILE

Creates a profile that controls password requirements for users.

Syntax

CREATE PROFILE name LIMIT [ password-parameter setting ]...

password-parameter

PASSWORD_LIFE_TIME
PASSWORD_GRACE_TIME
FAILED_LOGIN_ATTEMPTS
PASSWORD_LOCK_TIME
PASSWORD_REUSE_MAX
PASSWORD_REUSE_TIME
PASSWORD_MAX_LENGTH
PASSWORD_MIN_LENGTH
PASSWORD_MINUTES
PASSWORD_MIN_UPPERCASE_LETTERS
PASSWORD_MIN_LOWERCASE_LETTERS
PASSWORD_MIN_DIGITS
PASSWORD_MIN_SYMBOLS

Parameters

Note: All parameters that are not explicitly set in a new profile are set to default, and inherit their settings from the default profile.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the profile to create, where name conforms to conventions described in Identifiers.</td>
</tr>
<tr>
<td>PASSWORD_LIFE_TIME</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PASSWORD_GRACE_TIME</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• ≥ 1: The number of days a password can be used after it expires.</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: No grace period.</td>
</tr>
<tr>
<td>FAILED_LOGIN_ATTEMPTS</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• ≥ 1: The number of consecutive failed login attempts Vertica allows before locking your account.</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: Vertica allows an unlimited number of failed login attempts.</td>
</tr>
<tr>
<td>PASSWORD_LOCK_TIME</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• ≥ 1: The number of days your account is locked after too many failed login attempts. The account is automatically unlocked when the lock time elapses.</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: Account remains indefinitely inaccessible until a superuser manually unlocks it.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_MAX</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• ≥ 1: The number of times you must change your password before you can reuse an earlier password.</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: You can reuse an earlier password without any intervening changes.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_TIME</td>
<td>Set to an integer value, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• ≥ 1: The number of days that must pass after a password is set before you can reuse it.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PASSWORD_MAX_LENGTH</td>
<td>The maximum number of characters allowed in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 8 and 100, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: Maximum of 100 characters</td>
</tr>
<tr>
<td>PASSWORD_MIN_LENGTH</td>
<td>The minimum number of characters required in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• 0 to PASSWORD_MAX_LENGTH</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: Minimum of PASSWORD_MAX_LENGTH</td>
</tr>
<tr>
<td>PASSWORD_MIN_LETTERS</td>
<td>Minimum number of letters (a-z and A-Z) that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
<tr>
<td>PASSWORD_MIN_UPPERCASE_LETTERS</td>
<td>Minimum number of uppercase letters (A-Z) that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
<tr>
<td>PASSWORD_MIN_LOWERCASE_LETTERS</td>
<td>Minimum number of lowercase letters (a-z) that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
<tr>
<td>PASSWORD_MIN_DIGITS</td>
<td>Minimum number of digits (0-9) that must be in a password, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</td>
</tr>
<tr>
<td></td>
<td>• UNLIMITED: 0 (no minimum)</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| PASSWORD_MIN_SYMBOLS                      | Minimum number of symbols—printable non-letter and non-digit characters such as $, #, @—that must be in a password, one of the following:  
  • Integer between 0 and PASSWORD_MAX_LENGTH, inclusive  
  • UNLIMITED: 0 (no minimum)                                                                                                           |

**Privileges**

Superuser

**Profile Settings and Client Authentication**

The following profile settings affect client authentication methods, such as LDAP or GSS:

- FAILED_LOGIN_ATTEMPTS
- PASSWORD_LOCK_TIME

All other profile settings are used only by Vertica to manage its passwords.

**Example**

```sql
=> CREATE PROFILE sample_profile LIMIT PASSWORD_MAX_LENGTH 20;
```

**See Also**

- ALTER PROFILE
- DROP PROFILE
- Creating a Database Name and Password
CREATE PROJECTION

Creates metadata for a projection in the Vertica catalog.

**Note:** For detailed information about using CREATE PROJECTION to create live aggregate projections and Top-K projections, see CREATE PROJECTION (Live Aggregate Projections). To create live aggregate projections that support user-defined transform functions, see CREATE PROJECTION (UDTFs).

**Syntax**

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection

...[ ( 

........{ projection-col | grouped-clause

........ [ ENCODING encoding-type ]

........ [ ACCESSRANK integer ]

........}[,...]

...)

AS SELECT

...select-list from-clause

...[ ORDER BY column-expr[,...] ]

...[ segmentation-spec ]

...[ KSAFE [ k-num ] ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IF NOT EXISTS</strong></td>
<td>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created. The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does. For related information, see <strong>ON_ERROR_STOP</strong>.</td>
</tr>
<tr>
<td><strong>[database.]schema</strong></td>
<td>Specifies a schema. The projection and its anchor table must be in the same schema. If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>
| **projection** | Identifies the projection to create, where *projection* conforms to conventions described in Identifiers. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema. The projection is created in the same schema as the anchor table.

If the projection is segmented, Vertica uses this string as the projection base name when it creates unique identifiers for buddy projections. For more information, see Projection Naming in the Administrator's Guide. |
|---------------------------------------------------------------|
| **projection-col** | The name of a projection column. The list of projection columns must match the *select-list* columns and expressions in number, type, and sequence.

If projection column names are omitted, Vertica uses the anchor table column names specified in *select-list*. |
| **grouped-clause** | See GROUPED Clause. |
| **ENCODING** **encoding-type** | Specifies the column encoding type, by default set to AUTO. |
| **ACCESSRANK** **integer** | Overrides the default access rank for a column. Use this parameter to increase or decrease the speed at which Vertica accesses a column. For more information, see Overriding Default Column Ranking. |
| **select-list** | Specifies the columns or column expressions to select from one or more tables, one of the following:

- * (asterisk)
  Lists all columns in the queried tables.

- *expression [ [AS] output-name] }[,...]*
  A table column or column expression to select from the queried tables. You can optionally qualify *expression* with an output name, which can be used in two ways:

  - Label the column for display.
  - Refer to the column in the projection's ORDER BY clause. |
| **from-clause** | A comma-separated list of data sources to query. |
| ORDER BY | Specifies columns from the SELECT list on which to sort the projection. The ORDER BY clause cannot include qualifiers ASC or DESC. Vertica always stores projection data in ascending sort order. If you omit the ORDER BY clause, Vertica uses **select-list** to sort the projection. |
| segmentation-spec | Specifies how to distribute projection data with one of the following clauses:  
- **hash-segmentation-clause**: Specifies to segment projection data evenly and distribute across cluster nodes. Vertica recommends segmenting large tables.  
- **unsegmented-clause**: Specifies to create an unsegmented projection.  
If the anchor table and projection both omit specifying segmentation, the projection is defined with a hash segmentation clause that includes all columns in the SELECT list, as follows:  
`SEGMENTED BY HASH(column-expr[,...]) ALL NODES OFFSET 0;` |
| KSAFE `[k-num]` | Specifies K-safety for the projection, where `k-num` must be equal to or greater than system K-safety. Vertica ignores this parameter if set for unsegmented projections. If you omit `k-num`, Vertica uses system K-safety.  
Vertica sets projection K-safety as follows:  
- KSAFE and OFFSET clause omitted: Uses system K-safety.  
- OFFSET clause is omitted and KSAFE is specified: Uses KSAFE setting.  
- KSAFE is omitted and the OFFSET clause is specified: Uses OFFSET setting.  
If the CREATE PROJECTION statement specifies KSAFE and the OFFSET clause, Vertica returns an error. For general information, see K-Safety in Vertica Concepts. |
Privileges

Superuser, or the following:

- Anchor table owner
- CREATE privilege on the schema

Requirements

- To prevent data loss and inconsistencies, tables must have at least one superprojection. You cannot drop a projection if that projection is the table's only superprojection.
- You cannot drop a buddy projection if dropping that projection violates system K-safety.

Creating Projections with Expressions

The following example shows a projection that calculates the product of two numbers. The anchor table is defined as follows:

```sql
=> CREATE TABLE values (a INT, b INT);
```

To create a projection that calculates the product of a and b, use a statement like the following:

```sql
=> CREATE PROJECTION values_product (a, b, product_value) 
  AS SELECT a, b, a*b FROM values 
  SEGMENTED BY HASH(a) ALL NODES KSAFE;
```

To query that projection, you must use the name that Vertica assigned to it:

```sql
=> SELECT * FROM values_product_b0;
```

or

```sql
=> SELECT * FROM values_product_b1;
```
Grouping Correlated Columns

The following example shows how to group highly correlated columns bid and ask. The stock column is stored separately.

```
=> CREATE TABLE trades (stock CHAR(5), bid INT, ask INT);
=> CREATE PROJECTION tradeproj (stock ENCODING RLE,
    GROUPED(bid ENCODING DELTAVAL, ask))
   AS (SELECT * FROM trades) KSAFE 1;
```

The following example shows how to create a projection that uses expressions in the column definition. The projection contains two integer columns a and b, and a third column product_value that stores the product of a and b:

```
=> CREATE TABLE values (a INT, b INT)
=> CREATE PROJECTION product (a, b, product_value) AS
   SELECT a, b, a*b FROM values ORDER BY a KSAFE;
```

Working with Projections

Encoding Types

Vertica supports various encoding and compression types, specified by the following ENCODING parameter arguments:

- AUTO (default)
- BLOCK_DICT
- BLOCKDICT_COMP
- BZIP_COMP
- COMMONDELTA_COMP
- DELTARANGE_COMP
- DELTAVAL
AUTO (default)

AUTO encoding is ideal for sorted, many-valued columns such as primary keys. It is also suitable for general purpose applications for which no other encoding or compression scheme is applicable. Therefore, it serves as the default if no encoding/compression is specified.

<table>
<thead>
<tr>
<th>Column data type</th>
<th>Default encoding type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY/VARBINARY</td>
<td>Lempel-Ziv-Oberhumer-based (LZO) compression</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td></td>
</tr>
<tr>
<td>CHAR/VARCHAR</td>
<td></td>
</tr>
<tr>
<td>FLOAT</td>
<td></td>
</tr>
<tr>
<td>DATE/TIME/TIMESTAMP</td>
<td>Compression scheme based on the delta between consecutive column values.</td>
</tr>
<tr>
<td>INTEGER</td>
<td></td>
</tr>
<tr>
<td>INTERVAL</td>
<td></td>
</tr>
</tbody>
</table>

The CPU requirements for this type are relatively small. In the worst case, data might expand by eight percent (8%) for LZO and twenty percent (20%) for integer data.

BLOCK_DICT

For each block of storage, Vertica compiles distinct column values into a dictionary and then stores the dictionary and a list of indexes to represent the data block.

BLOCK_DICT is ideal for few-valued, unsorted columns where saving space is more important than encoding speed. Certain kinds of data, such as stock prices, are typically few-valued within a localized area after the data is sorted, such as by stock symbol and timestamp, and are good candidates for BLOCK_DICT. By contrast, long CHAR/VARCHAR columns are not good candidates for BLOCK_DICT encoding.

CHAR and VARCHAR columns that contain 0x00 or 0xFF characters should not be encoded with BLOCK_DICT. Also, BINARY/VARBINARY columns do not support BLOCK_DICT encoding.

BLOCK_DICT encoding requires significantly higher CPU usage than default encoding schemes. The maximum data expansion is eight percent (8%).
**BLOCKDICT_COMP**

This encoding type is similar to BLOCK_DICT except dictionary indexes are entropy coded. This encoding type requires significantly more CPU time to encode and decode and has a poorer worst-case performance. However, if the distribution of values is extremely skewed, using BLOCK_DICT_COMP encoding can lead to space savings.

**BZIP_COMP**

BZIP_COMP encoding uses the bzip2 compression algorithm on the block contents. See [bzip](https://bzip.org/) web site for more information. This algorithm results in higher compression than the automatic LZO and gzip encoding; however, it requires more CPU time to compress. This algorithm is best used on large string columns such as VARCHAR, VARBINARY, CHAR, and BINARY. Choose this encoding type when you are willing to trade slower load speeds for higher data compression.

**COMMONDELTA_COMP**

This compression scheme builds a dictionary of all deltas in the block and then stores indexes into the delta dictionary using entropy coding.

This scheme is ideal for sorted FLOAT and INTEGER-based (DATE/TIME/TIMESTAMP/INTERVAL) data columns with predictable sequences and only occasional sequence breaks, such as timestamps recorded at periodic intervals or primary keys. For example, the following sequence compresses well: 300, 600, 900, 1200, 1500, 600, 1200, 1800, 2400. The following sequence does not compress well: 1, 3, 6, 10, 15, 21, 28, 36, 45, 55.

If delta distribution is excellent, columns can be stored in less than one bit per row. However, this scheme is very CPU intensive. If you use this scheme on data with arbitrary deltas, it can cause significant data expansion.

**DELTARANGE_COMP**

This compression scheme is primarily used for floating-point data; it stores each value as a delta from the previous one.

This scheme is ideal for many-valued FLOAT columns that are sorted or confined to a range. Do not use this scheme for unsorted columns that contain NULL values, as the storage cost for representing a NULL value is high. This scheme has a high cost for both compression and decompression.
To determine if DELTARANGE_COMP is suitable for a particular set of data, compare it to other schemes. Be sure to use the same sort order as the projection, and select sample data that will be stored consecutively in the database.

**DELTAVAL**

For INTEGER and DATE/TIME/TIMESTAMP/INTERVAL columns, data is recorded as a difference from the smallest value in the data block. This encoding has no effect on other data types.

DELTAVAL is best used for many-valued, unsorted integer or integer-based columns. CPU requirements for this encoding type are minimal, and data never expands.

**GCDDELTA**

For INTEGER and DATE/TIME/TIMESTAMP/INTERVAL columns, and NUMERIC columns with 18 or fewer digits, data is recorded as the difference from the smallest value in the data block divided by the greatest common divisor (GCD) of all entries in the block. This encoding has no effect on other data types.

ENCODING GCDDELTA is best used for many-valued, unsorted, integer columns or integer-based columns, when the values are a multiple of a common factor. For example, timestamps are stored internally in microseconds, so data that is only precise to the millisecond are all multiples of 1000. The CPU requirements for decoding GCDDELTA encoding are minimal, and the data never expands, but GCDDELTA may take more encoding time than DELTAVAL.

**GZIP_COMP**

This encoding type uses the gzip compression algorithm. See gzip web site for more information. This algorithm results in better compression than the automatic LZO compression, but lower compression than BZIP_COMP. It requires more CPU time to compress than LZO but less CPU time than BZIP_COMP. This algorithm is best used on large string columns such as VARCHAR, VARBINARY, CHAR, and BINARY. Use this encoding when you want a better compression than LZO, but at less CPU time than bzip2.

**RLE**

RLE (run length encoding) replaces sequences (runs) of identical values with a single pair that contains the value and number of occurrences. Therefore, it is best used for low cardinality columns that are present in the ORDER BY clause of a projection.
The Vertica execution engine processes RLE encoding run-by-run and the Vertica optimizer gives it preference. Use it only when run length is large, such as when low-cardinality columns are sorted.

The storage for RLE and AUTO encoding of CHAR/VARCHAR and BINARY/VARBINARY is always the same.

Valid Encoding for Numeric Data Types

- Valid encoding types for numeric data type columns with precision <= 18 include AUTO, BLOCK_DICT, BLOCKDICT_COMP, COMMONDELTA_COMP, DELTAVAL, GCDDELTA, and RLE.
- Valid encoding types for numeric data type columns with precision > 18 include AUTO, BLOCK_DICT, BLOCKDICT_COMP, RLE.
- For information on numeric data types, see the section, Numeric Data Types.

GROUPED Clause

Groups two or more columns into a single disk file. This minimizes file I/O for work loads that:

- Read a large percentage of the columns in a table.
- Perform single row look-ups.
- Query against many small columns.
- Frequently update data in these columns.

If you have data that is always accessed together and it is not used in predicates, you can increase query performance by grouping these columns. Once grouped, queries can no longer independently retrieve from disk all records for an individual column independent of the other columns within the group.

**Note:** RLE encoding is reduced when an RLE column is grouped with one or more non-RLE columns.

When grouping columns you can:

- Group some of the columns:
  
  (a, GROUPED(b, c), d)
• Group all of the columns:

\[(\text{GROUPED}(a, b, c, d))\]

• Create multiple groupings in the same projection:

\[(\text{GROUPED}(a, b), \text{GROUPED}(c, d))\]

**Note:** Vertica performs dynamic column grouping. For example, to provide better read and write efficiency for small loads, Vertica ignores any projection-defined column grouping (or lack thereof) and groups all columns together by default.

## Hash Segmentation Clause

Specifies how to segment projection data for distribution across some or all cluster nodes. You can specify segmentation for a table and a projection. If a table definition specifies segmentation, Vertica uses it for that table's auto-projections.

It is strongly recommended that you use Vertica's built-in **HASH** function, which distributes data evenly across the cluster, and facilitates optimal query execution.

### Syntax

```sql
SEGMEMTED BY expression { ALL NODES [ OFFSET offset ] | NODES node [ ,... ] }
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SEGMENTED BY</strong></td>
<td>A general SQL expression. Hash segmentation is the preferred method of segmentation. Vertica recommends using its built-in <strong>HASH</strong> function, whose arguments resolve to table columns. If you use an expression other than <strong>HASH</strong>, Vertica issues a warning. The segmentation expression should specify columns with a large number of unique data values and acceptable skew in their data distribution. In general, primary key columns that meet these criteria are good candidates for hash segmentation. For details, see <strong>Expression Requirements</strong> below.</td>
</tr>
</tbody>
</table>

**Expression Requirements**

- The expression should specify columns with a large number of unique data values and acceptable skew in their data distribution.
- In general, primary key columns that meet these criteria are good candidates for hash segmentation.
**Expression Requirements**

A segmentation expression must specify table columns as they are defined in the source table. Projection column names are not supported.

The following restrictions apply to segmentation expressions:

- All leaf expressions must be constants or column references to a column in the CREATE PROJECTION's SELECT list.
- The expression must return the same value over the life of the database.
- Aggregate functions are not allowed.
- The expression must return non-negative INTEGER values in the range $0 \leq x < 2^{63}$, and values are generally distributed uniformly over that range.

**Note:** If the expression produces a value outside the expected range—for example, a negative value—no error occurs, and the row is added to the projection's first segment.

**Examples**

The following CREATE PROJECTION statement creates projection `public.employee_dimension_super`. It specifies to include all columns in table `public.employee_dimension`. The hash segmentation clause invokes the Vertica HASH function to segment projection data on the column `employee_key`; it also includes the ALL NODES clause, which specifies to distribute projection data evenly across all nodes in the cluster:
CREATE PROJECTION public.employee_dimension_super
  AS SELECT * FROM public.employee_dimension
  ORDER BY employee_key
  SEGMENTED BY hash(employee_key) ALL NODES;

Unsegmented Clause

Specifies to distribute identical copies of table or projection data across the cluster. Use this clause to facilitate distributed query execution on tables and projections that are too small to benefit from segmentation.

Vertica uses the same name to identify all instances of an unsegmented projection. For more information about projection name conventions, see Projection Naming.

Syntax

UNSEGMENTED {NODE node | ALL NODES}

Parameters

| NODE node | Creates an unsegmented projection only on the specified node node. To obtain a list of all cluster nodes, query the system table V_CATALOG.NODES. |
| ALL NODES | Creates instances of the unsegmented projection on all cluster nodes. You must set this option if projection or system K-safety is greater than 0, otherwise Vertica regards the projection as unsafe and does not use it. |

Example

This example creates an unsegmented projection for table store.store_dimension:

=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
  AS SELECT store_key, store_name, store_city, store_state
  FROM store.store_dimension
  UNSEGMENTED ALL NODES;

CREATE PROJECTION

=> SELECT anchor_table_name anchor_table, projection_name, node_name
  FROM PROJECTIONS WHERE projection_basename='store_dimension_proj';
anchor_table | projection_name | node_name
CREATE PROJECTION (Live Aggregate Projections)

Creates metadata for live aggregate projections in the Vertica catalog. Top-K projections are a type of live aggregate projection.

Information here focuses on creating live aggregate projections. For details about creating other types of projections, including projections with expressions, see CREATE PROJECTION.

Syntax

Grouping aggregate function results

CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
... [ ( 
........{ projection-col | grouped-clause
........ [ ENCODING encoding-type ]
........ [ ACCESSRANK integer ]
........ )[,... ]
... ) ]
... GROUP BY column-expr
... [ KSAFE [ k-num ] ]

Top-K aggregation

CREATE PROJECTION [ IF NOT EXISTS ] projection-name
... [ ( 
........{ projection-col | grouped-clause
........ [ ENCODING encoding-type ]
........ [ ACCESSRANK integer ]
........ ) [,,... ]
...... )
... ]
... LIMIT num-rows OVER (PARTITION BY column-expr ORDER BY column-expr)
... [ KSAFE [ k-num ] ]
**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF NOT EXISTS</td>
<td>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created. The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does. For related information, see ON_ERROR_STOP.</td>
</tr>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema. The projection and its anchor table must be in the same schema. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>projection</td>
<td>Identifies the projection to create, where projection conforms to conventions described in Identifiers. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema. The projection is created in the same schema as the anchor table.</td>
</tr>
<tr>
<td>projection-col</td>
<td>The name of a projection column. If you do not specify projection column names, Vertica uses the anchor table column names in the SELECT statement.</td>
</tr>
<tr>
<td>grouped-clause</td>
<td>See GROUPED Clause.</td>
</tr>
<tr>
<td>ENCODING encoding-type</td>
<td>Specifies the column encoding type, by default set to AUTO.</td>
</tr>
<tr>
<td>ACCESSRANK integer</td>
<td>Overrides the default access rank for a column. Use this parameter to increase or decrease the speed at which Vertica accesses a column. For more information, see Overriding Default Column Ranking.</td>
</tr>
<tr>
<td>table-col expr-with-table-cols</td>
<td>A table column or expression of table columns to be included in the projection. If you specify projection column names, the two lists of projection columns and table columns/expressions must exactly match in number and...</td>
</tr>
</tbody>
</table>
A schema table with the columns to include in the projection, as follows:

```
table-name [ AS ] alias [ ( column-alias [, ...] ) ]
```

One or more column expressions from the SELECT list. The first `column-expr` must be the first column expression in the SELECT list, the second `column-expr` must be the second column expression in the SELECT list, and so on.

The number of rows to return from the specified partition.

Specifies window partitioning by one or more column expressions from the SELECT list. The first `column-expr` is the first column expression in the SELECT list, the second `column-expr` is the second column expression in the SELECT list, and so on.

The order in which the top `k` rows are returned, by default in ascending (ASC) order. All column expressions must be from the SELECT list, where the first `column-expr` must be the first column expression in the SELECT list to follow the last `PARTITION BY` column expression.

Top-K projections support `ORDER BY NULLS FIRST/LAST`.

Specifies K-safety for the projection, where `k-num` must be equal to or greater than system K-safety. Vertica ignores this parameter if set for unsegmented projections. If you omit `k-num`, Vertica uses system K-safety.

Vertica sets projection K-safety as follows:

- **KSAFE and OFFSET clause omitted**: Uses system K-safety.
- **OFFSET clause is omitted and KSAFE is specified**: Uses KSAFE setting.
- **KSAFE is omitted and the OFFSET clause is specified**: Uses OFFSET setting.

If the `CREATE PROJECTION` statement specifies KSAFE and the OFFSET clause, Vertica returns an error.
For general information, see K-Safety in Vertica Concepts.

Privileges

Superuser, or the following:

- Anchor table owner
- CREATE privilege on the schema

Requirements and Restrictions

Examples

See:

- Live Aggregate Projection Example
- Top-K Projection Examples

CREATE PROJECTION (UDTFs)

Creates metadata in the Vertica catalog for projections that invoke user-defined transform functions (UDTFs).

Important: Currently, live aggregate projections can only reference UDTFs that are developed in C++.
Syntax

CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
...[
........{ projection-col | grouped-clause
........ [ ENCODING encoding-type ]
........ [ ACCESSRANK integer ]
........} [, ... ]
...] ]
AS {
........batch-query FROM { prepass-query sq-results | table-ref }
........| prepass-query
...}

batch-query

SELECT { table-column | expr-with-table-cols }[,...], batch-udtf(batch-args)
...OVER (PARTITION BATCH BY partition-col-expr[,...] )
...[ AS (batch-output-cols) ]

prepass-query

SELECT { table-col | expr-with-table-cols }[,...], prepass-udtf(prepass-args)
...OVER (PARTITION PREPASS BY partition-col-expr[,...] )
...[ AS (prepass-output-cols) ] FROM table-ref

Parameters

<table>
<thead>
<tr>
<th>IF NOT EXISTS</th>
<th>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created. The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does. For related information, see ON_ERROR_STOP.</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema. The projection and its anchor table must be in the same schema. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>projection</td>
<td>Identifies the projection to create, where projection</td>
</tr>
</tbody>
</table>
forms to conventions described in Identifiers. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema. The projection is created in the same schema as the anchor table.

**projection-column**

The name of a projection column. If you do not specify projection column names, Vertica uses the anchor table column names that are specified in the SELECT statement.

**grouped-clause**

See GROUPED Clause.

**ENCODING encoding-type**

Specifies the column encoding type, by default set to AUTO.

**ACCESSRANK integer**

Overrides the default access rank for a column. Use this parameter to increase or decrease the speed at which Vertica accesses a column. For more information, see Overriding Default Column Ranking.

**table-col expr-with-table-cols**

A table column or expression of table columns to include in the projection.

**batch-udtf(batch-args)**

The batch UDTF to invoke each time the following events occur:

- Tuple mover mergeout
- Queries on the projection
- If invoked singly, on data load operations

**Important:** If the projection definition includes a pre-pass subquery, **batch-args** must exactly match the pre-pass UDTF output columns, in name and order.

**prepass-udtf (prepass-args)**

The pre-pass UDTF to invoke on each load operation such as COPY or INSERT.

If specified in a subquery, the pre-pass UDTF returns transformed data to the batch query for further processing. Otherwise, the pre-pass query results are added to projection data storage.
OVER (PARTITION BATCH BY partition-col-expr [, ...])

Specifies the UDTF type and how to partition the data it returns:

- BATCH identifies the UDTF as a batch UDTF.
- PREPASS identifies the UDTF as a pre-pass UDTF.

In both cases, the OVER clause specifies partitioning with one or more column expressions from the SELECT list. The first `partition-col-expr` is the first column expression in the SELECT list, the second `partition-col-expr` is the second column expression in the SELECT list, and so on.

**Note:** The projection is implicitly segmented and ordered on PARTITION BY columns.

<table>
<thead>
<tr>
<th><code>AS (batch-output-cols)</code></th>
<th>Optionally names columns that are returned by the UDTF. If a pre-pass subquery omits this clause, the outer batch query UDTF arguments (<code>batch-args</code>) must reference the column names as they are defined in the pre-pass UDTF.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>AS (prepass-output-cols)</code></td>
<td>A schema table with the columns to include in the projection.</td>
</tr>
<tr>
<td><code>table-ref</code></td>
<td>Subquery result set that is returned to the outer batch UDTF.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser, or the following:

- Anchor table owner
- CREATE privilege on the schema
- EXECUTE privileges on all UDTFs that are referenced by the projection
Restrictions

Vertica does not regard live aggregate projections as superprojections, even one that includes all table columns.

UDTF Types

CREATE PROJECTION can define live aggregate projections that invoke user-defined transform functions (UDTFs). Vertica invokes UDFTs at multiple points of projection processing:

- **Pre-pass UDFTs:** Invoked when data is loaded into the projection's anchor table—for example through COPY or INSERT statements. A pre-pass UDTF transforms the new data before it is stored in the projection's ROS containers. You identify a pre-pass UDTF in the projection's PARTITION BY clause, through the keyword PREPASS.

- **Batch UDFTs:** Invoked on three events: the Vertica tuple mover consolidates stored projection data (mergeout); the projection is queried; and if invoked singly, data load operations. In all cases, the UDTF aggregates projection data and stores the aggregated results. Aggregation is cumulative across mergeout and load operations, and is completed (if necessary) on query execution. You identify a batch UDTF in the projection's PARTITION BY clause, through the keyword BATCH.

Vertica stores all UDTF results in projection ROS containers, thereby enabling faster response time when you query the projection.

UDTF Specification Options

A projection definition can specify up to two UDFTs, in any of the following ways:

- **Single pre-pass UDTF:** The pre-pass UDTF transforms newly loaded data and stores it in the projection. Use the following syntax:

  ```sql
  => CREATE PROJECTION projection-name AS SELECT ..., udtf(args)
     OVER(PARTITION PREPASS BY partition-cols) AS (prepass-output-columns) FROM table-ref;
  ```

- **Single batch UDTF:** The batch UDTF transforms and aggregates projection data on mergeout, insert, and query operations. Use the following syntax:
CREATE PROJECTION projection-name AS SELECT ..., udtf(args)
    OVER(PARTITION BATCH BY partition-cols) AS (batch-output-columns) FROM table-ref;

- **Pre-pass and batch UDTFs**: You can define a projection with a subquery that invokes a pre-pass UDTF. The pre-pass UDTF returns transformed data to the top-level batch query. The batch UDTF then iteratively aggregates all projection data.

Use the following syntax:

CREATE PROJECTION projection-name AS SELECT ..., batch-udtf(batch-args)
    OVER ( PARTITION BATCH BY partition-cols ) AS (batch-output-columns)
FROM ( SELECT ..., prepass-udtf(prepass-args)
    OVER ( PARTITION PREPASS BY partition-cols ) AS (prepass-output-columns)
    FROM table-ref ) sq-ref;

**Examples**

See Examples in Pre-Aggregating UDTF Results.

**See Also**

Pre-Aggregating UDTF Results

### CREATE RESOURCE POOL

Creates a custom resource pool and sets one or more resource pool parameters.

**Syntax**

CREATE RESOURCE POOL pool-name [ parameter-name setting ]...

**Parameters**

**Note**: You can set all resource pool parameters to their DEFAULT value. The V_CATALOG.RESOURCE_POOL_DEFAULTS system table contains default parameter values.
Query this table to determine default settings for all resource pools.

Default values specified in this table pertain only to user-defined resource pools. For built-in pool default values, see Built-In Pool Configuration.

<table>
<thead>
<tr>
<th>pool-name</th>
<th>The name of the resource pool. Built-in pool names cannot be used for user-defined pools.</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameter-name</td>
<td>The parameter to set, listed below.</td>
</tr>
<tr>
<td>CASCADE TO</td>
<td>Specifies a secondary resource pool for executing queries that exceed the RUNTIMECAP setting of their assigned resource pool:</td>
</tr>
<tr>
<td></td>
<td>CASCADE TO secondary-pool</td>
</tr>
<tr>
<td>CPUAFFINITYMODE</td>
<td>Specifies whether the resource pool has exclusive or shared use of the CPUs specified in CPUAFFINITYSET:</td>
</tr>
<tr>
<td></td>
<td>CPUAFFINITYMODE {</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>• SHARED: Queries that run in this pool share its CPUAFFINITYSET CPUs with other Vertica resource pools.</td>
</tr>
<tr>
<td></td>
<td>• EXCLUSIVE: Dedicates CPUAFFINITYSET CPUs to this resource pool only, and excludes other Vertica resource pools. If CPUAFFINITYSET is set as a percentage, then that percentage of CPU resources available to Vertica is assigned solely for this resource pool.</td>
</tr>
<tr>
<td></td>
<td>• ANY (default): Queries in this resource pool can run on any CPU, invalid if CPUAFFINITYSET designates CPU resources.</td>
</tr>
<tr>
<td>CPUAFFINITYSET</td>
<td>Specifies which CPUs are available to this resource pool. All cluster nodes must have the same number of CPUs. The CPU resources assigned to this set are unavailable to general resource pools.</td>
</tr>
<tr>
<td></td>
<td>CPUAFFINITYSET {</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>cpu-index[, ...]: Dedicates one or more comma-delimited CPUs to this pool.</td>
<td></td>
</tr>
<tr>
<td>cpu-index_i-cpu-index_n: Dedications a range of contiguous CPU indexes to this pool</td>
<td></td>
</tr>
<tr>
<td>integer%: Percentage of all available CPUs to use for this pool. Vertica rounds this percentage down to include whole CPU units.</td>
<td></td>
</tr>
<tr>
<td>NONE (default): No affinity set is assigned to this resource pool. The queries associated with this pool are executed on any CPU.</td>
<td></td>
</tr>
</tbody>
</table>

**EXECUTIONPARALLELISM**

Limits the number of threads used to process any single query issued in this resource pool.

EXECUTIONPARALLELISM { integer | AUTO }

- **integer**: A value between 1 and the number of cores. Setting this parameter to a reduced value increases throughput of short queries issued in the pool, especially if the queries are executed concurrently.

- **AUTO** (default): Vertica sets this value based on the number of cores, available memory, and amount of data in the system. Unless memory is limited, or the amount of data is very small, Vertica sets this value to the number of cores on the node.

**MAXCONCURRENcy**

Sets the maximum number of concurrent execution slots available to the resource pool, across the cluster:

MAXCONCURRENcy { integer | NONE }

NONE (default) specifies unlimited number of concurrent execution slots.

**MAXMEMORYSIZE**

The maximum size per node the resource pool can grow by borrowing memory from the GENERAL pool:

MAXMEMORYSIZE { 'integer%' }
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORYSIZE</td>
<td>The amount of total memory available to the Vertica resource manager that is allocated to this pool per node:</td>
</tr>
<tr>
<td></td>
<td>MEMORYSIZE {</td>
</tr>
<tr>
<td></td>
<td>'integer%'</td>
</tr>
<tr>
<td></td>
<td>'integer{K</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>• <em>integer%</em>: Percentage of total memory</td>
</tr>
<tr>
<td></td>
<td>• *integer{K</td>
</tr>
<tr>
<td></td>
<td>• NONE: Unlimited; pool can borrow any amount of available memory from the GENERAL pool.</td>
</tr>
<tr>
<td>PLANNEDCONCURRENCY</td>
<td>Specifies the preferred number queries to execute concurrently in the resource pool. This setting applies to the entire cluster:</td>
</tr>
<tr>
<td></td>
<td>PLANNEDCONCURRENCY { <em>integer</em></td>
</tr>
<tr>
<td></td>
<td>• <em>integer</em>: The preferred number of concurrently executing queries. When possible, query resource budgets are limited to allow this level of concurrent execution.</td>
</tr>
<tr>
<td></td>
<td>• AUTO (default): Value is calculated automatically at query runtime. Vertica sets this parameter to the lower of these two calculations, but never less than 4:</td>
</tr>
<tr>
<td></td>
<td>■ Number of logical cores</td>
</tr>
<tr>
<td></td>
<td>■ Memory divided by 2GB</td>
</tr>
</tbody>
</table>
For clusters where the number of logical cores differs on different nodes, AUTO can apply differently on each node. Distributed queries run like the minimal effective planned concurrency. Single node queries run with the planned concurrency of the initiator.

**Tip:** Change this parameter only after evaluating performance over a period of time.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PRIORITY</strong></td>
<td>Specifies priority of queries in this pool when they compete for resources in the GENERAL pool:</td>
</tr>
<tr>
<td></td>
<td>`PRIORITY { integer</td>
</tr>
<tr>
<td></td>
<td>• <code>integer</code>: A negative or positive integer value, where higher numbers denote higher priority:</td>
</tr>
<tr>
<td></td>
<td>- User-defined pools: -100 to 100</td>
</tr>
<tr>
<td></td>
<td>- Built-in pools SYSQUERY, RECOVERY, and TM: -110 to 110</td>
</tr>
<tr>
<td></td>
<td>• <code>HOLD</code>: Sets priority to -999. Queries in this pool are queued until QUEUETIMEOUT is reached.</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: 0</td>
</tr>
<tr>
<td><strong>QUEUETIMEOUT</strong></td>
<td>Species how long a request can wait for pool resources before it is rejected:</td>
</tr>
<tr>
<td></td>
<td>`QUEUETIMEOUT { integer</td>
</tr>
<tr>
<td></td>
<td>• <code>integer</code>: Maximum wait time in seconds</td>
</tr>
<tr>
<td></td>
<td>• <code>NONE</code>: No maximum wait time, request can be queued indefinitely.</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: 300 seconds</td>
</tr>
<tr>
<td><strong>RUNTIMECAP</strong></td>
<td>Prevents runaway queries by setting the maximum time a query in the pool can execute. If a query exceeds this setting, it tries to cascade to a secondary pool:</td>
</tr>
<tr>
<td></td>
<td>`RUNTIMECAP { interval</td>
</tr>
<tr>
<td></td>
<td>• <code>interval</code>: An interval of 1 minute or 100 seconds; should not exceed one year.</td>
</tr>
</tbody>
</table>
• NONE: No time limit on queries running in this pool.

   To specify a value in days, provide an integer value. To provide a value less than one day, provide the interval in the format hours:minutes:seconds. For example a value of 1:30:00 would equal 90 minutes.

   If the user or session also has a RUNTIMECAP, the shorter limit applies.

<table>
<thead>
<tr>
<th>RUNTIMEPRIORITYTHRESHOLD</th>
<th>Specifies in seconds a time limit in which a query must finish before the resource manager assigns to it the resource pool's RUNTIMEPRIORITY. All queries begin running at a HIGH priority. When a query's duration exceeds this threshold, it is assigned the RUNTIMEPRIORITY of the resource pool.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RUNTIMEPRIORITYTHRESHOLD seconds</td>
</tr>
<tr>
<td></td>
<td>Default: 2</td>
</tr>
</tbody>
</table>

Privileges
Superuser

Examples
This example shows how to create a resource pool with MEMORYSIZE of 1800 MB.

```sql
=> CREATE RESOURCE POOL ceo_pool MEMORYSIZE '1800M' PRIORITY 10;
CREATE RESOURCE POOL
```

Assuming the CEO report user already exists, associate this user with the preceding resource pool using ALTER USER statement.
GRANT USAGE ON RESOURCE POOL ceo_pool to ceo_user;
GRANT PRIVILEGE ALTER USER ceo_user RESOURCE POOL ceo_pool;
ALTER USER ceo_user RESOURCE POOL ceo_pool;

Issue the following command to confirm that the ceo_user is associated with the ceo_pool:

```
=> SELECT * FROM users WHERE user_name = 'ceo_user';
```

<table>
<thead>
<tr>
<th>user_id</th>
<th>45035996273733402</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_name</td>
<td>ceo_user</td>
</tr>
<tr>
<td>is_super_user</td>
<td>f</td>
</tr>
<tr>
<td>profile_name</td>
<td>default</td>
</tr>
<tr>
<td>is_locked</td>
<td>f</td>
</tr>
<tr>
<td>lock_time</td>
<td></td>
</tr>
<tr>
<td>resource_pool</td>
<td>ceo_pool</td>
</tr>
<tr>
<td>memory_cap_kb</td>
<td>unlimited</td>
</tr>
<tr>
<td>temp_space_cap_kb</td>
<td>unlimited</td>
</tr>
<tr>
<td>run_time_cap</td>
<td>unlimited</td>
</tr>
<tr>
<td>all_roles</td>
<td></td>
</tr>
<tr>
<td>default_roles</td>
<td>&quot;$user&quot;, public, v_catalog, v_monitor, v_internal</td>
</tr>
</tbody>
</table>

This example shows how to create and designate secondary resource pools.

```
=> CREATE RESOURCE POOL rp3 RUNTIMECAP '5 minutes';
=> CREATE RESOURCE POOL rp2 RUNTIMECAP '3 minutes' CASCADE TO rp3;
=> CREATE RESOURCE POOL rp1 RUNTIMECAP '1 minute' CASCADE TO rp2;
=> SET SESSION RESOURCE_POOL = rp1;
```

**Built-In Pools**

Vertica is preconfigured with built-in pools for various system tasks:
Built-in pools can be customized to suit your usage requirements. See `ALTER RESOURCE POOL` for details on resource pool settings.

**GENERAL**

A special, catch-all pool used to answer requests that have no specific resource pool associated with them. Any memory left over after memory has been allocated to all other pools is automatically allocated to the GENERAL pool. The `MEMORYSIZE` parameter of the GENERAL pool is undefined (variable), however, the GENERAL pool must be at least 1GB in size and cannot be smaller than 25% of the memory in the system.

The `MAXMEMORYSIZE` parameter of the GENERAL pool has special meaning; when set as a % value it represents the percent of total physical RAM on the machine that the Resource Manager can use for queries. By default, it is set to 95%. The GENERAL.MAXMEMORYSIZE governs the total amount of RAM that the Resource Manager can use for queries, regardless of whether it is set to a percent or to a specific value (for example, '10GB')

User-defined pools can borrow memory from the GENERAL pool to satisfy requests that need extra memory until the MAXMEMORYSIZE parameter of that pool is reached. If the pool is configured to have MEMORYSIZE equal to MAXMEMORYSIZE, it cannot borrow any memory from the GENERAL pool and is said to be a standalone resource pool. When multiple pools request memory from the GENERAL pool, they are granted access to general pool memory.
according to their priority setting. In this manner, the GENERAL pool provides some elasticity to account for point-in-time deviations from normal usage of individual resource pools.

Vertica recommends reducing the GENERAL pool MAXMEMORYSIZE if your catalog uses over 5% of overall memory.

**BLOBDATA**

The BLOBDATA pool controls resource usage for in-memory blobs. *In-memory blobs* are objects used by a number of the machine learning SQL functions. You should adjust this pool if you plan on processing large machine learning workloads. For information about tuning the pool, see Tuning for Machine Learning.

If a query using the BLOBDATA pool exceeds its query planning budget, then it spills to disk. For more information about tuning your query budget, see Target Memory Determination for Queries in Concurrent Environments.

**DBD**

The DBD pool controls resource usage for Database Designer processing. Use of this pool is enabled by configuration parameter `DBDUseOnlyDesignerResourcePool`, by default set to false.

By default, `QUEUETIMEOUT` is set to 0 for this pool. When resources are under pressure, this setting causes the DBD to time out immediately, and not be queued to run later. Database Designer then requests the user to run the designer later, when resources are more available.

![Important: Do not change QUEUETIMEOUT or other DBD pool settings.](image)

**JVM**

The JVM pool controls Java Virtual Machine resources used by Java User Defined Extensions. When a Java UDx starts the JVM, it draws resources from the those specified in the JVM resource pool. Vertica does not reserve memory in advance for the JVM pool. When needed, the pool can expand to 10% of physical memory or 2 GB of memory, whichever is smaller. If you are buffering large amounts of data, you may need to increase the size of the JVM resource pool.

You can adjust the size of your JVM resource pool by changing its configuration settings. Unlike other resource pools, the JVM resource pool does not release resources until a session is closed.
METADATA

The pool that tracks memory allocated for catalog data and storage data structures. This pool increases in size as Vertica metadata consumes additional resources. Memory assigned to the METADATA pool is subtracted from the GENERAL pool, enabling the Vertica resource manager to make more effective use of available resources. If the METADATA resource pool reaches 75% of the GENERAL pool, Vertica stops updating METADATA memory size and displays a warning message in the vertica.log file. You can enable or disable the METADATA pool with the EnableMetadataMemoryTracking general parameter.

If you have created a "dummy" or "swap" resource pool to protect resources for use by your operating system, you can replace that pool with the METADATA pool.

Users cannot change the parameters of the METADATA resource pool.

RECOVERY

The pool used by queries issued when recovering another node of the database. The MAXCONCURRENCY parameter is used to determine how many concurrent recovery threads to use. You can use the PLANNEDCONCURRENCY parameter (by default, set to twice the MAXCONCURRENCY) to tune how to apportion memory to recovery queries.

See Tuning for Recovery in the Administrator's Guide.

REFRESH

The pool used by queries issued by PROJECTION_REFRESHES operations. Refresh does not currently use multiple concurrent threads; thus, changes to the MAXCONCURRENCY values have no effect.

See Scenario: Tuning for Refresh in the Administrator's Guide.

SYSDATA

The pool reserved for temporary storage of intermediate results of queries against system monitoring and catalog tables. If the SYSDATA pool size is too low, Vertica cannot execute queries for large system tables or during high concurrent access to system tables.

Note: MAXMEMORYSIZE of the SYSDATA pool cannot be changed if any of its memory is in use.
SYSQUERY

The pool that runs queries against system monitoring and catalog tables. The SYSQUERY pool reserves resources for system table queries so that they are never blocked by contention for available resources.

TM

The Tuple Mover (TM) pool. You can set the MAXCONCURRENCY parameter for the TM pool to allow more than one concurrent TM operation to occur.

See Tuning Tuple Mover Pool Settings in the Administrator's Guide.

WOSDATA

The Write Optimized Store (WOS) resource pool. Data loads to the WOS automatically spill to the ROS once it exceeds a certain amount of WOS usage; the PLANNEDCONCURRENCY parameter of the WOS is used to determine this spill threshold. For instance, if PLANNEDCONCURRENCY of the WOSDATA pool is set to 4, once a load has occupied one quarter of the WOS, it spills to the ROS.

The WOSDATA pool is limited to a size of 2GB or 25% of the GENERAL pool's limits, whichever is less. However, when the GENERAL pool has a limit of 20GB or higher, the WOSDATA pool will instead have 2GB of dedicated memory.

Note: MAXMEMORYSIZE of the WOSDATA pool cannot be changed if any of its memory is in use. For example, you cannot change MAXMEMORYSIZE unless you first disable trickle loading jobs and wait until the WOS is empty.

See Scenario: Tuning for Continuous Load and Query in the Administrator's Guide.

Built-In Pool Configuration

The tables in this section list the default configuration settings for the Vertica built-in resource pools:

- GENERAL
- BLOBDATA
Some built-in resource pool parameter values have restrictions, which are noted in the tables. For guidance about how to tune the General resource pool, see *Best Practices for Managing Workload Resources* in the Administrator's Guide.

## GENERAL

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORYSIZE</td>
<td>N/A (cannot be set)</td>
</tr>
</tbody>
</table>
| MAXMEMORYSIZE  | Sets the maximum memory to use for all resource pools. Specify this value as a percentage of total RAM. For example, if your node has 64GB of memory, setting MAXMEMORYSIZE to 50% allocates half of the available memory. The total memory for all resource pools cannot exceed 32GB. Setting this parameter to 100% generates warning messages that swapping could result. Changing the MAXMEMORYSIZE parameter has the following restrictions:  
  - Must be 1GB or greater.  
  - Cannot be less than 25% of total system RAM. |
<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Setting</strong></td>
<td><strong>Value</strong></td>
</tr>
<tr>
<td></td>
<td>Default: 95%, with minimum of 25% (at least 1GB), maximum 100%</td>
</tr>
<tr>
<td>PRIORITY</td>
<td>0</td>
</tr>
<tr>
<td>RUNTIMEPRIORITY</td>
<td>Medium</td>

</tr>
<tr>
<td>RUNTIMECAP</td>
<td>NONE</td>
</tr>
</tbody>
</table>
| PLANNEDCONCURRENCY          | An integer representing the number of concurrent queries you expect to run against the resource pool. When set to the default value of AUTO, Vertica automatically sets PLANNEDCONCURRENCY at query runtime, choosing the lower of these two values:  
  - Number of cores  
  - Memory/2GB  
  
The value 4 is the minimum value for PLANNEDCONCURRENCY.  
For systems with a large number of cores, the PLANNEDCONCURRENCY setting for the GENERAL pool defaults to a value that is too low. For this configuration, Vertica recommends adjusting to a value equaling the number of cores:  
  ALTER RESOURCE POOL general PLANNEDCONCURRENCY <#cores>;  
**Default**: AUTO |
| MAXCONCURRENCY              | Unlimited  
Restrictions: Setting to 0 generates warnings that no system queries may be able to run in the system.                                                                 |
| SINGLEINITIATOR             | False. This parameter is included for backwards compatibility only. Do not change the value.                                           |

<td>Restrictions: cannot set to &lt; 25%.</td>
<td></td>
</tr>
<tr>
<td>EXECUTIONPARALLELISM</td>
<td>AUTO</td>
</tr>
<tr>
<td>PRIORITY</td>
<td>107</td>
</tr>
<tr>
<td>RUNTIMEPRIORITY</td>
<td>MEDIUM</td>
</tr>
</tbody>
</table>
### Setting | Value
--- | ---
RUNTIMEPRIORITYTHRESHOLD | 60
QUEUETIMEOUT | 300
RUNTIMECAP | NONE
PLANNEDCONCURRENCY | Twice MAXCONCURRENCY
MAXCONCURRENCY | \((\text{# of cores} / 2) + 1\)
Restrictions: Cannot set to 0 or NONE (unlimited)
SINGLEINITIATOR | True. This parameter is included for backwards compatibility. Do not change the value.

### REFRESH

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORYSIZE</td>
<td>0%</td>
</tr>
<tr>
<td>MAXMEMORYSIZE</td>
<td>Unlimited</td>
</tr>
<tr>
<td>EXECUTIONPARALLELISM</td>
<td>AUTO</td>
</tr>
<tr>
<td>PRIORITY</td>
<td>-10</td>
</tr>
<tr>
<td>RUNTIMEPRIORITY</td>

## CREATE ROLE

Creates a role. After creating a role, use **GRANT statements** to specify role permissions.

### Syntax

```
CREATE ROLE role
```

### Parameters

| role | The name for the new role, where `role` conforms to conventions described in **Identifiers**. |

### Privileges

Superuser

### Examples

This example shows to create an empty role called `roleA`.

```sql
=> CREATE ROLE roleA;
CREATE ROLE
```
See Also

- ALTER ROLE RENAME
- DROP ROLE

**CREATE SCHEMA**

Defines a schema.

**Syntax**

```sql
CREATE SCHEMA [ IF NOT EXISTS ] [ database. ] schema
... [ AUTHORIZATION username]
... [ DEFAULT { INCLUDE | EXCLUDE } [ SCHEMA ] PRIVILEGES ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF NOT EXISTS</td>
<td>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created. The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does. For related information, see ON_ERROR_STOP.</td>
</tr>
<tr>
<td>[ database. ] schema</td>
<td>Identifies the schema to create, where schema conforms to conventions described in Identifiers. This name must be unique among all other schema names in the database. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>AUTHORIZATION username</td>
<td>Assigns ownership of the schema to a user. If a user name is not provided, the user who creates the schema is assigned ownership. Only superusers can create a schema that is</td>
</tr>
</tbody>
</table>
DEFAULT
{INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES

Specifies whether to enable or disable inheritance of privileges for tables in the schema. INCLUDE PRIVILEGES grants the tables in the schema the same privileges granted to the schema.

If you omit INCLUDE PRIVILEGES, you must grant privileges individually for each table in the schema.

For more information see Grant Inherited Privileges.

### Privileges

- Superuser
- **CREATE privilege for the database**

Optionally, **CREATE SCHEMA** can include the following sub-statements to create tables within the schema:

- **CREATE TABLE**
- **GRANT Statements**

These sub-statements are treated as if they were entered as individual commands after **CREATE SCHEMA** executes. The following exceptions apply:

- The AUTHORIZATION statement indicates all tables are owned by the specified user.
- **CREATE SCHEMA** statement and all associated sub-statements are treated as a single transaction. If any statement fails, Vertica rolls back the entire **CREATE SCHEMA** statement.

### Examples

The following example creates a schema named s1 with no objects.

```
=> CREATE SCHEMA s1;
```

The following command creates schema s2 if it does not already exist:

```
=> CREATE SCHEMA IF NOT EXISTS schema2;
```
If the schema already exists, Vertica returns a rollback message:

```sql
=> CREATE SCHEMA IF NOT EXISTS schema2;
NOTICE 4214: Object "schema2" already exists; nothing was done
```

The following series of commands create a schema named s1 with a table named t1 and grants Fred and Aniket access to all existing tables and ALL privileges on table t1:

```sql
=> CREATE SCHEMA s1;
=> CREATE TABLE t1 (c INT);
=> GRANT USAGE ON SCHEMA s1 TO Fred, Aniket;
=> GRANT ALL ON TABLE t1 TO Fred, Aniket;
```

This example sets the default behavior for new table t2 to automatically inherit the schema's privileges:

```sql
=> CREATE SCHEMA s1 DEFAULT INCLUDE SCHEMA PRIVILEGES;
=> CREATE TABLE s1.t2(i INT);
```

This example sets the default for new tables to not automatically inherit privileges from the schema:

```sql
=> CREATE SCHEMA s2 DEFAULT EXCLUDE SCHEMA PRIVILEGES;
```

See Also

- ALTER SCHEMA
- SET SEARCH_PATH
- DROP SCHEMA

**CREATE SEQUENCE**

Defines a new named sequence number generator object. Along with AUTO_INCREMENT and IDENTITY sequences, you can use named sequences to set the default values of primary key columns. Sequences guarantee uniqueness, and avoid constraint enforcement problems and overhead. For more information about sequence types and their usage, see Sequence Types in the Administrator's Guide.
Syntax

CREATE SEQUENCE [[\textit{database}\textperiodcentered}\textit{schema}\textperiodcentered]\textit{sequence} ...
[ \textit{INCREMENT} \text{BY} \ \textit{integer} ] ...
[ MINVALUE \ \textit{integer} \ | \ \text{NO} \ MINVALUE ] ...
[ MAXVALUE \ \textit{maxvalue} \ | \ \text{NO} \ MAXVALUE ] ...
[ \text{START} \ \text{WITH} \ \textit{integer} ] ...
[ \textit{CACHE} \ | \ \text{NO} \ \text{CACHE} ] ...
[ CYCLE \ | \ \text{NO} \ CYCLE ]

Parameters

<table>
<thead>
<tr>
<th>[\textit{database}\textperiodcentered]\textit{schema}</th>
<th>\textbf{Specifies a schema}, by default public. If \textit{schema} is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>\textit{myschema.thisDbObject}</td>
</tr>
<tr>
<td>If you specify a database, it must be the current database.</td>
<td></td>
</tr>
<tr>
<td>\textit{sequence}</td>
<td>Identifies the sequence to create, where \textit{sequence-name} conforms to conventions described in \texttt{Identifiers}. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</td>
</tr>
<tr>
<td>\texttt{INCREMENT [BY] } \textit{integer}</td>
<td>A positive or negative integer that specifies how much to increment or decrement the sequence on each call to \texttt{NEXTVAL}, by default set to 1.</td>
</tr>
<tr>
<td>\texttt{Note: Setting this parameter to } \textit{integer} \texttt{guarantees that column values always increment by at least } \textit{integer}. However, column values can sometimes increment by more than \textit{integer} unless you also set the \text{NO} \ \text{CACHE} parameter.</td>
<td></td>
</tr>
<tr>
<td>\texttt{MINVALUE } \textit{integer} \text{NO MINVALUE (default)}</td>
<td>Determines the minimum value a sequence can generate. If you omit this clause or specify NO MINVALUE, default values are used: 1 and \text{2}^{63}-1 for ascending and descending sequences, respectively.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>\texttt{MAXVALUE } \textit{integer} \text{NO MAXVALUE (default)}</td>
<td>Determines the maximum value for the sequence. If you omit this clause or specify NO MAXVALUE, default values are used: \text{2}^{63}-1 and -1 for ascending and descending sequences, respectively.</td>
</tr>
<tr>
<td>Clause</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>START [WITH] integer</td>
<td>Sets the sequence start value to <code>integer</code>. The next call to <code>NEXTVAL</code> returns <code>integer</code>. If you omit this clause, the sequence start value is set to MINVALUE for ascending sequences, and MAXVALUE for descending sequences.</td>
</tr>
</tbody>
</table>
| CACHE integer NO CACHE | Specifies whether to cache unique sequence numbers on each node for faster access. `CACHE` takes an integer argument as follows:  
  - >1 specifies how many unique numbers each node caches per session.  
  - 0 or 1 specifies to disable caching (equivalent to NO CACHE).  
If you omit this clause, the sequence cache is set to 250,000. For details, see Sequence Caching in the Administrator's Guide. |
| CYCLE NO CYCLE (default) | Specifies whether the sequence can wrap when its minimum or maximum values are reached:  
  - CYCLE: The sequence wraps as follows:  
    - When an incrementing sequence reaches its upper limit, it is reset to its minimum value.  
    - When a decrementing sequence reaches its lower limit, it is reset to its maximum value.  
  - NO CYCLE (default): Calls to `NEXTVAL` return an error after the sequence reaches its maximum or minimum value. |

**Privileges**

Superuser, or user with CREATE privilege on the sequence schema.

For details on privileges required to use and manage sequence, see Named Sequence Privileges in the Administrator's Guide.

**Examples**

See Also

- AUTO_INCREMENT and IDENTITY Sequences in the Administrator's Guide
- ALTER SEQUENCE
- DROP SEQUENCE

**CREATE SUBNET**

Identifies the subnet to which the nodes of a Vertica database belong. Use this statement to configure import/export from a database to other Vertica clusters.

**Syntax**

```
CREATE SUBNET subnet-name WITH 'subnet-prefix'
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>subnet-name</code></td>
<td>A name you assign to the subnet, where <code>subnet-name</code> conforms to conventions described in Identifiers.</td>
</tr>
<tr>
<td><code>subnet-prefix</code></td>
<td>The routing prefix expressed in quad-dotted decimal representation. Refer to system table NETWORK_INTERFACES to get the prefix of all available IP networks.</td>
</tr>
</tbody>
</table>

You can then configure the database to use the subnet for import/export. For details, see Identify the Database or Nodes Used for Import/Export in the Administrator's Guide.

**Privileges**

dbadmin
Examples

=> CREATE SUBNET mySubnet WITH '123.4.5.6';

**CREATE TABLE**

Creates a table in the logical schema.

**Syntax**

**Create with column definitions**

```
CREATE TABLE [ IF NOT EXISTS ] [ [[database.]schema.]table
... ( column-definition[, ... ] )
... [ table-constraint ]
... [ load-method ]
... [ ORDER BY column[, ... ] ]
... [ segmentation-spec ]
... [ KSAFE [ k-num ] ]
... [ partition-clause ]
... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
```

**Create from another table**

```
CREATE TABLE [ IF NOT EXISTS ] [ [[database.]schema.]table ( AS-clause | LIKE-clause )
```

**AS-clause**

```
... [ ( column-name-list ) ]
... [ load-method ]
... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
AS [ /*+ hint[, hint] */ ] [ AT epoch ] query [ ENCODED BY column-ref-list ]
```

**LIKE-clause**

```
LIKE [[database.]schema.]existing-table
...[ {INCLUDING | EXCLUDING} PROJECTIONS ]
...[ load-method ]
...[ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
```

**Parameters**

| **IF NOT EXISTS** | Specifies to generate an informational message if an object |
already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created.

The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does.

For related information, see **ON_ERROR_STOP**.

<table>
<thead>
<tr>
<th><strong>[database.]schema</strong></th>
<th>Specifies a schema, by default public. If <em>schema</em> is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>

| **table** | Identifies the table to create, where *table* conforms to conventions described in **Identifiers**. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema. |

| **column-definition** | Defines a table column. A table can have up to 1600 columns.                                           |

| **table-constraint**  | Adds a constraint to table metadata.                                                                      |

<table>
<thead>
<tr>
<th><strong>load-method</strong></th>
<th>Specifies default load behavior for all DML operations on this table, such as INSERT and COPY, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- AUTO (default): Initially loads data into WOS, suitable for smaller bulk loads.</td>
</tr>
<tr>
<td></td>
<td>- DIRECT: Loads data directly into ROS containers, suitable for large (&gt;100 MB) bulk loads.</td>
</tr>
<tr>
<td></td>
<td>- TRICKLE: Loads data only into WOS, suitable for frequent incremental loads.</td>
</tr>
</tbody>
</table>

For details, see **Choosing a Load Method** in the Administrator's Guide.

| **ORDER BY column [,...]** | Specifies columns from the SELECT list on which to sort the superprojection that is automatically created for this table. The ORDER BY clause cannot include qualifiers ASC or DESC. Vertica always stores projection data in ascending sort order. |
If you omit the ORDER BY clause, Vertica uses the SELECT list order as the projection sort order. This option is invalid for external tables.

### segmentation-spec

**Invalid for external tables**, specifies how to distribute data for auto-projections of this table. Supply one of the following clauses:

- **hash-segmentation-clause**: Specifies to segment data evenly and distribute across cluster nodes. Vertica recommends segmenting large tables. For details, see Hash Segmentation Clause.

- **unsegmented-clause**: Specifies to create an unsegmented projection. For details, see Unsegmented Clause.

If this clause is omitted, Vertica generates auto-projections with default hash segmentation.

### KSAFE \([k\text{-num}]\)

Specifies K-safety of auto-projections created for this table, where \(k\text{-num}\) must be equal to or greater than system K-safety. If you omit this option, the projection uses the system K-safety level. For general information, see K-Safety in Vertica Concepts.

**Note:** This option is invalid for external tables.

### partition-clause

Logically divides table data storage through a PARTITION BY clause:

```
PARTITION BY partition-expression [ GROUP BY group-expression ]
```

For details, see Partition Clause.

This option is invalid for external tables.

### column-name-list

Valid only when creating a table from a query (AS **query**), defines column names that map to the query output. If you omit this list, Vertica uses the query output column names. The names in **column-name-list** and queried columns must be the same in number.

For example:

```
CREATE TABLE customer_occupations (name, profession)
AS SELECT customer_name, occupation FROM customer_dimension;
```
This clause and the ENCODED BY clause are mutually exclusive. Column name lists are invalid for external tables.

### { INCLUDE | EXCLUDE } [SCHEMA] PRIVILEGES

Specifies default inheritance of schema privileges for this table:

- **EXCLUDE [SCHEMA] PRIVILEGES** (default) disables inheritance of privileges from the schema
- **INCLUDE [SCHEMA] PRIVILEGES** grants the table the same privileges granted to its schema

For more information see [Grant Inherited Privileges](#).

### AS *query*

Creates and loads a table from the results of a query, specified as follows:

```sql
AS [ /*+hint[, hint]*/ ] [ AT epoch ] query
```

You can qualify the AS clause with one or both of the following hints:

- A load method hint: **AUTO, DIRECT, or TRICKLE**
  
  **Note:** The CREATE TABLE statement can also specify a load method. However, this load method applies to load operations only after the table is created.

- **LABEL**

  For details, see [Creating a Table from a Query](#) in the Administrator's Guide.

### ENCODED BY *column-ref-list*

A list of columns from the source table, where each column is qualified by one or both of the following encoding options:

- **ACCESSRANK integer**: Overrides the default access rank for a column, useful for prioritizing access to a column. See [Prioritizing Column Access Speed](#) in the Administrator's Guide.

- **ENCODING encoding-type**: Specifies the type of encoding to use on the column. The default encoding type is AUTO.

This option and *column-name-list* are mutually exclusive. This option is invalid for external tables.
LIKE `existing-table`

Creates the table by replicating an existing table. You can qualify the LIKE clause with one of the following options:

- **EXCLUDING PROJECTIONS** (default): Do not copy projections from the source table.
- **INCLUDING PROJECTIONS**: Copy current projections from the source table for the new table.
- **Load-method**: See description above.
- `{INCLUDE|EXCLUDE} [SCHEMA] PRIVILEGES`: See description above.

For details, see [Replicating a Table](https://www.vertica.com/support/documentation/9.0.x/manuals/sqlreference_manual/page3468.html) in the Administrator's Guide.

### Privileges

The following privileges are required:

- **CREATE** privileges on the table schema

- If creating a table that includes a named sequence:
  - **SELECT** privilege on sequence object
  - **USAGE** privilege on sequence schema

- If creating a table with the LIKE clause, owner privileges on the source table

### Examples

In the Administrator's Guide, see:

- [Creating Tables](https://www.vertica.com/support/documentation/9.0.x/manuals/sqlreference_manual/page3468.html)
- [Replicating a Table](https://www.vertica.com/support/documentation/9.0.x/manuals/sqlreference_manual/page3468.html)
- [Creating a Table from a Query](https://www.vertica.com/support/documentation/9.0.x/manuals/sqlreference_manual/page3468.html)
See Also

- CREATE TEMPORARY TABLE
- CREATE EXTERNAL TABLE AS COPY
- CREATE FLEX TABLE

Column-Definition

Specifies the name, data type, and constraints to be applied to a column.

Syntax

```
column-name  data-type
...  [ column-constraint ]
...  [ ENCODING  encoding-type ]
...  [ ACCESSRANK  integer ]
```

Parameters

<table>
<thead>
<tr>
<th>column-name</th>
<th>The name of a column to be created or added.</th>
</tr>
</thead>
<tbody>
<tr>
<td>data-type</td>
<td>One of the following data types:</td>
</tr>
<tr>
<td></td>
<td>• BINARY</td>
</tr>
<tr>
<td></td>
<td>• BOOLEAN</td>
</tr>
<tr>
<td></td>
<td>• CHARACTER</td>
</tr>
<tr>
<td></td>
<td>• DATE/TIME</td>
</tr>
<tr>
<td></td>
<td>• NUMERIC</td>
</tr>
</tbody>
</table>

For information on data types, see SQL Data Types.

Tip: When specifying the maximum column width in a CREATE TABLE statement, use the width in bytes (octets) for any of the string types. Each UTF-8 character might
require four bytes, but European languages generally require a little over one byte per character, while Oriental languages generally require a little under three bytes per character.

<table>
<thead>
<tr>
<th><strong>column_constraint</strong></th>
<th>Specifies a column constraint for this column.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ENCODING encoding-type</strong></td>
<td>Specifies the column encoding type, by default set to AUTO.</td>
</tr>
<tr>
<td><strong>ACCESSRANK integer</strong></td>
<td>Overrides the default access rank for a column. Use this parameter to increase or decrease the speed at which Vertica accesses a column. For more information, see Overriding Default Column Ranking.</td>
</tr>
</tbody>
</table>

**Example**

The following example creates a table named Employee_Dimension and its associated superprojection in the Public schema. The Employee_key column is designated as a primary key, and RLE encoding is specified for the Employee_gender column definition:

```sql
=> CREATE TABLE Public.Employee_Dimension ( 
   Employee_key integer PRIMARY KEY NOT NULL, 
   Employee_gender varchar(8) ENCODING RLE, 
   Courtesy_title varchar(8), 
   Employee_first_name varchar(64), 
   Employee_middle_initial varchar(8), 
   Employee_last_name varchar(64), 
);
```

**Column-Name-List**

Used to rename columns when creating a table or temporary table from a query (CREATE TABLE AS SELECT); also used to specify the column's encoding type and access rank.

**Syntax**

```
column-name-list
... [ ENCODING encoding-type ]
... [ ACCESSRANK integer ]
... [ GROUPED ( column-reference[,....] ) ]
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column-name</td>
<td>Specifies the new name for the column.</td>
</tr>
<tr>
<td>ENCODING encoding-type</td>
<td>Specifies the type of encoding to use on the column. The default encoding type is AUTO.</td>
</tr>
<tr>
<td>ACCESSRANK integer</td>
<td>Overrides the default access rank for a column, useful for prioritizing access to a column. See Prioritizing Column Access Speed in the Administrator's Guide.</td>
</tr>
<tr>
<td>GROUPED</td>
<td>Groups two or more columns. For detailed information, see GROUPED Clause.</td>
</tr>
</tbody>
</table>

Requirements

- A column in the list can not specify the column's data type or any constraint. These are derived from the queried table.

- If the query output has expressions other than simple columns (for example, constants or functions) then an alias must be specified for that expression, or the column name list must include all queried columns.

- CREATE TABLE can specify encoding types and access ranks in the column name list or the query's ENCODED BY clause, but not in both. For example, the following CREATE TABLE statement sets encoding and access rank on two columns in the column name list:

  ```sql
  => CREATE TABLE promo1 (state ENCODING RLE ACCESSRANK 1, zip ENCODING RLE, ...)
      AS SELECT * FROM customer_dimension ORDER BY customer_state;
  ```

  The next statement specifies the same encoding and access rank in the query's ENCODED BY clause.

  ```sql
  => CREATE TABLE promo2
      AS SELECT * FROM customer_dimension ORDER BY customer_state
      ENCODED BY customer_state ENCODING RLE ACCESSRANK 1, customer_zip ENCODING RLE;
  ```
Column-Constraint

Adds a constraint to a column's metadata. See Adding Constraints in the Administrator's Guide.

Syntax

**Permanent table**

```sql
[ { AUTO_INCREMENT | IDENTITY } [ (args) ] ]
[ CONSTRAINT constraint-name ]
[ ...[ CHECK (expression) [ ENABLED | DISABLED ] ]
[ ...[ DEFAULT default-expr ] [ SET USING using-expr ] | DEFAULT USING expr ]
[ ...[ NULL | NOT NULL ]
[ ...[ { PRIMARY KEY | REFERENCES table [ (column) ] } [ ENABLED | DISABLED ] ]
[ ...[ UNIQUE [ ENABLED | DISABLED ] ]
```

**Temporary table**

```sql
[ CONSTRAINT constraint-name ]
[ ...[ CHECK (expression) [ ENABLED | DISABLED ] ]
[ ...[ DEFAULT default-expr ]
[ ...[ NULL | NOT NULL ]
[ ...{ PRIMARY KEY | REFERENCES table [ (column) ] } [ ENABLED | DISABLED ] ]
[ ...{ SET USING using-expr ]
[ ...{ UNIQUE [ ENABLED | DISABLED ] ]
```

Parameters

**Note:** A number of parameters can be qualified with the keyword ENABLED or DISABLED. For details, see Enforcing Constraints below.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO_INCREMENT IDENTITY</td>
<td>Creates a table column whose values are automatically generated by the database, and cannot be changed. You can set this constraint on only one table column. AUTO_INCREMENT and IDENTITY are synonyms. For details this constraint and optional arguments, see AUTO_INCREMENT and IDENTITY Sequences in the Administrator's Guide.</td>
</tr>
<tr>
<td>CONSTRAINT constraint-name</td>
<td>Assigns a name to the constraint. Vertica recommends that you name all constraints.</td>
</tr>
<tr>
<td>CHECK</td>
<td>Adds check condition expression, which returns a Boolean value.</td>
</tr>
<tr>
<td><strong>expression</strong></td>
<td></td>
</tr>
<tr>
<td>----------------</td>
<td>---</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Specifies this column's default value:</td>
</tr>
<tr>
<td></td>
<td><strong>DEFAULT default-exp</strong></td>
</tr>
<tr>
<td></td>
<td>Vertica evaluates the DEFAULT expression and sets the column on load operations, if the operation omits a value for the column. For details about valid expressions, see Defining Column Values.</td>
</tr>
<tr>
<td>SET USING</td>
<td>Specifies to set values in this column from the specified expression:</td>
</tr>
<tr>
<td></td>
<td><strong>SET USING using-exp</strong></td>
</tr>
<tr>
<td></td>
<td>Vertica evaluates the SET USING expression and refreshes column values only when the function REFRESH_COLUMNS is invoked. For details about valid expressions, see Defining Column Values.</td>
</tr>
<tr>
<td>DEFAULT USING</td>
<td>Defines the column with DEFAULT and SET USING constraints, specifying the same expression for both. DEFAULT USING columns support the same expressions as SET USING columns, and are subject to the same restrictions.</td>
</tr>
<tr>
<td>NULL NOT NULL</td>
<td>Specifies whether the column can contain null values:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NULL</strong>: Allows null values in the column. If you set this constraint on a primary key column, Vertica ignores it and sets it to NOT NULL.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NOT NULL</strong>: Specifies that the column must be set to a value during insert and update operations. If the column has no default value and no value is provided, INSERT or UPDATE returns an error.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you omit this constraint, the default is NULL for all columns except primary key columns, which Vertica always sets to NOT NULL.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>External tables</strong>: If you specify NOT NULL and the column contains null values, queries are liable to return errors or generate unexpected behavior. Specify NOT NULL for an external table column only if you are sure that the column does not contain nulls.</td>
</tr>
<tr>
<td><strong>PRIMARY KEY</strong></td>
<td>Defines the column as the table's primary key.</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td><strong>REFERENCES</strong></td>
<td>Identifies this column as a foreign key:</td>
</tr>
<tr>
<td></td>
<td>REFERENCES <em>table</em> [<em>column</em>]</td>
</tr>
<tr>
<td></td>
<td>where <em>column</em> is the primary key in <em>table</em>. If you omit <em>column</em>, Vertica references the primary key in <em>table</em>.</td>
</tr>
<tr>
<td><strong>UNIQUE</strong></td>
<td>Requires column data to be unique with respect to all table rows.</td>
</tr>
</tbody>
</table>

**Privileges**

Table owner or user WITH GRANT OPTION is grantor.

- REFERENCES privilege on table to create foreign key constraints that reference this table
- USAGE privilege on schema that contains the table

**Enforcing Constraints**

The following constraints can be qualified with the keyword ENABLED or DISABLED:

- **PRIMARY KEY**
- **UNIQUE**
- **CHECK**

If you omit ENABLED or DISABLED, Vertica determines whether to enable the constraint automatically by checking the appropriate configuration parameter:

- EnableNewPrimaryKeysByDefault
- EnableNewUniqueKeysByDefault
- EnableNewCheckConstraintsByDefault

For details, see Enforcing Primary Key, Unique Key, and Check Constraints Automatically.
Partition Clause

Specifies partitioning of table data, through a PARTITION BY clause in the table definition:

```
PARTITION BY partition-expression [ GROUP BY group-expression ]
```

<table>
<thead>
<tr>
<th>PARTITION BY partition-expression</th>
<th>For each table row, resolves to a partition key that is derived from one or more table columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP BY group-expression</td>
<td>For each table row, resolves to a partition group key that is derived from the partition key. Vertica uses group keys to merge partitions into separate partition groups. GROUP BY must use the same expression as PARTITION BY. For example:</td>
</tr>
<tr>
<td></td>
<td><code>...PARTITION BY (i+j) GROUP BY (CASE WHEN (i+j) &lt; 5 THEN 1 WHEN (i+j) &lt; 10 THEN 2 ELSE 3);</code></td>
</tr>
</tbody>
</table>

**Caution:** Avoid partitioning tables on LONG VARBINARY and LONG VARCHAR columns. Doing so can adversely impact performance.

For details on partitioning table data by groups, see Partition Grouping and Hierarchical Partitioning in the Administrator's Guide.

Partitioning Requirements and Restrictions

PARTITION BY expressions can specify leaf expressions, functions, and operators. The following requirements and restrictions apply:

- All table projections must include all columns referenced in the expression; otherwise, Vertica cannot resolve the expression.

- The expression can reference multiple columns, but it must resolve to a single non-null value for each row.

- All leaf expressions must be constants or table columns.
- All other expressions must be functions and operators. The following restrictions apply to functions:
  - They must be immutable—that is, they return the same value regardless of time and locale and other session- or environment-specific conditions.
  - They cannot be aggregate functions.
  - They cannot be Vertica meta-functions.
- The expression cannot include queries.

GROUP BY expressions do not support modulo (%) operations.

Partitioning Tables in the Administrator's Guide

Table-Constraint

Adds a constraint to table metadata. You can specify table constraints with CREATE TABLE, or add a constraint to an existing table with ALTER TABLE. For details, see Adding Constraints in the Administrator's Guide.

Note: Adding a constraint to a table that is referenced in a view does not affect the view.

Syntax

```
[ CONSTRAINT constraint-name ]
{
  ... PRIMARY KEY (column[,...]) [ ENABLED | DISABLED ]
  ... | FOREIGN KEY (column[,...]) REFERENCES table [ (column[,...]) ]
  ... | UNIQUE (column[,...]) [ ENABLED | DISABLED ]
  ... | CHECK (expression) [ ENABLED | DISABLED ]
}
```

Parameters

<p>| CONSTRAINT constraint-name | Assigns a name to the constraint. Vertica recommends that you name all constraints. |</p>
<table>
<thead>
<tr>
<th>Constraint</th>
<th>Description</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PRIMARY KEY</strong></td>
<td>Defines one or more NOT NULL columns as the primary key as follows:</td>
<td>PRIMARY KEY (column[,...]) [ ENABLED</td>
</tr>
<tr>
<td></td>
<td>You can qualify this constraint with the keyword ENABLED or DISABLED. See Enforcing Constraints below.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you do not name a primary key constraint, Vertica assigns the name C_PRIMARY.</td>
<td></td>
</tr>
<tr>
<td><strong>FOREIGN KEY</strong></td>
<td>Adds a referential integrity constraint defining one or more columns as foreign keys as follows:</td>
<td>FOREIGN KEY (column[,...]) REFERENCES table [(column[,...])]</td>
</tr>
<tr>
<td></td>
<td>If you omit column references, If you omit column, Vertica references the primary key in table.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you do not name a foreign key constraint, Vertica assigns the name C_FOREIGN.</td>
<td></td>
</tr>
<tr>
<td><strong>UNIQUE</strong></td>
<td>Specifies that the data in a column or group of columns is unique with respect to all table rows, as follows:</td>
<td>UNIQUE (column[,...]) [ENABLED</td>
</tr>
<tr>
<td></td>
<td>You can qualify this constraint with the keyword ENABLED or DISABLED. See Enforcing Constraints below.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you do not name a unique constraint, Vertica assigns the name C_UNIQUE.</td>
<td></td>
</tr>
<tr>
<td><strong>CHECK</strong></td>
<td>Specifies a check condition as an expression that returns a Boolean value, as follows:</td>
<td>CHECK (expression) [ENABLED</td>
</tr>
<tr>
<td></td>
<td>You can qualify this constraint with the keyword ENABLED or DISABLED. See Enforcing Constraints below.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you do not name a check constraint, Vertica assigns the name C_CHECK.</td>
<td></td>
</tr>
</tbody>
</table>
Privileges

Table owner or user WITH GRANT OPTION is grantor.

- REFERENCES privilege on table to create foreign key constraints that reference this table
- USAGE privilege on schema that contains the table

Enforcing Constraints

A table can specify whether Vertica automatically enforces a primary key, unique key or check constraint with the keyword ENABLED or DISABLED. If you omit ENABLED or DISABLED, Vertica determines whether to enable the constraint automatically by checking the appropriate configuration parameter:

- EnableNewPrimaryKeysByDefault
- EnableNewUniqueKeysByDefault
- EnableNewCheckConstraintsByDefault

For details, see Enforcing Primary Key, Unique Key, and Check Constraints Automatically.

Examples

The following example creates a table (t01) with a primary key constraint.

```
CREATE TABLE t01 (id int CONSTRAINT sampleconstraint PRIMARY KEY);
```

This example creates the same table without the constraint, and then adds the constraint with ALTER TABLE ADD CONSTRAINT

```
CREATE TABLE t01 (id int);
ALTER TABLE t01 ADD CONSTRAINT sampleconstraint PRIMARY KEY(id);
WARNING 2623: Column "id" definition changed to NOT NULL
```

The following example creates a table (addapk) with two columns, adds a third column to the table, and then adds a primary key constraint on the third column.

```
CREATE TABLE addapk (col1 INT, col2 INT);

CREATE TABLE

ALTER TABLE addapk ADD COLUMN col3 INT;

ALTER TABLE

ALTER TABLE addapk ADD CONSTRAINT col3constraint PRIMARY KEY (col3) ENABLED;

WARNING 2623: Column "col3" definition changed to NOT NULL

ALTER TABLE

Using the sample table addapk, check that the primary key constraint is enabled (is_enabled is t).

=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_name IN ('addapk');

<table>
<thead>
<tr>
<th>constraint_name</th>
<th>column_name</th>
<th>constraint_type</th>
<th>is_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>col3constraint</td>
<td>col3</td>
<td>p</td>
<td>t</td>
</tr>
</tbody>
</table>

(1 row)

This example disables the constraint using ALTER TABLE ALTER CONSTRAINT.

=> ALTER TABLE addapk ALTER CONSTRAINT col3constraint DISABLED;

Check that the primary key is now disabled (is_enabled is f).

=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_name IN ('addapk');

<table>
<thead>
<tr>
<th>constraint_name</th>
<th>column_name</th>
<th>constraint_type</th>
<th>is_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>col3constraint</td>
<td>col3</td>
<td>p</td>
<td>f</td>
</tr>
</tbody>
</table>

(1 row)

For a general discussion of constraints, see About Constraints. For additional examples of creating and naming constraints, see Naming Constraints.

CREATE TEMPORARY TABLE

Creates a table whose data persists only during the current session. Temporary table data is not visible to other sessions.
Syntax

Create with column definitions

  ... ( column-definition[,... ] )
  ... [ table-constraint ]
  ... [ ON COMMIT { DELETE | PRESERVE } ROWS ]
  ... [ Load-method ]
  ... [ NO PROJECTION ]
  ... [ ORDER BY table-column[,... ]]
  ... [ segmentation-spec ]
  ... [ KSAFE [k-num] ]
  ... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]

Create from another table

CREATE TEMP[ORARY] TABLE [ IF NOT EXISTS ] [[database.]schema.]table-name
  ... ( column-name-list )
  ... [ ON COMMIT { DELETE | PRESERVE } ROWS ]
  ... [ Load-method ]
AS [ /*+ hint[, hint] */ ] [ AT epoch ] query [ ENCODED BY column-ref-list ]

Parameters

<table>
<thead>
<tr>
<th>scope</th>
<th>Specifies visibility of the table definition:</th>
</tr>
</thead>
<tbody>
<tr>
<td>GLOBAL (default): The table definition is visible to all sessions, and persists until you explicitly drop the table.</td>
<td></td>
</tr>
<tr>
<td>LOCAL: the table definition is visible only to the session in which it is created, and is dropped when the session ends.</td>
<td></td>
</tr>
</tbody>
</table>

Regardless of this setting, retention of temporary table data is set by the keywords ON COMMIT DELETE and ON COMMIT PRESERVE (see below).

For more information, see Creating Temporary Tables in the Administrator's Guide.

<table>
<thead>
<tr>
<th>IF NOT EXISTS</th>
<th>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The IF NOT EXISTS clause is useful for SQL scripts where you</td>
<td></td>
</tr>
</tbody>
</table>
want to create an object if it does not already exist, and reuse the existing object if it does.

For related information, see **ON_ERROR_STOP**.

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Specifies a schema, by default public. If <em>schema</em> is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database. If you do not specify a schema, the table is created in the default schema.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>table-name</th>
<th>Identifies the table to create, where <em>table-name</em> conforms to conventions described in <em>identifiers</em>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>column-definition</th>
<th>Defines a table column. A table can have up to 1600 columns.</th>
<th>table-constraint</th>
<th>Adds a constraint to table metadata.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>ON COMMIT</th>
<th>Specifies whether data is transaction- or session-scoped:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>**ON COMMIT {PRESERVE</td>
</tr>
</tbody>
</table>

- DELETE (default) marks the temporary table for transaction-scoped data. Vertica removes all table data after each commit.

- PRESERVE marks the temporary table for session-scoped data, which is preserved beyond the lifetime of a single transaction. Vertica removes all table data when the session ends.

<table>
<thead>
<tr>
<th>load-method</th>
<th>Specifies default load behavior for all DML operations on this table, such as INSERT and COPY, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>AUTO</strong> (default): Initially loads data into WOS, suitable for smaller bulk loads.</td>
</tr>
<tr>
<td></td>
<td><strong>DIRECT</strong>: Loads data directly into ROS containers, suitable for large (&gt;100 MB) bulk loads.</td>
</tr>
</tbody>
</table>
- **TRICKLE**: Loads data only into WOS, suitable for frequent incremental loads.

  For details, see *Choosing a Load Method* in the Administrator's Guide.

**NO PROJECTION**

Prevents Vertica from creating auto-projections for this table. A superprojection is created only when data is explicitly loaded into this table.

**NO PROJECTION** is invalid with the following clauses:

- **ORDER BY**
- **KSAFE**
- Any segmentation clause (*hash-segmentation-clause* or *unsegmented-clause*).

**{INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES**

Specifies default inheritance of schema privileges for this table:

- **EXCLUDE [SCHEMA] PRIVILEGES** (default) disables inheritance of privileges from the schema
- **INCLUDE [SCHEMA] PRIVILEGES** grants the table the same privileges granted to its schema

For more information see *Grant Inherited Privileges*.

**ORDER BY**

**table-column[,...]**

Specifies columns from the SELECT list on which to sort the superprojection that is automatically created for this table. The **ORDER BY** clause cannot include qualifiers ASC or DESC. Vertica always stores projection data in ascending sort order.

If you omit the **ORDER BY** clause, Vertica uses the SELECT list order as the projection sort order.

This option is invalid for external tables.

**segmentation-spec**

Invalid for external tables, specifies how to distribute data for auto-projections of this table. Supply one of the following clauses:

- **hash-segmentation-clause**: Specifies to segment data evenly and distribute across cluster nodes. Vertica recommends segmenting large tables. For details, see *Hash
### Segmentation Clause

- **unsegmented-clause**: Specifies to create an unsegmented projection. For details, see [Unsegmented Clause](#).

If this clause is omitted, Vertica generates auto-projections with default hash segmentation.

### KSAFE \([k-num]\)

Specifies K-safety of auto-projections created for this table, where \(k-num\) must be equal to or greater than system K-safety. If you omit this option, the projection uses the system K-safety level. For general information, see [K-Safety](#) in Vertica Concepts.

**Note**: This option is invalid for external tables.

### column-name-list

Valid only when creating a table from a query (AS `query`), defines column names that map to the query output. If you omit this list, Vertica uses the query output column names. The names in `column-name-list` and queried columns must be the same in number.

For example:

```sql
CREATE TABLE customer_occupations (name, profession)
AS SELECT customer_name, occupation FROM customer_dimension;
```

This clause and the ENCODED BY clause are mutually exclusive. Column name lists are invalid for external tables.

### AS `query`

Creates and loads a table from the results of a query, specified as follows:

```sql
AS [ /*+hint[, hint]*/ ] [ AT epoch ] query
```

You can qualify the AS clause with one or both of the following hints:

- A load method hint: **AUTO, DIRECT, or TRICKLE**

**Note**: The CREATE TABLE statement can also specify a load method. However, this load method applies to load operations only after the table is created.

- **LABEL**
For details, see Creating a Table from a Query in the Administrator's Guide.

<table>
<thead>
<tr>
<th>ENCODED BY</th>
<th>column-ref-list</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A list of columns from the source table, where each column is qualified by one or both of the following encoding options:</td>
</tr>
<tr>
<td></td>
<td>- <strong>ACCESSRANK</strong> <em>integer</em>: Overrides the default access rank for a column, useful for prioritizing access to a column. See Prioritizing Column Access Speed in the Administrator's Guide.</td>
</tr>
<tr>
<td></td>
<td>- <strong>ENCODING</strong> <em>encoding-type</em>: Specifies the type of encoding to use on the column. The default encoding type is AUTO.</td>
</tr>
<tr>
<td></td>
<td>This option and <em>column-name-list</em> are mutually exclusive. This option is invalid for external tables</td>
</tr>
</tbody>
</table>

Privileges

The following privileges are required:

- CREATE privileges on the table schema

- If creating a temporary table that includes a named sequence:
  - SELECT privilege on sequence object
  - USAGE privilege on sequence schema

Restrictions

- Queries on temporary tables are subject to the same restrictions on SQL support as persistent tables.

- You cannot add projections to non-empty, global temporary tables (ON COMMIT PRESERVE ROWS). Make sure that projections exist before you load data. See Auto-Projections in the Administrator's Guide.

- While you can add projections for temporary tables that are defined with ON COMMIT DELETE ROWS specified, be aware that you might lose all data.

- Moveout and mergeout operations cannot be used on session-scoped temporary data.
In general, session-scoped temporary table data is not visible using system (virtual) tables.

Temporary tables do not recover. If a node fails, queries that use the temporary table also fail. Restart the session and populate the temporary table.

See Also

- Creating Temporary Tables
- ALTER TABLE
- CREATE TABLE

CREATE TEXT INDEX

Creates a text index used to perform text searches.

Syntax

```
CREATE TEXT INDEX [[database.]schema.]txtindex-name
  ON [schema.]source-table (unique-id, text-field [, column-name, ...])
  [STEMMER {stemmer-name(stemmer-input-data-type)} | NONE]
  [TOKENIZER tokenizer-name(tokenizer-input-data-type)];
```

Parameters

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td></td>
<td>If you do not specify a schema, the table is created in the default schema.</td>
</tr>
</tbody>
</table>
### Table

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>txtindex-name</code></td>
<td>The text index name.</td>
</tr>
<tr>
<td><code>source-table</code></td>
<td>The source table to index.</td>
</tr>
<tr>
<td><code>unique-id</code></td>
<td>The name of the column in the source table that contains a unique identifier. Any data type is permissible. The column must be the primary key in the source table.</td>
</tr>
<tr>
<td><code>text-field</code></td>
<td>The name of the column in the source table that contains the text field. Valid data types are:</td>
</tr>
<tr>
<td></td>
<td>• CHAR</td>
</tr>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• LONG VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• VARBINARY</td>
</tr>
<tr>
<td></td>
<td>• LONG VARBINARY</td>
</tr>
<tr>
<td></td>
<td>Nulls are allowed.</td>
</tr>
<tr>
<td><code>column-name</code></td>
<td>The name of a column or columns to be included as additional columns.</td>
</tr>
<tr>
<td><code>stemmer-name</code></td>
<td>The name of the stemmer</td>
</tr>
<tr>
<td><code>stemmer-input-data-type</code></td>
<td>The input data type of the <code>stemmer-name</code> function.</td>
</tr>
<tr>
<td><code>tokenizer-name</code></td>
<td>Specifies the name of the tokenizer.</td>
</tr>
<tr>
<td><code>tokenizer-input-data-type</code></td>
<td>This value is the input data type of the <code>tokenizer-name</code> function. It can accept any number of arguments.</td>
</tr>
<tr>
<td></td>
<td>If a Vertica Tokenizers is used, then this parameter can be omitted.</td>
</tr>
</tbody>
</table>

### Privileges

The index automatically inherits the query permissions of its parent table. The table owner and dbadmin will be allowed to create and/or modify the indices.
Important: Do not alter the contents or definitions of the text index. If the contents or definitions of the text index are altered, then the results will not appropriately match the source table.

Requirements

- Requires there be a column with a unique identifier set as the primary key.
- The source table must have an associated projection, and must be both sorted and segmented by the primary key.

Behavior

If data within a table is partitioned, then an extra column appears in the text index, showing the partition.

Examples

The following example shows how to create a text index with an additional unindexed column on the table t_log using the CREATE TEXT INDEX statement:

```sql
=> CREATE TEXT INDEX t_log_index ON t_log (id, text, day_of_week);
CREATE INDEX
=> SELECT * FROM t_log_index;
token | doc_id | day_of_week
---|---|---
'catalog' | 1 | Monday
'dbadmin' | 2 | Monday
2014-06-04 | 1 | Monday
2014-06-04 | 2 | Monday
2014-06-04 | 3 | Monday
2014-06-04 | 4 | Monday
2014-06-04 | 5 | Monday
2014-06-04 | 6 | Monday
2014-06-04 | 7 | Monday
2014-06-04 | 8 | Monday
45035996273704966 | 3 | Tuesday
45035996273704968 | 4 | Tuesday
<INFO> | 1 | Tuesday
<INFO> | 6 | Tuesday
<INFO> | 7 | Tuesday
<INFO> | 8 | Tuesday
<WARNING> | 2 | Tuesday
<WARNING> | 3 | Tuesday
<WARNING> | 4 | Tuesday
```
The following example shows a text index, tpart_index, created from a partitioned source table:

```sql
=> SELECT * FROM tpart_index;
```

```
token | doc_id | partition
-------|--------|----------
0      | 4      | 2014
0      | 5      | 2014
11:00:49.568 | 4 | 2014
11:00:49.568 | 5 | 2014
11:00:49.569 | 6 | 2014
<INFO> | 6 | 2014
<WARNING> | 4 | 2014
<WARNING> | 5 | 2014

Object | 5 | 2014
[Catalog] | 4 | 2014
[Catalog] | 5 | 2014
'catalog' | 1 | 2013
'dbadmin' | 2 | 2013
0 | 3 | 2013
11:00:49.568 | 1 | 2013
11:00:49.568 | 2 | 2013
11:00:49.568 | 3 | 2013
11:00:49.570 | 7 | 2013
11:00:49.571 | 8 | 2013
45035996273704966 | 3 | 2013
```

See Also

- DROP TEXT INDEX
- DROP TEXT INDEX
CREATE USER

Adds a name to the list of authorized database users.

Note: New users lack default access to schema PUBLIC. Be sure to assign new users USAGE privileges to the PUBLIC schema (GRANT USAGE ON SCHEMA PUBLIC)

Syntax

CREATE USER name [ user-parameter setting[,...] ]

user-parameter

ACCOUNT
GRACEPERIOD
IDENTIFIED BY
IDLESESSIONTIMEOUT
MAXCONNECTIONS
MEMORYCAP
PASSWORD EXPIRE
PROFILE
RESOURCE POOL
RUNTIMECAP
SEARCH_PATH
TEMPSPACECAP

Parameters

| name | Specifies the name of the new user. Names that contain special characters must be double-quoted. To enforce case-sensitivity, use double-quotes. For details on name requirements, see Creating a Database Name and Password. |
| ACCOUNT { LOCK | UNLOCK } | Locks or unlocks a user's access to the database, set to one of the following: |
| | • UNLOCK (default) |
| | • LOCK prevents a new user from logging in. This can be useful when creating an account for a user who does not need immediate access. |
Tip: To automate account locking, set a maximum number of failed login attempts with `CREATE PROFILE`.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>GRACEPERIOD limit</strong></td>
<td>Specifies how long a user query can block on any session socket, where <code>limit</code> is one of the following:</td>
</tr>
<tr>
<td></td>
<td>• NONE (default): Removes any grace period previously set on session queries.</td>
</tr>
<tr>
<td></td>
<td>• <code>'interval'</code>: Specifies as an <code>interval</code> the maximum grace period for current session queries, up to 20 days.</td>
</tr>
<tr>
<td></td>
<td>For details, see <a href="#">Handling Session Socket Blocking</a>.</td>
</tr>
<tr>
<td><strong>IDENTIFIED BY 'password'</strong></td>
<td>Sets the new user's password, where <code>password</code> must conform to the password complexity policy set by the user's profile.</td>
</tr>
<tr>
<td></td>
<td>If you supply an empty string or omit this parameter, the user is assigned no password and is not prompted for one when connecting.</td>
</tr>
<tr>
<td></td>
<td>For details, see <a href="#">Password Guidelines</a> and <a href="#">Creating a Database Name and Password</a>.</td>
</tr>
<tr>
<td><strong>IDLESESSIONTIMEOUT limit</strong></td>
<td>The length of time the system waits before disconnecting an idle session, where <code>limit</code> is one of the following:</td>
</tr>
<tr>
<td></td>
<td>• NONE (default): No limit set for this user. If you omit this parameter, no limit is set for this user.</td>
</tr>
<tr>
<td></td>
<td>• <code>'interval'</code>: An interval value, up to one year.</td>
</tr>
<tr>
<td></td>
<td>For details, see <a href="#">Managing Client Connections</a>.</td>
</tr>
<tr>
<td><strong>MAXCONNECTIONS limit</strong></td>
<td>Indicates the maximum number of connections the user can have to the server, where <code>limit</code> is one of the following:</td>
</tr>
<tr>
<td></td>
<td>• NONE (default): No limit. If you omit this parameter, the user can have an unlimited number of connections.</td>
</tr>
<tr>
<td></td>
<td>• <code>'integer'</code> ON NODE: Sets the maximum number of connections to each node to <code>integer</code>.</td>
</tr>
<tr>
<td></td>
<td>• <code>'integer'</code> ON DATABASE: Sets the maximum number of connections across the database cluster to <code>integer</code>.</td>
</tr>
</tbody>
</table>
For details, see Managing Client Connections.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
</table>
| MEMORYCAP $\textit{limit}$ | Specifies how much memory can be allocated to user requests, where $\textit{limit}$ is specified in this format:  
- NONE (default): No limit
- $'\textit{max-expression}'$: A string value that specifies the memory limit, one of the following:
  - $\textit{int\%}$ — Expresses the maximum as a percentage of total memory available to the Resource Manager, where $\textit{int}$ is an integer value between 0 and 100. For example:
    - MEMORYCAP '40%'  
  - $\textit{int\{K|M|G|T\}}$ — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:
    - MEMORYCAP '10G'

| PASSWORD EXPIRE | Forces immediate expiration of the user's password. The user must change the password on the next login.  
**Note:** PASSWORD EXPIRE has no effect when using external password authentication methods such as LDAP or Kerberos.

| PROFILE $\textit{profile}$ | Assigns a $\textit{profile}$ that controls password requirements for this user, where $\textit{profile}$ is one of the following:
- DEFAULT (default): Assigns the default database profile to this user.
- $\textit{profile-name}$: A profile that is defined by CREATE PROFILE. If you omit this parameter, the user is assigned the default profile.

| RESOURCE POOL $\textit{pool-name}$ | Assigns a default resource pool to this user. The user must also be granted privileges to this pool, unless privileges to the pool are set to PUBLIC.

| RUNTIMECAP $\textit{limit}$ | Specifies how long this user's queries can execute, where
**Limit** is one of the following:

- **NONE** (default): No limit set for this user. If you omit this parameter, no limit is set for this user.
- **'interval'**: An interval value, up to one year.

A query's runtime limit can be set at three levels: the user's runtime limit, the user's resource pool, and the session setting. For more information, see [Setting a Runtime Limit for Queries](https://www.vertica.com/docs/9.0.1/guidesDEVGuidePDF/Vertica-Analytic-Database-GUIDEDEVG_9.0.1.pdf) in the Administrator's Guide.

### SEARCH_PATH path

Specifies the user's default search path that tells Vertica which schemas to search for unqualified references to tables and UDFs, where *path* is one of the following:

- **DEFAULT** (default): Sets the search path as follows:
  
  "$user", public, v_catalog, v_monitor, v_internal

- A comma-delimited list of schemas.

### TEMPSPACECAP limit

Limits how much temporary file storage is available for user requests, where *limit* is one of the following:

- **NONE** (default): No limit
- **'max-expression'**: A string value that specifies the storage limit, one of the following:
  
  - *int%* — Expresses storage as a percentage of total file space is available, where *int* is an integer value between 0 and 100. For example:
    
    TEMPSPACECAP '40%

  - *int{K|M|G|T}* — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:
    
    TEMPSPACECAP '10G'
Privileges

Superuser

User Name Best Practices

Vertica database user names are logically separate from user names of the operating system in which the server runs. If all the users of a particular server also have accounts on the server's machine, it makes sense to assign database user names that match their operating system user names. However, a server that accepts remote connections might many database users with no local operating system account. In this case, there is no need to connect database and system user names.

Examples

```sql
=> CREATE USER Fred IDENTIFIED BY 'Mxyzptlk';
=> GRANT USAGE ON SCHEMA PUBLIC to Fred;
```

See Also

- `ALTER USER`
- `DROP USER`

**CREATE VIEW**

Defines a view. Views are read only, so they do not support insert, update, delete, or copy operations.

Syntax

```
CREATE [ OR REPLACE ] VIEW [[database.]schema.]view [ (column[,...]) ]
  [ {INCLUDE|EXCLUDE} [SCHEMA] PRIVILEGES ] AS query
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>OR REPLACE</strong></td>
<td>Specifies to overwrite the existing view <code>view-name</code>. If you omit this option and <code>view-name</code> already exists, CREATE VIEW returns an error.</td>
</tr>
<tr>
<td></td>
<td>Any grants assigned to the view before you execute a CREATE OR REPLACE remain on the updated view. See <strong>GRANT (View)</strong>.</td>
</tr>
<tr>
<td><code>[database]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><strong>view</strong></td>
<td>Identifies the view to create, where <code>view-name</code> conforms to conventions described in <strong>Identifiers</strong>. It must also be unique among all names of</td>
</tr>
<tr>
<td></td>
<td>sequences, tables, projections, views, and models within the same schema.</td>
</tr>
<tr>
<td><strong>column[,...]</strong></td>
<td>A list of names to use as view column names. Vertica maps view column names to query columns according to the order of their respective lists. By</td>
</tr>
<tr>
<td></td>
<td>default, the view uses column names as they are specified in the query. Each view can contain up to 1600 columns.</td>
</tr>
<tr>
<td><strong>query</strong></td>
<td>A <strong>SELECT</strong> statement that the temporary view executes. The SELECT statement can reference tables, temporary tables, and other views.</td>
</tr>
<tr>
<td>`{INCLUDE</td>
<td>EXCLUDE}`</td>
</tr>
<tr>
<td><code>[SCHEMA] PRIVILEGES</code></td>
<td>- INCLUDE PRIVILEGES: Inherit schema privileges.</td>
</tr>
<tr>
<td></td>
<td>- EXCLUDE PRIVILEGES: Do not inherit schema privileges.</td>
</tr>
<tr>
<td></td>
<td>For details, see <strong>Grant Inherited Privileges</strong>.</td>
</tr>
</tbody>
</table>
Privileges

See Creating Views

Examples

The following example shows how to create a view that contains data from multiple tables.

```sql
=> CREATE VIEW temp_t0 AS SELECT * from t0_p1 UNION ALL
   SELECT * from t0_p2 UNION ALL
   SELECT * from t0_p3 UNION ALL
   SELECT * from t0_p4 UNION ALL
   SELECT * from t0_p5;
```

See Also

- ALTER VIEW
- CREATE LOCAL TEMPORARY VIEW
- Creating Views
- DROP VIEW
- GRANT (View)
- REVOKE (View)

DELETE

Removes the specified rows from a table and returns a count of the deleted rows. A count of 0 is not an error, but indicates that no rows matched the condition. An unqualified DELETE statement (omits a WHERE clause) removes all rows but leaves intact table columns, projections, and constraints.

DELETE supports subqueries and joins, so you can delete values in a table based on values in other tables.
Syntax

DELETE [ /*+ hint[, hint] */ ] FROM [[database.]schema.]table [ where-clause ]

Parameters

<table>
<thead>
<tr>
<th>/*+ hint [, hint] */</th>
<th>One or both of the following hints:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• DIRECT</td>
</tr>
<tr>
<td></td>
<td>• LABEL</td>
</tr>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>table</td>
<td>Any table, including temporary tables.</td>
</tr>
<tr>
<td>where-clause</td>
<td>Specifies which rows to mark for deletion. If you omit this clause, DELETE behavior varies depending on whether the table is persistent or temporary. See below for details.</td>
</tr>
</tbody>
</table>

Privileges

Table owner or user with GRANT OPTION is grantor.

- DELETE privilege on table
- USAGE privilege on the schema of the target table
- SELECT privilege on a table when the DELETE statement includes a WHERE or SET clause that specifies columns from that table.
Restrictions

You cannot execute DELETE on a projection.

Deleting from Persistent Tables

Unlike TRUNCATE TABLE, DELETE does not delete data from disk storage. Rather, it marks rows for deletion in the WOS. These rows are no longer valid in the current epoch. By default, DELETE uses WOS. If WOS fills up, the operation overflows to the ROS.

Deleting from a Temporary Table

DELETE execution on temporary tables varies, depending on whether the table was created with ON COMMIT DELETE ROWS (default) or ON COMMIT PRESERVE ROWS:

- If DELETE contains a WHERE clause that specifies which rows to remove, behavior is identical: DELETE marks the rows for deletion. In both cases, you cannot roll back to an earlier savepoint.

- If DELETE omits a WHERE clause and the table was created with ON COMMIT PRESERVE ROWS, Vertica marks all table rows for deletion. If the table was created with ON COMMIT DELETE ROWS, DELETE behaves like TRUNCATE TABLE and removes all rows from storage.

  Note: If you issue an unqualified DELETE statement on a temporary table created with ON COMMIT DELETE ROWS, Vertica removes all rows from storage but does not end the transaction.

Examples

The following command removes all rows from temporary table temp1:

  => DELETE FROM temp1;

The following command deletes all records from anchor table T where C1 = C2 - C1.

  => DELETE FROM T WHERE C1=C2-C1;
The following command deletes all records from the customer table in the retail schema where the state attribute is in MA or NH:

```sql
=> DELETE FROM retail.customer WHERE state IN ('MA', 'NH');
```

For examples that show how to nest a subquery within a DELETE statement, see Subqueries in UPDATE and DELETE in Analyzing Data.

Directed Query Statements

The following statements let you create and manage directed queries:

<table>
<thead>
<tr>
<th>ACTIVATE DIRECTED QUERY</th>
<th>Activates a directed query.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE DIRECTED QUERY</td>
<td>Saves an association between an input query and a query that is annotated with optimizer hints.</td>
</tr>
<tr>
<td>DEACTIVATE DIRECTED QUERY</td>
<td>Deactivates one or more directed queries.</td>
</tr>
<tr>
<td>DROP DIRECTED QUERY</td>
<td>Removes a directed query from the database.</td>
</tr>
<tr>
<td>GET DIRECTED QUERY</td>
<td>Returns a list of directed queries stored in the database for a given input query.</td>
</tr>
<tr>
<td>SAVE QUERY</td>
<td>Saves an input query to associate with a custom directed query.</td>
</tr>
</tbody>
</table>
ACTIVATE DIRECTED QUERY

Activates a directed query and makes it available to the query optimizer across all sessions.

Syntax
ACTIVATE DIRECTED QUERY  

Parameters

<table>
<thead>
<tr>
<th>query-name</th>
<th>Identifies the directed query to activate.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>To obtain identifiers for directed queries, use GET DIRECTED QUERY, or query the system table V_CATALOG.DIRECTED_QUERIES.</td>
</tr>
</tbody>
</table>

Privileges

Superuser

Activation Life Cycle

After you activate a directed query, it remains active until it is explicitly deactivated by DEACTIVATE DIRECTED QUERY or removed from storage by DROP DIRECTED QUERY. If a directed query is active at the time of database shutdown, Vertica automatically reactivates it when you restart the database.

Examples

See Activating and Deactivating Directed Queries.

CREATE DIRECTED QUERY

Saves an association between an input query and a query that is annotated with optimizer hints.
Syntax

Optimizer-generated

CREATE DIRECTED QUERY OPTIMIZER directedqueryID [COMMENT 'comments']
input-query

User-generated (custom)

CREATE DIRECTED QUERY CUSTOM directedqueryID [COMMENT 'comments']
annotated-query

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPTIMIZER</td>
<td>Directs the query optimizer to generate an annotated query from input-query, and associate both in the new directed query.</td>
</tr>
<tr>
<td>CUSTOM</td>
<td>Specifies to associate annotated-query with the query previously specified by SAVE QUERY.</td>
</tr>
<tr>
<td>directedqueryID</td>
<td>A unique identifier for the directed query, a string that conforms to conventions described in Identifiers.</td>
</tr>
</tbody>
</table>
| COMMENT 'comments'         | Comments about the directed query, up to 128 characters. Comments can be useful for future reference—for example, explain why a given directed query was created. If you omit this argument, Vertica inserts one of the following comments:  
  - Optimizer-generated directed query  
  - Custom directed query |
| input-query                | The input query to associate with an optimizer-generated directed query. The input query supports only one optimizer hint, IGNORECONST. |
| annotated-query            | A query with embedded optimizer hints to associate with the input query most recently saved with SAVE QUERY. |
Privileges

Superuser

Description

CREATE DIRECTED QUERY associates an input query with a query annotated with optimizer hints. It stores the association under a unique identifier. CREATE DIRECTED QUERY has two variants:

- CREATE DIRECTED QUERY OPTIMIZER directs the query optimizer to generate annotated SQL from the specified input query. The annotated query contains hints that the optimizer can use to recreate its current query plan for that input query.

- CREATE DIRECTED QUERY CUSTOM specifies an annotated query supplied by the user. Vertica associates the annotated query with the input query specified by the last SAVE QUERY statement.

In both cases, Vertica associates the annotated query and input query, and registers their association in the system table V_CATALOG.DIRECTED_QUERIES under query_name.

Caution: Vertica associates a saved query and directed query without checking whether the two are compatible. Be careful to sequence SAVE QUERY and CREATE DIRECTED QUERY CUSTOM so the saved and directed queries are correctly matched.

See Also

Creating Directed Queries

DEACTIVATE DIRECTED QUERY

Deactivates one or more directed queries previously activated by ACTIVATE DIRECTED QUERY.

Syntax

DEACTIVATE DIRECTED QUERY {query-name|input-query}
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query-name</td>
<td>Identifies the directed query to deactivate. To obtain identifiers for directed queries, use GET DIRECTED QUERY, or query the system table V_CATALOG.DIRECTED_QUERIES.</td>
</tr>
<tr>
<td>input-query</td>
<td>The input query of the directed queries to deactivate. Use this argument to deactivate multiple direct queries that map to the same input query.</td>
</tr>
</tbody>
</table>

Privileges

Superuser

DROP DIRECTED QUERY

Removes a directed query from the database. If the directed query is active, Vertica deactivates it before removal.

Syntax

DROP DIRECTED QUERY directedqueryID

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>directedqueryID</td>
<td>Identifies the directed query to remove from the database. To obtain identifiers for directed queries, use GET DIRECTED QUERY, or query the system table V_CATALOG.DIRECTED_QUERIES.</td>
</tr>
</tbody>
</table>

Privileges

Superuser
GET DIRECTED QUERY

Returns a list of directed queries that map to the specified input query

Syntax

GET DIRECTED QUERY input-query

Parameters

<table>
<thead>
<tr>
<th>input-query</th>
<th>An input query that is associated with one or more directed queries.</th>
</tr>
</thead>
</table>

Returns

A list of one or more directed queries that map to the specified input query. Each list item includes six fields:

<table>
<thead>
<tr>
<th>query-name</th>
<th>A unique identifier that is associated with this directed query and used by statements such as ACTIVATE DIRECTED QUERY.</th>
</tr>
</thead>
<tbody>
<tr>
<td>is_active</td>
<td>A Boolean field that specifies whether the directed query is active.</td>
</tr>
<tr>
<td>vertica_version</td>
<td>The Vertica version that was current when this directed query was created.</td>
</tr>
<tr>
<td>comment</td>
<td>A user-supplied comment specified on creation of the direct query.</td>
</tr>
<tr>
<td>creation_date</td>
<td>The creation timestamp of this directed query.</td>
</tr>
<tr>
<td>annotated_query</td>
<td>The annotated query that was saved with CREATE DIRECTED QUERY.</td>
</tr>
</tbody>
</table>

Privileges

None required
Examples

See Getting Directed Queries in the Administrator's Guide.

See Also

V_CATALOG.DIRECTED_QUERIES

SAVE QUERY

Saves an input query to associate with a custom directed query.

Syntax

SAVE QUERY input-query

Parameters

| input-query | The input query to associate with a custom directed query. The input query supports only one optimizer hint, IGNORECONST. |

Privileges

Superuser

Description

SAVE QUERY saves the specified input query for use by the next invocation of CREATE DIRECTED QUERY CUSTOM. CREATE DIRECTED QUERY CUSTOM pairs the saved query with its annotated query argument to create a directed query. Both statements must be issued in the same user session.

The saved query remains available until the one of the following events occurs:
• The next invocation of CREATE DIRECTED QUERY, whether invoked with CUSTOM or OPTIMIZER.

• Another invocation of SAVE QUERY.

• The session ends.

Caution: Vertica associates a saved query with a directed query without checking whether the input and annotated queries are compatible. Be careful to sequence SAVE QUERY and CREATE DIRECTED QUERY CUSTOM so the saved and directed queries are correctly matched.

Examples

See Custom Directed Queries.

**DISCONNECT**

Closes a previously established connection to another Vertica database. You must have previously used the CONNECT statement to perform a COPY FROM VERTICA or EXPORT TO VERTICA statement.

Syntax

```sql
DISCONNECT database-name
```

Parameters

| database-name | The name of the database whose connection to close. |

Privileges

No special permissions required.
Example

```sql
=> DISCONNECT ExampleDB;
DISCONNECT
```

See Also

- CONNECT
- COPY FROM VERTICA
- EXPORT TO VERTICA

**DROP ACCESS POLICY**

Removes an access policy from a column or row. If you attempt to run a DROP TABLE statement on a table that contains an access policy, the following message appears:

```
NOTICE 4927: The AccessPolicy depends on Table tablename
ROLLBACK 3128: DROP failed due to dependencies
DETAIL: Cannot drop Table `tablename` because other objects depend on it
Projection `projection` has column `column_name` as part of its sort order
Projection public.p_1 has column `column_name` as part of its sort order
HINT: Use DROP .. CASCADE to drop or modify the dependent objects
```

Syntax

```
DROP ACCESS POLICY ON `tablename`
FOR { COLUMN `columnname` | ROWS };
```

Parameters

<table>
<thead>
<tr>
<th><code>tablename</code></th>
<th>The name of the table that contains the column access policy you want to remove.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>columnname</code></td>
<td>The name of the column that contains the access policy you want to remove.</td>
</tr>
</tbody>
</table>
Privileges

You must be a dbadmin user to drop an access policy.

Examples

These examples show various cases where you can drop an access policy.

**Drop Column Access Policy from Customer Table for a Specified Column**

=> DROP ACCESS POLICY ON customer FOR COLUMN Customer_Number;

**Drop Access Policy and Table Using the CASCADE Keyword with DROP TABLE**

=> DROP TABLE <tablename> CASCADE;

**Drop Row Access Policy on customer_info table**

=> DROP ACCESS POLICY ON customer_info FOR ROWS;

**DROP AGGREGATE FUNCTION**

Drops a User Defined Aggregate Function (UDAF) from the Vertica catalog.

Syntax

```
DROP AGGREGATE FUNCTION [[database.]schema.]function[, ...]
  ... ( [ [argname] argtype[,,...] ] )
```

Parameters

<table>
<thead>
<tr>
<th><code>[database.]schema</code></th>
<th>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
</tbody>
</table>
If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th><strong>function</strong></th>
<th>Specifies a name of the SQL function to drop. If the function name is schema-qualified, the function is dropped from the specified schema (as noted above).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>argname</strong></td>
<td>Specifies the name of the argument, typically a column name.</td>
</tr>
<tr>
<td><strong>argtype</strong></td>
<td>Specifies the data type for argument(s) that are passed to the function. Argument types must match Vertica type names. See SQL Data Types.</td>
</tr>
</tbody>
</table>

**Privileges**

One of the following:

- Superuser
- Owner

**Notes**

- To drop a function, you must specify the argument types because several functions might share the same name with different parameters.
- Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL functions), Vertica returns an error when those objects are used and not when the function is dropped.

**Example**

The following command drops the ag_avg function:

```sql
=> DROP AGGREGATE FUNCTION ag_avg(numeric);
DROP AGGREGATE FUNCTION
```
See Also

- ALTER FUNCTION (UDF)
- CREATE AGGREGATE FUNCTION
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
- USER_FUNCTION
- Using User-Defined SQL Functions
- Developing User-Defined Extensions (UDxs)
- Aggregate Functions (UDAFs)

**DROP AUTHENTICATION**

Drops an authentication method that has been created but not granted to any users. If you try to drop an authentication method that has been granted to one or more users, the DROP operation fails. To successfully drop an authentication method that is currently granted to a user, use the CASCADE keyword.

**Syntax**

`DROP AUTHENTICATION auth_method_name [ CASCADE ]`

**Parameters**

| `auth_method_name` | Name of the authentication method to drop.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type: VARCHAR (not case sensitive)</td>
<td></td>
</tr>
</tbody>
</table>
Privileges

Must have DBADMIN privileges.

Examples

To delete an authentication record for md5_auth, use the following command:

```sql
=> DROP AUTHENTICATION md5_auth;
```

To delete an authentication record for a method that has been granted to a user, use the CASCADE keyword:

```sql
=> CREATE AUTHENTICATION localpwd METHOD 'password' LOCAL;
=> GRANT AUTHENTICATION localpwd TO jsmith;
=> DROP AUTHENTICATION localpwd CASCADE;
```

- ALTER AUTHENTICATION
- CREATE AUTHENTICATION
- GRANT (Authentication)
- REVOKE (Authentication)

**DROP FAULT GROUP**

A drop operation removes the specified fault group and its child fault groups, placing all nodes under the parent of the dropped fault group.

To drop all fault groups, use `ALTER DATABASE..DROP ALL FAULT GROUP` syntax.

To add an orphaned node back to a fault group, you must manually re-assign it to a new or existing fault group using a combination of `CREATE FAULT GROUP` and `ALTER FAULT GROUP..ADD NODE` statements.

Tip: For a list of all fault groups defined in the cluster, query the `V_CATALOG.FAULT_GROUPS` system table.
Syntax

```
DROP FAULT GROUP name
```

Parameters

| name   | Specifies the name of the fault group to drop. |

Privileges

Must be a superuser to drop a fault group.

Example

The following example drops the `group2` fault group from the cluster:

```
exampledb=> DROP FAULT GROUP group2;
```

See Also

- `V_CATALOG.FAULT_GROUPS` and `V_CATALOG.CLUSTER_LAYOUT`
- Fault Groups in the Administrator's Guide
- High Availability With Fault Groups in Vertica Concepts
DROP FUNCTION

Drops a SQL function or User Defined Function (UDF) from the Vertica catalog.

Syntax

```
DROP FUNCTION [[database.]schema.]function[,....] ( [ arg-list ] )
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>database. schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>function</code></td>
<td>The SQL function to drop.</td>
</tr>
<tr>
<td><code>arg-list</code></td>
<td>A comma-delimited list of arguments as defined for this function when it was created, specified as follows:</td>
</tr>
<tr>
<td></td>
<td><code>[arg-name] arg-type[,....]</code></td>
</tr>
<tr>
<td></td>
<td>where <code>arg-name</code> optionally qualifies <code>arg-type</code>:</td>
</tr>
<tr>
<td></td>
<td>• <code>arg-name</code> is typically a column name.</td>
</tr>
<tr>
<td></td>
<td>• <code>arg-type</code> is the name of an SQL data type supported by Vertica.</td>
</tr>
</tbody>
</table>

Privileges

One of the following:

- Superuser
- Schema or function owner
Requirements

- To drop a function, you must specify the argument types because several functions might share the same name with different parameters.

- Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL functions), Vertica returns an error when those objects are used and not when the function is dropped.

Example

The following command drops the `zerowhennull` function in the `macros` schema:

```
=> DROP FUNCTION macros.zerowhennull(x INT);
DROP FUNCTION
```

See Also

- `ALTER FUNCTION (UDF)`
- `CREATE FUNCTION (SQL Functions)`
- `GRANT (User Defined Extension)`
- `REVOKE (User Defined Extension)`
- `USER_FUNCTIONS`
- `Using User-Defined SQL Functions`

DROP SOURCE

Drops a User Defined Load Source function from the Vertica catalog.

Syntax

`DROP SOURCE [[database.]schema.]source()`
Parameters

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>

| source() | Specifies the source function to drop. You must append empty parentheses to the function name. |

Privileges

One of the following:

- Superuser
- Source function owner

Example

The following command drops the curl source function:

```sql
=> DROP SOURCE curl();
DROP SOURCE
```

See Also

- ALTER FUNCTION (UDF)
- CREATE SOURCE
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
• USER_FUNCTIONS
• Load (UDLs)

DROP FILTER

Drops a User Defined Load Filter function from the Vertica catalog.

Syntax

DROP FILTER [[database.]schema.]filter()

Parameters

| [database.]schema | Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:
| myschema.thisDbObject |
| filter()          | Specifies the filter function to drop. You must append empty parentheses to the function name. |

Privileges

Only the superuser or owner can drop the filter function.

Example

The following command drops the Iconverter filter function:

=> drop filter Iconverter();
DROP FILTER
See Also

- ALTER FUNCTION (UDF)
- CREATE FILTER
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
- USER_FUNCTIONS
- Load (UDLs)

DROP PARSER

Drops a User Defined Load Parser function from the Vertica catalog.

Syntax

DROP PARSER([database.]schema.]parser())

Parameters

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>parser()</td>
<td>The name of the parser function to drop. You must append empty parentheses to the function name.</td>
</tr>
</tbody>
</table>

Privileges

Only the superuser or owner can drop the parser function.
Example

The following command drops the BasicIntegerParser parser function:

```
=> DROP PARSER BasicIntegerParser();
```

See Also

- ALTER FUNCTION (UDF)
- CREATE PARSER
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
- USER_FUNCTIONS
- Load (UDLs)

**DROP LIBRARY**

Removes a shared library from the database. The library file is deleted from managed directories on the Vertica nodes. The user defined functions (UDFs) in the library are no longer available. See Developing User-Defined Extensions (UDxs) in Extending Vertica for details.

**Syntax**

```
DROP LIBRARY [[database.]schema.]library [CASCADE]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
</tbody>
</table>
If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th>Library</th>
<th>The name of the library to drop, the same name used in CREATE LIBRARY to load the library.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASCADE</td>
<td>Drops any functions that were defined using the library. DROP LIBRARY fails if CASCADE is omitted and one or more UDFs use the target library.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**Example**

To drop the library MyFunctions:

```sql
=> DROP LIBRARY MyFunctions CASCADE;
```

**DROP MODEL**

Removes a model from the Vertica database. You can drop multiple models at one time.

**Syntax**

```
DROP MODEL [IF EXISTS] [[db-name.][schema.]model-name
```

**Parameters**

| IF EXISTS | Specifies not to report an error if one or more of the models to drop does not exist. This clause is useful in SQL scripts where you want to drop a model if it exists before recreating it. |
Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:

```sql
myschema
```

The model to drop.

### Privileges

Any user who creates a model can drop or alter his or her own model. If you are the dbadmin user, you can drop or alter any model in the database.

### Examples

This example shows how you can remove a model.

```sql
=> DROP MODEL mySVMModel;
DROP MODEL
```

### DROP NETWORK INTERFACE

Removes a network interface from Vertica. You can use the CASCADE option to also remove the network interface from any node definition. (See Identify the Database or Nodes Used for Import/Export for more information.)

#### Syntax

```sql
DROP NETWORK INTERFACE network-interface-name [CASCADE]
```

#### Parameters

The parameters are defined as follows:

| network-interface-name | The network interface you want to remove. |
Privileges

Must be a superuser to drop a network interface.

Examples

This example shows how to drop a network interface.

```sql
=> DROP NETWORK INTERFACE myNetwork;
```

**DROP NOTIFIER**

Drops a push-based notifier created by `CREATE NOTIFIER`.

Syntax

```
DROP NOTIFIER notifier-name
```

Parameters

<table>
<thead>
<tr>
<th>notifier-name</th>
<th>This notifier's unique identifier.</th>
</tr>
</thead>
</table>

**DROP PROCEDURE**

Removes an external procedure from Vertica. Only the reference to the procedure is removed. The external file remains in the `database/procedures` directory of each database node.

Syntax

```
DROP PROCEDURE [[database.]schema.]procedure( [ arg-list ] )
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>procedure</td>
<td>Specifies the procedure to drop.</td>
</tr>
<tr>
<td>arg-List</td>
<td>A comma-delimited list of arguments defined for this procedure when it was created, specified as follows:</td>
</tr>
<tr>
<td></td>
<td><code>[arg-name] arg-type[, ...]</code></td>
</tr>
<tr>
<td></td>
<td>where <code>arg-name</code> optionally qualifies <code>arg-type</code>. If no arguments are defined for this procedure, specify empty parentheses.</td>
</tr>
</tbody>
</table>

Privileges

- Superuser or procedure owner
- USAGE privilege on schema, or schema owner

Example

```
=> DROP PROCEDURE helloplanet(arg1 varchar);
```

See Also

CREATE PROCEDURE
**DROP PROFILE**

Removes a profile from the database. Only the superuser can drop a profile.

**Syntax**

```sql
DROP PROFILE name [, ...] [ CASCADE ]
```

**Parameters**

<table>
<thead>
<tr>
<th>name</th>
<th>The name of one or more profiles (separated by commas) to be removed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASCADE</td>
<td>Moves all users assigned to the profile or profiles being dropped to the DEFAULT profile. If you do not include CASCADE in the DROP PROFILE command and a targeted profile has users assigned to it, the command returns an error.</td>
</tr>
</tbody>
</table>

**Privileges**

Must be a superuser to drop a profile.

**Notes**

You cannot drop the DEFAULT profile.

**Example**

```sql
=> DROP PROFILE sample_profile;
```
See Also

- ALTER PROFILE
- CREATE PROFILE

**DROP PROJECTION**

Marks a projection to drop from the catalog so it is unavailable to user queries.

**Syntax**

```
DROP PROJECTION { [[database.]schema.]projection [ , ... ] } ... [ RESTRICT | CASCADE ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `[database.]schema` | Specifies a schema, by default public. If `schema` is any schema other than public, you must supply the schema name. For example:  
  `myschema.thisDbObject`  
  If you specify a database, it must be the current database. |
| `projection`    | Specifies a projection to drop:  
  - If the projection is unsegmented, all projection replicas in the database cluster are dropped.  
  - If the projection is segmented, drop all buddy projections by specifying the projection base name. You can also specify the name of a specific buddy projection as long as dropping it so does not violate system K-safety.  
    See Projection Naming for projection name conventions. |
<p>| <code>RESTRICT | CASCADE</code> | Specifies whether to drop the projection when it contains |</p>
<table>
<thead>
<tr>
<th>objects:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• RESTRICT (default): Drop the projection only if it contains no objects.</td>
</tr>
<tr>
<td>• CASCADE: Drop the projection even if it contains objects.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser, or owner of the anchor table

**Restrictions**

The following restrictions apply to dropping a projection:

- The projection cannot be the anchor table's superprojection.
- You cannot drop a buddy projection if doing so violates system K-safety.
- Another projection must be available to enforce the same primary or unique key constraint.

**See Also**

- CREATE PROJECTION
- DROP TABLE
- GET_PROJECTIONS
- GET_PROJECTION_STATUS
- MARK DESIGN KSAFE
- Adding Nodes
**DROP RESOURCE POOL**

Drops a user-created resource pool. All memory allocated to the pool is returned back to the GENERAL pool.

**Syntax**

```
DROP RESOURCE POOL pool-name
```

**Parameters**

| pool-name | Specifies the name of the resource pool to be dropped. |

**Privileges**

Must be a superuser to drop a resource pool.

**Dropping a Secondary Pool**

If you try to drop a resource pool that is a secondary pool for another resource pool, Vertica returns an error. The error lists the resource pools that depend on the secondary pool you tried to drop. To drop a secondary resource pool, first set the CASCADE TO parameter to DEFAULT on the primary resource pool, and then drop the secondary pool.

For example, you can drop resource pool rp2, which is a secondary pool for rp1, as follows:

```
=> ALTER RESOURCE POOL rp1 CASCADE TO DEFAULT;
=> DROP RESOURCE POOL rp2;
```

**Transferring Resource Requests**

Any requests queued against the pool are transferred to the GENERAL pool according to the priority of the pool compared to the GENERAL pool. If the pool’s priority is higher than the
GENERAL pool, the requests are placed at the head of the queue; otherwise the requests are placed at the end of the queue.

Any users who are using the pool are switched to use the GENERAL pool with a NOTICE:

| NOTICE: Switched the following users to the General pool: username |

DROP RESOURCE POOL returns an error if the user does not have permission to use the GENERAL pool. Existing sessions are transferred to the GENERAL pool regardless of whether the session's user has permission to use the GENERAL pool. This can result in additional user privileges if the pool being dropped is more restrictive than the GENERAL pool. To prevent giving users additional privileges, follow this procedure to drop restrictive pools:

1. Revoke the permissions on the pool for all users.
2. Close any sessions that had permissions on the pool.
3. Drop the resource pool.

Examples

The following command drops the resource pool that was created for the CEO:

```sql
=> DROP RESOURCE POOL ceo_pool;
```

See Also

- ALTER RESOURCE POOL
- CREATE RESOURCE POOL
- Managing Workloads

**DROP ROLE**

Removes a role from the database. Only the database superuser can drop a role.

Use the CASCADE option to drop a role that is assigned to one or more users or roles.
NOTE: You cannot use the DROP ROLE command on a role added to the Vertica database with the LDAPLink service.

Syntax

```
DROP ROLE role [CASCADE];
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>role</td>
<td>The name of the role to drop</td>
</tr>
<tr>
<td>CASCADE</td>
<td>Revoke the role from users and other roles before dropping the role</td>
</tr>
</tbody>
</table>

Privileges

Must be a superuser to drop a role.

Examples

```
=> DROP ROLE appadmin;
NOTICE: User bob depends on Role appadmin
ROLLBACK: DROP ROLE failed due to dependencies
DETAIL: Cannot drop Role appadmin because other objects depend on it
HINT: Use DROP ROLE ... CASCADE to remove granted roles from the dependent users/roles
=> DROP ROLE appadmin CASCADE;
DROP ROLE
```

See Also

- ALTER ROLE RENAME
- CREATE ROLE
DROP SCHEMA

Permanently removes a schema from the database. Be sure that you want to remove the schema before you drop it, because DROP SCHEMA is an irreversible process. Use the CASCADE parameter to drop a schema containing one or more objects.

Syntax

DROP SCHEMA [database.]schema[,...] [ CASCADE | RESTRICT ]

Parameters

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Name of the schema to drop. If you specify a database, it must be the current database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASCADE</td>
<td>Specifies to drop the schema and all objects in it, regardless of who owns those objects.</td>
</tr>
<tr>
<td></td>
<td>Caution: Objects in other schemas that depend on objects in the dropped schema—for example, user-defined functions—also are silently dropped.</td>
</tr>
<tr>
<td>RESTRICT</td>
<td>Drops the schema only if it is empty (default).</td>
</tr>
</tbody>
</table>

Privileges

Schema owner
## Restrictions

- You cannot drop the PUBLIC schema.
- If a user is accessing an object within a schema that is in the process of being dropped, the schema is not deleted until the transaction completes.
- Canceling a DROP SCHEMA statement can cause unpredictable results.

## Examples

The following example drops schema S1 only if it doesn't contain any objects:

```sql
=> DROP SCHEMA S1;
```

The following example drops schema S1 whether or not it contains objects:

```sql
=> DROP SCHEMA S1 CASCADE;
```

## DROP SEQUENCE

Removes the specified named sequence number generator.

### Syntax

```sql
DROP SEQUENCE [[database.]schema.]sequence[, ...]
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>
**sequence**  |  Specifies the sequence to drop.

**Privileges**

One of the following:

- Superuser
- Sequence or schema owner

**Restrictions**

- For sequences specified in a table's default expression, the default expression fails the next time you try to load data. Vertica does not check for these instances.
- DROP SEQUENCE does not support the CASCADE keyword. Sequences used in a default expression of a column cannot be dropped until all references to the sequence are removed from the default expression.

**Example**

The following command drops the sequence named *sequential*.

```
=> DROP SEQUENCE sequential;
```

**See Also**

- ALTER SEQUENCE
- CREATE SEQUENCE
- CURRVAL
- GRANT (Sequence)
- NEXTVAL
Sequence Types

Named Sequence Privileges

**DROP SUBNET**

Removes a subnet from Vertica. You can use the CASCADE option to also remove the subnet from any database definition. (See Identify the Database or Nodes Used for Import/Export for more information.)

**Syntax**

```
DROP SUBNET subnet-name [CASCADE]
```

**Parameters**

The parameters are defined as follows:

<table>
<thead>
<tr>
<th>subnet-name</th>
<th>The subnet you want to remove.</th>
</tr>
</thead>
</table>

If you remove a subnet, be sure your database is not configured to allow export on the public subnet. (See Identify the Database or Nodes Used for Import/Export for more information.)

**Privileges**

Must be a superuser to drop a subnet.

**Examples**

This example shows how to remove a subnet.

```
=> DROP SUBNET mySubnet;
```
**DROP TABLE**

Removes a table and its projections. When you run DROP TABLE, the change is auto-committed.

**Syntax**

```
DROP TABLE [ IF EXISTS ] [[database.]schema.]table [ , ... ] [ CASCADE ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF EXISTS</td>
<td>Specifies not to report an error if one or more of the tables to drop does not exist. This clause is useful in SQL scripts where you want to drop a table if it exists before recreating it.</td>
</tr>
<tr>
<td>[ schema ]</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code> If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>table</td>
<td>The table to drop.</td>
</tr>
<tr>
<td>CASCADE</td>
<td>Specifies to drop all projections for this table before the table is dropped. CASCADE is optional if only auto-projections are associated with this table; otherwise it is required. This option is not valid for external tables.</td>
</tr>
</tbody>
</table>

**Privileges**

- Table owner with USAGE privilege on table's schema
- Schema owner
Requirements

- Do not cancel an executing DROP TABLE. Doing so can leave the database in an inconsistent state.
- Check that the target table is not in use, either directly or indirectly—for example, in a view.
- If you drop and restore a table that is referenced by a view, the new table must have the same name and column definitions.

Examples

See Dropping Tables in the Administrator's Guide.

See Also

- DROP PROJECTION
- TRUNCATE TABLE

**DROP TEXT INDEX**

Drops a text index used to perform text searches.

Syntax

```
DROP TEXT INDEX [ IF EXISTS ] [[database.]schema.]idx-table
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF EXISTS</td>
<td>If specified, DROP TEXT INDEX does not report an error if one or more of the tables to be dropped does not exist. You can use this clause in SQL scripts where you want to drop a table, if it exists,</td>
</tr>
</tbody>
</table>
| **[database.]schema** | Specifies a schema, by default public. If **schema** is any schema other than public, you must supply the schema name. For example:

```
myschema.thisDbObject
```

If you specify a database, it must be the current database. |
| **idx-table** | Specifies the text index name. When using more than one schema, specify the schema that contains the index in the DROP TEXT INDEX statement. |

### Privileges

Table owner and dbadmin with USAGE privilege on schema that contains the table or schema owner.

### Behavior

When a source table is dropped that has a text index associated with it, the text index is also dropped.

### Examples

The following example drops the text index `t_text_index`:

```
=> DROP TEXT INDEX t_text_index;
DROP INDEX
```

### See Also

- [Using Text Search](#)
- [CREATE TEXT INDEX](#)
DROP TRANSFORM FUNCTION

Drops a user-defined transform function (UDTF) from the Vertica catalog.

Syntax

```
DROP TRANSFORM FUNCTION [[database.]schema.]function( [ arg-list ] )
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>function</td>
<td>Specifies the transform function to drop.</td>
</tr>
<tr>
<td>arg-list</td>
<td>A comma-delimited list of arguments as defined for this function when it was created, specified as follows:</td>
</tr>
<tr>
<td></td>
<td>[arg-name] arg-type[,...]</td>
</tr>
<tr>
<td></td>
<td>If multiple functions share the same name, specify the argument types of the function you wish to drop.</td>
</tr>
<tr>
<td></td>
<td>• arg-name is typically a column name. You (optionally) use an arg-name to qualify an arg-type.</td>
</tr>
<tr>
<td></td>
<td>• arg-type is the name of an SQL data type supported by Vertica.</td>
</tr>
<tr>
<td></td>
<td>You do not need to include an arg-list when dropping a polymorphic function.</td>
</tr>
</tbody>
</table>

Privileges

One of the following:
- Superuser
- Schema or function owner

Example

The following command drops the `tokenize` UDF in the `macros` schema:

```sql
=> DROP TRANSFORM FUNCTION macros.tokenize(varchar);
```

The following command drops the `Pagerank` polymorphic function in the `online` schema:

```sql
=> DROP TRANSFORM FUNCTION online.Pagerank();
```

See Also

CREATE TRANSFORM FUNCTION

**DROP USER**

Removes a name from the list of authorized database users.

NOTE: You cannot use the DROP USER command on a user added to the Vertica database with the LDAPLink service.

Syntax

```sql
DROP USER name [ , ... ] [ CASCADE ]
```

Parameters

<table>
<thead>
<tr>
<th>name</th>
<th>Specifies the name or names of the user to drop.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASCADE</td>
<td>[Optional] Drops all user-defined objects created by the user dropped, including</td>
</tr>
</tbody>
</table>
Privileges

Must be a superuser to drop a user.

Examples

DROP USER <username> fails if objects exist that were created by the user, such as schemas, and tables and their associated projections:

```sql
=> DROP USER user1;
NOTICE: Table T_tbd1 depends on User user1
ROLLBACK: DROP failed due to dependencies
DETAIL: Cannot drop User user1 because other objects depend on it
HINT: Use DROP ... CASCADE to drop the dependent objects too
```

DROP USER <name> CASCADE succeeds regardless of any pre-existing user-defined objects. The statement forcibly drops all user-defined objects, such as schemas, tables and their associated projections:

```sql
=> DROP USER user1 CASCADE;
```

Caution: Tables owned by the user being dropped cannot be recovered after you issue DROP USER CASCADE.

DROP USER <username> succeeds if no user-defined objects exist (no schemas, tables or projections defined by the user):

```sql
=> CREATE USER user2;
CREATE USER
=> DROP USER user2;
DROP USER
```

See Also

- ALTER USER
- CREATE USER
DROP VIEW

Removes the specified view. Vertica does not check for dependencies on the dropped view. After dropping a view, other views that reference it fail.

If you drop a view and replace it with another view or table with the same name and column names, other views that reference that name use the new view. If you change the column data type in the new view, the server coerces the old data type to the new one if possible; otherwise, it returns an error.

Syntax

DROP VIEW [\[[database.]schema.]view [, ... ]

Parameters

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td>view</td>
<td>Specifies the view to drop.</td>
</tr>
</tbody>
</table>

Privileges

One of the following

- View owner and USAGE privileges
- Schema owner
Examples

```sql
=> DROP VIEW myview;
```

**END**

Ends the current transaction and makes all changes that occurred during the transaction permanent and visible to other users.

**Syntax**

```
COMMIT [ WORK | TRANSACTION ]
```

**Parameters**

<table>
<thead>
<tr>
<th>WORK</th>
<th>TRANSACTION</th>
<th>Have no effect; they are optional keywords for readability.</th>
</tr>
</thead>
</table>

**Privileges**

No special permissions required.

**Notes**

`COMMIT` is a synonym for `END`.

**Examples**

This example shows how to end a transaction.

```sql
=> CREATE TABLE sample_table (a INT);
=> INSERT INTO sample_table (a) VALUES (1);
```
See Also

- Transactions
- Creating Transactions
- BEGIN
- ROLLBACK
- START TRANSACTION

**EXPLAIN**

Returns a formatted description of the Vertica optimizer's plan for executing the specified statement.

**Syntax**

```
EXPLAIN [/*+ ALLNODES */] [explain-options] sql-statement
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/<em>+ALLNODES</em>/</td>
<td>Specifies to create a query plan that assumes all nodes are active, not valid with LOCAL option.</td>
</tr>
<tr>
<td>explain-options</td>
<td>One or more EXPLAIN options, specified in the order shown:</td>
</tr>
<tr>
<td></td>
<td>[ LOCAL ] [ VERBOSE ] [ JSON ] [ ANNOTATED ]</td>
</tr>
<tr>
<td></td>
<td>• LOCAL: On a multi-node database, shows the local query plans assigned to each node, which together comprise the total (global) query plan. If you omit this option, Vertica shows only</td>
</tr>
</tbody>
</table>
the global query plan. Local query plans are shown only in DOT language source, which can be rendered in Graphviz.

This option is incompatible with the hint /*+ALL NODES*/. If you specify both, EXPLAIN returns with an error.

- **VERBOSE**: Increases the level of detail in the rendered query plan.
- **JSON**: Renders the query plan in JSON format. This option is compatible only with VERBOSE.
- **ANNOTATED**: Embeds optimizer hints that encapsulate the query plan for this query. Vertica uses these hints to create directed queries. For more information, see Directed Queries in the Administrator's Guide. This option is compatible with LOCAL and VERBOSE.

### sql-statement

A query or DML statement—for example, SELECT, INSERT, UPDATE, COPY, and MERGE.

### Privileges

The same privileges required by the specified statement.

### Requirements

The following requirements apply to EXPLAIN's ability to produce useful information:

- EXPLAIN produces useful output only if projections are available for the queried tables.

- Qualifier options must be specified in the order shown earlier, otherwise EXPLAIN returns with an error. If an option is incompatible with any preceding options, EXPLAIN ignores them.
See Also

EXPLAIN Output Options in the Administrator's Guide

**EXPORT TO PARQUET**

Exports a table, columns from a table, or query results to files in the Parquet format. You can use an OVER() clause to partition the data before export. Partitioning data can improve query performance by enabling partition pruning; see Improving Query Performance for Data Stored in HDFS.

You can export data stored in Vertica in ROS format and data from external tables.

EXPORT TO PARQUET returns the number of rows written.

During the export, Vertica writes files to a temporary directory in the same location as the destination and renames the directory when the export is complete. Do not attempt to use the files in the temporary directory.

**Syntax**

```
EXPORT TO PARQUET ( directory = 'directory'
    [, compression = 'compression-type' ]
    [, rowGroupSizeMB = size ]
    [ OVER (over-clause ) ]
AS SELECT query-expression;
```

**Parameters**

| **directory** | The destination directory for the Parquet files. The directory must not exist, and the current user must have permission to write it. The directory can be in HDFS or on the local file system. |
| **compression-type** | Column compression type, one of Snappy or Uncompressed. The default is Snappy. |
| **size** | The uncompressed size of exported row groups, in MB. The maximum value is 512 and the default is 64. The row groups in the |
exported files are smaller because Parquet files are compressed on write. For best performance, set size to be smaller than the HDFS block size.

Arguments

| over-clause | Specifies how to partition table data using PARTITION BY. Within partitions you can sort by using ORDER BY. See SQL Analytics. This clause may contain column references but not expressions. This clause, if present, can contain only column references, not an expression. If you partition data, Vertica creates a Hive-style partition directory structure. See Using Partition Columns for a description of the structure. If you omit this clause, Vertica optimizes for maximum parallelism. |
| query-expression | Specifies the data to be exported. See SELECT for the syntax. You must provide an alias column label for selected column targets that are expressions. |

Privileges

- SELECT privileges on the source table
- USAGE privileges on source table schema
- Write privileges for the destination directory

Data Types

EXPORT TO PARQUET does not support the following data types:

- INTERVAL
- TIME/TIMETZ
- **UUID Data Type**

  Decimal precision must be \( \leq 38 \).

  Vertica does not convert \text{TIMESTAMP} values to UTC. To avoid problems arising from time zones, use \text{TIMESTAMPZ} instead of \text{TIMESTAMP}.

  The exported Hive types might not be identical to the Vertica types. For example, a Vertica INT is exported as a Hive BIGINT. When defining Hive external tables to read exported data, you might have to adjust column definitions.

  This operation exports raw Flex columns as binary data.

**Output Files**

If you specify a directory in the local file system that is not shared storage, Vertica distributes the files among nodes according to how the export is partitioned. To write all local files on one node, use an empty \text{OVER}() clause.

If you specify a directory in the local file system, you must have a USER storage location.

Output file names follow the pattern: [8-character hash]-[node name]-[thread_id].parquet.

Vertica does not support simultaneous exports to the same directory in HDFS. The results are undefined.

Parquet files exported to a local filesystem by any Vertica user are owned by the Vertica superuser. Parquet files exported to HDFS are owned by the Vertica user who exported the data.

**Examples**

The following example demonstrates exporting all columns from the T1 table in the public schema, using Snappy compression (the default).

```sql
=> EXPORT TO PARQUET(directory = 'hdfs:///user1/data')
    AS SELECT * FROM public.T1;

Rows Exported
-----------
  87436
(1 row)
```

The following example demonstrates exporting the results of a query using more than one table.
The following example demonstrates partitioning and exporting data. EXPORT TO PARQUET first partitions the data on 'b' and then, within each partition, sorts by 'd'.

```
=> EXPORT TO PARQUET(directory='hdfs:///user2/data')
   OVER(PARTITION BY b ORDER BY d) AS SELECT b, d FROM public.T2;
```

Rows Exported
-----------------
120931
(1 row)

The following example uses an alias column label for a selected column target that is an expression.

```
=> EXPORT TO PARQUET(directory='hdfs:///user3/data')
   OVER(ORDER BY col1) AS SELECT col1 + col1 AS A, col2
   FROM public.T3;
```

Rows Exported
-----------------
14336
(1 row)

**EXPORT TO VERTICA**

Exports an entire table, columns from a table, or query results to another Vertica database. Exported data is always written in AUTO mode.

**Important:** The source database can be one major release behind the target database.

**Syntax**

```
EXPORT TO VERTICA database.[schema.]target-table
   ... [ ( target-column[,...] ) ]
   ... { AS SELECT query-expression | FROM [schema.]source-table[ ( source-column[,...] ) ] };
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>database</strong></td>
<td>A string containing the name of the database to receive the exported data. There must be an active connection to this database for the export to succeed.</td>
</tr>
<tr>
<td>[scope. ]<strong>target-table</strong></td>
<td>The table to store the exported data (schema specification is optional). This table must already exist.</td>
</tr>
<tr>
<td><strong>target-column</strong></td>
<td>A list of columns in the target table to store the exported data.</td>
</tr>
<tr>
<td><strong>query-expression</strong></td>
<td>Specifies the data to be exported. See SELECT for the syntax.</td>
</tr>
<tr>
<td>[scope. ]<strong>source-table</strong></td>
<td>The table that contains the data to export.</td>
</tr>
<tr>
<td><strong>source-column</strong></td>
<td>A list of the columns in the source table to export. If present, only these columns are exported.</td>
</tr>
</tbody>
</table>

Privileges

- SELECT privileges on the source table
- USAGE privilege on source table schema
- INSERT privileges for the destination table in target database
- USAGE privilege on destination table schema

Connecting to the Target Database

Before you can export data to another database, you must establish a connection to the target database with CONNECT. See Exporting Data to Another Vertica Database for details.

By default, EXPORT TO VERTICA exports data to another database over the Vertica private network. Connecting to a public network requires some configuration. For details about exporting data across a public network, see Using Public and Private IP Networks.
The export operation fails if either side of the connection is a single-node cluster installed to localhost, or you do not specify a host name or IP address.

Source and Target Column Mapping

You can optionally name a subset of source and target columns to participate in the export operation. EXPORT TO VERTICA tries to match columns in the source table with corresponding columns in the destination table. If you do not supply a list of source and destination columns, EXPORT TO VERTICA tries to match columns in the source table with corresponding columns in the destination table. Auto-projections for the target table are similar to the projections for the source table.

The following table compares the different combinations of naming source and target columns, and the requirements that pertain to each option.

<table>
<thead>
<tr>
<th>Omit source columns</th>
<th>Specify source columns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Omit target columns</td>
<td>Match all columns in source table to columns in target table. The number of columns in the two tables can differ, but the target table must have at least as many columns as the source table.</td>
</tr>
<tr>
<td>Specify target columns</td>
<td>Match source columns to the named target columns. The number of named target columns must equal the number of columns in the source table.</td>
</tr>
</tbody>
</table>

Node Failure During EXPORT

See Handling Node Failure During Copy/Export in the Administrator's Guide.

Examples

See Exporting Data to Another Vertica Database in the Administrator's Guide.
See Also

COPY FROM VERTICA
**GRANT Statements**

GRANT statements grant privileges on database objects to specific users.

**GRANT (Authentication)**

Associates (or *grants*) an authentication record to one or more users or roles.

**Syntax**

```
GRANT AUTHENTICATION auth-method-name TO
   { Public | user_or_role | user_or_role1, user_or_role2, user_or_role3, ... }
```

**Parameters**

<table>
<thead>
<tr>
<th>auth_method_name</th>
<th>Name of the authentication method you want to associate with one or more users or roles. Type: VARCHAR</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_or_role, user_or_role1, user_or_role2, user_or_role3, ...</td>
<td>Names of users or roles with whom you want to associate the authentication method. Type: VARCHAR.</td>
</tr>
</tbody>
</table>

**Privileges**

Must have DBADMIN privileges.

**Examples**

This example uses a GRANT AUTHENTICATION statement to associate v_ldap authentication with user jsmith:

```sql
=> GRANT AUTHENTICATION v_ldap TO jsmith;
```
This example uses a GRANT AUTHENTICATION statement to associate v_gss authentication to the role DBprogrammer:

```sql
=> CREATE ROLE DBprogrammer;
=> GRANT AUTHENTICATION v_gss to DBprogrammer;
```

This example sets the default client authentication method to v_localpwd:

```sql
=> GRANT AUTHENTICATION v_localpwd TO Public;
```

See Also

- ALTER AUTHENTICATION
- CREATE AUTHENTICATION
- DROP AUTHENTICATION
- REVOKE (Authentication)

GRANT (Database)

Grants the right to create schemas within the database to a user or role. By default, only the superuser has the right to create a database schema.

Syntax

```
GRANT { ...
   | { CREATE [, ...]
   | { TEMP } }
   | { ALL [ PRIVILEGES ]
   | { CONNECT } }
   | ON DATABASE database-name [ , ...]
   | TO { username | rolename } [ , ...]
   | [ WITH GRANT OPTION ]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE</td>
<td>Allows the user to create schemas within the specified database.</td>
</tr>
<tr>
<td>TEMP</td>
<td>Allows the user to create temporary tables in the database.</td>
</tr>
<tr>
<td>CONNECT</td>
<td>Allows the user to connect to a database.</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>ALL</td>
<td>Applies to all privileges.</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>Is for SQL standard compatibility and is ignored.</td>
</tr>
<tr>
<td>database-name</td>
<td>Identifies the database in which to grant the privilege.</td>
</tr>
<tr>
<td>username</td>
<td>Grants the privilege to the specified user or role.</td>
</tr>
<tr>
<td>rolename</td>
<td></td>
</tr>
<tr>
<td>WITH GRANT OPTION</td>
<td>Allows the recipient of the privilege to grant it to other users.</td>
</tr>
</tbody>
</table>

**Example**

The following example grants user Fred the right to create schemas on vmartdb.

```sql
=> GRANT CREATE ON DATABASE vmartdb TO Fred;
```

**See Also**

- [REVOKE (Database)](Vertica Analytic Database (9.0.x) Page 3551 of 6180)
- [Granting and Revoking Privileges](Vertica Analytic Database (9.0.x) Page 3551 of 6180)

**GRANT (Library)**

Grants privileges on a library to a database user or role. Only the superuser can grant privileges to a library. To execute functions inside the library, a user must have separate EXECUTE privileges for those functions.

For example, when working with the Connector Framework Service you may need to grant a user usage privileges to a library to be able to set UDSession parameters. For more information see [Implementing CFS](Vertica Analytic Database (9.0.x) Page 3551 of 6180).

**Syntax**

```
grant { usage | all } on library [[database.]schema.]library [, ...]
  to { username | role | public } [, ...]
```
## Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`{ USAGE</td>
<td>ALL }`</td>
</tr>
<tr>
<td></td>
<td>- USAGE</td>
</tr>
<tr>
<td></td>
<td>- ALL</td>
</tr>
<tr>
<td><code>[ database. ] schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>library</code></td>
<td>The library on which to grant the privilege. If using more than one schema, you must specify the schema that where the library resides.</td>
</tr>
<tr>
<td>`{ username</td>
<td>role</td>
</tr>
<tr>
<td></td>
<td>- <code>username</code>—Assigns privileges to a specific user</td>
</tr>
<tr>
<td></td>
<td>- <code>role</code>—Assigns privileges to a role</td>
</tr>
<tr>
<td></td>
<td>- PUBLIC—Assigns privileges to all users and roles.</td>
</tr>
</tbody>
</table>

### Example

The following command grants USAGE privileges on the `idolLib` library in the `v_idol` schema to `user1`:

```sql
=> GRANT USAGE ON LIBRARY v_idol.Idollib TO user1;
```

### See Also

- `REVOKE (Library)`
- `Granting and Revoking Privileges`
GRANT (Model)

Grants access to models to a database user or role.

Syntax

```
GRANT {ALL | USAGE }
... ON MODEL [ [ db-name.]schema.]modelname [ , ... ]
... TO { username | role | PUBLIC}
... [ WITH GRANT OPTION ]
```

Parameters

<table>
<thead>
<tr>
<th>ALL</th>
<th>USAGE</th>
<th>Applies to all privileges.</th>
</tr>
</thead>
<tbody>
<tr>
<td>[db-name.]schema.database-name</td>
<td>Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:</td>
<td></td>
</tr>
<tr>
<td>username</td>
<td>role</td>
<td>PUBLIC</td>
</tr>
<tr>
<td>WITH GRANT OPTION</td>
<td>Allows the user to grant the same privileges to other users.</td>
<td></td>
</tr>
</tbody>
</table>

Example

This example grants USAGE privileges on the mySvmClassModel model to user1:

```
=> GRANT USAGE ON MODEL mySvmClassModel TO user1;
```

See Also

- REVOKE (Model)
- Managing Model Security
GRANT (Procedure)

Grants privileges on a procedure to a database user or role. Only the superuser can grant privileges to a procedure. To grant privileges to a schema containing the procedure, users must have USAGE privileges. See GRANT (Schema).

External procedures that you create with CREATE PROCEDURE are always run with Linux dbadmin privileges. If a dbadmin or pseudosuperuser grants a non-dbadmin permission to run a procedure using GRANT (Procedure), be aware that the non-dbadmin user runs the procedure with full Linux dbadmin privileges.

Syntax

```
GRANT { EXECUTE | ALL [ PRIVILEGES ] } 
ON PROCEDURE [[database.]schema.]procedure [,...] 
( [ argname ] argtype [,,... ] ) 
TO { username | role | PUBLIC } [, ...]
```

Parameters

| { EXECUTE | ALL } | The type of privilege to grant the procedure. Either EXECUTE or ALL are applicable privileges to grant. When using more than one schema, specify the schema that contains the procedure. |
| PRIVILEGES | [Optional] For SQL standard compatibility and is ignored. |
| [database.]schema | Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: |
| procedure | The SQL or User Defined procedure on which to grant the privilege. If using more than one schema, you must specify the schema that contains the procedure. |
| argname | The optional argument name for the procedure. |

If you specify a database, it must be the current database.

```sql
myschema.thisDbobject
```
argtype | The required argument data type or types of the procedure.

{ username | role  
  | PUBLIC }[,...] | The recipient of the procedure privileges, which can be one or more users, one or more roles, or all users and roles (PUBLIC).

- **username**—Indicates a specific user
- **role**—Specifies a particular role
- **PUBLIC**—Indicates that all users and roles have granted privileges to the procedure.

---

**Example**

The following command grants EXECUTE privileges on the tokenize procedure to users Bob and Jules, and to the Operator role:

```sql
=> GRANT EXECUTE ON PROCEDURE tokenize(varchar) TO Bob, Jules, Operator;
```

**See Also**

- REVOKE (Procedure)
- Granting and Revoking Privileges

**GRANT (Resource Pool)**

Grants privileges on one or more resource pools to a database user or role. Once granted usage rights, users can switch to using the resource pool with ALTER USER (*username*) or with SET SESSION RESOURCE POOL.

**Syntax**

```sql
GRANT USAGE
  ON RESOURCE POOL resource-pool [,...]
TO { username | role | PUBLIC }[,...]
```
Parameters

<table>
<thead>
<tr>
<th>resource-pool</th>
<th>The resource pools on which to grant the privilege.</th>
</tr>
</thead>
<tbody>
<tr>
<td>{ username</td>
<td>role</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>username</strong>—Indicates one or more user names.</td>
</tr>
<tr>
<td></td>
<td>• <strong>role</strong>—Indicates one or more roles.</td>
</tr>
<tr>
<td></td>
<td>• PUBLIC— Indicates that all users and roles have granted privileges to the procedure.</td>
</tr>
</tbody>
</table>

Examples

This examples shows how to grant user Joe usage on resource pool Joe_pool.

```sql
=> CREATE USER Joe;
CREATE USER
=> CREATE RESOURCE POOL Joe_pool;
CREATE RESOURCE POOL
=> GRANT USAGE ON RESOURCE POOL Joe_pool TO Joe;
GRANT PRIVILEGE
```

See Also

- **REVOKE (Resource Pool)**
- **Granting and Revoking Privileges**

**GRANT (Role)**

Adds a predefined role to users or other roles. Granting a role does not activate the role automatically; the user must enable it using the **SET ROLE** command.

Granting a privilege to a role immediately affects active user sessions. When you grant a new privilege, it becomes immediately available to every user with the role active.
Syntax

```
GRANT role [, ...] TO { user | role | PUBLIC } [, ...]
... [ WITH ADMIN OPTION ];
```

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>role [, ...]</code></td>
<td>The name of one or more roles to be granted to users or roles</td>
</tr>
<tr>
<td>`user</td>
<td>role</td>
</tr>
<tr>
<td></td>
<td>keyword PUBLIC is supplied, then all users have access to the role.</td>
</tr>
<tr>
<td><code>WITH ADMIN OPTION</code></td>
<td>Grants users and roles administrative privileges for the role. They are able to grant the role to and revoke the role from other users or roles.</td>
</tr>
</tbody>
</table>

Notes

Vertica will return a NOTICE if you grant a role with or without admin option, to a grantee who has already been granted that role. For example:

```sql
=> GRANT commentor to Bob;
NOTICE 4622: Role "commentor" was already granted to user "Bob"
```

Creating Roles

These examples create three roles, appdata, applogs, and appadmin, and grant one of the roles to a user, bob:

```sql
=> CREATE ROLE appdata;
CREATE ROLE
=> CREATE ROLE applogs;
CREATE ROLE
=> CREATE ROLE appadmin;
CREATE ROLE
=> GRANT appdata TO bob;
GRANT ROLE
```
Activating a Role

After granting a role to a user, the role must be activated. You can activate a role on a session basis, or as part of the user's login.

To activate a role for a user's session:

=> CREATE ROLE appdata;
CREATE ROLE
=> GRANT appdata TO bob;
GRANT ROLE
=> SET ROLE appdata;
SET ROLE

To activate a role as part of the user's login:

=> CREATE ROLE appdata;
CREATE ROLE
=> GRANT appdata TO bob;
GRANT ROLE
=> ALTER USER bob DEFAULT ROLE appdata;
ALTER USER

Granting One Role To Another

Grant two roles to another role:

=> GRANT appdata, applogs TO appadmin;
-- grant to other roles
GRANT ROLE

Now, any privileges assigned to either appdata or applogs are automatically assigned to appadmin as well.

Checking for Circular References

When you grant one role to another role, Vertica combines the newly granted role's permissions with the existing role's permissions. Vertica also checks for circular references when you grant one role to another. The GRANT ROLE function fails with an error if a circular reference is found.

=> GRANT appadmin TO appdata;
WARNING: Circular assignation of roles is not allowed
HINT: Cannot grant appadmin to appdata
GRANT ROLE
Granting Administrative Privileges

A superuser can assign a user or role administrative access to a role by supplying the optional WITH ADMIN OPTION argument to the GRANT statement. Administrative access allows the user to grant and revoke access to the role for other users (including granting them administrative access). Giving users the ability to grant roles lets a superuser delegate role administration to other users.

Note: A user with a DBADMIN role must have the ADMIN OPTION enabled to be able to grant a DBADMIN role to another user.

As with all user privilege models, database superusers should be cautious when granting any user a role with administrative privileges. For example, if the database superuser grants two users a role with administrative privileges, both users can revoke the role of the other user. This example shows granting the appadmin role (with administrative privileges) to users bob and alice. After each user has been granted the appadmin role, either use can connect as the other will full privileges.

```sql
=> GRANT appadmin TO bob, alice WITH ADMIN OPTION;
GRANT ROLE
=> \connect - bob
You are now connected as user "bob".
=> REVOKE appadmin FROM alice;
REVOKE ROLE
```

See Also

- REVOKE (Role)
- Granting and Revoking Privileges

GRANT (Schema)

Grants privileges on a schema to a database user or role.

Note: If a schema was created with Inherited Privileges enabled, any privileges you grant the schema are inherited by all the objects in the table. Otherwise, you need to grant privileges on each object in the table. For more information see CREATE SCHEMA
New users do not have access to schema PUBLIC by default. You must grant USAGE on the PUBLIC schema to all users you create.

**Syntax**

```
GRANT { ... { CREATE | USAGE } [ , ... ] | ALL [ PRIVILEGES ] }
... | { { SELECT | INSERT | UPDATE | DELETE | REFERENCES | TRUNCATE } [ ,... ] ... }
... ON SCHEMA [db-name.]schema [ , ... ]
... TO { username | role | PUBLIC } [ , ... ]
... [ WITH GRANT OPTION ]
```

**Parameters**

<table>
<thead>
<tr>
<th>CREATE</th>
<th>Grants the user read access to the schema and the right to create tables and views within the schema.</th>
</tr>
</thead>
<tbody>
<tr>
<td>USAGE</td>
<td>Grants the user access to the objects contained within the schema. This allows the user to look up objects within the schema. Note that the user must also be granted access to the individual objects. See the GRANT TABLE and GRANT VIEW statements.</td>
</tr>
<tr>
<td>SELECT</td>
<td>With Inherited Privileges enabled on the schema, grants the user SELECT privileges on any column of any table in the schema. See Inherit Privileges on a Schema.</td>
</tr>
<tr>
<td>INSERT</td>
<td>With Inherited Privileges enabled on the schema, grants the user privileges to INSERT tuples into tables in the schema and use the COPY command to load data into the tables. See Inherit Privileges on a Schema.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>With Inherited Privileges enabled on the schema, grants the user privileges to UPDATE tuples in a schema table. See Inherit Privileges on a Schema.</td>
</tr>
<tr>
<td>DELETE</td>
<td>With Inherited Privileges enabled on the schema, grants the user privileges to DELETE rows from a schema table. See Inherit Privileges on a Schema.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>With Inherited Privileges enabled on the schema, grants the ability to create a foreign key constraint. You must have this privilege on both the referencing and referenced tables. You also need USAGE on the schema that contains the table. See Inherit Privileges on a Schema.</td>
</tr>
</tbody>
</table>
With Inherited Privileges enabled on the schema, grants the user TRUNCATE privileges on rows from a schema table. See Inherit Privileges on a Schema.

| ALL            | Grants the user CREATE and USAGE privileges on the schema. |
| PRIVILEGES     | Used for SQL standard compatibility.                     |
| [db-name.]     | [Optional] Specifies the current database name. Using a database name prefix is optional, and does not affect the command in any way. You must be connected to the specified database. |
| schema         | Identifies the schema to which you are granting privileges. |
| username       | Grants the privilege to a specific user.                  |
| role           | Grants the privilege to a specific role.                   |
| PUBLIC         | Grants the privilege to all users.                         |
| WITH GRANT OPTION | Allows the recipient of the privilege to grant it to other users. |

**Examples**

This example shows how to grant user Joe usage on schema online_sales.

```sql
=> CREATE USER Joe;
CREATE USER
=> GRANT USAGE ON SCHEMA online_sales TO Joe;
GRANT PRIVILEGE
```

**See Also**

- REVOKE (Schema)
- Granting and Revoking Privileges

**GRANT (Sequence)**

Grants privileges on a sequence generator to a user or role. Optionally grants privileges on all sequences within one or more schemas.
Syntax

GRANT { SELECT | ALL [ PRIVILEGES ] }... ON SEQUENCE [[database.]schema.]sequence-name[,...]
... | ON ALL SEQUENCES IN SCHEMA schema-name[,...]
... TO { username | role | PUBLIC }[,...]
... [ WITH GRANT OPTION ]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT</td>
<td>Allows the right to use both the CURRVAL and NEXTVAL functions on the specified sequence.</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>Is for SQL standard compatibility and is ignored.</td>
</tr>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>sequence-name</td>
<td>Specifies the sequence on which to grant the privileges. When using more than one schema, specify the schema that contains the sequence on which to grant privileges.</td>
</tr>
<tr>
<td>ON ALL SEQUENCES</td>
<td>Grants privileges on all sequences within one or more schemas to a user and/or role.</td>
</tr>
<tr>
<td>IN SCHEMA</td>
<td></td>
</tr>
<tr>
<td>username</td>
<td>Grants the privilege to the specified user.</td>
</tr>
<tr>
<td>role</td>
<td>Grants the privilege to the specified role.</td>
</tr>
<tr>
<td>PUBLIC</td>
<td>Grants the privilege to all users.</td>
</tr>
<tr>
<td>WITH GRANT OPTION</td>
<td>Allows the user to grant the same privileges to other users.</td>
</tr>
</tbody>
</table>

Privileges

**USAGE on the schema** that contains the sequence
Examples

This example shows how to grant user Joe all privileges on sequence my_seq.

```sql
=> CREATE SEQUENCE my_seq START 100;
CREATE SEQUENCE
=> GRANT ALL PRIVILEGES ON SEQUENCE my_seq TO Joe;
GRANT PRIVILEGE
```

See Also

- `REVOKE (Sequence)`
- `Granting and Revoking Privileges`

**GRANT (Storage Location)**

Grants privileges to non-superusers or roles to read from or write to a Vertica storage location. First, a superuser creates a special class of storage location with the USER keyword through the usage parameter. Creating a storage location with a USER type specifies that the location can be made accessible to non-dbadmin users. The superuser must then grant users or roles the appropriate privileges through the `GRANT (Storage Location)` statement.

**Note:** `GRANT/REVOKE (Storage Location)` statements are applicable only to `USER` storage locations. If the storage location is dropped, all privileges are revoked automatically.

**Syntax**

```
GRANT { READ | WRITE | ALL [ PRIVILEGES ] } ... ON LOCATION 'path' [ ON node ] ... TO { username | role | PUBLIC } [, ...] ... [ WITH Grant OPTION ]
```

**Parameters**

<table>
<thead>
<tr>
<th>READ</th>
<th>Permits the grantee to copy data from files in the storage location into a table.</th>
</tr>
</thead>
</table>
### WRITE
Permits the grantee to export data from the database to the storage location. With WRITE privileges, grantees can also save COPY statement rejected data and exceptions files to the storage location.

### ALL
Grants all available privileges to the grantee for the storage location.

### PRIVILEGES
[Optional] For SQL standard compatibility and is ignored.

### ON LOCATION 'path' [ ON node ]
- **path** — Specifies the path name mount point of the storage location
- **node** — [Optional] Grants access to the storage location residing on the node. If you leave this blank, *node* defaults to all nodes on the specified path in that cluster. If a path exists for only some nodes, the entire grant rolls back, even on the nodes that reside in the path.

### { username | role | PUBLIC } [, ...]
Specifies the privilege grantee, which can be one or more users, one or more roles, or all users (PUBLIC).
- **username** — A specific user
- **role** — A particular role
- PUBLIC — Grants the specified privileges to all users and roles.

### WITH GRANT OPTION
[Optional] Allows the grantee to grant the same privileges to others.

### Notes
Only a superuser can add, alter, retire, drop, and restore a location. The superuser can grant only READ and/or WRITE access privileges to storage locations for other users or roles.
Examples

In the following series of commands, a superuser creates a new storage location and grants it to user Bob:

```sql
=> CREATE LOCATION '/home/dbadmin/UserStorage/BobStore' NODE 'v_mcdb_node0007' USAGE 'USER';
CREATE LOCATION
```

Now the superuser grants a user named Bob all available privileges to the /BobStore location:

```sql
=> GRANT ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' TO Bob;
GRANT PRIVILEGE
```

Revoke all storage location privileges from Bob:

```sql
=> REVOKE ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' FROM Bob;
REVOKE PRIVILEGE
```

Grant privileges to Bob on the BobStore location again, specifying a node:

```sql
=> GRANT ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' ON v_mcdb_node0007 TO Bob;
GRANT PRIVILEGE
```

Revoke all storage location privileges from Bob:

```sql
=> REVOKE ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' ON v_mcdb_node0007 FROM Bob;
REVOKE PRIVILEGE
```

See Also

- Storage Management Functions
- REVOKE (Storage Location)
- Granting and Revoking Privileges

GRANT (Table)

Grants privileges on a table to a user or role. Optionally grants privileges on all tables within one or more schemas.
Note: Granting privileges on all tables in a schema also includes privileges on all views in the same schema.

Syntax

```sql
GRANT { privilege[, ...] | ALL [ PRIVILEGES ] }
... ON {
... [ TABLE ] [[database.]schema.]table [, ... ]
... | ALL TABLES IN SCHEMA [database.]schema [, ... ]
... TO { username | role | PUBLIC } [, ... ]
... [ WITH GRANT OPTION ]
```

Parameters

<table>
<thead>
<tr>
<th><code>privilege</code></th>
<th>One of the following privileges:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Important: Only SELECT privileges can be granted on system tables.</td>
</tr>
<tr>
<td></td>
<td>• SELECT: Query tables of this schema. SELECT privileges are granted by default to the PUBLIC role.</td>
</tr>
<tr>
<td></td>
<td>• INSERT: Insert rows into tables of this schema, or and load data into tables with COPY.</td>
</tr>
<tr>
<td></td>
<td>Note: COPY FROM STDIN is allowed for users with INSERT privileges, while COPY FROM file requires admin privileges.</td>
</tr>
<tr>
<td></td>
<td>• UPDATE: Update rows of tables of this schema.</td>
</tr>
<tr>
<td></td>
<td>• DELETE: Delete rows of tables of this schema.</td>
</tr>
<tr>
<td></td>
<td>• REFERENCES: Create foreign key constraints for tables of this schema. This privilege must be set on both referencing and referenced tables.</td>
</tr>
<tr>
<td></td>
<td>• TRUNCATE: Truncate table contents. Non-owners of the tables can also execute the following partition operations on them:</td>
</tr>
<tr>
<td>Action/Keyword</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>DROP_PARTITIONS</td>
<td>Removes partitions from a table.</td>
</tr>
<tr>
<td>SWAP_PARTITIONS_BETWEEN_TABLES</td>
<td>Exchanges partitions between two tables.</td>
</tr>
<tr>
<td>MOVE_PARTITIONS_TO_TABLE</td>
<td>Moves partitions to a different table.</td>
</tr>
</tbody>
</table>

**ALL [PRIVILEGES]**

Grants all **table privileges** that also belong to the grantor. Grantors cannot grant privileges that they themselves lack.

The optional keyword PRIVILEGES conforms with the SQL standard.

**[database.]schema**

Specifies a schema, by default public. If **schema** is any schema other than public, you must supply the schema name. For example:

| myschema.thisDbObject |

One exception applies: you can specify system tables without their schema name.

If you specify a database, it must be the current database.

**table**

The table on which to grant the privileges.

*Note: The table can be a global temporary table, but not a local temporary table. See [Creating Temporary Tables](#) in the Administrator's Guide.*

**ON ALL TABLES IN SCHEMA**

Grants privileges on all tables (and by default all views) within one or more schemas to a user and/or role.

**username**

Grants the privilege to the specified user.

**role**

Grants the privilege to the specified role.

**PUBLIC**

Grants the privilege to all users.

**WITH GRANT OPTION**

Allows the user to grant the same privileges to other users.
Notes

- The user must also be granted USAGE on the schema that contains the table. See `GRANT (Schema)`.

- To use the `DELETE` or `UPDATE` commands with a `WHERE Clause`, a user must have both `SELECT` and `UPDATE` and `DELETE` privileges on the table.

Examples

Grant user Joe all privileges on table `customer_dimension`:

```
=> CREATE USER Joe;
CREATE USER
=> GRANT ALL PRIVILEGES ON TABLE customer_dimension TO Joe;
GRANT PRIVILEGE
```

Grant user Joe `SELECT` privileges on all system tables:

```
=> GRANT SELECT ON ALL TABLES IN SCHEMA V_MONITOR, V_CATALOG TO Joe;
GRANT PRIVILEGE
```

See Also

- `REVOKE (Table)`

- `Granting and Revoking Privileges`

**GRANT (User Defined Extension)**

Grants privileges on a user-defined extension (UDx) to a database user or role. Optionally grants all privileges on the user-defined extension within one or more schemas. You can grant privileges on the following user-defined extension types:

- User Defined Functions (UDF)
  - User Defined SQL Functions
  - User Defined Scalar Functions (UDSF)
- User Defined Transform Functions (UDTF)
- User Defined Aggregate Functions (UDAF)
- User Defined Analytic Functions (UDAnF)
- User Defined Load Functions (UDL)
  - UDL Filter
  - UDL Parser
  - UDL Source

**Syntax**

```sql
GRANT { EXECUTE | ALL }
... ON FUNCTION [[database.]schema.]function [,]...
... | ON AGGREGATE FUNCTION [[database.]schema.]function [,]...
... | ON ANALYTIC FUNCTION [[database.]schema.]function [,]...
... | ON TRANSFORM FUNCTION [[database.]schema.]function [,]...
... | ON FILTER [[database.]schema.]filter [,]...
... | ON PARSER [[database.]schema.]parser [,]...
... | ON SOURCE [[database.]schema.]source [,]...
... | ON ALL FUNCTIONS IN SCHEMA schema [,]...
... ( [ argname ] argtype [,]... )
... TO { username | role | PUBLIC } [,]...
```

**Parameters**

| { EXECUTE | ALL } | The type of privilege to grant the UDX: |
|----------------|---------------------------------------|
|                | - EXECUTE grants permission to call a user-defined extension. |
|                | - ALL grants all privileges on the user-defined extension |

<table>
<thead>
<tr>
<th>database.</th>
<th>schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
</table>
|           | [myschema.]thisDbObject | If you specify a database, it must be the current
| function | The name of the UDX on which to grant the privilege. If you use more than one schema, you must specify the schema that contains the UDX, as noted in the previous row. |
| filter parser source | ON ALL FUNCTIONS IN SCHEMA Grants privileges on all UDX's within one or more schemas to a user, role, or all users and roles. |
| argname | [Optional] The argument name for the UDX. When you GRANT, REVOKE, or DROP privileges for a polymorphic function, you must include an argument with the command. |
| argtype | The argument data type of the UDX. |
| { username | role | PUBLIC } [,...] | The recipient of the UDX privileges, which can be one or more users, one or more roles, or all users and roles (PUBLIC). |
|  | • username - Indicates a specific user |
|  | • role - Specifies a particular role |
|  | • PUBLIC - Indicates that all users and roles have granted privileges to the UDX. |

**Privileges**

Only a superuser and owner can grant privileges on a UDX. To grant privileges to a specific schema UDX or to all UDX's within one or more schemas, grantees must have USAGE privileges on the schema. See GRANT (Schema).

**Examples**

The following command grants EXECUTE privileges on the `myzeroifnull` SQL function to users Bob and Jules, and to the Operator role. The function takes one integer argument:

```sql
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Bob, Jules, Operator;
```
The following command grants EXECUTE privileges on all functions in the zero-schema schema to user Bob:

```sql
=> GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA zero-schema TO Bob;
```

The following command grants EXECUTE privileges on the `tokenize` transform function to user Bob and to the Operator role:

```sql
=> GRANT EXECUTE ON TRANSFORM FUNCTION tokenize(VARCHAR) TO Bob, Operator;
```

The following command grants EXECUTE privileges on the `ExampleSource()` source to user Alice.

```sql
=> CREATE USER Alice;
=> GRANT USAGE ON SCHEMA hdfs TO Alice;
=> GRANT EXECUTE ON SOURCE ExampleSource() TO Alice;
```

The next command grants ALL privileges on the `ExampleSource()` source to user Alice:

```sql
=> GRANT ALL ON SOURCE ExampleSource() TO Alice;
```

The following command grants ALL privileges on the polymorphic function `Pagerank` to the `dbadmin` role:

```sql
=> GRANT ALL ON TRANSFORM FUNCTION Pagerank(z varchar) to dbadmin;
```

**GRANT (View)**

Grants privileges on a view to a database user or role.

**Syntax**

```sql
GRANT ... { SELECT | ALL [ PRIVILEGES ]} 
... ON [[database.]schema.]viewname [, ...] 
... TO { username | role | PUBLIC } [, ...] 
... [ WITH GRANT OPTION ]
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT</td>
<td>Grants a user or role SELECT operations to a view and any resources referenced within it.</td>
</tr>
<tr>
<td>ALL</td>
<td>Grants a user or role all privileges to a view, and any resources referenced within it.</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>[Optional] For SQL standard compatibility and is ignored.</td>
</tr>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code> If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>viewname</td>
<td>Specifies the view on which to grant the privileges. When using more than one schema, specify the schema that contains the view, as noted above.</td>
</tr>
<tr>
<td>username</td>
<td>Grants the privilege to the specified user.</td>
</tr>
<tr>
<td>role</td>
<td>Grants the privilege to the specified role.</td>
</tr>
<tr>
<td>PUBLIC</td>
<td>Grants the privilege to all users.</td>
</tr>
<tr>
<td>WITH GRANT OPTION</td>
<td>Permits the user to grant the same privileges to other users.</td>
</tr>
</tbody>
</table>

Examples

This example shows how to grant user Joe all privileges on view ship.

```sql
=> CREATE VIEW ship AS SELECT * FROM public.shipping_dimension;
CREATE VIEW
=> GRANT ALL PRIVILEGES ON ship TO Joe;
GRANT PRIVILEGE
```
See Also

- `REVOKE (View)`
- `Granting and Revoking Privileges`
- `Using Views`
- `Privileges Required for Common Database Operations`

**INSERT**

Inserts values into all projections of the specified table. You must insert one complete tuple at a time. By default, `INSERT` first uses WOS. When WOS is full, the inserted tuple overflows to ROS.

If no projections are associated with the target table, Vertica creates a superprojection to store the inserted values.

`INSERT` works for flex tables as well as regular database tables.

**Syntax**

```
INSERT [ /*+ hint[, hint] */ ] INTO [[database.]schema.]table-name
... [ ( column-list ) ]
... { DEFAULT VALUES | VALUES ( values-list ) | SELECT query-expression }
```

**Parameters**

<table>
<thead>
<tr>
<th>/*+ hint [, hint] */</th>
<th>One or both of the following hints:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• A load hint, one of the following: <code>AUTO</code>, <code>DIRECT</code>, or <code>TRICKLE</code></td>
</tr>
<tr>
<td></td>
<td>• <code>LABEL</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><code>[database.]schema</code></th>
<th>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
</table>
If you specify a database, it must be the current database.

**table-name**
The target table. You cannot invoke INSERT on a projection. This can be a flex table.

**column-list**
A comma-delimited list of one or more target columns in this table, listed in any order. VALUES clause values are mapped to columns in the same order. If you omit this list, Vertica maps VALUES clause values to columns according to column order in the table definition.

A list of target columns is invalid with DEFAULT VALUES.

**DEFAULT VALUES**
Fills all columns with their default values as specified in the table definition.

You cannot specify a list of target columns with this option.

**VALUES (values-list)**
A comma-delimited list of one or more values to insert in the target columns, where each value is one of the following:

- **expression** resolves to a value to insert in the target column. The expression must not nest other expressions or include Vertica meta-functions.

- DEFAULT inserts the default value as specified in the table definition.

If no value is supplied for a column, Vertica implicitly adds a DEFAULT value, if defined. Otherwise Vertica inserts a NULL value. If the column is defined as NOT NULL, INSERT returns an error.

**SELECT query-expression**
Specifies a query that returns the rows to insert. Isolation level applies only to the SELECT clauses and works like any query.

**Privileges**

- Table owner or user with GRANT OPTION is grantor
- INSERT privilege on table
- USAGE privilege on schema that contains the table

Restrictions

- Vertica does not support subqueries as the target of an INSERT statement.
- If any primary key, unique key, or check constraints are enabled for automatic enforcement, Vertica enforces those constraints when you insert values into a table. If a violation occurs, Vertica rolls back the SQL statement and returns an error. This behavior occurs for INSERT, UPDATE, COPY, and MERGE SQL statements.

  Note: Automatic constraint enforcement requires that you have SELECT privileges on the table containing the constraint.

Examples

```sql
=> INSERT INTO t1 VALUES (101, 102, 103, 104);
=> INSERT INTO customer VALUES (10, 'male', 'DPR', 'MA', 35);
=> INSERT INTO retail.t1 (C0, C1) VALUES (1, 1001);
=> INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2004-05-07';
```

Vertica does not support subqueries or nested expressions as the target of an INSERT statement. For example, the following query returns an error message:

```sql
=> INSERT INTO t1 (col1, col2) VALUES ('abc', (SELECT mycolumn FROM mytable));
ERROR 4821: Subqueries not allowed in target of insert
```

You can rewrite the above query as follows:

```sql
=> INSERT INTO t1 (col1, col2) (SELECT 'abc', mycolumn FROM mytable);
OUTPUT
-------
0
(1 row)
```

The following example shows how to use INSERT . . . VALUES with flex tables:

```sql
=> CREATE FLEX TABLE flex1();
CREATE TABLE
=> INSERT INTO flex1(a,b) VALUES (1, 'x');
OUTPUT
-------
1
```
The next example shows how to use `INSERT...SELECT` with flex tables:

```sql
=> CREATE FLEX TABLE f1x2();
CREATE TABLE
=> INSERT INTO f2x2(a, b) SELECT a, b, '2016-08-10 11:10' c, 'Hello' d, 3.1415 e, f from f1x1;
OUTPUT
-------
1
(1 row)
=> SELECT MapToString(__raw__) FROM f2x2;
MapToString
-----------------
{
  "a" : "1",
  "b" : "x",
  "c" : "2016-08-10",
  "d" : "Hello",
  "e" : 3.1415,
  "f" : null
}
(1 row)
```

### MERGE

Performs update and insert operations on a target table based on the results of a join with another data set, such as a table or view. The join can match a source row with only one target row; otherwise, Vertica returns an error.

A `MERGE` operation uses WOS by default. If WOS fills up, data overflows to ROS.

For detailed information, see [Merging Table Data](#).

### Syntax

```
MERGE [ /*+ hint[, hint] */ ]
... INTO [[database.]schema.]target-table [ [AS] alias ]
... USING source-dataset
... ON join-condition
... matching-clause[ matching-clause ]
```
Returns

Number of target table rows updated or inserted

Parameters

```sql
/*+ hint[, hint]*/  
One or both of the following hints:
  • A load hint, one of the following: AUTO, DIRECT, or TRICKLE
  • LABEL
```

```
[database.]schema  
Specifies a schema, by default public. If `schema` is any schema other than public, you must supply the schema name. For example:

```sql
myschema.thisDbObject
```

If you specify a database, it must be the current database.

`target-table`  
The table on which to perform update and insert operations. `MERGE` takes an X (exclusive) lock on the target table during the operation.

`source-dataset`  
The data to join to `target-table`, one of the following:

```sql
  • `[[database.]schema.]table [ [AS] alias ]`
  • `[[database.]schema.]view [ [AS] alias ]`
  • `(subquery) sq-alias`
```

The specified data set typically supplies the data used to update the target table and populate new rows. You can specify an external table.
### ON join-condition

The conditions on which to join the target table and source data set.

Tip: The Vertica query optimizer can create an optimized query plan for a MERGE statement only if the target table join column has a unique or primary key constraint. For details, see [MERGE Optimization](#) in the Administrator's Guide.

### matching-clause

One of the following clauses:

- **WHEN MATCHED THEN UPDATE**
- **WHEN NOT MATCHED THEN INSERT**

MERGE supports one instance of each clause, and must include at least one.

### WHEN MATCHED THEN UPDATE

For each **target-table** row that is joined (matched) to **source-dataset**, specifies to update one or more columns:

```
WHEN MATCHED [ AND update-filter ] THEN UPDATE
SET { target-column = expression }[, ...]
```

**update-filter** optionally filters the set of matching rows. The update filter can specify any number of conditions. Vertica evaluates each matching row against this filter, and updates only the rows that evaluate to true. For details, see [Update and Insert Filters](#) in the Administrator's Guide.

The following requirements apply:

- A MERGE statement can contain only one **WHEN MATCHED** clause.

- **target-column** can only specify a column name in the target table. It cannot be qualified with a table name.

For details, see [Merging Table Data](#) in the
### WHEN NOT MATCHED THEN INSERT

For each **source-dataset** row that is not joined (not matched) to **target-table**, specifies to:

- Insert a new row into **target-table**.
- Populate each new row with the values specified in **values-list**.

```
WHEN NOT MATCHED [ AND insert-filter ] THEN INSERT
[ ( column-list ) ] VALUES ( values-list )
```

- **column-list** is a comma-delimited list of one or more target columns in the target table, listed in any order. MERGE maps **column-list** columns to **values-list** values in the same order, and each column-value pair must be compatible. If you omit **column-list**, Vertica maps **values-list** values to columns according to column order in the table definition.

- **insert-filter** optionally filters the set of non-matching rows. The insert filter can specify any number of conditions. Vertica evaluates each non-matching source row against this filter. For each row that evaluates to true, Vertica inserts a new row in the target table. For details, see [Update and Insert Filters](#) in the Administrator's Guide.

The following requirements apply:

- A MERGE statement can contain only one **WHEN NOT MATCHED** clause.
- **column-list** can only specify column names in the target table. It cannot be qualified with a table name.
- Insert filter conditions can only reference the source data. If any condition references the target table, Vertica returns an error.

For details, see [Merging Table Data](#) in the Administrator's Guide.
Privileges

MERGE requires the following privileges:

- SELECT permissions on the source data and INSERT, UPDATE, and DELETE permissions on the target table.

- Automatic constraint enforcement requires SELECT permissions on the table containing the constraint.

- SELECT permissions on the target table if the condition in the syntax reads data from the target table. The following example grants user1 access to target table t2:

For example, the following GRANT statement grants user1 access to target table t2. This allows user1 to run the MERGE statement that follows:

```sql
=> GRANT SELECT, INSERT, UPDATE, DELETE ON TABLE t2 to user1;
GRANT PRIVILEGE
=>
```

You are now connected as user "user1".

```sql
=> MERGE INTO t2 USING t1 ON t1.a = t2.a
  WHEN MATCHED THEN UPDATE SET b = t1.b
  WHEN NOT MATCHED THEN INSERT (a, b) VALUES (t1.a, t1.b);
```

Improving MERGE Performance

You can improve MERGE performance in several ways:

- Design projections for optimal MERGE performance.

- Facilitate creation of optimized query plans.

- Use a source data set that is smaller than the target table.

For details, see MERGE Optimization in the Administrator's Guide.
Constraint Enforcement

MERGE respects all enforced constraints in the target table. If the merge operation attempts to copy values that violate those constraints, MERGE returns with an error and rolls back the merge operation.

Caution: If you run MERGE multiple times using the same target and source table, each iteration is liable to introduce duplicate values into the target columns and return with an error.

Columns Prohibited from Merge

The following columns cannot be specified in a merge operation; attempts to do so return with an error:

- Identity/auto-increment columns, or columns whose default value is set to a named sequence.
- Vmap columns such as __raw__ in flex tables.

Examples

See Basic MERGE Example in the Administrator's Guide.

PROFILE

Profiles a single SQL statement.

Syntax

PROFILE { sql-statement }
Parameters

| sql-statement | A query (SELECT) statement or DML statement—for example, you can profile INSERT, UPDATE, COPY, and MERGE. |

Output

Writes profile summary to stderr, saves details to system catalog V_MONITOR.EXECUTION_ENGINE_PROFILES.

Privileges

The same privileges required to run the profiled statement

Description

PROFILE generates detailed information about how the target statement executes, and saves that information in the system catalog V_MONITOR.EXECUTION_ENGINE_PROFILES. Query output is preceded by a profile summary: profile identifiers transaction_id and statement_id, initiator memory for the query, and total memory required. For example:

```sql
=> PROFILE SELECT customer_name, annual_income FROM public.customer_dimension WHERE (customer_gender, annual_income) IN (SELECT customer_gender, MAX(annual_income) FROM public.customer_dimension GROUP BY customer_gender);
NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996274683334 and statement_id=7;
NOTICE 3557: Initiator memory for query: [on pool general: 708421 KB, minimum: 554324 KB]
NOTICE 5077: Total memory required by query: [708421 KB]
+----------+-----------------
| customer_name | annual_income |
|------------+--------------|
| Emily G. Vogel | 999998 |
| James M. McNulty | 999979 |
(2 rows)
```

Use profile identifiers to query the table for profile information on a given query.
See Also

Profiling Single Statements

**RELEASE SAVEPOINT**

Destroys a savepoint without undoing the effects of commands executed after the savepoint was established.

**Syntax**

```
RELEASE [ SAVEPOINT ] savepoint_name
```

**Parameters**

- `savepoint_name`  
  Specifies the name of the savepoint to destroy.

**Privileges**

No special permissions required.

**Notes**

Once destroyed, the savepoint is unavailable as a rollback point.

**Example**

The following example establishes and then destroys a savepoint called `my_savepoint`. The values 101 and 102 are both inserted at commit.

```
=> INSERT INTO product_key VALUES (101);
=> SAVEPOINT my_savepoint;
```
See Also

- **SAVEPOINT**
- **ROLLBACK TO SAVEPOINT**
REVOKE Statements

REVOKE statements let you revoke privileges on database objects from users and roles.

REVOKE (Authentication)

Revotes an authentication method that you have granted to (associated with) one or more users or roles.

Syntax

REVOKE AUTHENTICATION auth-method-name FROM
   { Public | user_or_role | user_or_role1, user_or_role2, user_or_role3, ... }

Parameters

<table>
<thead>
<tr>
<th>auth_method_name</th>
<th>Name of the authentication method which you want to revoke from one or more users.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Type: VARCHAR</td>
</tr>
<tr>
<td>user_or_role, user_or_role1, user_or_role2, user_or_role3, ...</td>
<td>Names of users or user roles from whom you want to revoke the authentication method.</td>
</tr>
<tr>
<td></td>
<td>Type: VARCHAR</td>
</tr>
</tbody>
</table>

Privileges

Must have DBADMIN privileges.
Examples

This example revokes v_ldap authentication from user jsmith:

```sql
=> REVOKE AUTHENTICATION v_ldap FROM jsmith;
```

This example revokes v_gss authentication from the role DBprogrammer:

```sql
=> REVOKE AUTHENTICATION v_gss FROM DBprogrammer;
```

This example removes localpwd as the default client authentication method:

```sql
=> REVOKE AUTHENTICATION localpwd from Public;
```

See Also

- ALTER AUTHENTICATION
- CREATE AUTHENTICATION
- DROP AUTHENTICATION
- GRANT (Authentication)

REVOKE (Database)

Revokes the right for the specified user or role to create schemas in the specified database.

Syntax

```sql
REVOKE [ GRANT OPTION FOR ]
... { CREATE | TEMP [ , ... ] }
... | CONNECT
... | ALL [ PRIVILEGES ]
... ON DATABASE database-name [ , ... ]
... FROM { username | role }[ , ... ]
... [ CASCADE ]
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT OPTION FOR</td>
<td>Revokes the grant option for the privilege, not the privilege itself. If omitted, revokes both the privilege and the grant option.</td>
</tr>
<tr>
<td>CREATE</td>
<td>Revokes the right to create schemas in the specified database.</td>
</tr>
<tr>
<td>TEMP</td>
<td>Revokes the right to create temp tables in the database.</td>
</tr>
<tr>
<td>ALL</td>
<td>Applies to all privileges.</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>Is for SQL standard compatibility and is ignored.</td>
</tr>
<tr>
<td>database-name</td>
<td>Identifies the database from which to revoke the privilege.</td>
</tr>
<tr>
<td>username</td>
<td>Identifies the user from whom to revoke the privilege.</td>
</tr>
<tr>
<td>role</td>
<td>Identifies the role from which to revoke the privilege.</td>
</tr>
<tr>
<td>CASCADE</td>
<td>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.</td>
</tr>
</tbody>
</table>

Examples

The following example revokes Fred's right to create schemas on vmartdb:

```sql
=> REVOKE CREATE ON DATABASE vmartdb FROM Fred;
```

The following revokes Fred's right to create temporary tables in vmartdb:

```sql
=> REVOKE TEMP ON DATABASE vmartdb FROM Fred;
```

See Also

- GRANT (Database)
- Granting and Revoking Privileges
REVOKE (Library)

Revokes the USAGE privilege on a library from a user or role.

To revoke functions inside the library, a user must have separate REVOKE privileges for those functions.

Syntax

REVOKE { USAGE | ALL }  
... ON LIBRARY [ [ db-name.]schema.]library-name [ , ... ]  
... FROM { username | PUBLIC | role } [ , ... ]  
...[ CASCADE ]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[[db-name.]schema.]</td>
<td>Specifies a schema and an optional database to which you are connected. Include the schema name if multiple schemas exist in the database.</td>
</tr>
<tr>
<td>library-name</td>
<td>The library from which to revoke the USAGE privilege. When using more than one schema, specify the schema that contains the procedure.</td>
</tr>
<tr>
<td>username</td>
<td>role</td>
</tr>
<tr>
<td>CASCADE</td>
<td>Reverses the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.</td>
</tr>
</tbody>
</table>
Privileges

You must have DBADMIN privileges to run REVOKE (Library).

Examples

This example revokes user1's USAGE privilege on the idolLib library in the v_idol schema.

```sql
=> REVOKE USAGE ON LIBRARY v_idol.IdolLib FROM user1;
```

See Also

- GRANT (Library)
- Granting and Revoking Privileges

REVOKE (Model)

Revolves privileges on a model from a user or role.

Syntax

```
REVOKE { ALL | USAGE }
... ON MODEL [ [ db-name.]schema.]modelname [ , ... ]
... FROM { username | role | PUBLIC} [ , ... ]
... [ CASCADE ]
```

Parameters

```
[[db-name.]schema]  Specifies a schema. If multiple schemas are defined in the database,
```
include the schema name. For example:

```sql
myschema
```

### `modelName`

Specifies the model from which to remove privileges.

### `username | role | PUBLIC`

The name of the user, role or group to be granted access.

### `CASCADE`

Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The **CASCADE** keyword first revokes
the privilege from the initial user or role, and then from other grantees extended the privilege.

Example

This example revokes user1's USAGE privilege on the mySvmClassModel model:

```sql
=> REVOKE USAGE ON mySvmClassModel FROM user1;
```

See Also

- GRANT (Model)
- Managing Model Security

REVOKE (Procedure)

Revolves the execute privilege on a procedure from a user or role.

Syntax

```
REVOKE EXECUTE
... ON PROCEDURE [[database.]schema.]procedure[,...]
... ( [ argname ] argtype[,.... ] )
... FROM { PUBLIC | { username | role }[,...] }
...[ CASCADE ]
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject</td>
</tr>
<tr>
<td>procedure</td>
<td>Specifies the procedure on which to revoke the execute privilege.</td>
</tr>
<tr>
<td>argname</td>
<td>Optionally specifies the argument names used when creating the procedure.</td>
</tr>
<tr>
<td>argtype</td>
<td>Specifies the argument types used when creating the procedure.</td>
</tr>
<tr>
<td>username</td>
<td>Specifies the user from whom to revoke the privilege.</td>
</tr>
<tr>
<td>role</td>
<td>Specifies the role from whom to revoke the privilege.</td>
</tr>
<tr>
<td>CASCADE</td>
<td>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.</td>
</tr>
</tbody>
</table>

Privileges

You must have DBADMIN privileges to run REVOKE (Procedure).

Examples

This example revokes Bob's execute privilege on the tokenize procedure.

```sql
=> REVOKE EXECUTE ON PROCEDURE tokenize(varchar) FROM Bob;
```
See Also

- GRANT (Procedure)
- Granting and Revoking Privileges

REVOKE (Resource Pool)

Revolves a user's or role's access privilege to a resource pool.

Syntax

REVOKE USAGE... ON RESOURCE POOL resource-pool
... FROM { username | PUBLIC | role } [ , ... ]
...[ CASCADE ]

Parameters

<table>
<thead>
<tr>
<th>resource-pool</th>
<th>Specifies the resource pool from which to revoke the usage privilege.</th>
</tr>
</thead>
<tbody>
<tr>
<td>username</td>
<td>Revokes the privilege from the specified user.</td>
</tr>
<tr>
<td>PUBLIC</td>
<td>Revokes the privilege from all users.</td>
</tr>
<tr>
<td>role</td>
<td>Revokes the privilege from the specified role.</td>
</tr>
<tr>
<td>CASCADE</td>
<td>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.</td>
</tr>
</tbody>
</table>

Notes

- Vertica checks privileges on resource pools during runtime. If the user running a query does not have the USAGE privilege on the appropriate pool, the query fails with an error. In this case, the user can use ALTER USER ... RESOURCE POOL to access another resource pool.
Note the user may need to be granted usage on the resource pool with GRANT USAGE ON RESOURCE POOL.

- Revoking a user's permission from a resource pool in another session affects the user's access current session. In this case, the current session fails with an error stating that the resource pool in the current session does not exist.

**Examples**

This example shows how to revoke user Joe's usage privilege on the Joe_pool resource pool.

```sql
=> REVOKE USAGE ON RESOURCE POOL Joe_pool FROM Joe;
REVOKE PRIVILEGE
```

**See Also**

- [GRANT (Resource Pool)]
- [Granting and Revoking Privileges]

**REVOKE (Role)**

Revokes a role (and administrative access, applicable) from a grantee. A user that has administrator access to a role can revoke the role for other users.

You can also remove a role's access to another role.

**Syntax**

```sql
REVOKE [ ADMIN OPTION FOR ] role [, ...] 
[ ... FROM { user | role | PUBLIC } [, ...] 
[ CASCADE ];
```

**Parameters**

<table>
<thead>
<tr>
<th>ADMIN OPTION FOR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Revokes just the user's or role's administration access to the role, and not the role itself.</td>
</tr>
</tbody>
</table>
role
The name of one or more roles from which you want to revoke access.

user | role | PUBLIC
The name of a user or role whose permission you want to revoke. You can use the PUBLIC option to revoke access to a role that was previously made public.

CASCADE
Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

Examples
This example shows the revocation of the pseudosuperuser role from the dbadmin user:

```sql
=> REVOKE pseudosuperuser from dbadmin;
```

This example shows the revocation of administration access from the dbadmin user for the pseudosuperuser role. The ADMIN OPTION command does not remove the pseudosuperuser role.

```sql
=> REVOKE ADMIN OPTION FOR pseudosuperuser FROM dbadmin;
```

Notes
If the role you are trying to revoke was not already granted to the user, Vertica returns a NOTICE:

```sql
=> REVOKE commentor FROM Sue;
NOTICE 2022: Role "commentor" was not already granted to user "Sue"
REVOKE ROLE
```

See Also
- GRANT (Role)
- Granting and Revoking Privileges
REVOKE (Schema)

Revolves privileges on a schema from a user or role.

Note: In a database with trust authentication, the GRANT and REVOKE statements appear to work as expected but have no actual effect on the security of the database.

Syntax

REVOKE [ GRANT OPTION FOR ] { ...
  { CREATE | USAGE } [...]
  { SELECT | INSERT | UPDATE | DELETE | REFERENCES } [...]
  ALL [ PRIVILEGES ]

ON SCHEMA [db-name.] schema [...]

FROM { username | PUBLIC | role } [...]

[ CASCADE ]

Parameters

<table>
<thead>
<tr>
<th>GRANT OPTION FOR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE</td>
<td>Revokes the right to create tables and views in the schema.</td>
</tr>
<tr>
<td>USAGE</td>
<td>Revokes user access to the objects contained in the schema. Note that the user can also have access to the individual objects revoked. See the GRANT TABLE and GRANT VIEW statements.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Revokes the user's ability to perform a SELECT on any column of any table in the schema.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Revokes the user's ability to INSERT tuples into tables in the schema and use the COPY command to load data into the tables.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Revokes the user's ability to UPDATE tuples in a schema table.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Revokes the user's ability to DELETE rows from a schema table.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>Revokes the user's privilege on both the referencing and referenced tables for creating a foreign key constraint.</td>
</tr>
<tr>
<td>ALL</td>
<td>Revokes all privileges previously granted.</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>Is for SQL standard compatibility and is ignored.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>[db-name.]</td>
<td>[Optional] Specifies the current database name. Using a database name prefix is optional, and does not affect the command in any way. You must be connected to the specified database.</td>
</tr>
<tr>
<td>schema</td>
<td>Identifies the schema from which to revoke privileges.</td>
</tr>
<tr>
<td>username</td>
<td>Revokes the privilege to a specific user.</td>
</tr>
<tr>
<td>PUBLIC</td>
<td>Revokes the privilege to all users.</td>
</tr>
<tr>
<td>role</td>
<td>Revokes the privilege to a specific role.</td>
</tr>
<tr>
<td>CASCADE</td>
<td>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows how to revoke user Joe's usage privileges on the online_sales schema.

```sql
=> REVOKE USAGE ON SCHEMA online_sales FROM Joe;
REVOKE PRIVILEGE
```

**See Also**

- [GRANT (Schema)]
- [Granting and Revoking Privileges]

**REVOKE (Sequence)**

Revokes privileges on a sequence generator from a user or role. Optionally revokes privileges on all sequences within one or more schemas.
Syntax

```
REVOKE [ GRANT OPTION FOR ]
... { SELECT | ALL [ PRIVILEGES ] }
... ON SEQUENCE [ [database.]schema.]sequence [ , ... ]
... | ON ALL SEQUENCES IN SCHEMA schema [, ...]
... FROM { username | PUBLIC | role } [ , ... ]
...[ CASCADE ]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT</td>
<td>Revokes the right to use both the CURRVAL and NEXTVAL functions on the specified sequence.</td>
</tr>
<tr>
<td>ALL</td>
<td>Applies to all privileges.</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>Is for SQL standard compatibility and is ignored.</td>
</tr>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td>sequence</td>
<td>Specifies the sequence from which to revoke privileges.</td>
</tr>
<tr>
<td>ON ALL SEQUENCES IN SCHEMA</td>
<td>Revokes privileges on all sequences within one or more schemas from a user and/or role.</td>
</tr>
<tr>
<td>username</td>
<td>Revokes the privilege from the specified user.</td>
</tr>
<tr>
<td>PUBLIC</td>
<td>Revokes the privilege from all users.</td>
</tr>
<tr>
<td>role</td>
<td>Revokes the privilege from the specified role.</td>
</tr>
<tr>
<td>CASCADE</td>
<td>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and</td>
</tr>
</tbody>
</table>
then from other grantees extended the privilege.

Examples

This example shows how to revoke user Joe's privileges on the my_seq sequence.

```sql
=> REVOKE ALL PRIVILEGES ON SEQUENCE my_seq FROM Joe;
REVOKE PRIVILEGE
```

See Also

- **GRANT (Sequence)**
- **Granting and Revoking Privileges**

**REVOKE (Storage Location)**

Revokes privileges from a user or role to read from or write to a storage location.

**Note:** The REVOKE (Storage Location) statement is applicable only to 'USER' storage locations. See **GRANT (Storage Location)** for more information. If the storage location is dropped, all user privileges are removed as part of that.

Syntax

```
REVOKE [ GRANT OPTION FOR ]
... { READ | WRITE | ALL [ PRIVILEGES ] }
... ON LOCATION [ 'path' [ ON node ] ]
... FROM { username | role | PUBLIC } [, ...]
... [ CASCADE ]
```

Parameters

<table>
<thead>
<tr>
<th>REVOKE OPTION FOR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REVOKE OPTION FOR</td>
<td>Revokes GRANT privileges from the grantee.</td>
</tr>
<tr>
<td>READ</td>
<td>Revokes privileges from the grantee to copy data from files in a storage locations into a table.</td>
</tr>
</tbody>
</table>
### WRITE

Revoices privileges to export Vertica data from the database to a storage location. Revoking WRITE privileges prevents the grantee from exporting COPY statement rejected data and exceptions files to a storage location.

### ALL

Revoices all privileges from the grantee to the storage location.

### PRIVILEGES

For SQL standard compatibility and is ignored.

```sql
{ username | role | PUBLIC } [...]  
```

Revoices privileges from one or more users, one or more roles, or all users (PUBLIC).

- **username** – A specific user
- **role** – A particular role
- PUBLIC – Revokes privileges from all users and roles.

### ON LOCATION ( ‘path’ [ ON node ] )

- **path** — Specifies the path name mount point of the storage location
- **node** — [Optional] Revokes access to the storage location residing on the node. If you leave this blank, `node` defaults to all nodes on the specified path in that cluster. If a path exists for only some nodes, the entire grant rolls back, even on the nodes that reside in the path.

### CASCADE

Revoices privileges from the grantee. Using the CASCADE keyword when revoking privileges first removes them from the initial grantee. The statement then revokes all privileges from other users and roles to whom the grantee extended storage location access.

## Examples

For examples, see [GRANT (Storage Location)](Vertica Analytic Database (9.0.x))
See Also

- Granting and Revoking Privileges

REVOKE (Table)

Revokes privileges on a table from a user or role. Optionally revokes privileges on all tables within one or more schemas.

Note: Revoking privileges on all tables within a schema includes all views in the same schema.

In a database with trust authentication, the GRANT and REVOKE statements appear to work as expected but have no actual effect on the security of the database.

Syntax

REVOKE [ GRANT OPTION FOR ] { privilege[,...] | ALL [ PRIVILEGES ] }

... ON {

..... [ TABLE ] [[database.]schema.]tablename [ ,... ]

..... | ON ALL TABLES IN SCHEMA schema-name [,...] }

... FROM { username | PUBLIC | role } [ ,... ]

... [ CASCADE ]

Parameters

<table>
<thead>
<tr>
<th>GRANT OPTION FOR</th>
<th>Revokes the grant option for the privilege, not the privilege itself. If omitted, revokes both the privilege and the grant option.</th>
</tr>
</thead>
<tbody>
<tr>
<td>privilege</td>
<td>One of the following privileges:</td>
</tr>
<tr>
<td></td>
<td><strong>Important</strong>: Only SELECT privileges can be revoked on system tables.</td>
</tr>
<tr>
<td></td>
<td>• SELECT: Query tables of this schema.</td>
</tr>
<tr>
<td></td>
<td>• INSERT: Insert rows into tables of this schema, or and load data into tables with COPY.</td>
</tr>
</tbody>
</table>
Note: COPY FROM STDIN is allowed all users with INSERT privileges, while COPY FROM file requires admin privileges.

- **UPDATE**: Update rows of tables of this schema.
- **DELETE**: Delete rows of tables of this schema.
- **REFERENCES**: Create foreign key constraints for tables of this schema.
- **TRUNCATE**: Truncate table contents. Non-owners of the tables can no longer execute the following partition operations on them:
  - DROP_PARTITIONS
  - SWAP_PARTITIONS_BETWEEN_TABLES
  - MOVE_PARTITIONS_TO_TABLE

### ALL [PRIVILEGES]

Revoke all table privileges. The optional keyword PRIVILEGES is supported to comply with the SQL standard.

### [database.]schema

Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:

```sql
myschema.thisDbObject
```

One exception applies: you can specify system tables without their schema name.

If you specify a database, it must be the current database.

### tablename

Specifies the table from which to remove privileges.

### ON ALL TABLES IN SCHEMA

Revoke privileges on all tables (and by default views) within one or more schemas from a user and/or role.

### username

Revoke the privilege from the specified user.

### PUBLIC

Revoke the privilege from all users.
<table>
<thead>
<tr>
<th>role</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>CASCADE</td>
<td>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows how to revoke user Joe's privileges on the customer_dimension table.

```sql
=> REVOKE ALL PRIVILEGES ON TABLE customer_dimension FROM Joe;
REVOKE PRIVILEGE
```

**See Also**

- [GRANT (Table)](#)
- [Granting and Revoking Privileges](#)

**REVOKE (User Defined Extension)**

Revokes the EXECUTE privilege on a user-defined extension (UDx) from a database user or role. Optionally revokes privileges on all user-defined extensions within one or more schemas. You can revoke privileges on the following user-defined extension types:

- User Defined Functions (UDF)
  - User Defined SQL Functions
  - User Defined Scalar Functions (UDSF)
  - User Defined Transform Functions (UDTF)
  - User Defined Aggregate Functions (UDAF)
  - User Defined Analytic Functions (UDAnF)
- **User Defined Load Functions (UDL)**
  - UDL Filter
  - UDL Parser
  - UDL Source

### Syntax

```
REVOKE EXECUTE
... ON FUNCTION [ schema.]function [,..]  
... | ON AGGREGATE FUNCTION [[database.]schema.]function [,..]  
... | ON ANALYTIC FUNCTION [[database.]schema.]function [,..]  
... | ON TRANSFORM FUNCTION [[database.]schema.]function [,..]  
... | ON FILTER [[database.]schema.]filter [,..]  
... | ON PARSER [[database.]schema.]parser[,..]  
... | ON SOURCE [[database.]schema.]source [,..]  
... | ON ALL FUNCTIONS IN SCHEMA schema [,..]  
... ( [ argname ] argtype [,..] )  
... FROM { username | role | PUBLIC } [,..]  
... [ CASCADE ]
```

### Parameters

<table>
<thead>
<tr>
<th><strong>Parameter</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td><code>function</code></td>
<td>The name of the U Dx from which to revoke the EXECUTE privilege. If you use more than one schema, you must specify the schema that contains the U D x, as noted in the previous row.</td>
</tr>
<tr>
<td><code>filter</code></td>
<td></td>
</tr>
<tr>
<td><code>parser</code></td>
<td></td>
</tr>
<tr>
<td><code>source</code></td>
<td></td>
</tr>
<tr>
<td><strong>ON ALL FUNCTIONS IN SCHEMA</strong></td>
<td>Revokes EXECUTE privileges on all U Dx's within one or more schemas from a user, role, or all users and roles.</td>
</tr>
<tr>
<td><code>argname</code></td>
<td>[Optional] The argument name or names for the</td>
</tr>
</tbody>
</table>
When you `GRANT`, `REVOKE`, or `DROP` privileges for a polymorphic function, you must include an argument with the command.

<table>
<thead>
<tr>
<th>argtype</th>
<th>The argument data type or types of the UDX.</th>
</tr>
</thead>
<tbody>
<tr>
<td>`{ username</td>
<td>role</td>
</tr>
<tr>
<td><code>CASCADE</code></td>
<td>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.</td>
</tr>
</tbody>
</table>

**Privileges**

You must have DBADMIN privileges, or be the owner of the UDX, to run `REVOKE` (User Defined Extension).

**Examples**

The following command revokes EXECUTE privileges from user Bob on the `myzeroifnull` function:

```
> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Bob;
```

The following command revokes ALL privileges from user Doug on the `Pagerank` polymorphic function:

```
> REVOKE ALL ON TRANSFORM FUNCTION Pagerank (t float) FROM Doug;
```

The following command revokes EXECUTE privileges on all functions in the `zero-schema` schema from user Bob:

```
> REVOKE EXECUTE ON ALL FUNCTIONS IN SCHEMA zero-schema FROM Bob;
```

The following command revokes EXECUTE privileges from user Bob on the `tokenize` function:
> REVOKE EXECUTE ON TRANSFORM FUNCTION tokenize(VARCHAR) FROM Bob;

The following command revokes ALL privileges on the ExampleSource() source from user Alice:

> REVOKE ALL ON SOURCE ExampleSource() FROM Alice;

- Granting and Revoking Privileges in the Administrator's Guide
- Developing User-Defined Extensions (UDxs) in Extending Vertica

REVOKE (View)

Revoke user privileges on a view.

**Important:** In a database with trust authentication, the GRANT and REVOKE statements appear to work as expected but have no actual effect on the security of the database.

Syntax

```
REVOKE [ GRANT OPTION FOR ]...
{ SELECT | ALL [ PRIVILEGES ]}
... ON [[ database. ]schema. ]viewname [ , ... ]
... FROM { username | PUBLIC } [ , ... ]
... [ CASCADE ]
```

Parameters

<table>
<thead>
<tr>
<th>GRANT OPTION FOR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT</td>
<td>Revokes the user's ability to perform SELECT operations on a view and its referenced resources.</td>
</tr>
<tr>
<td>ALL</td>
<td>Revokes all previously granted privileges.</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>Is for SQL standard compatibility and is ignored.</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>viewname</code></td>
<td>Specifies the view on which to revoke the privileges.</td>
</tr>
<tr>
<td><code>username</code></td>
<td>Revokes the privilege from the specified user.</td>
</tr>
<tr>
<td><code>PUBLIC</code></td>
<td>Revokes the privilege from all users.</td>
</tr>
<tr>
<td><code>CASCADE</code></td>
<td>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The <code>CASCADE</code> keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.</td>
</tr>
</tbody>
</table>

### Examples

This example shows how to revoke SELECT privileges from user Joe on the view named `test_view`.

```
=> REVOKE SELECT ON test_view FROM Joe;
REVOKE PRIVILEGE
```

You can also use the database name and schema name in the command:

```
=> REVOKE SELECT ON VMart.public.test_view FROM Joe;
REVOKE PRIVILEGE
```

### See Also

- [GRANT (View)]
- [Granting and Revoking Privileges]
ROLLBACK

Ends the current transaction and discards all changes that occurred during the transaction.

Syntax

ROLLBACK [ WORK | TRANSACTION ]

Parameters

| WORK | TRANSACTION | Have no effect; they are optional keywords for readability. |

Privileges

No special permissions required.

Notes

When an operation is rolled back, any locks that are acquired by the operation are also rolled back.

ABORT is a synonym for ROLLBACK.

Examples

This example shows how to roll back from a DELETE transaction.

=> SELECT * FROM sample_table;
a
---
1
(1 row)
=> DELETE FROM sample_table WHERE a = 1;
This example shows how to roll back the changes you made since the BEGIN statement.

```
=> SELECT * FROM sample_table;
a
---
(0 rows)
=> ROLLBACK;
=> SELECT * FROM sample_table;
a
---
1
(1 row)
```

See Also

- Transactions
- Creating Transactions
- BEGIN
- COMMIT
- END
- START TRANSACTION

**ROLLBACK TO SAVEPOINT**

Rolls back all commands that have been entered within the transaction since the given savepoint was established.

**Syntax**

```
ROLLBACK TO [SAVEPOINT] savepoint_name
```
Parameters

| savepoint_name | Specifies the name of the savepoint to roll back to. |

Privileges

No special permissions required.

Notes

- The savepoint remains valid and can be rolled back to again later if needed.
- When an operation is rolled back, any locks that are acquired by the operation are also rolled back.
- ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.

Example

The following example rolls back the values 102 and 103 that were entered after the savepoint, my_savepoint, was established. Only the values 101 and 104 are inserted at commit.

```sql
=> INSERT INTO product_key VALUES (101);
=> SAVEPOINT my_savepoint;
=> INSERT INTO product_key VALUES (102);
=> INSERT INTO product_key VALUES (103);
=> ROLLBACK TO SAVEPOINT my_savepoint;
=> INSERT INTO product_key VALUES (104);
=> COMMIT;
```

See Also

- RELEASE SAVEPOINT
- SAVEPOINT
SAVEPOINT

Creates a special mark, called a savepoint, inside a transaction. A savepoint allows all commands that are executed after it was established to be rolled back, restoring the transaction to the state it was in at the point in which the savepoint was established.

Tip: Savepoints are useful when creating nested transactions. For example, a savepoint could be created at the beginning of a subroutine. That way, the result of the subroutine could be rolled back if necessary.

Syntax

SAVEPOINT savepoint_name

Parameters

| savepoint_name | Specifies the name of the savepoint to create. |

Privileges

No special permissions required.

Notes

- Savepoints are local to a transaction and can only be established when inside a transaction block.
- Multiple savepoints can be defined within a transaction.
- If a savepoint with the same name already exists, it is replaced with the new savepoint.
Example

The following example illustrates how a savepoint determines which values within a transaction can be rolled back. The values 102 and 103 that were entered after the savepoint, my_savepoint, was established are rolled back. Only the values 101 and 104 are inserted at commit.

```sql
=> INSERT INTO T1 (product_key) VALUES (101);
=> SAVEPOINT my_savepoint;
=> INSERT INTO T1 (product_key) VALUES (102);
=> INSERT INTO T1 (product_key) VALUES (103);
=> ROLLBACK TO SAVEPOINT my_savepoint;
=> INSERT INTO T1 (product_key) VALUES (104);
=> COMMIT;
=> SELECT product_key FROM T1;

101
104
(2 rows)
```

See Also

- RELEASE SAVEPOINT
- ROLLBACK TO SAVEPOINT

SELECT

Retrieves a result set from one or more tables.

Syntax

```sql
[[ AT EPOCH {LATEST | epoch-number} | AT TIME 'timestamp']]
[ AT epoch ]

SELECT [* | /*+ LABEL(label-name)*/ ] [ ALL | DISTINCT ]
... { * | expression [ [AS] output-name] }[,...]
... [ INTO TABLE ]
... [ from-clause ]
... [ WHERE condition ]
... [ TIMESERIES slice-time ]
```
... [ GROUP BY expression[, ...] ]
... [ HAVING condition[, ...] ]
... [ MATCH ]
... [ UNION { ALL | DISTINCT } ]
... [ EXCEPT ]
... [ INTERSECT ]
... [ ORDER BY expression [ ASC | DESC ][, ...] ]
... [ LIMIT { count | ALL } ]
... [ OFFSET start ]
... [ FOR UPDATE [ OF table-name[, ...] ] ]

Parameters

Note: SELECT clauses such as INTO and WHERE are discussed in sub-sections of this page.

<table>
<thead>
<tr>
<th>AT epoch</th>
<th>Returns data from the specified epoch, where epoch is one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• EPOCH LATEST: Return data from the latest committed DML transaction.</td>
</tr>
<tr>
<td></td>
<td>• EPOCH integer: Return data from the integer-specified epoch.</td>
</tr>
<tr>
<td></td>
<td>• TIME 'timestamp': Return data from the timestamp-specified epoch.</td>
</tr>
<tr>
<td></td>
<td>These options are ignored if used to query temporary tables.</td>
</tr>
<tr>
<td></td>
<td>For details, see Historical Queries in Analyzing Data.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>/<em>+LABEL (label-name)</em>/</th>
<th>Assigns a label to a query so you can identify it for profiling and debugging.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>In a UNION statement, only the first SELECT statement can be labeled; Vertica ignores labels in subsequent SELECT statements.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ALL</th>
<th>DISTINCT</th>
<th>ALL (default): Retains duplicate rows in result set or group.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• DISTINCT: Removes duplicate rows from the result set or group.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The ALL or DISTINCT qualifier must immediately follow the SELECT keyword. Only one instance of this keyword can appear in the select list.</td>
</tr>
</tbody>
</table>

| * | Lists all columns in the queried tables. |
Caution: Selecting all columns from the queried tables can produce a very large wide set, which can adversely affect performance.

(expression [AS output-name])

A table column or column expression to select from the queried tables. You can optionally qualify expression with an output name, which can be used in several ways:

- Label the column for display.
- Refer to the column's value in ORDER BY and GROUP BY clauses (it cannot be referenced in WHERE or HAVING clauses).

from-clause

A comma-separated list of data sources to query.

FOR UPDATE

Specifies to obtain an X lock on all tables specified in the query, most often used from READ COMMITTED isolation.

FOR UPDATE requires update/delete permissions on the queried tables and cannot be issued from a read-only transaction.

Privileges

You must have USAGE privileges on the schemas that contain the queried tables, as well as one, but not both, of the following:

- Owner or user with GRANT OPTION privileges
- SELECT privilege

If the SELECT statement queries a view, the view owner must have SELECT privileges on the view's anchor tables or views.

Example

When multiple clients run transactions as in the following example query, deadlocks can occur if FOR UPDATE is not used. Two transactions acquire an S lock, and when both attempt to upgrade to an X lock, they encounter deadlocks:

```sql
=> SELECT balance FROM accounts WHERE account_id=3476 FOR UPDATE;
...
```
UPDATE accounts SET balance = balance+10 WHERE account_id=3476;
=> COMMIT;

- Subqueries
- Joins

EXCEPT Clause

Combines two or more SELECT queries. EXCEPT returns distinct results of the left-hand query that are not also found in the right-hand query.

Note: MINUS is an alias for EXCEPT.

Syntax

```sql
SELECT
    ...
    EXCEPT select
    ...
    [ EXCEPT select ]...
    ...
    [ ORDER BY { column-name
    ...
    | ordinal-number }
    ...
    [ ASC | DESC ] [ , ... ] ]
    ...
    [ LIMIT { integer | ALL }]
    ...
    [ OFFSET integer ]
```
Notes

- Use the EXCEPT clause to filter out specific results from a SELECT statement. The EXCEPT query operates on the results of two or more SELECT queries. It returns only those rows in the left-hand query that are not also present in the right-hand query.

- Vertica evaluates multiple EXCEPT clauses in the same SELECT query from left to right, unless parentheses indicate otherwise.

- You cannot use the ALL keyword with an EXCEPT query.

- The results of each SELECT statement must be union compatible. Each statement must return the same number of columns, and the corresponding columns must have compatible data types. For example, you cannot use the EXCEPT clause on a column of type INTEGER and a column of type VARCHAR. If statements do not meet these criteria, Vertica returns an error.

  Note: The Data Type Coercion Chart lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

- You can use EXCEPT in FROM, WHERE, and HAVING clauses.

- You can order the results of an EXCEPT operation by including an ORDER BY operation in the statement. When you write the ORDER BY list, specify the column names from the leftmost SELECT statement, or specify integers that indicate the position of the columns by which to sort.

- The rightmost ORDER BY, LIMIT, or OFFSET clauses in an EXCEPT query do not need to be enclosed in parentheses, because the rightmost query specifies that Vertica perform the operation on the results of the EXCEPT operation. Any ORDER BY, LIMIT, or OFFSET clauses contained in SELECT queries that appear earlier in the EXCEPT query must be enclosed in parentheses.

- Vertica supports EXCEPT noncorrelated subquery predicates. For example:

```sql
=> SELECT * FROM T1
  WHERE T1.x IN
    (SELECT MAX(c1) FROM T2
     EXCEPT
     SELECT MAX(cc1) FROM T3
     EXCEPT
     SELECT MAX(d1) FROM T4);
```
Examples

Consider the following three tables:

**Company_A**

<table>
<thead>
<tr>
<th>Id</th>
<th>emp_lname</th>
<th>dept</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>auto parts</td>
<td>1000</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
<td>auto parts</td>
<td>2500</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>floral</td>
<td>500</td>
</tr>
<tr>
<td>3214</td>
<td>Smithson</td>
<td>sporting goods</td>
<td>1500</td>
</tr>
</tbody>
</table>

(4 rows)

**Company_B**

<table>
<thead>
<tr>
<th>Id</th>
<th>emp_lname</th>
<th>dept</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>4321</td>
<td>Marvin</td>
<td>home goods</td>
<td>250</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
<td>electronics</td>
<td>20000</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>home goods</td>
<td>500</td>
</tr>
<tr>
<td>3214</td>
<td>Smithson</td>
<td>home goods</td>
<td>1500</td>
</tr>
</tbody>
</table>

(4 rows)

**Company_C**

<table>
<thead>
<tr>
<th>Id</th>
<th>emp_lname</th>
<th>dept</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>3214</td>
<td>Smithson</td>
<td>sporting goods</td>
<td>1500</td>
</tr>
<tr>
<td>5432</td>
<td>Madison</td>
<td>sporting goods</td>
<td>400</td>
</tr>
<tr>
<td>7865</td>
<td>Cleveland</td>
<td>outdoor</td>
<td>1500</td>
</tr>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>floral</td>
<td>1000</td>
</tr>
</tbody>
</table>

(4 rows)

The following query returns the IDs and last names of employees that exist in Company_A, but not in Company_B:

```sql
=> SELECT id, emp_lname FROM Company_A
      EXCEPT
      SELECT id, emp_lname FROM Company_B;
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>emp_lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
</tr>
</tbody>
</table>
```

(2 rows)

The following query sorts the results of the previous query by employee last name:

```sql
=> SELECT id, emp_lname FROM Company_A
      EXCEPT
      SELECT id, emp_lname FROM Company_B
      ORDER BY emp_lname ASC;
```

```sql
<table>
<thead>
<tr>
<th>id</th>
<th>emp_lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
</tr>
</tbody>
</table>
```
If you order by the column position, the query returns the same results:

```sql
=> SELECT id, emp_lname FROM Company_A
   EXCEPT
   SELECT id, emp_lname FROM Company_B
   ORDER BY 2 ASC;
```

id | emp_lname
---+----------------
5678 | Alice
1234 | Stephen
(2 rows)

The following query returns the IDs and last names of employees that exist in Company_A, but not in Company_B or Company_C:

```sql
=> SELECT id, emp_lname FROM Company_A
   EXCEPT
   SELECT id, emp_lname FROM Company_B
   EXCEPT
   SELECT id, emp_lname FROM Company_C;
```

id | emp_lname
---+----------------
5678 | Alice
1234 | Stephen
(1 row)

The following query shows the results of mismatched data types:

```sql
=> SELECT id, emp_lname FROM Company_A
   EXCEPT
   SELECT emp_lname, id FROM Company_B;
ERROR 3429: For 'EXCEPT', types int and varchar are inconsistent
DETAIL:  Columns: id and emp_lname
```

Using the VMart example database, the following query returns information about all Connecticut-based customers who bought items through stores and whose purchases amounted to more than $500, except for those customers who paid cash:

```sql
=> SELECT customer_key, customer_name FROM public.customer_dimension
   WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact
                             WHERE sales_dollar_amount > 500
                             EXCEPT
                             SELECT customer_key FROM store.store_sales_fact
                             WHERE tender_type = 'Cash')
   AND customer_state = 'CT';
customer_key | customer_name
-------------+----------------
15084 | Doug V. Lampert
21730 | Juanita F. Peterson
### See Also

- Subqueries

### FROM Clause

A comma-separated list of data sources to query.

### Syntax

```
FROM dataset [, ...] [ TABLESAMPLE(percent) ]
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dataset</code></td>
<td>A set of data to query, one of the following:</td>
</tr>
<tr>
<td></td>
<td>- Table reference</td>
</tr>
<tr>
<td></td>
<td>- Joined tables</td>
</tr>
<tr>
<td></td>
<td>- Named subquery:</td>
</tr>
<tr>
<td></td>
<td>* subquery [AS] name</td>
</tr>
<tr>
<td>TABLESAMPLE(percent)</td>
<td>Valid only for user-defined tables, specifies to return a simple random</td>
</tr>
<tr>
<td></td>
<td>sampling of records, where <code>percent</code> specifies the approximate</td>
</tr>
</tbody>
</table>
sampling size. The `percent` value must be > 0 and < 100, and can be a decimal value. The number of records returned is not guaranteed to be the exact percentage specified.

Each row of the data set has the same opportunity to be selected. Vertica performs this sampling before other filters in the query are applied.

This clause is not valid for views, or data collector and system tables.

**Examples**

Return all records from the `customer_dimension` table:

```sql
=> SELECT * FROM customer_dimension;
```

The following example shows how to use the `TABLESAMPLE` clause. In this example, the query returns 50% of the rows in the table:

```sql
=> SELECT * FROM user_name TABLESAMPLE(50);

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
<td>Barry</td>
</tr>
<tr>
<td>982</td>
<td>Nero</td>
</tr>
<tr>
<td>8761</td>
<td>Lou</td>
</tr>
</tbody>
</table>

(3 rows)
```

In the next example, the query returns a small percentage of the rows in the `customer_dimension` table:

```sql
=> SELECT customer_name, customer_state FROM customer_dimension TABLESAMPLE(.015);

<table>
<thead>
<tr>
<th>customer_name</th>
<th>customer_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Steve X. Dobisz</td>
<td>UT</td>
</tr>
<tr>
<td>Ben C. Kramer</td>
<td>IA</td>
</tr>
<tr>
<td>Alexandra A. Peterson</td>
<td>IL</td>
</tr>
<tr>
<td>Dean B. Nielson</td>
<td>SD</td>
</tr>
<tr>
<td>Sally F. McNulty</td>
<td>CT</td>
</tr>
<tr>
<td>Americare</td>
<td>CA</td>
</tr>
<tr>
<td>Wendy K. Carcetti</td>
<td>NJ</td>
</tr>
<tr>
<td>Steve V. Williams</td>
<td>TN</td>
</tr>
<tr>
<td>Joseph P. Gauthier</td>
<td>CA</td>
</tr>
</tbody>
</table>

(9 rows)
```
Table-Reference

Syntax

```
[[database.]schema.]table [AS alias]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>database</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code> If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>table</code></td>
<td>A table in the logical schema.</td>
</tr>
<tr>
<td><code>[AS] alias</code></td>
<td>A temporary name used for references to <code>table</code>.</td>
</tr>
</tbody>
</table>

Joined-Table

Specifies how to join tables.

Syntax

```
table-reference [join-type] JOIN table-reference[ TABLESAMPLE(sampling-pct) ] [ ON join-predicate ]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>table-reference</code></td>
<td>A table or another <code>joined-table</code>.</td>
</tr>
<tr>
<td><code>join-type</code></td>
<td>Valid Values:</td>
</tr>
<tr>
<td></td>
<td>• <code>INNER</code> (default). <code>INNER</code> JOIN is equivalent to a query that specifies its join predicate in a WHERE clause.</td>
</tr>
<tr>
<td></td>
<td>• <code>LEFT</code> [ <code>OUTER</code> ]</td>
</tr>
</tbody>
</table>
- **RIGHT [ OUTER ]
- **FULL [ OUTER ]
- **NATURAL
- **CROSS

**TABLESAMPLE**

Specifies to use simple random sampling to return an approximate percentage of records. All rows in the total potential return set are equally eligible to be included in the sampling. Vertica performs this sampling before other filters in the query are applied. The number of records returned is not guaranteed to be the exact percentage of records defined by `sampling-pct`.

The **TABLESAMPLE** option is valid only with user-defined tables and Data Collector (DC) tables. Views and system tables are not supported.

**sampling-pct**

Specifies the percentage of records to be returned as a part of sampling. The value must be greater than 0 and less than 100.

**ON join-predicate**

An equi-join based on one or more columns in the joined tables. invalid for NATURAL and CROSS joins, required for all other join types.

### Alternative JOIN Syntax Options

Vertica supports two older join syntax conventions:

- Table joins specified by join predicate in a WHERE clause
- Table joins specified by a USING clause

For details, see Join Syntax in Analyzing Data.

### Examples

The following SELECT statement qualifies its JOIN clause with the **TABLESAMPLE** option:

```sql
=> SELECT user_id.id, user_name.name FROM user_name TABLESAMPLE(50)
    JOIN user_id TABLESAMPLE(50) ON user_name.id = user_id.id;
```

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>-----</td>
<td>-----------</td>
</tr>
<tr>
<td></td>
<td>-----------</td>
</tr>
</tbody>
</table>

---

---
GROUP BY Clause

Use the GROUP BY clause with aggregate functions in a SELECT statement to collect data across multiple records. Vertica groups the results into one or more sets of rows that match an expression.

The GROUP BY clause without aggregates is similar to using SELECT DISTINCT. **ROLLUP** is an extension to the GROUP BY clause. ROLLUP performs subtotal aggregations.

Syntax

```sql
GROUP BY [/*+GBYTYPE(algorithm)*/] expression-or-aggregate-expression [ , ... ]
```

Arguments

| /*+GBYTYPE(algorithm)*/ | Specifies which algorithm has precedence for implementing this GROUP BY clause, over the algorithm the Vertica query optimizer might otherwise choose. You can set **algorithm** to one of the following values:
| --- | --- |
| HASH: GROUPBY HASH algorithm
| PIPE: GROUPBY PIPELINED algorithm
For more information about both algorithms, see GROUP BY Implementation Options. |

| expression-or-aggregate-expression | An **expression** is:
| --- | --- |
| Any expression, including constants and column references in the tables specified in the FROM clause. For example:
| column1, ..., column_n, (expression) |
An **aggregate-expression** is:
- An ordered list of columns, expressions, CUBE, GROUPING SETS, or ROLLUP aggregates.

You can include CUBE and ROLLUP aggregates within a GROUPING SETS aggregate. CUBE and ROLLUP aggregates can result in a large amount of output. In that case, use GROUPING SETS to return only certain results.

You cannot include any aggregates within a CUBE or ROLLUP expression.

You can append multiple GROUPING SETS, CUBE, or ROLLUP aggregates in the same query. Examples:

```sql
GROUP BY a,b,c,d, ROLLUP(a,b)
GROUP BY a,b,c,d, CUBE((a,b),c,d)
GROUP BY a,b,c,d, CUBE(a,b), ROLLUP (c,d)
GROUP BY ROLLUP(a), CUBE(b), GROUPING SETS(c)
GROUP BY a,b,c,d, GROUPING SETS (((a,d),(b,c),CUBE(a,b)))
GROUP BY a,b,c,d, GROUPING SETS (((a,d),(b,c),(a,b),(a),(b),()))
```

Usage Considerations

- `expression` cannot include aggregate functions. However, you can use the GROUP BY clause with CUBE, GROUPING SETS, and ROLLUP to return summary values for each group.

- When you create a GROUP BY clause, you must include all non-aggregated columns that appear in the SELECT list.

- If the GROUP BY clause includes a WHERE clause, Vertica ignores all rows that do not satisfy the WHERE clause.

Examples

This example shows how to use the WHERE clause with GROUP BY. In this case, the example retrieves all employees whose last name begins with S, and ignores all rows that do not meet this criteria. The GROUP BY clause uses the ILIKE function to retrieve only last names beginning with S. The aggregate function SUM computes the total vacation days for each group.

```sql
=> SELECT employee_last_name, SUM(vacation_days)
    FROM employee_dimension
    WHERE employee_last_name ILIKE 'S%'```
The GROUP BY clause in the following example groups results by vendor region, and vendor region’s biggest deal:

```sql
=> SELECT vendor_region, MAX(deal_size) AS "Biggest Deal"
    FROM vendor_dimension
    GROUP BY vendor_region;
    vendor_region | Biggest Deal
-----------------|-------------
    East          | 990889
    Midwest       | 699163
    Northwest     | 76101
    South         | 854136
    Southwest     | 609807
    West          | 964005
(6 rows)
```

The following query modifies the previous one with a HAVING clause, which specifies to return only groups whose maximum deal size exceeds $900,000:

```sql
=> SELECT vendor_region, MAX(deal_size) AS "Biggest Deal"
    FROM vendor_dimension
    GROUP BY vendor_region
    HAVING MAX(deal_size) > 900000;
    vendor_region | Biggest Deal
-----------------|-------------
    East          | 990889
    West          | 964005
(2 rows)
```

The GROUP BY clause without aggregates is similar to using SELECT DISTINCT. For example, the following two queries return the same results:

```sql
=> SELECT DISTINCT household_id FROM customer_dimension;
=> SELECT household_id FROM customer_dimension GROUP BY household_id;
```

See Also

- CUBE Aggregate
- GROUP_ID
- GROUPING
ROLLUP Aggregate

Automatically performs subtotal aggregations as an extension to the GROUP BY clause. ROLLUP performs these aggregations across multiple dimensions, at different levels, within a single SQL query.

You can use the ROLLUP clause with three grouping functions:

- GROUPING
- GROUP_ID
- GROUPING_ID

Syntax

ROLLUP grouping-expression[, ...]

Parameters

<table>
<thead>
<tr>
<th>group-expression</th>
<th>One or both of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:</td>
</tr>
<tr>
<td></td>
<td>column1, (column2+1), column3+column4</td>
</tr>
<tr>
<td></td>
<td>- A multilevel expression, one of the following:</td>
</tr>
<tr>
<td></td>
<td>▪ ROLLUP</td>
</tr>
<tr>
<td></td>
<td>▪ CUBE</td>
</tr>
<tr>
<td></td>
<td>▪ GROUPING SETS</td>
</tr>
</tbody>
</table>
Restrictions

GROUP BY ROLLUP does not sort results. To sort data, an ORDER BY clause must follow the GROUP BY clause.

Levels of Aggregation

If $n$ is the number of grouping columns, ROLLUP creates $n+1$ levels of subtotals and grand total. Because ROLLUP removes the right-most column at each step, specify column order carefully.

Suppose that ROLLUP(A, B, C) creates four groups:

- (A, B, C)
- (A, B)
- (A)
- ()

Because ROLLUP removes the right-most column at each step, there are no groups for (A, C) and (B, C).

If you enclose two or more columns in parentheses, GROUP BY treats them as a single entity. For example:

- ROLLUP(A, B, C) creates four groups:
  - (A, B, C)
  - (A, B)
  - (A)
  - ()

- ROLLUP((A, B), C) treats (A, B) as a single entity and creates three groups:
  - (A, B, C)
  - (A, B)
  - ()

Example: Aggregating the Full Data Set

The following example shows how to use the GROUP BY clause to determine family expenses for electricity and books over several years. The SUM aggregate function computes the total amount of money spent in each category per year.

Suppose you have a table that contains information about family expenses for books and electricity:
For the expenses table, ROLLUP computes the subtotals in each category between 2005–2007:

- Books: $99.96
- Electricity: $449.96
- Grand total: $549.92.

Use the ORDER BY clause to sort the results:

```
=> SELECT * FROM expenses ORDER BY Category, Year;
 Year | Category | Amount
--------+---------+-------
 2005  | Books   | 39.98 
 2007  | Books   | 29.99 
 2008  | Books   | 29.99 
 2005  | Electricity | 109.99
 2006  | Electricity | 109.99
 2007  | Electricity | 229.98
```

Example: Using ROLLUP with the HAVING Clause

This example shows how to use the HAVING clause with ROLLUP to restrict the GROUP BY results. The following query produces only those ROLLUP categories where year is subtotalled, based on the expression in the GROUPING function:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
 GROUP BY ROLLUP(Category, Year) ORDER BY 1,2, GROUPING_ID();
 Category | Year | SUM
--------+------+-------
 Books   | 2005 | 39.98 
 Books   | 2007 | 29.99 
 Books   | 2008 | 29.99 
 Books   |      | 99.96 
 Electricity | 2005 | 109.99
 Electricity | 2006 | 109.99
 Electricity | 2007 | 229.98
 Electricity |      | 449.96
 |      | 549.92
```
The next example rolls up on (Category, Year), but not on the full results. The GROUPING_ID function specifies to aggregate less than three levels:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
  GROUP BY ROLLUP(Category,Year) HAVING GROUPING_ID(Category,Year)<3
  ORDER BY 1, 2, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
</tr>
</tbody>
</table>

GROUP_ID

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. This function returns one or more integers, starting with zero (0), as identifiers.

For the number of duplicates \( n \) for a particular grouping, \( \text{GROUP_ID} \) returns a range of sequential numbers, 0 to \( n-1 \). For the first each unique group it encounters, \( \text{GROUP_ID} \) returns the value 0. If \( \text{GROUP_ID} \) finds the same grouping again, the function returns 1, then returns 2 for the next found grouping, and so on.

**Note:** Use \( \text{GROUP_ID} \) only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING SETS, and ROLLUP.
Behavior Type

Immutable
Syntax

GROUP_ID ()
Examples

This example shows how GROUP_ID creates unique identifiers when a query produces duplicate groupings. For an expenses table, the following query groups the results by category of expense and year and rolls up the sum for those two columns. The results have duplicate groupings for category and NULL. The first grouping has a GROUP_ID of 0, and the second grouping has a GROUP_ID of 1.

```sql
=> SELECT Category, Year, SUM(Amount), GROUPING_ID(Category, Year), GROUP_ID() FROM expenses GROUP BY Category, ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING_ID</th>
<th>GROUP_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

- CUBE Aggregate
- GROUPING
- GROUPING_ID
- GROUPING SETS Aggregate
- GROUP BY Clause
- ROLLUP Aggregate

GROUPING

Disambiguates the use of NULL values when GROUP BY queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. Such NULL values from the original data can also occur in rows. GROUPING returns 1, if the value of expression is:

- NULL, representing an aggregated value
- 0 for any other value, including NULL values in rows

Note: Use GROUPING only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING SETS, and ROLLUP.
Behavior Type

Immutable
Syntax

GROUPING ( expression )
## Parameters

| $expression$ | An expression in the GROUP BY clause |
Examples

The following query uses the GROUPING function, taking one of the GROUP BY expressions as an argument. For each row, GROUPING returns one of the following:

- 0: The column is part of the group for that row
- 1: The column is not part of the group for that row

The 1 in the GROUPING(Year) column for electricity and books indicates that these values are subtotals. The right-most column values for both GROUPING(Category) and GROUPING(Year) are 1. This value indicates that neither column contributed to the GROUP BY. The final row represents the total sales.

```sql
=> SELECT Category, Year, SUM(Amount),
    GROUPING(Category), GROUPING(Year) FROM expenses
GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2008</td>
<td>449.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
See Also

- CUBE Aggregate
- GROUP_ID
- GROUPING_ID
- GROUPING SETS Aggregate
- GROUP BY Clause
- ROLLUP Aggregate

GROUPING_ID

Concatenates the set of Boolean values generated by the GROUPING function into a bit vector. GROUPING_ID treats the bit vector as a binary number and returns it as a base-10 value that identifies the grouping set combination.

By using GROUPING_ID you avoid the need for multiple, individual GROUPING functions. GROUPING_ID simplifies row-filtering conditions, because rows of interest are identified using a single return from GROUPING_ID = n. Use GROUPING_ID to identify grouping combinations.

Note: Use GROUPING_ID only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING SETS, and ROLLUP.
Behavior Type

Immutable
### Syntax

GROUPING_ID ( [expression[,...] ] )

<table>
<thead>
<tr>
<th>expression</th>
<th>An expression that matches one of the expressions in the GROUP BY clause.</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>If the GROUP BY clause includes a list of expressions, GROUPING_ID returns a number corresponding to the GROUPING bit vector associated with a row.</td>
</tr>
</tbody>
</table>
Examples

This example shows how calling GROUPING_ID without an expression returns the GROUPING bit vector associated with a full set of multilevel aggregate expressions. The GROUPING_ID value is comparable to GROUPING_ID(a, b) because GROUPING_ID() includes all columns in the GROUP BY ROLLUP:

```sql
=> SELECT a, b, COUNT(*), GROUPING_ID() FROM T GROUP BY ROLLUP(a, b);
```

In the following query, the GROUPING(Category) and GROUPING(Year) columns have three combinations:

- 0,0
- 0,1
- 1,1

```sql
=> SELECT Category, Year, SUM(Amount),
   GROUPING(Category), GROUPING(Year) FROM expenses
   GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

GROUPING_ID converts these values as follows:

<table>
<thead>
<tr>
<th>Binary Set Values</th>
<th>Decimal Equivalents</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>3</td>
</tr>
<tr>
<td>0</td>
<td>Category, Year</td>
</tr>
</tbody>
</table>

The following query returns the single number for each GROUP BY level that appears in the grid column:

```sql
SELECT Category, Year, SUM(Amount),
   GROUPING(Category), GROUPING(Year)
FROM expenses
GROUP BY ROLLUP(Category, Year)
ORDER BY Category, Year, GROUPING_ID();
```
=> SELECT Category, Year, SUM(Amount),
    GROUPING(Category), GROUPING(Year), GROUPING_ID(Category, Year) AS gr_id
FROM expenses GROUP BY ROLLUP(Category, Year);

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
<th>gr_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

The gr_id value determines the GROUP BY level for each row:

<table>
<thead>
<tr>
<th>GROUP BY Level</th>
<th>GROUP BY Row Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Total sum</td>
</tr>
<tr>
<td>1</td>
<td>Category</td>
</tr>
<tr>
<td>0</td>
<td>Category, year</td>
</tr>
</tbody>
</table>

You can also use the DECODE function to give the values more meaning by comparing each search value individually:

=> SELECT Category, Year, SUM(AMOUNT), DECODE(GROUPING_ID(Category, Year),
    3, 'Total',
    1, 'Category',
    0, 'Category,Year')
AS GROUP_NAME FROM expenses GROUP BY ROLLUP(Category, Year);

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUP_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>Category</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
<td>Category</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
<td>Total</td>
</tr>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>Category,Year</td>
</tr>
</tbody>
</table>

- ROLLUP Aggregate

CUBE Aggregate

Automatically performs all possible aggregations of the specified columns, as an extension to the GROUP BY clause.

You can use the ROLLUP clause with three grouping functions:

- GROUPING
- GROUP_ID
- GROUPING_ID

Syntax

GROUP BY `group-expression[, ...]`

Parameters

<table>
<thead>
<tr>
<th><code>group-expression</code></th>
<th>One or both of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:</td>
</tr>
<tr>
<td></td>
<td>column1, (column2+1), column3+column4</td>
</tr>
</tbody>
</table>
A multilevel expression, one of the following:
- ROLLUP
- CUBE
- GROUPING SETS

**Restrictions**

- GROUP BY CUBE does not order data. If you want to sort data, use the ORDER BY Clause. The ORDER BY clause must come after the GROUP BY clause.

- You can use CUBE inside a GROUPING SETS expression, but not inside a ROLLUP expression or another CUBE expression.

**Levels of CUBE Aggregation**

If \( n \) is the number of grouping columns, CUBE creates \( 2^n \) levels of aggregations. For example: CUBE \( (A, B, C) \) creates all possible permutations, resulting in eight groups:

- \( (A, B, C) \)
- \( (A, B) \)
- \( (A, C) \)
- \( (B, C) \)
- \( (A) \)
- \( (B) \)
- \( (C) \)
- \( () \)

If you increase the number of CUBE columns, the number of CUBE groupings increases exponentially. The CUBE query may be resource intensive and produce combinations that are not of interest. In that case, consider using the GROUPING SETS Aggregate, which allows you to choose specific groupings.
Example: Using CUBE to Return All Groupings

Suppose you have a table that contains information about family expenses for books and electricity:

```sql
=> SELECT * FROM expenses ORDER BY Category, Year;

<table>
<thead>
<tr>
<th>Year</th>
<th>Category</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>2005</td>
<td>Books</td>
<td>39.98</td>
</tr>
<tr>
<td>2007</td>
<td>Books</td>
<td>29.99</td>
</tr>
<tr>
<td>2008</td>
<td>Books</td>
<td>29.99</td>
</tr>
<tr>
<td>2005</td>
<td>Electricity</td>
<td>109.99</td>
</tr>
<tr>
<td>2006</td>
<td>Electricity</td>
<td>109.99</td>
</tr>
<tr>
<td>2007</td>
<td>Electricity</td>
<td>229.98</td>
</tr>
</tbody>
</table>
```

To aggregate the data by both Category and Year using the CUBE aggregate:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
   GROUP BY CUBE(Category, Year) ORDER BY 1, 2, GROUPING_ID();

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
</tr>
<tr>
<td></td>
<td>2005</td>
<td>149.97</td>
</tr>
<tr>
<td></td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td></td>
<td>2007</td>
<td>259.97</td>
</tr>
<tr>
<td></td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
</tr>
</tbody>
</table>
```

The results include subtotals for each category and year, and a grand total ($549.92).

Example: Using CUBE with the HAVING Clause

This example shows how you can restrict the GROUP BY results, use the HAVING clause with the CUBE aggregate. This query returns only the category totals and the full total:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
   GROUP BY CUBE(Category, Year) HAVING GROUPING(Year)=1;

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
</tr>
</tbody>
</table>
```

The next query returns only the aggregations for the two categories for each year. The GROUPING ID function specifies to omit the grand total ($549.92):
```sql
SELECT Category, Year, SUM(Amount) FROM expenses
GROUP BY CUBE(Category,Year) HAVING GROUPING_ID(Category,Year)<2
ORDER BY 1, 2, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electrical</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td>Electrical</td>
<td></td>
<td>449.96</td>
</tr>
</tbody>
</table>

- GROUPING
- GROUPING_ID
- GROUPING SETS Aggregate
- ROLLUP Aggregate

**GROUPING SETS Aggregate**

The GROUPING SETS aggregate is an extension to the GROUP BY clause that automatically performs subtotal aggregations on groupings that you specify.

You can use the GROUPING SETS clause with three grouping functions:

- GROUPING
- GROUP_ID
- GROUPING_ID

To sort data, use the ORDER BY clause. The ORDER BY clause must follow the GROUP BY clause.
Syntax

GROUP BY group-expression[,...]

Parameters

<table>
<thead>
<tr>
<th>group-expression</th>
<th>One or both of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:</td>
</tr>
<tr>
<td></td>
<td>column1, (column2+1), column3+column4</td>
</tr>
<tr>
<td></td>
<td>• A multilevel expression, one of the following:</td>
</tr>
<tr>
<td></td>
<td>▪ ROLLUP</td>
</tr>
<tr>
<td></td>
<td>▪ CUBE</td>
</tr>
<tr>
<td></td>
<td>▪ GROUPING SETS</td>
</tr>
</tbody>
</table>

Defining the Groupings

GROUPING SETS allows you to specify exactly which groupings you want in the results. You can also concatenate the groupings as follows:

The following example clauses result in the groupings shown.

<table>
<thead>
<tr>
<th>This clause...</th>
<th>Defines groupings...</th>
</tr>
</thead>
<tbody>
<tr>
<td>...GROUP BY GROUPING SETS(A,B,C,D)...</td>
<td>(A), (B), (C), (D)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS((A),(B),(C),(D))...</td>
<td>(A), (B), (C), (D)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS((A,B,C,D))...</td>
<td>(A, B, C, D)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS(A,B),GROUPING SETS(C,D)...</td>
<td>(A, C), (B, C), (A, D), (B, C)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS((A,B)),GROUPING SETS(C,D)...</td>
<td>(A, B, C), (A, B, D)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS(A,B),GROUPING SETS(ROLLUP(C,D))...</td>
<td>(A,B), (A,B,C), (A,B,C,D)</td>
</tr>
</tbody>
</table>
This clause...

...GROUP BY A, B, C, GROUPING SETS(ROLLUP(C, D))...

Defines groupings...

(A, B, C, D), (A, B, C), (A, B, C)

The clause contains two groups (A, B, C). In the HAVING clause, use the GROUP_ID function as a predicate, to eliminate the second grouping.

Example: Selecting Groupings

This example shows how to select only those groupings you want. Suppose you want to aggregate on columns only, and you do not need the grand total. The first query omits the total. In the second query, you add () to the GROUPING SETS list to get the total. Use the ORDER BY clause to sort the results by grouping:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
    GROUP BY GROUPING SETS((Category, Year), (Year))
    ORDER BY 1, 2, GROUPING_ID();

Category | Year | SUM
---------|------|-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Electrical | 2005 | 109.99
Electrical | 2006 | 109.99
Electrical | 2007 | 229.98
      | 2005 | 149.97
      | 2006 | 109.99
      | 2007 | 259.97
      | 2008 | 29.99
```

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
    GROUP BY GROUPING SETS((Category, Year), (Year), ())
    ORDER BY 1, 2, GROUPING_ID();

Category | Year | SUM
---------|------|-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Electrical | 2005 | 109.99
Electrical | 2006 | 109.99
Electrical | 2007 | 229.98
      | 2005 | 149.97
      | 2006 | 109.99
      | 2007 | 259.97
      | 2008 | 29.99
      | 549.92
```

- CUBE Aggregate
- GROUPING
- GROUP_ID
- GROUPING_ID
- GROUP BY Clause
- ROLLUP Aggregate

HAVING Clause

Restricts the results of a GROUP BY Clause.

Syntax

HAVING condition [, ...]

Parameters

| condition | Must unambiguously reference a grouping column, unless the reference appears within an aggregate function |

Notes

- Semantically, the HAVING clause occurs after the GROUP BY operation.
- You can use expressions in the HAVING clause.
- The HAVING clause was added to the SQL standard because you cannot use WHERE with Aggregate Functions.
Example

The following example returns the employees with salaries greater than $50,000:

```sql
=> SELECT employee_last_name, MAX(annual_salary) as "highest_salary"
   FROM employee_dimension
   GROUP BY employee_last_name
   HAVING MAX(annual_salary) > 50000;
```

<table>
<thead>
<tr>
<th>employee_last_name</th>
<th>highest_salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bauer</td>
<td>920149</td>
</tr>
<tr>
<td>Brown</td>
<td>569079</td>
</tr>
<tr>
<td>Campbell</td>
<td>649998</td>
</tr>
<tr>
<td>Carcetti</td>
<td>195175</td>
</tr>
<tr>
<td>Dobisz</td>
<td>840902</td>
</tr>
<tr>
<td>Farmer</td>
<td>804890</td>
</tr>
<tr>
<td>Fortin</td>
<td>481490</td>
</tr>
<tr>
<td>García</td>
<td>811231</td>
</tr>
<tr>
<td>Garnett</td>
<td>963104</td>
</tr>
<tr>
<td>Gauthier</td>
<td>927335</td>
</tr>
</tbody>
</table>

(10 rows)

INTERSECT Clause

Calculates the intersection of the results of two or more SELECT queries. INTERSECT returns distinct values by both the query on the left and right sides of the INTERSECT operand.

Syntax

```
select ... INTERSECT select ...
[ INTERSECT select ]...
[ ORDER BY { column-name | ordinal-number } [ ASC | DESC ] ]
[ , ... ]
[ LIMIT { integer | ALL } ]
[ OFFSET integer ]
```

Notes

- Use the INTERSECT clause to return all elements that are common to the results of all the SELECT queries. The INTERSECT query operates on the results of two or more SELECT queries. INTERSECT returns only the rows that are returned by all the specified queries.

- You cannot use the ALL keyword with an INTERSECT query.
The results of each SELECT query must be union compatible; they must return the same number of columns, and the corresponding columns must have compatible data types. For example, you cannot use the INTERSECT clause on a column of type INTEGER and a column of type VARCHAR. If the SELECT queries do not meet these criteria, Vertica returns an error.

**Note:** The Data Type Coercion Chart lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

Order the results of an INTERSECT operation by using an ORDER BY clause. In the ORDER BY list, specify the column names from the leftmost SELECT statement or specify integers that indicate the position of the columns by which to sort.

You can use INTERSECT in FROM, WHERE, and HAVING clauses.

The rightmost ORDER BY, LIMIT, or OFFSET clauses in an INTERSECT query do not need to be enclosed in parentheses because the rightmost query specifies that Vertica perform the operation on the results of the INTERSECT operation. Any ORDER BY, LIMIT, or OFFSET clauses contained in SELECT queries that appear earlier in the INTERSECT query must be enclosed in parentheses.

The order by column names is from the first select.

Vertica supports INTERSECT noncorrelated subquery predicates. For example:

```sql
=> SELECT * FROM T1
   WHERE T1.x IN
       (SELECT MAX(c1) FROM T2
        INTERSECT
         SELECT MAX(cc1) FROM T3
        INTERSECT
         SELECT MAX(d1) FROM T4);
```

### Examples

Consider the following three tables:

**Company_A**

<table>
<thead>
<tr>
<th>id</th>
<th>emp_name</th>
<th>dept</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>auto parts</td>
<td>1000</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
<td>auto parts</td>
<td>2500</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>floral</td>
<td>500</td>
</tr>
<tr>
<td>3214</td>
<td>Smithson</td>
<td>sporting goods</td>
<td>1500</td>
</tr>
</tbody>
</table>

**Company_B**
The following query returns the IDs and last names of employees that exist in both Company_A and Company_C:

```sql
=> SELECT id, emp_lname FROM Company_A
    INTERSECT
    SELECT id, emp_lname FROM Company_C;
```
```
id | emp_lname
----------
3214 | Smithson
9012 | Katherine
```
(2 rows)

The following query returns the same two employees in descending order of sales:

```sql
=> SELECT id, emp_lname, sales FROM Company_A
    INTERSECT
    SELECT id, emp_lname, sales FROM Company_B
    ORDER BY sales DESC;
```
```
id | emp_lname | sales
----------
3214 | Smithson | 1500
9012 | Katherine | 500
```
(2 rows)

You can also use the integer that represents the position of the sales column (3) to return the same result:

```sql
=> SELECT id, emp_lname, sales FROM Company_A
    INTERSECT
    SELECT id, emp_lname, sales FROM Company_B
    ORDER BY 3 DESC;
```
```
id | emp_lname | sales
----------
3214 | Smithson | 1500
9012 | Katherine | 500
```
(2 rows)
The following query returns the employee who works for both companies whose sales in Company_B are greater than 1000:

```sql
=> SELECT id, emp_lname, sales FROM Company_A
    INTERSECT
    (SELECT id, emp_lname, sales FROM company_B WHERE sales > 1000)
    ORDER BY sales DESC;
id | emp_lname | sales
--------+------------+-----
3214 | Smithson  | 1500
(1 row)
```

In the following query returns the ID and last name of the employee who works for all three companies:

```sql
=> SELECT id, emp_lname FROM Company_A
    INTERSECT
    SELECT id, emp_lname FROM Company_B
    INTERSECT
    SELECT id, emp_lname FROM Company_C;
id | emp_lname
--------+------------
3214 | Smithson
(1 row)
```

The following query shows the results of a mismatched data types; these two queries are not union compatible:

```sql
=> SELECT id, emp_lname FROM Company_A
    INTERSECT
    SELECT emp_lname, id FROM Company_B;
ERROR 3429: For 'INTERSECT', types int and varchar are inconsistent
DETAIL: Columns: id and emp_lname
```

Using the VMart example database, the following query returns information about all Connecticut-based customers who bought items online and whose purchase amounts were between $400 and $500:

```sql
=> SELECT customer_key, customer_name from public.customer_dimension
    WHERE customer_key IN (SELECT customer_key
                       FROM online_sales.online_sales_fact
                       WHERE sales_dollar_amount > 400
                    INTERSECT
                    SELECT customer_key FROM online_sales.online_sales_fact
                       WHERE sales_dollar_amount < 500)
                    AND customer_state = 'CT';
customer_key | customer_name
--------------+------------------
39           | Sarah S. Winkler
44           | Meghan H. Overstreet
70           | Jack X. Cleveland
103          | Alexandra I. Vu
110          | Matt. Farmer
173          | Mary R. Reyes
```
The previous query returns the same data as:

```sql
=> SELECT customer_key, customer_name FROM public.customer_dimension
    WHERE customer_key IN (SELECT customer_key
                            FROM online_sales.online_sales_fact
                            WHERE sales_dollar_amount > 400
                            AND sales_dollar_amount < 500)
    AND customer_state = 'CT';
```

INTO TABLE Clause

Creates a table from a query result set.

Syntax

**Permanent table**

INTO [TABLE] [[database.].schema.]table

**Temporary table**

INTO [scope] TEMP[ORARY] [TABLE] [[database.].schema.]table
...
[ ON COMMIT { PRESERVE | DELETE } ROWS ]
## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>scope</strong></td>
<td>Specifies visibility of a temporary table definition:</td>
</tr>
<tr>
<td></td>
<td>- GLOBAL (default): The table definition is visible to all sessions, and persists until you explicitly drop the table.</td>
</tr>
<tr>
<td></td>
<td>- LOCAL: The table definition is visible only to the session in which it is created, and is dropped when the session ends.</td>
</tr>
<tr>
<td></td>
<td>Regardless of this setting, retention of temporary table data is set by the keywords ON COMMIT DELETE ROWS and ON COMMIT PRESERVE ROWS (see below).</td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="#">Creating Temporary Tables</a> in the Administrator's Guide.</td>
</tr>
<tr>
<td><strong>[database.]schema</strong></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><strong>table</strong></td>
<td>The name of the table to create.</td>
</tr>
<tr>
<td>**ON COMMIT { PRESERVE</td>
<td>DELETE } ROWS**</td>
</tr>
<tr>
<td></td>
<td>- DELETE (default) marks the temporary table for transaction-scoped data. Vertica removes all table data after each commit.</td>
</tr>
<tr>
<td></td>
<td>- PRESERVE marks the temporary table for session-scoped data, which is preserved beyond the lifetime of a single transaction. Vertica removes all table data when the session ends.</td>
</tr>
</tbody>
</table>
Examples

The following SELECT statement has an INTO TABLE clause that creates table newTable from customer_dimension:

```sql
=> SELECT * INTO TABLE newTable FROM customer_dimension;
```

The following SELECT statement creates temporary table newTempTable. By default, temporary tables are created at a global scope, so its definition is visible to other sessions and persists until it is explicitly dropped. No customer_dimension data is copied into the new table, and Vertica issues a warning accordingly:

```sql
=> SELECT * INTO TEMP TABLE newTempTable FROM customer_dimension;
WARNING 4102: No rows are inserted into table "public"."newTempTable" because ON COMMIT DELETE ROWS is the default for create temporary table
HINT: Use "ON COMMIT PRESERVE ROWS" to preserve the data in temporary table
CREATE TABLE
```

The following SELECT statement creates local temporary table newTempTableLocal. This table is visible only to the session in which it was created, and is automatically dropped when the session ends. The INTO TABLE clause includes ON COMMIT PRESERVE ROWS, so Vertica copies all selection data into the new table:

```sql
=> SELECT * INTO LOCAL TEMP TABLE newTempTableLocal ON COMMIT PRESERVE ROWS
FROM customer_dimension;
CREATE TABLE
```

LIMIT Clause

Specifies the maximum number of result set rows to return.

Syntax

```
LIMIT { rows | ALL }
```

Parameters

<table>
<thead>
<tr>
<th>rows</th>
<th>The maximum number of rows to return.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>(default) Returns all rows.</td>
</tr>
</tbody>
</table>
Dependencies

- Use an ORDER BY clause with LIMIT. Otherwise, the query returns an undefined subset of the result set. For example, the following SELECT statement omits ORDER BY. Successive iterations of this query are liable to return a different set of five records from the customer_dimension table:

```
=> SELECT customer_name, customer_city FROM customer_dimension LIMIT 5;
   customer_name | customer_city
---------------|---------------
Craig S. Robinson | Fayetteville
Mark M. Kramer | Joliet
Barbara S. Farmer | Alexandria
Julie S. McNulty | Grand Prairie
Meghan R. Garcia | Athens
(5 rows)
```

In contrast, the following SELECT statement includes an ORDER BY clause and returns a consistent set of results:

```
=> SELECT customer_name, customer_city FROM customer_dimension
   ORDER BY customer_city, customer_name LIMIT 5;
   customer_name | customer_city
---------------|---------------
Alexander . Dobisz | Abilene
Alexander B. McCabe | Abilene
Alexander J. Goldberg | Abilene
Alexander M. Fortin | Abilene
Alexander P. Moore | Abilene
(5 rows)
```

- LIMIT must follow the SELECT statement's ORDER BY clause.
- When a SELECT statement specifies both LIMIT and OFFSET, Vertica first processes the OFFSET statement, and then applies the LIMIT statement to the remaining rows.

MATCH Clause

A SQL extension that lets you screen large amounts of historical data in search of event patterns, the MATCH clause provides subclasses for analytic partitioning and ordering and matches rows from the result table based on a pattern you define.

You specify a pattern as a regular expression, which is composed of event types defined in the DEFINE subclause, where each event corresponds to a row in the input table. Then you can search for the pattern within a sequence of input events. Pattern matching returns the contiguous sequence of rows that conforms to PATTERN subclause. For example, pattern P (A
B* C) consist of three event types: A, B, and C. When Vertica finds a match in the input table, the associated pattern instance must be an event of type A followed by 0 or more events of type B, and an event of type C.

Pattern matching is particularly useful for clickstream analysis where you might want to identify users' actions based on their Web browsing behavior (page clicks). A typical online clickstream funnel is:

Company home page -> product home page -> search -> results -> purchase online

Using the above clickstream funnel, you can search for a match on the user's sequence of web clicks and identify that the user:

- Landed on the company home page
- Navigated to the product page
- Ran a search
- Clicked a link from the search results
- Made a purchase

For examples that use this clickstream model, see Event Series Pattern Matching in Analyzing Data.

**Syntax**

```
MATCH ( [ PARTITION BY table_column ] ORDER BY table_column
... DEFINE event_name AS boolean_expr [, ...]
... PATTERN pattern_name AS ( regexp )
... [ ROWS MATCH { ALL EVENTS | FIRST EVENT } ] )
```

**Parameters**

| PARTITION BY | [Optional] Defines the window data scope in which the pattern, defined in the PATTERN subclause, is matched. The partition clause partitions the data by matched patterns defined in the PATTERN subclause. For each partition, data is sorted by the ORDER BY clause. If the partition clause is omitted, the entire data set is considered a single partition. |
| ORDER BY     | Defines the window data scope in which the pattern, defined in the PATTERN subclause, is matched. For each partition, the order clause |
specifies how the input data is ordered for pattern matching.

**Note:** The `ORDER BY` clause is mandatory.

<table>
<thead>
<tr>
<th>DEFINE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defines the <strong>boolean</strong> expressions that make up the event types in the regular expressions. For example:</td>
</tr>
<tr>
<td>The <code>DEFINE</code> subclause accepts a maximum of 52 events. See <a href="#">Event Series Pattern Matching</a> in Machine Learning for Predictive Analytics for examples.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>event_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is the name of the event to evaluate for each row; for example, Entry, Onsite, Purchase.</td>
</tr>
<tr>
<td><strong>Note:</strong> Event names are case insensitive and follow the same naming conventions as those used for tables and columns.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>boolean_expr</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is an expression that returns true or false. <code>boolean_expr</code> can include <a href="#">Boolean Operators</a> and relational (comparison) operators. For example:</td>
</tr>
<tr>
<td>Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>PATTERN pattern_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is the name of the pattern, which you define in the PATTERN subclause; for example, <code>P</code> is the pattern name defined below:</td>
</tr>
<tr>
<td><strong>PATTERN P AS (...)</strong></td>
</tr>
<tr>
<td>A <code>PATTERN</code> is a <strong>search pattern</strong> that is comprised of a name and a regular expression.</td>
</tr>
<tr>
<td><strong>Note:</strong> Vertica supports one pattern per query.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>regexp</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is a regular expression comprised of event types (defined in the <code>DEFINE</code> subclause), and one or more of the quantifiers below. When Vertica evaluates the <code>MATCH</code> clause, the regular expression identifies the rows that meet the expression criteria.</td>

</tbody>
</table>

**ROWS MATCH**

[Optional] Defines how to resolve more than one event evaluating to true for a single row.

- If you use ROWS MATCH ALL EVENTS, Vertica returns the following run-time error if more than one event evaluates to true for a single row:

  ```
  ERROR: pattern events must be mutually exclusive
  HINT: try using ROWS MATCH FIRST EVENT
  ```

- For ROWS MATCH FIRST EVENT, if more than one event evaluates to true for a single row, Vertica chooses the event defined first in the SQL statement to be the event it uses for the row.

**Pattern Semantic Evaluation**

- The semantic evaluating ordering of the SQL clauses is: FROM -> WHERE -> PATTERN MATCH -> SELECT.

- Data is partitioned as specified in the PARTITION BY clause. If the partition clause is omitted, the entire data set is considered a single partition.
For each partition, the order clause specifies how the input data is ordered for pattern matching.

Events are evaluated for each row. A row could have 0, 1, or N events evaluate to true. If more than one event evaluates to true for the same row, Vertica returns a run-time error unless you specify ROWS MATCH FIRST EVENT. If you specify ROWS MATCH FIRST EVENT and more than one event evaluates to TRUE for a single row, Vertica chooses the event that was defined first in the SQL statement to be the event it uses for the row.

Vertica performs pattern matching by finding the contiguous sequence of rows that conforms to the pattern defined in the PATTERN subclause. For each match, Vertica outputs the rows that contribute to the match. Rows not part of the match (do not satisfy one or more predicates) are not output.

Vertica reports only non-overlapping matches. If an overlap occurs, Vertica chooses the first match found in the input stream. After finding the match, Vertica looks for the next match, starting at the end of the previous match.

Vertica reports the longest possible match, not a subset of a match. For example, consider pattern: A*B with input: AAAB. Because A uses the greedy regular expression quantifier (*), Vertica reports all A inputs (AAAB), not AAB, AB, or B.

Notes and Restrictions

- DISTINCT and GROUP BY/HAVING clauses are not allowed in pattern match queries.

- The following expressions are not allowed in the DEFINE subclause:
  - Subqueries, such as DEFINE X AS c IN (SELECT c FROM table1)
  - Analytic functions, such as DEFINE X AS c < LEAD(1) OVER (ORDER BY 1)
  - Aggregate functions, such as DEFINE X AS c < MAX(1)

- You cannot use the same pattern name to define a different event; for example, the following is not allowed for X:

```sql
DEFINE X AS c1 < 3
X AS c1 >= 3
```
Used with MATCH clause, Vertica Pattern Matching Functions provide additional data about the patterns it finds. For example, you can use the functions to return values representing the name of the event that matched the input row, the sequential number of the match, or a partition-wide unique identifier for the instance of the pattern that matched.

Examples

For examples, see Event Series Pattern Matching in Machine Learning for Predictive Analytics.

- PATTERN_ID

MINUS Clause

MINUS is an alias for EXCEPT.

OFFSET Clause

Omits a specified number of rows from the beginning of the result set.

Syntax

OFFSET rows

Parameters

| rows  | Specifies the number of result set rows to omit. |
Dependencies

- Use an ORDER BY clause with OFFSET. Otherwise, the query returns an undefined subset of the result set.

- OFFSET must follow the ORDER BY clause in a SELECT statement or UNION clause.

- When a SELECT statement or UNION clause specifies both LIMIT and OFFSET, Vertica first processes the OFFSET statement, and then applies the LIMIT statement to the remaining rows.

Example

The following query returns 14 rows from the customer_dimension table:

```sql
=> SELECT customer_name, customer_gender FROM customer_dimension
WHERE occupation='Dancer' AND customer_city = 'San Francisco' ORDER BY customer_name;
```

<table>
<thead>
<tr>
<th>customer_name</th>
<th>customer_gender</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amy X. Lang</td>
<td>Female</td>
</tr>
<tr>
<td>Anna H. Li</td>
<td>Female</td>
</tr>
<tr>
<td>Brian O. Weaver</td>
<td>Male</td>
</tr>
<tr>
<td>Craig O. Pavlov</td>
<td>Male</td>
</tr>
<tr>
<td>Doug Z. Goldberg</td>
<td>Male</td>
</tr>
<tr>
<td>Harold S. Jones</td>
<td>Male</td>
</tr>
<tr>
<td>Jack E. Perkins</td>
<td>Male</td>
</tr>
<tr>
<td>Joseph W. Overstreet</td>
<td>Male</td>
</tr>
<tr>
<td>Kevin . Campbell</td>
<td>Male</td>
</tr>
<tr>
<td>Raja Y. Wilson</td>
<td>Male</td>
</tr>
<tr>
<td>Samantha O. Brown</td>
<td>Female</td>
</tr>
<tr>
<td>Steve H. Gauthier</td>
<td>Male</td>
</tr>
<tr>
<td>William . Nielson</td>
<td>Male</td>
</tr>
<tr>
<td>William Z. Roy</td>
<td>Male</td>
</tr>
</tbody>
</table>

(14 rows)

If you modify the previous query to specify an offset of 8 (OFFSET 8) clause, Vertica skips the first eight rows of the previous result set. The query returns the following results:

```sql
=> SELECT customer_name, customer_gender FROM customer_dimension
WHERE occupation='Dancer' AND customer_city = 'San Francisco' ORDER BY customer_name OFFSET 8;
```

<table>
<thead>
<tr>
<th>customer_name</th>
<th>customer_gender</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kevin . Campbell</td>
<td>Male</td>
</tr>
<tr>
<td>Raja Y. Wilson</td>
<td>Male</td>
</tr>
<tr>
<td>Samantha O. Brown</td>
<td>Female</td>
</tr>
<tr>
<td>Steve H. Gauthier</td>
<td>Male</td>
</tr>
<tr>
<td>William . Nielson</td>
<td>Male</td>
</tr>
<tr>
<td>William Z. Roy</td>
<td>Male</td>
</tr>
</tbody>
</table>

(6 rows)
ORDER BY Clause

Sorts a query result set on one or more columns.

Syntax

ORDER BY expression [ ASC | DESC ] [, ...]

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- Name or ordinal number of a SELECT list item. You cannot use an integer value for an ORDER BY clause that is inside an analytic function's OVER clause.</td>
</tr>
<tr>
<td></td>
<td>- Arbitrary expression formed from columns that do not appear in the SELECT list</td>
</tr>
<tr>
<td></td>
<td>- CASE expression</td>
</tr>
</tbody>
</table>

Notes

- The ordinal number refers to the position of the result column, counting from the left beginning at one. This makes it possible to order by a column that does not have a unique name. (You can assign a name to a result column using the AS clause.)

- While the user's current locale and collation sequence are used to compare strings and determine the results of the ORDER BY clause of a query, Vertica projection data is always stored sorted by the ASCII (binary) collating sequence.

- For INTEGER, INT, and DATE/TIME data types, NULL appears first (smallest) in ascending order.

- For FLOAT, BOOLEAN, CHAR, and VARCHAR, NULL appears last (largest) in ascending order.

- The ORDER BY clause may contain only columns or expressions that are in the window partition clause (see Window Partition Clause).
Examples

The follow example returns all the city and deal size for customer Metamedia, sorted by deal size in descending order.

```sql
=> SELECT customer_city, deal_size FROM customer_dimension WHERE customer_name = 'Metamedia'
   ORDER BY deal_size DESC;
```

<table>
<thead>
<tr>
<th>customer_city</th>
<th>deal_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>El Monte</td>
<td>4479561</td>
</tr>
<tr>
<td>Athens</td>
<td>3815416</td>
</tr>
<tr>
<td>Ventura</td>
<td>3792937</td>
</tr>
<tr>
<td>Peoria</td>
<td>3227765</td>
</tr>
<tr>
<td>Arvada</td>
<td>2671849</td>
</tr>
<tr>
<td>Coral Springs</td>
<td>2643674</td>
</tr>
<tr>
<td>Fontana</td>
<td>2374465</td>
</tr>
<tr>
<td>Rancho Cucamonga</td>
<td>2214002</td>
</tr>
<tr>
<td>Wichita Falls</td>
<td>2117962</td>
</tr>
<tr>
<td>Beaumont</td>
<td>1898295</td>
</tr>
<tr>
<td>Arvada</td>
<td>1321897</td>
</tr>
<tr>
<td>Waco</td>
<td>1026854</td>
</tr>
<tr>
<td>Joliet</td>
<td>945404</td>
</tr>
<tr>
<td>Hartford</td>
<td>445795</td>
</tr>
</tbody>
</table>

(14 rows)

The following example uses a transform function. It returns an error because the ORDER BY column is not in the window partition.

```sql
=> CREATE TABLE t(geom geometry(200), geog geography(200));
=> SELECT PolygonPoint(geom) OVER(PARTITION BY geom) AS SEL_0 FROM t ORDER BY geog;
ERROR 2521: Cannot specify anything other than user defined transforms and partitioning expressions in the ORDER BY list
```

The following example, using the same table, corrects this error.

```sql
=> SELECT PolygonPoint(geom) OVER(PARTITION BY geom) AS SEL_0 FROM t ORDER BY geom;
```

TIMESERIES Clause

Provides gap-filling and interpolation (GFI) computation, an important component of time series analytics computation. See Time Series Analytics in Analyzing Data for details and examples.
Syntax

```
TIMESERIES slice-time AS 'length-and-time-unit-exp' OVER (
... [ PARTITION BY (column-expr[,]) ]
... ORDER BY time-expr )
... [ ORDER BY table-column[, ] ]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>slice-time</code></td>
<td>A time column produced by the TIMESERIES clause, which stores the time slice start times generated from gap filling. <strong>Note:</strong> This parameter is an alias, so you can use any name that an alias would take.</td>
</tr>
<tr>
<td><code>length-and-time-unit-exp</code></td>
<td>An INTERVAL DAY TO SECOND literal that specifies the length of time unit of time slice computation. For example: TIME SERIES slice_time AS '3 seconds' ...</td>
</tr>
<tr>
<td><code>OVER()</code></td>
<td>Specifies partitioning and ordering for the function. OVER() also specifies that the time series function operates on a query result set—that is, the rows that are returned after the FROM, WHERE, GROUP BY, and HAVING clauses are evaluated.</td>
</tr>
<tr>
<td><code>PARTITION BY (column-expr</code></td>
<td>Partitions the data by the specified column expressions. <strong>Gap filling and interpolation</strong> is performed on each partition separately.</td>
</tr>
<tr>
<td><code>[,])</code></td>
<td></td>
</tr>
<tr>
<td><code>ORDER BY time-expr</code></td>
<td>Sorts the data by the TIMESTAMP expression <code>time-expr</code>, which computes the time information of the time series data. <strong>Note:</strong> The TIMESERIES clause requires an ORDER BY operation on the timestamp column.</td>
</tr>
</tbody>
</table>
Notes

If the window-partition-clause is not specified in TIMESERIES OVER(), for each defined time slice, exactly one output record is produced; otherwise, one output record is produced per partition per time slice. Interpolation is computed there.

Given a query block that contains a TIMESERIES clause, the following are the semantic phases of execution (after evaluating the FROM and the optional WHERE clauses):

1. Compute time-expression.

2. Perform the same computation as the TIME_SLICE() function on each input record based on the result of time-exp and 'length-and-time-unit-expr'.
   a. Perform gap filling to generate time slices missing from the input.
   b. Name the result of this computation as slice_time, which represents the generated “time series” column (alias) after gap filling.

3. Partition the data by expression, slice-time. For each partition, do step 4.

4. Sort the data by time-exp. Interpolation is computed here.

There is semantic overlap between the TIMESERIES clause and the TIME_SLICE function with the following key differences:

- TIMESERIES only supports the interval qualifier DAY TO SECOND; it does not allow YEAR TO MONTH.

- Unlike TIME_SLICE, the time slice length and time unit expressed in length-and-time-unit-expr must be constants so gaps in the time slices are well-defined.

- TIMESERIES performs gap filling; the TIME_SLICE function does not.

- TIME_SLICE can return the start or end time of a time slice, depending on the value of its fourth input parameter (start-or-end). TIMESERIES, on the other hand, always returns the start time of each time slice. To output the end time of each time slice, write a SELECT statement like the following:

  ```sql
  => SELECT slice_time + <slice_length>;
  ```
Restrictions

- When the TIMESERIES clause occurs in a SQL query block, only the following clauses can be used in the same query block:
  - SELECT
  - FROM
  - WHERE
  - ORDER BY

- GROUP BY and HAVING clauses are not allowed. If a GROUP BY operation is needed before or after gap-filling and interpolation (GFI), use a subquery and place the GROUP BY in the outer query. For example:

```sql
=> SELECT symbol, AVG(first_bid) as avg_bid FROM ( 
  SELECT symbol, slice_time, TS_FIRST_VALUE(bid1) AS first_bid 
  FROM Tickstore 
  WHERE symbol IN ('MSFT', 'IBM') 
  TIMESERIES slice_time AS '5 seconds' OVER (PARTITION BY symbol ORDER BY ts) 
) AS resultOfGFI 
GROUP BY symbol;
```

- When the TIMESERIES clause is present in the SQL query block, the SELECT list can include only the following:
  - Time series aggregate functions such as `TS_FIRST_VALUE` and `TS_LAST_VALUE`
  - `slice_time` column
  - `PARTITION` BY expressions
  - `TIME_SLICE` function

For example, the following two queries return a syntax error because `bid1` is not a `PARTITION` BY or `GROUP` BY column:

```sql
=> SELECT bid, symbol, TS_FIRST_VALUE(bid) FROM Tickstore 
  TIMESERIES slice_time AS '5 seconds' OVER (PARTITION BY symbol ORDER BY ts); 
ERROR: column "Tickstore.bid" must appear in the PARTITION BY list of Timeseries clause or be used in a Timeseries Output function
=> SELECT bid, symbol, AVG(bid) FROM Tickstore 
  GROUP BY symbol; 
ERROR: column "Tickstore.bid" must appear in the GROUP BY clause or be used in an aggregate function
```
Examples

For examples, see Gap Filling and Interpolation (GFI) in Analyzing Data.

See Also

- TIME_SLICE
- TS_FIRST_VALUE
- TS_LAST_VALUE
- Gap Filling and Interpolation (GFI)

UNION Clause

Combines the results of multiple SELECT statements. You can include UNION in FROM, WHERE, and HAVING clauses.

Syntax

```
select-stmt UNION { ALL | DISTINCT } select-stmt [ UNION { ALL | DISTINCT } select-stmt ]...
... [ ORDER BY expression { ASC | DESC }[,..] ]
... [ LIMIT { count | ALL } ]
... [ OFFSET start ]
```

Parameters

<table>
<thead>
<tr>
<th>select-stmt</th>
<th>A SELECT statement that returns one or more rows, depending on whether you specify keywords DISTINCT or ALL.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The following options also apply:</td>
</tr>
<tr>
<td></td>
<td>- The first SELECT statement can include the hint LABEL. Vertica ignores LABEL hints in subsequent SELECT statements.</td>
</tr>
<tr>
<td></td>
<td>- Each SELECT statement can specify its own ORDER BY, LIMIT, and OFFSET clauses. A SELECT statement with one or more of these clauses must be enclosed by parentheses. See also:</td>
</tr>
</tbody>
</table>
ORDER BY, LIMIT, and OFFSET Clauses in UNION

<table>
<thead>
<tr>
<th>DISTINCT</th>
<th>ALL</th>
<th>Specifies whether to return unique rows:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• DISTINCT (default) returns only unique rows.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ALL concatenates all rows, including duplicates. For best performance, use UNION ALL.</td>
</tr>
</tbody>
</table>

Requirements

- All rows of the UNION result set must be in the result set of at least one of its SELECT statements.
- Each SELECT statement must specify the same number of columns.
- Data types of corresponding SELECT statement columns must be compatible, otherwise Vertica returns an error.

ORDER BY, LIMIT, and OFFSET Clauses in UNION

A UNION statement can specify its own ORDER BY, LIMIT, and OFFSET clauses. For example, given the tables described below in Examples, the following query orders the UNION result set by emp_name and limits output to the first two rows:

```
=> SELECT id, emp_name FROM company_a UNION ALL SELECT id, emp_name FROM company_b ORDER BY emp_name LIMIT 2;
  id | emp_name
-------
5678 | Alice
8765 | Bob
(2 rows)
```

Each SELECT statement in a UNION clause can specify its own ORDER BY, LIMIT, and OFFSET clauses. In this case, the SELECT statement must be enclosed by parentheses. Vertica processes the SELECT statement ORDER BY, LIMIT, and OFFSET clauses before it processes the UNION clauses.

For example, each SELECT statement in the following UNION specifies its own ORDER BY and LIMIT clauses. Vertica processes the individual queries and then concatenates the two result sets:

```
=> (SELECT id, emp_name FROM company_a ORDER BY emp_name LIMIT 2)
   UNION ALL
(SELECT id, emp_name FROM company_b ORDER BY emp_name LIMIT 2);
```
The following requirements and restrictions determine how Vertica processes a UNION clause that contains ORDER BY, LIMIT, and OFFSET clauses:

- A UNION's ORDER BY clause must specify columns from the first (leftmost) SELECT statement.
- Always use an ORDER BY clause with LIMIT and OFFSET. Otherwise, the query returns an undefined subset of the result set.
- ORDER BY must precede LIMIT and OFFSET.
- When a SELECT or UNION statement specifies both LIMIT and OFFSET, Vertica first processes the OFFSET statement, and then applies the LIMIT statement to the remaining rows.

**UNION in Non-Correlated Subqueries**

Vertica supports UNION in noncorrelated subquery predicates. For example:

```sql
=> SELECT DISTINCT customer_key, customer_name FROM public.customer_dimension WHERE customer_key IN
  (SELECT customer_key FROM store.store_sales_fact WHERE sales_dollar_amount > 500
  UNION
  SELECT customer_key FROM online_sales.online_sales_fact WHERE sales_dollar_amount > 500)
  AND customer_state = 'CT';
```

<table>
<thead>
<tr>
<th>customer_key</th>
<th>customer_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>7021</td>
<td>Luigi T. Dobisz</td>
</tr>
<tr>
<td>1971</td>
<td>Betty V. Dobisz</td>
</tr>
<tr>
<td>46284</td>
<td>Ben C. Gauthier</td>
</tr>
<tr>
<td>33885</td>
<td>Tanya Y. Taylor</td>
</tr>
<tr>
<td>5449</td>
<td>Sarah O. Robinson</td>
</tr>
<tr>
<td>29059</td>
<td>Sally Z. Fortin</td>
</tr>
<tr>
<td>11200</td>
<td>Foodhope</td>
</tr>
<tr>
<td>15582</td>
<td>John J. McNulty</td>
</tr>
<tr>
<td>24638</td>
<td>Alexandra F. Jones</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
```

**Examples**

The examples that follow use these two tables:
### company_a

<table>
<thead>
<tr>
<th>ID</th>
<th>emp_name</th>
<th>dept</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>auto parts</td>
<td>1000</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
<td>auto parts</td>
<td>2500</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>floral</td>
<td>500</td>
</tr>
</tbody>
</table>

### company_b

<table>
<thead>
<tr>
<th>ID</th>
<th>emp_name</th>
<th>dept</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>4321</td>
<td>Marvin</td>
<td>home goods</td>
<td>250</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>home goods</td>
<td>500</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
<td>electronics</td>
<td>20000</td>
</tr>
</tbody>
</table>

Find all employee IDs and names from company_a and company_b

The UNION statement specifies DISTINCT to combine unique IDs and last names of employees; Katherine works for both companies, so she appears only once in the result set. DISTINCT is the default and can be omitted:

```
=> SELECT id, emp_name FROM company_a UNION DISTINCT SELECT id, emp_name FROM company_b ORDER BY id;
```

```
+----------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>emp_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
</tr>
<tr>
<td>4321</td>
<td>Marvin</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
</tr>
</tbody>
</table>
(5 rows)
```

The next UNION statement specifies the option ALL. Katherine works for both companies, so the query returns two records for her:

```
=> SELECT id, emp_name FROM company_a UNION ALL SELECT id, emp_name FROM company_b ORDER BY id;
```

```
+----------+--------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>emp_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
</tr>
<tr>
<td>4321</td>
<td>Marvin</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
</tr>
</tbody>
</table>
(6 rows)
```

Find the top two top performing salespeople in each company

Each SELECT statement specifies its own ORDER BY and LIMIT clauses, so the UNION statement concatenates the result sets as returned by each query:

```
=> (SELECT id, emp_name, sales FROM company_a ORDER BY sales DESC LIMIT 2) 
  UNION ALL 
  (SELECT id, emp_name, sales FROM company_b ORDER BY sales DESC LIMIT 2); 
```

```
+----------+----------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>emp_name</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>1000</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
<td>2500</td>
</tr>
<tr>
<td>4321</td>
<td>Marvin</td>
<td>250</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>500</td>
</tr>
</tbody>
</table>
(6 rows)
```
Find all employee orders by sales
The UNION statement specifies its own ORDER BY clause, which Vertica applies to the entire result:

```sql
 => SELECT id, emp_name, sales FROM company_a
      UNION
    SELECT id, emp_name, sales FROM company_b
    ORDER BY sales;
```

```
-+-+--------+
<table>
<thead>
<tr>
<th>id</th>
<th>emp_name</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>4321</td>
<td>Marvin</td>
<td>250</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>500</td>
</tr>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>1000</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
<td>2500</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
<td>20000</td>
</tr>
</tbody>
</table>
(5 rows)
```

Calculate the sum of sales for each company grouped by department
Each SELECT statement has its own GROUP BY clause. UNION combines the aggregate results from each query:

```sql
 => (SELECT 'Company A' as company, dept, SUM(sales) FROM company_a
     GROUP BY dept)
     UNION
   (SELECT 'Company B' as company, dept, SUM(sales) FROM company_b
     GROUP BY dept)
     ORDER BY 1;
```

```
 company | dept       | sum  
---------|------------|------
 Company A | auto parts | 3500 |
 Company A | floral | 500 |
 Company B | electronics | 20000 |
 Company B | home goods | 750 |
(4 rows)
```

See Also

- SELECT
- EXCEPT Clause
• INTERSECT Clause
• Subqueries

WHERE Clause

Eliminates rows from the result table that do not satisfy one or more predicates.

Syntax

WHERE boolean-expression [ subquery ] ... 

Parameters

| boolean-expression | Is an expression that returns true or false. Only rows for which the expression is true become part of the result set. |

The boolean-expression can include Boolean Operators and the following elements:

• BETWEEN-predicate
• Boolean-Predicate
• Column-Value-Predicate
• IN-predicate
• Join-Predicate
• LIKE-predicate
• NULL-predicate

Notes

You can use parentheses to group expressions, predicates, and boolean operators. For example:

```sql
=> ... WHERE NOT (A=1 AND B=2) OR C=3;
```
Example

The following example returns the names of all customers in the Eastern region whose name starts with 'Amer'. Without the WHERE clause filter, the query returns all customer names in the customer_dimension table.

```sql
=> SELECT DISTINCT customer_name
    FROM customer_dimension
    WHERE customer_region = 'East'
    AND customer_name ILIKE 'Amer%';
```

<table>
<thead>
<tr>
<th>Americare</th>
<th>Americom</th>
<th>Americore</th>
<th>Americorp</th>
<th>Ameridata</th>
<th>Amerigen</th>
<th>Amerihope</th>
<th>Amerimedia</th>
<th>Amerishop</th>
<th>Ameristar</th>
<th>Ameritech</th>
</tr>
</thead>
</table>
(11 rows)

WITH Clause

WITH clauses are individually-evaluated SELECT statements for use in a larger container query. You can use WITH clauses to simplify complicated queries and reduce statement repetition.

WITH clauses are evaluated through inline expansion or (optionally) through materialization. For details, see WITH Clauses in SELECT.

Syntax

The following syntax statement is illustrative, rather than syntactically exact, to show the possibility of numerous successive WITH queries in use with others:

```sql
WITH... with-query-1 [(col-name[,,...])AS (SELECT ...),
... with-query-2 [(col-name[,,...])AS (SELECT ...[with-query-1]),
. .
... with-query-n [(col-name[,,...])AS (SELECT ...[with-query-1, with-query-2, with-query-n[,,...]])
SELECT
. .
```
Restrictions

- Each WITH clause query must be uniquely named. Same-name aliases for WITH clause query names return with an error.
- WITH clauses do not support INSERT, UPDATE, or DELETE statements.
- WITH clauses cannot be used recursively; they can only be specified in succession.

Examples

See WITH Clauses in SELECT.

See Also

- SELECT
- Subqueries
- WITH Clauses in SELECT

**SET DATESTYLE**

Specifies how to format date/time output for the current session. Use `SHOW DATESTYLE` to verify the current output settings.

Syntax

```
SET DATESTYLE TO { arg | 'arg' }[, arg | 'arg']
```

Parameters

`SET DATESTYLE` has a single parameter, which can be set to one or two arguments that specify date ordering and style. Each argument can be specified singly or in combination with the other; if combined, they can be specified in any order.
The following table describes each style and the date ordering arguments it supports:

<table>
<thead>
<tr>
<th>Date style arguments</th>
<th>Order arguments</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO (ISO 8601/SQL standard)</td>
<td>n/a</td>
<td>2016-03-16 00:00:00</td>
</tr>
<tr>
<td>GERMAN</td>
<td>n/a</td>
<td>16.03.2016 00:00:00</td>
</tr>
<tr>
<td>SQL</td>
<td>MDY (default)</td>
<td>03/16/2016 00:00:00</td>
</tr>
<tr>
<td></td>
<td>DMY</td>
<td>16/03/2016 00:00:00</td>
</tr>
<tr>
<td>POSTGRES</td>
<td>MDY (default)</td>
<td>Wed Mar 16 00:00:00 2016</td>
</tr>
<tr>
<td></td>
<td>DMY</td>
<td>Wed 16 Mar 00:00:00 2016</td>
</tr>
</tbody>
</table>

Vertica ignores the order argument for date styles ISO and GERMAN. If the date style is SQL or POSTGRES, the order setting determines whether dates are output in MDY or DMY order. Neither SQL nor POSTGRES support YMD order. If you specify YMD for SQL or POSTGRES, Vertica ignores it and uses their default MDY order.

Date styles and ordering can also affect how Vertica interprets input values. For more information, see Date/Time Literals.

None

Input Dependencies

In some cases, input format can determine output, regardless of date style and order settings:

- Vertica ISO output for DATEDSTYLE is ISO long form, but several input styles are accepted. If the year appears first in the input, YMD is used for input and output, regardless of the DATEDSTYLE value.

- INTERVAL input and output share the same format, with the following exceptions:
  - Units like CENTURY or WEEK are converted to years and days.
  - AGO is converted to the appropriate sign.

  If the date style is set to ISO, output follows this format:
Example

=> CREATE TABLE t(a DATETIME);
CREATE TABLE
=> INSERT INTO t values ('3/16/2016');
OUTPUT
--------
  1
(1 row)
=> SHOW DATESTYLE;
   name   | setting
-----------+----------
 datestyle | ISO, MDY
(1 row)

=> SELECT * FROM t;
a
-------------------
  2016-03-16 00:00:00
(1 row)

=> SET DATESTYLE TO German;
SET
=> SHOW DATESTYLE;
   name   | setting
-----------+----------
 datestyle | German, DMY
(1 row)

=> SELECT * FROM t;
a
-------------------
  16.03.2016 00:00:00
(1 row)

=> SET DATESTYLE TO SQL;
SET
=> SHOW DATESTYLE;
   name   | setting
-----------+----------
 datestyle | SQL, DMY
(1 row)

=> SELECT * FROM t;
a
-------------------
  16/03/2016 00:00:00
(1 row)

=> SET DATESTYLE TO Postgres, MDY;
SET
=> SHOW DATESTYLE;
### SET ESCAPE_STRING_WARNING

Issues a warning when a backslash is used in a string literal during the current session.

#### Syntax

```
SET ESCAPE_STRING_WARNING TO { ON | OFF }
```

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| ON        | [Default] Issues a warning when a back slash is used in a string literal.  
            Tip: Organizations that have upgraded from earlier versions of Vertica can use this as a debugging tool for locating backslashes that used to be treated as escape characters, but are now treated as literals. |
| OFF       | Ignores back slashes within string literals. |

#### Privileges

No special permissions required.

#### Notes

- This statement works under vsql only.
- Turn off standard conforming strings before you turn on this parameter.
Tip: To set escape string warnings across all sessions, use the EscapeStringWarnings configuration parameter. See the Internationalization Parameters in the Administrator's Guide.

Examples

The following example shows how to turn OFF escape string warnings for the session.

```sql
=> SET ESCAPE_STRING_WARNING TO OFF;
```

See Also

- `SET STANDARD_CONFORMING_STRINGS`

SET INTERVALSTYLE

Specifies whether to include units in interval output for the current session.

Syntax

```sql
SET INTERVALSTYLE TO [ plain | units ]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plain</td>
<td>Sets the default interval output to omit units. PLAIN is the default value.</td>
</tr>
<tr>
<td>units</td>
<td>Enables interval output to include subtype unit identifiers. When INTERVALSTYLE is set to units, the DATESTYLE parameter controls output. If you enable units and they do not display in the output, check the DATESTYLE parameter value, which must be set to ISO or POSTGRES for interval units to display.</td>
</tr>
</tbody>
</table>

Privileges

None
Examples

See Setting Interval Unit Display.

**SET LOCALE**

Specifies locale for the current session.

**Syntax**

```sql
SET LOCALE TO ICU-locale-identifier
```

**Parameters**

| **ICU-locale-identifier** | Specifies the ICU locale identifier to use, by default set to:  
en_US@collation=binary  
You can also use the vsqI command `\locale` to set the current locale. An unqualified `\locale` command shows the current setting: |
|---------------------------|---------------------------------------------------------------|
|                           | => `\locale`  
en_GB  
=> `\locale` en_US@collation=binary;  
INFO 2567: Canonical locale: 'en_US'  
Standard collation: 'LEN_KBINARY'  
English (United States)  
=> `\locale`  
en_US@collation=binary; |

If set to null, Vertica sets locale to en_US_POSIX:

```sql
=> set locale to '';  
INFO 2567: Canonical locale: 'en_US_POSIX'  
Standard collation: 'LEN'  
English (United States, Computer)  
SET
```

The following requirements apply:

- Vertica only supports the COLLATION keyword.
Single quotes are mandatory to specify collation.

For a complete list of locale identifiers, see the ICU Project

Privileges

None

Commonly Used Locales

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>de_DE</td>
<td>German (Germany)</td>
</tr>
<tr>
<td>en_GB</td>
<td>English (Great Britain)</td>
</tr>
<tr>
<td>es_ES</td>
<td>Spanish (Spain)</td>
</tr>
<tr>
<td>fr_FR</td>
<td>French (France)</td>
</tr>
<tr>
<td>pt_BR</td>
<td>Portuguese (Brazil)</td>
</tr>
<tr>
<td>pt_PT</td>
<td>Portuguese (Portugal)</td>
</tr>
<tr>
<td>ru_RU</td>
<td>Russian (Russia)</td>
</tr>
<tr>
<td>ja_JP</td>
<td>Japanese (Japan)</td>
</tr>
<tr>
<td>zh_CN</td>
<td>Chinese (China, simplified Han)</td>
</tr>
<tr>
<td>zh_Hant_TW</td>
<td>Chinese (Taiwan, traditional Han)</td>
</tr>
</tbody>
</table>

Examples

Set session locale to en_GB:

```sql
=> SET LOCALE TO en_GB;
INFO 2567: Canonical locale: 'en_GB'
Standard collation: 'LEN'
English (United Kingdom)
SET
```

Use the short form of a locale:
=> SET LOCALE TO LEN;
INFO 2567: Canonical locale: 'en'
Standard collation: 'LEN'
English
SET

Specify collation:

=> SET LOCALE TO 'tr_tr@collation=standard';
INFO 2567: Canonical locale: 'tr_TR@collation=standard'
Standard collation: 'LTR'
Turkish (Turkey, collation=standard) Türkçe (Türkiye, Siralama=standard)
SET

See Also

- Implement Locales for International Data Sets
- About Locale

SET ROLE

Enables a role for the user's current session. The user can access privileges that have been granted to the role.

**Note:** If you set EnableAllRolesOnLogin=1, this eliminates the need for the user to run SET ROLE <rolenames> to enable any roles that have been granted to any user. For more information see Security Parameters.

Syntax

\[
\text{SET ROLE} \ {role \ [, \ \ldots] \ | \ NONE \ | \ ALL \ | \ ALL \ EXCEPT \ [, \ \ldots] \ | \ DEFAULT}
\]

Parameters

\[
\begin{array}{c|c}
\text{role} \ [, \ \ldots] \ | \ NONE \ | \ ALL \ | \ ALL \ EXCEPT \ [, \ \ldots] \ | \ DEFAULT & \text{The name of one or more roles to set as the current role, or one of the following keywords:} \\
\end{array}
\]
- NONE disables all roles for the current user session.
- ALL enables all of the roles to which the user has been granted access. Use `GRANT (Role)` to assign a role to a user.
- ALL EXCEPT enable all the roles to which the user has access, with the exception of the role or roles indicated with this command.
- DEFAULT sets the roles assigned to the user as the default roles.

### Privileges

As a user, you can only set a role that has been granted to you. Use the `SHOW AVAILABLE ROLES` command to retrieve a list of the roles available to you.

### Notes

- The DBADMIN user creates default roles that the DBADMIN then grants to a user. The DBADMIN can also grant a default role to a user using `ALTER USER`.

- Enabling a role does not affect any other roles that are currently enabled. A user session can have more than one role enabled at a time. The user's permissions are the union of all the roles that are currently active, plus any permissions granted directly to the user.

### Examples

This example shows the following:

- `SHOW AVAILABLE_ROLES`; lists the roles available to the user, but not enabled.
- `SET ROLE applogs`; enables the applogs role for the user.
- `SHOW ENABLED_ROLES`; lists the applogs role as enabled (SET) for the user.
- SET ROLE appuser; enables the appuser role for the user.

- SHOW ENABLED_ROLES now lists both applogs and appuser as enabled roles for the user.

- SET ROLE NONE disables all the users' enabled roles.

- SHOW ENABLED_ROLES shows that no roles are enabled for the user.

```
=> SHOW AVAILABLE_ROLES;
+----------------+---------+
| name           | setting |
|----------------+---------|
| available roles | applogs, appadmin, appuser |
+----------------+---------+
(1 row)
=> SET ROLE applogs;
SET

=> SHOW ENABLED_ROLES;
+----------------+---------+
| name           | setting |
|----------------+---------|
| enabled roles   | applogs  |
+----------------+---------+
(1 row)

=> SET ROLE appuser;
SET

=> SHOW ENABLED_ROLES;
+----------------+---------+
| name           | setting |
|----------------+---------|
| enabled roles   | applogs, appuser |
+----------------+---------+
(1 row)

=> SET ROLE NONE;
SET

=> SHOW ENABLED_ROLES;
+----------------+---------+
| name           | setting |
|----------------+---------|
| enabled roles   |         |
+----------------+---------+
(1 row)
```

**Set User Default Roles**

Though the DBADMIN user is normally responsible for setting a user's default roles, as a user you can set your own role. For example, if you run SET ROLE NONE all of your enabled roles are disabled. Then it was determined you need access to role1 as a default role. The DBADMIN uses **ALTER USER** to assign you a default role:

```
=> ALTER USER user1 default role role1;
```

This example sets role1 as user1's default role because the DBADMIN assigned this default role using ALTER USER.
Set All Roles as Default

This example makes all roles granted to user1 default roles:

```sql
user1 => SET ROLE default;
user1 => SHOW ENABLED_ROLES;
    name  | setting
---------------------
enabled roles | role1
(1 row)
```

Set All Roles as Default With EXCEPT

This example makes all the roles granted to the user default roles with the exception of role1.

```sql
user1 => set role all except role1;
user1 => SHOW ENABLED_ROLES
    name  | setting
---------------------
enabled roles | role2, role3
(1 row)
```

SET SEARCH_PATH

Specifies the order in which Vertica searches schemas when a SQL statement specifies a table name that is unqualified by a schema name. SET SEARCH_PATH overrides the current session’s search path, which is initially set from the user profile. This search path remains in effect until the next SET SEARCH_PATH statement, or the session ends. For details, see Setting Search Paths in the Administrator’s Guide.

To view the current search path, use SHOW SEARCH_PATH.

Syntax

```sql
SET SEARCH_PATH { TO | = } { schema-list | DEFAULT }
```
Parameters

<table>
<thead>
<tr>
<th>schema-list</th>
<th>A comma-delimited list of schemas that indicates the order in which Vertica searches schemas for a table whose name is unqualified by a schema name. If the search path includes a schema that does not exist, or for which the user lacks access privileges, Vertica silently skips over that schema.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Sets the search path to the database default: &quot;$user&quot;, public, v_catalog, v_monitor, v_internal</td>
</tr>
</tbody>
</table>

Privileges

None

Examples

Show the current search path:

```
=> SHOW SEARCH_PATH;
 name | setting
-----------------------
 search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

Reset the search path to schemas store and public:

```
=> SET SEARCH_PATH TO store, public;
 => SHOW SEARCH_PATH;
 name | setting
-----------------------
 search_path | store, public, v_catalog, v_monitor, v_internal
(1 row)
```

Reset the search path to the database default settings:

```
=> SET SEARCH_PATH TO DEFAULT;
 SET
 => SHOW SEARCH_PATH;
 name | setting
-----------------------
 search_path | "$user", public, v_catalog, v_monitor, v_internal
```
**SET SESSION AUTOCOMMIT**

Sets whether statements automatically commit their transactions on completion. This statement is primarily used by the client drivers to enable and disable autocommit, you should never have to directly call it.

**Syntax**

```sql
SET SESSION AUTOCOMMIT TO { ON | OFF }
```

**Parameters**

<table>
<thead>
<tr>
<th>ON</th>
<th>Enable autocommit. Statements automatically commit their transactions when they complete. This is the default setting for connections made using the Vertica client libraries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Disable autocommit. Transactions are not automatically committed. This is the default for interactive sessions (connections made through vsql).</td>
</tr>
</tbody>
</table>

**Privileges**

No special permissions required.

**Examples**

This examples show how to set AUTOCOMMIT to 'on' and then to 'off'.

```
=> SET SESSION AUTOCOMMIT TO on;
SET
=> SET SESSION AUTOCOMMIT TO off;
SET
```
See Also

- Client Libraries

SET SESSION CHARACTERISTICS AS TRANSACTION

Sets the isolation level and access mode of all transactions that start after this statement is issued.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

Syntax

```
SET SESSION CHARACTERISTICS AS TRANSACTION setting[, setting]
```

`setting` = one or both of the following:

- `ISOLATION LEVEL argument`
- `READ ONLY | READ WRITE`

ISOLATION LEVEL Arguments

The `ISOLATION LEVEL` clause determines what data the transaction can access when other transactions run concurrently. You cannot change the isolation level after the first query (SELECT) or DML statement (INSERT, DELETE, UPDATE) if a transaction has run.

Set `ISOLATION LEVEL` to one of the following arguments:

<table>
<thead>
<tr>
<th>SERIALIZABLE</th>
<th>Sets the strictest level of SQL transaction isolation. This level emulates transactions serially, rather than concurrently. It holds locks and blocks write operations until the transaction completes.</th>
</tr>
</thead>
</table>
Applications that use SERIALIZABLE must be prepared to retry transactions in the event of serialization failures. This isolation level is not recommended for normal query operations.

Setting the transaction isolation level to SERIALIZABLE does not apply to temporary tables. Temporary tables are isolated by their transaction scope.

<table>
<thead>
<tr>
<th>Isolation Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPEATABLE READ</td>
<td>Automatically converted to SERIALIZABLE.</td>
</tr>
<tr>
<td>READ COMMITTED</td>
<td>The default setting, allows concurrent transactions.</td>
</tr>
<tr>
<td>READ UNCOMMITTED</td>
<td>Automatically converted to READ COMMITTED.</td>
</tr>
</tbody>
</table>

**READ WRITE/READ ONLY**

You can set the transaction access mode with one of the following:

<table>
<thead>
<tr>
<th>Access Mode</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ WRITE</td>
<td>Default</td>
</tr>
<tr>
<td>READ ONLY</td>
<td>Disallows SQL statements that require write access:</td>
</tr>
<tr>
<td></td>
<td>• INSERT, UPDATE, DELETE, and COPY operations on any non-temporary table.</td>
</tr>
<tr>
<td></td>
<td>• CREATE, ALTER, and DROP</td>
</tr>
<tr>
<td></td>
<td>• GRANT, REVOKE</td>
</tr>
<tr>
<td></td>
<td>• EXPLAIN if the SQL statement to explain requires write access.</td>
</tr>
</tbody>
</table>

**Note:** Setting the transaction session mode to read-only does not prevent all write operations.

**Privileges**

None
Viewing Session Transaction Characteristics

SHOW TRANSACTION_ISOLATION and SHOW TRANSACTION_READ_ONLY show the transaction settings for the current session:

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction_isolation</td>
<td>SERIALIZABLE</td>
</tr>
</tbody>
</table>

(1 row)

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction_read_only</td>
<td>true</td>
</tr>
</tbody>
</table>

(1 row)

**SET SESSION GRACEPERIOD**

Sets how long a session socket remains blocked while awaiting client input or output for a given query. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated. If no grace period is set, the query can maintain its block on the socket indefinitely.

Vertica applies a session's grace period and RUNTIMECAP settings independently. If no grace period is set, a query can continue to block indefinitely on a session socket, regardless of the query's RUNTIMECAP setting.

**Syntax**

`SET SESSION GRACEPERIOD duration`

**Parameters**

<table>
<thead>
<tr>
<th>duration</th>
<th>Specifies how long a query can block on any session socket, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>interval</td>
<td>'interval': Specifies as an interval the maximum grace period for current session queries, up to 20 days.</td>
</tr>
</tbody>
</table>
Privileges

- Superusers can increase session grace period to any value, regardless of database or node settings.

- Non-superusers can only set the session grace period to a value equal to or lower than their own user setting. If no grace period is explicitly set for a user, the grace period for that user is inherited from the node or database settings.

Examples

See Handling Session Socket Blocking in the Administrator's Guide.

**SET SESSION IDLESESSIONTIMEOUT**

Sets the maximum amount of time that a session can remain idle before it exits.

**Note:** An idle session has no queries running.

Syntax

```
SET SESSION IDLESESSIONTIMEOUT duration
```

Parameters

<table>
<thead>
<tr>
<th><strong>duration</strong></th>
<th>Specifies the amount of time a session can remain idle before it exits:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NONE</strong> (default): No idle timeout set on the session.</td>
<td></td>
</tr>
</tbody>
</table>
`interval`: Specifies as an `interval` the maximum amount of time a session can remain idle.

`=DEFAULT`: Sets the idle timeout period for this session to the user's `IDLESESSIONTIMEOUT` value.

### Privileges

- Superusers can increase the time a session can remain idle to any value, regardless of database or node settings.

- Non-superusers can only set the session idle time to a value equal to or lower than their own user setting. If no session idle time is explicitly set for a user, the session idle time for that user is inherited from the node or database settings.

### Examples

See [Managing Client Connections](#) in the Administrator's Guide.

### `SET SESSION MEMORYCAP`

Limits how much memory can be allocated to any request in this session. This limit only applies to the current session; it does not limit the total amount of memory used by multiple sessions.

#### Syntax

```
SET SESSION MEMORYCAP limit
```

#### Parameters

<table>
<thead>
<tr>
<th><code>limit</code></th>
<th>One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>max-expression</code>: A string value that specifies the memory limit, one of the following:</td>
</tr>
</tbody>
</table>
- `int%` — Expresses the maximum as a percentage of total memory available to the Resource Manager, where `int` is an integer value between 0 and 100. For example:

  \[
  \text{MEMORYCAP '40%'}
  \]

- `int{K|M|G|T}` — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:

  \[
  \text{MEMORYCAP '10G'}
  \]

- `=DEFAULT`: Sets the memory cap for queries in this session to the user's MEMORYCAP value. A new session is initially set to this value.

- `NONE`: Valid only for superusers, removes any grace period previously set on session queries.

### Privileges

- Superusers can increase session memory cap to any value.

- Non-superusers can only set the session memory cap to a value equal to or lower than their own user setting.

### Examples

**Set the session memory cap to 2 gigabytes:**

```sql
=> SET SESSION MEMORYCAP '2G';
SET
=> SHOW MEMORYCAP;
  name  | setting
----------
 memorycap | 2097152
(1 row)
```

**Revert the memory cap to the default setting as specified in the user profile:**

```sql
=> SET MEMORYCAP=DEFAULT;
SET
=> SHOW MEMORYCAP;
  name  | setting
----------
 memorycap | 2013336
```
See Also

Managing Workloads

**SET SESSION MULTIPLEACTIVERESULTSETS**

Enables or disable the execution of multiple active result sets (MARS) on a single JDBC connection. Using this option requires an active JDBC connection.

**Syntax**

```
SET SESSION MULTIPLEACTIVERESULTSETS TO {ON | OFF}
```

**Parameters**

<table>
<thead>
<tr>
<th>ON</th>
<th>Enable MultipleActiveResultSets. Allows you to execute multiple result sets on a single connection.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Disable MultipleActiveResultSets. Allows only one active result set per connection. (Default value.)</td>
</tr>
</tbody>
</table>

**Privileges**

No special permissions required.

**Examples**

This example shows how you can set MultipleActiveResultSets to on and then to off:
SET SESSION RESOURCE_POOL

Associates the user session with the specified resource pool.

Syntax

SET SESSION RESOURCE_POOL = { pool-name | DEFAULT }

Parameters

<table>
<thead>
<tr>
<th>pool-name</th>
<th>The name of an existing resource pool to associate with the current session.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Sets the session's resource pool to the user's default resource pool.</td>
</tr>
</tbody>
</table>

Privileges

- Superusers can assign their session to any available resource pool.
- Non-superusers must have USAGE privileges for the resource pool.

Examples

This example sets ceo_pool as the session resource pool:

```sql
=> SET SESSION RESOURCE_POOL = ceo_pool;
SET
```
See Also

- ALTER RESOURCE POOL
- CREATE RESOURCE POOL
- CREATE USER
- DROP RESOURCE POOL
- GRANT (Resource Pool)
- SET SESSION MEMORYCAP
- Managing Workloads

**SET SESSION RUNTIMECAP**

Sets the maximum amount of time queries can run in a given session. If a query exceeds its session's RUNTIMECAP setting, Vertica terminates the query and returns an error. You cannot increase the RUNTIMECAP beyond the limit that is set in your user profile.

Note: Vertica does not strictly enforce session RUNTIMECAP settings. If you time a query, you might discover that it runs longer than the RUNTIMECAP setting.

**Syntax**

```
SET SESSION RUNTIMECAP duration
```

**Parameters**

<table>
<thead>
<tr>
<th>duration</th>
<th>Specifies how long a given query can run in the current session, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• NONE (default): Removes a runtime limit for all current session queries.</td>
</tr>
<tr>
<td></td>
<td>• 'interval': Specifies as an interval the maximum runtime for current</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
session queries, up to one year—for example, 1 minute or 100 seconds.

- =DEFAULT: Sets maximum runtime for queries in this session to the user's RUNTIMECAP value.

Privileges

- Superusers can increase session RUNTIMECAP to any value.
- Non-superusers can only set the session RUNTIMECAP to a value equal to or lower than their own user RUNTIMECAP.

Examples

Set the maximum query runtime for the current session to 10 minutes:

```
=> SET SESSION RUNTIMECAP '10 minutes';
```

Revert the session RUNTIMECAP to your user default setting:

```
=> SET SESSION RUNTIMECAP =DEFAULT;
SET
=> SHOW RUNTIMECAP;
    name     | setting
--------------------------
    runtimecap | UNLIMITED
(1 row)
```

See Also

- Setting a Runtime Limit for Queries
- Managing Workloads

**SET SESSION TEMPSPACECAP**

Sets the maximum amount of temporary file storage space that any request issued by the session can consume.
Syntax

```
SET SESSION TEMPSPACECAP 'space-limit' = default | NONE
```

Parameters

| 'space-limit' | The maximum amount of temporary file space the session can use. To set a limit, use a numeric value followed by a unit (for example: '10G'). The unit can be one of the following:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
</tbody>
</table>
|   | % percentage of total temporary storage space available. (In this case, the numeric value must be 0-100).
|   | K—Kilobytes
|   | M—Megabytes
|   | G—Gigabytes
|   | T—Terabytes

Setting this value to `default` sets the session's TEMPSPACECAP to the user's TEMPSPACECAP value.

Setting this value to `NONE` results in the session having unlimited temporary storage space. This is the default value.

Privileges

- This command requires superuser privileges to increase the TEMPSPACECAP over the user's TEMPSPACECAP limit.

- Regular users can change the TEMPSPACECAP associated with their own sessions to any value less than or equal to their own TEMPSPACECAP. They cannot increase its value beyond their own TEMPSPACECAP value.
Notes

- This limit is per session, not per user. A user could open multiple sessions, each of which could use up to the TEMPSPACECAP.

- Any execution plan that exceeds its TEMPSPACECAP usage results in the error:

  ERROR: Exceeded temp space cap.

Examples

The following command sets a TEMPSPACECAP of 20gigabytes on the session:

```sql
=> SET SESSION TEMPSPACECAP '20G';
SET
=> SHOW TEMPSPACECAP;
  name   | setting
--------------------------------
  tempspacecap | 20971520
(1 row)
```

**Note**: SHOW displays the TEMPSPACECAP in kilobytes.

To return the memorycap to the previous setting:

```sql
=> SET SESSION TEMPSPACECAP NONE;
SET
=> SHOW TEMPSPACECAP;
  name   | setting
--------------------------------
  tempspacecap | UNLIMITED
(1 row)
```

See Also

- ALTER USER
- CREATE USER
- Managing Workloads
SET STANDARD_CONFORMING_STRINGS

Treats backslashes as escape characters for the current session.

Syntax

SET STANDARD_CONFORMING_STRINGS TO { ON | OFF }

Parameters

| ON | Makes ordinary string literals ('...') treat back slashes (\) literally. This means that back slashes are treated as string literals, not escape characters. (This is the default.) |
| OFF | Treats back slashes as escape characters. |

Privileges

No special permissions required.

Notes

- This statement works under vsql only.
- When standard conforming strings are on, Vertica supports SQL:2008 string literals within Unicode escapes.
- Standard conforming strings must be ON to use Unicode-style string literals (U' \nnnn ').

Tip: To set conforming strings across all sessions (permanently), use the StandardConformingStrings as described in Internationalization Parameters in the Administrator's Guide.
Examples

The following example shows how to turn off conforming strings for the session.

```sql
=> SET STANDARD_CONFORMING_STRINGS TO OFF;
```

The following command lets you verify the settings:

```sql
=> SHOW STANDARD_CONFORMING_STRINGS;

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>standard_conforming_strings</td>
<td>off</td>
</tr>
</tbody>
</table>
```

The following example shows how to turn on conforming strings for the session.

```sql
=> SET STANDARD_CONFORMING_STRINGS TO ON;
```

See Also

- `SET ESCAPE_STRING_WARNING`

SET TIME ZONE

Changes the TIME ZONE run-time parameter for the current session. Use `SHOW TIMEZONE` to show the session's current time zone.

If you set the timezone using POSIX format, the timezone abbreviation you use overrides the default timezone abbreviation. If the `date style` is set to POSTGRES, the timezone abbreviation you use is also used when converting a timestamp to a string.

Syntax

```sql
SET TIME ZONE TO { value | 'value' }
```

Note: Vertica treats literals `TIME ZONE` and `TIMEZONE` as synonyms.
Parameters

<table>
<thead>
<tr>
<th>value</th>
<th>One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A time zone literal supported by Vertica. To view the default list of valid literals, see the files in the following directory: opt/vertica/share/timezonesets</td>
</tr>
<tr>
<td></td>
<td>A signed integer representing an offset from UTC in hours</td>
</tr>
<tr>
<td></td>
<td>An interval value</td>
</tr>
<tr>
<td></td>
<td>Constants LOCAL and DEFAULT, which respectively set the time zone to the one specified in environment variable TZ, or if TZ is undefined, to the operating system time zone.</td>
</tr>
</tbody>
</table>

Privileges

None

Examples

=> SET TIME ZONE TO DEFAULT;
=> SET TIME ZONE TO 'PST8PDT'; -- Berkeley, California
=> SET TIME ZONE TO 'Europe/Rome'; -- Italy
=> SET TIME ZONE TO '-7'; -- UDT offset equivalent to PDT
=> SET TIME ZONE TO INTERVAL '-08:00 HOURS';

See Also

Using Time Zones With Vertica

Time Zone Names for Setting TIME ZONE

The following time zone names are recognized by Vertica as valid settings for the SQL time zone (the TIME ZONE run-time parameter).
Note: The names listed here are for convenience only and might be out of date. Refer to the Sources for Time Zone and Daylight Saving Time Data page for precise information.

These names are not the same as the names shown in /opt/vertica/share/timezonesets, which are recognized by Vertica in date/time input values. The TIME ZONE names shown below imply a local daylight-savings time rule, where date/time input names represent a fixed offset from UTC.

In many cases the same zone has several names. These are grouped together. The table is primarily sorted by commonly used zone names.

In addition to the names listed in the table, Vertica accepts time zone names of the form STDoffset or STDoffsetDST, where STD is a zone abbreviation, offset is a numeric offset in hours west from UTC, and DST is an optional daylight-savings zone abbreviation, assumed to stand for one hour ahead of the given offset. For example, if EST5EDT were not already a recognized zone name, it would be accepted and would be functionally equivalent to USA East Coast time. When a daylight-savings zone name is present, it is assumed to be used according to USA time zone rules, so this feature is of limited use outside North America. Be wary that this provision can lead to silently accepting bogus input, since there is no check on the reasonableness of the zone abbreviations. For example, SET TIME ZONE TO FOOBANKO works, leaving the system effectively using a rather peculiar abbreviation for GMT.

### SHOW

Displays run-time parameters for the current session.

**Syntax**

```
SHOW { parameter | ALL }
```
## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AUTOCOMMIT</strong></td>
<td>Displays whether statements automatically commit their transactions when they complete.</td>
</tr>
<tr>
<td><strong>AVAILABLE_ROLES</strong></td>
<td>Lists all roles available to the user.</td>
</tr>
<tr>
<td><strong>DATESTYLE</strong></td>
<td>Displays the current style of date values. See <a href="#">SET DATESTYLE</a>.</td>
</tr>
<tr>
<td><strong>ENABLED_ROLES</strong></td>
<td>Displays the roles enabled for the current session. See <a href="#">SET ROLE</a>.</td>
</tr>
<tr>
<td><strong>ESCAPE_STRING_WARNING</strong></td>
<td>Displays whether warnings are issued when backslash escapes are found in strings. See <a href="#">SET ESCAPE_STRING_WARNING</a>.</td>
</tr>
<tr>
<td><strong>INTERVALSTYLE</strong></td>
<td>Displays whether units are output when printing intervals. See <a href="#">SET INTERVALSTYLE</a>.</td>
</tr>
<tr>
<td><strong>LOCALE</strong></td>
<td>Displays the current locale. See <a href="#">SET LOCALE</a>.</td>
</tr>
<tr>
<td><strong>MEMORYCAP</strong></td>
<td>Displays the maximum amount of memory that any request use. See <a href="#">SET MEMORYCAP</a>.</td>
</tr>
<tr>
<td><strong>MULTIPLEACTIVERESULTSETS</strong></td>
<td>Displays whether multiple active result sets on one connection are allowed. See <a href="#">SET SESSION MULTIPLEACTIVERESULTSETS</a>.</td>
</tr>
<tr>
<td><strong>RESOURCE_POOL</strong></td>
<td>Displays the resource pool that the session is using. See <a href="#">SET RESOURCE_POOL</a>.</td>
</tr>
<tr>
<td><strong>RUNTIMECAP</strong></td>
<td>Displays the maximum amount of time that queries can run in the session. See <a href="#">SET RUNTIMECAP</a>.</td>
</tr>
<tr>
<td><strong>SEARCH_PATH</strong></td>
<td>Displays the order in which Vertica searches schemas. See <a href="#">SET SEARCH_PATH</a>.</td>
</tr>
<tr>
<td><strong>STANDARD_CONFORMING_STRINGS</strong></td>
<td>Displays whether backslash escapes are enabled for the session. See <a href="#">SET STANDARD_CONFORMING_STRINGS</a>.</td>
</tr>
<tr>
<td><strong>TEMPSPACECAP</strong></td>
<td>Displays the maximum amount of temporary file space that queries can use in the session. See <a href="#">SET</a>.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TIMEZONE</td>
<td>Displays the timezone set in the current session. See <code>SET TIMEZONE</code>.</td>
</tr>
<tr>
<td>TRANSACTION_ISOLATION</td>
<td>Displays the current transaction isolation setting, as described in <code>SET SESSION CHARACTERISTICS AS TRANSACTION</code>.</td>
</tr>
<tr>
<td>TRANSACTION_READ_ONLY</td>
<td>Displays the current read-only setting, as described in <code>SET SESSION CHARACTERISTICS AS TRANSACTION</code>.</td>
</tr>
<tr>
<td>ALL</td>
<td>Shows all run-time settings.</td>
</tr>
</tbody>
</table>

**Privileges**

None

**Examples**

Display all current runtime parameter settings:

```
=> SHOW ALL;
```

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>locale</td>
<td>en_US@collation=binary (LEN_KBINARY)</td>
</tr>
<tr>
<td>autocommit</td>
<td>off</td>
</tr>
<tr>
<td>standard_conforming_strings</td>
<td>on</td>
</tr>
<tr>
<td>escape_string_warning</td>
<td>on</td>
</tr>
<tr>
<td>datestyle</td>
<td>ISO, MDY</td>
</tr>
<tr>
<td>intervalstyle</td>
<td>plain</td>
</tr>
<tr>
<td>timezone</td>
<td>US/Eastern</td>
</tr>
<tr>
<td>search_path</td>
<td>&quot;$user&quot;, public, v_catalog, v_monitor, v_internal</td>
</tr>
<tr>
<td>transaction_isolation</td>
<td>READ COMMITTED</td>
</tr>
<tr>
<td>transaction_read_only</td>
<td>false</td>
</tr>
<tr>
<td>resource_pool</td>
<td>general</td>
</tr>
<tr>
<td>memorycap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>tempspacecap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>runtimecap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>enabled roles</td>
<td></td>
</tr>
<tr>
<td>available roles</td>
<td>applogs, appadmin</td>
</tr>
</tbody>
</table>

(15 rows)

Return current search path settings:

```
=> SHOW SEARCH_PATH;
```

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
</table>

Vertica Analytic Database (9.0.x)
Show the session's transaction isolation level:

```sql
=> SHOW TRANSACTION_ISOLATION;
   name           | setting
-----------------+---------------------
  transaction_isolation | READ COMMITTED
(1 row)
```

Return the current transaction isolation level, as set by `SET SESSION CHARACTERISTICS AS TRANSACTION`. False indicates that the default read/write setting is in effect:

```sql
=> SHOW TRANSACTION_READ_ONLY;
   name        | setting
-------------+----------
  transaction_read_only | false
(1 row)
```

To change to read only:

```sql
=> SET SESSION CHARACTERISTICS AS TRANSACTION READ ONLY;
```

The same `SHOW` command now returns true:

```sql
=> SHOW TRANSACTION_READ_ONLY;
   name        | setting
-------------+----------
  transaction_read_only | true
(1 row)
```

**SHOW CURRENT**

Displays active configuration parameter values that are set at all levels. Vertica first checks values set at the session level. If a value is not set for a configuration parameter at the session level, Vertica next checks if the value is set for the node where you are logged in, and then checks the database level. If no values are set, `SHOW CURRENT` shows the default value for the configuration parameter. If the configuration parameter requires a restart to take effect, the active values shown might differ from the set values.

**Syntax**

```
SHOW CURRENT { parameter-name[,...] | ALL }
```
Parameters

<table>
<thead>
<tr>
<th>parameter-name</th>
<th>Names of any configuration parameters you want to show.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Shows all configuration parameters set at all levels.</td>
</tr>
</tbody>
</table>

Privileges

- Superusers only

Examples

Show configuration parameters and their settings at all levels.

```
=> SHOW CURRENT ALL;
```

<table>
<thead>
<tr>
<th>level</th>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>ActivePartitionCount</td>
<td>1</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>AdvanceAHMInterval</td>
<td>180</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>AHMBackupManagement</td>
<td>0</td>
</tr>
<tr>
<td>DATABASE</td>
<td>AnalyzeRowCountInterval</td>
<td>3600</td>
</tr>
<tr>
<td>SESSION</td>
<td>ForceUDxFencedMode</td>
<td>1</td>
</tr>
<tr>
<td>NODE</td>
<td>MaxClientSessions</td>
<td>0</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

SHOW DATABASE

Displays configuration parameter values that are set for the database.

Note: If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.
Syntax

SHOW DATABASE  

Parameters

<table>
<thead>
<tr>
<th><strong>db-name</strong></th>
<th>Specifies the current database, set to the database name or DEFAULT.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>parameter-name</strong></td>
<td>Names of one or more configuration parameters to show. Non-superusers can only specify parameters whose settings are not masked by SHOW DATABASE...ALL, otherwise Vertica returns an error. If you specify a single parameter that is not set, SHOW DATABASE returns an empty row for that parameter. To obtain the names of database-level parameters, query system table \texttt{CONFIGURATION_PARAMETERS}.</td>
</tr>
<tr>
<td><strong>ALL</strong></td>
<td>Shows all configuration parameters set at the database level. For non-superusers, Vertica masks settings of security parameters, which only superusers can access.</td>
</tr>
</tbody>
</table>

Privileges

- **Superuser**: Shows all database parameter settings.
- **Non-superuser**: Masks all security parameter settings, which only superusers can access. To determine which parameters require superuser privileges, query system table \texttt{CONFIGURATION_PARAMETERS}.

Examples

Show to a non-superuser all configuration parameters that are set on the database:

\[
=> \text{SHOW DATABASE DEFAULT ALL;}
\]

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
</table>

Vertica Analytic Database (9.0.x)
SHOW settings for two configuration parameters:

```sql
=> SHOW DATABASE DEFAULT AllowNumericOverflow, NumericSumExtraPrecisionDigits;
```

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllowNumericOverflow</td>
<td>1</td>
</tr>
<tr>
<td>NumericSumExtraPrecisionDigits</td>
<td>0</td>
</tr>
</tbody>
</table>

(2 rows)

**SHOW NODE**

Displays configuration parameter values that are set for a node. If you specify a parameter that is not set, SHOW NODE returns an empty row for that parameter.

**Note:** If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.

### Syntax

```sql
SHOW NODE node-name { parameter-name [, ...] | ALL }
```

### Parameters

<table>
<thead>
<tr>
<th><strong>node-name</strong></th>
<th>Name of the target node.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>parameter-name</strong></td>
<td>Names of one or more node-level configuration parameters. To obtain the names of node-level parameters, query system table <code>CONFIGURATION_PARAMETERS</code>.</td>
</tr>
<tr>
<td><strong>ALL</strong></td>
<td>Shows all configuration parameters set at the node level.</td>
</tr>
</tbody>
</table>
Privileges

None

Examples

View all configuration parameters and their settings for node v_vmart_node0001:

```sql
=> SHOW NODE v_vmart_node0001 ALL;

name          | setting
---------------|---------
DefaultIdleSessionTimeout | 5 hour  
MaxClientSessions     | 20
```

**SHOW SESSION**

Displays configuration parameter values that are set for the current session. If you specify a parameter that is not set, SHOW SESSION returns an empty row for that parameter.

Note: If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.

Syntax

```sql
SHOW SESSION { parameter-name[,...] | ALL }
```

Parameters

<table>
<thead>
<tr>
<th>parameter-name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameter-name</td>
<td>Names of one or more session-level configuration parameters. To obtain the names of session-level parameters, query system table <code>CONFIGURATION_PARAMETERS</code>.</td>
</tr>
<tr>
<td>ALL</td>
<td>Shows all configuration parameters set at the session level.</td>
</tr>
</tbody>
</table>
Privileges

None

Examples

View all configuration parameters and their settings for the current session:

```sql
=> SHOW SESSION ALL;
```

```

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>locale</td>
<td>en_US@collation=binary (LEN_KBINARY)</td>
</tr>
<tr>
<td>autocommit</td>
<td>off</td>
</tr>
<tr>
<td>standard_conforming_strings</td>
<td>on</td>
</tr>
<tr>
<td>escape_string_warning</td>
<td>on</td>
</tr>
<tr>
<td>datestyle</td>
<td>ISO, MDY</td>
</tr>
<tr>
<td>intervalstyle</td>
<td>plain</td>
</tr>
<tr>
<td>timezone</td>
<td>America/New_York</td>
</tr>
<tr>
<td>search_path</td>
<td>&quot;$user&quot;, public, v_catalog, v_monitor, v_internal</td>
</tr>
<tr>
<td>transaction_isolation</td>
<td>READ COMMITTED</td>
</tr>
<tr>
<td>transaction_read_only</td>
<td>false</td>
</tr>
<tr>
<td>resource_pool</td>
<td>general</td>
</tr>
<tr>
<td>memorycap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>tempspacecap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>runtimecap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>enabled roles</td>
<td>dbduser*, dbadmin*, pseudosuperuser*</td>
</tr>
<tr>
<td>available roles</td>
<td>dbduser*, dbadmin*, pseudosuperuser*</td>
</tr>
<tr>
<td>ForceUDxFencedMode</td>
<td>1</td>
</tr>
</tbody>
</table>

(17 rows)
```

**START TRANSACTION**

Starts a transaction block.

**Syntax**

```sql
START TRANSACTION [ isolation_level ]
```

where `isolation_level` is one of:

```sql
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED }READ { ONLY | WRITE }
```
Parameters

Isolation level, described in the following table, determines what data the transaction can access when other transactions are running concurrently. The isolation level cannot be changed after the first query (SELECT) or DML statement (INSERT, DELETE, UPDATE) has run. A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

<table>
<thead>
<tr>
<th>WORK</th>
<th>TRANSACTION</th>
<th>Have no effect; they are optional keywords for readability.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISOLATION LEVEL {</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SERIALIZABLE</td>
<td></td>
<td>SERIALIZABLE—Sets the strictest level of SQL transaction isolation. This level emulates transactions serially, rather than concurrently. It holds locks and blocks write operations until the transaction completes. Not recommended for normal query operations.</td>
</tr>
<tr>
<td>REPEATABLE READ</td>
<td></td>
<td>REPEATABLE READ—Automatically converted to SERIALIZABLE by Vertica.</td>
</tr>
<tr>
<td>READ COMMITTED</td>
<td></td>
<td>READ COMMITTED (Default)—Allows concurrent transactions. Use READ COMMITTED isolation for normal query operations, but be aware that there is a subtle difference between them. See Transactions for more information.</td>
</tr>
<tr>
<td>READ UNCOMMITTED</td>
<td></td>
<td>READ UNCOMMITTED—Automatically converted to READ COMMITTED by Vertica.</td>
</tr>
<tr>
<td>READ {WRITE</td>
<td>ONLY}</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>INSERT, UPDATE, DELETE, and COPY if the table they would write to is not a temporary table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All CREATE, ALTER, and DROP commands</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GRANT, REVOKE, and EXPLAIN if the command it would run is among those listed.</td>
</tr>
</tbody>
</table>
Privileges

No special permissions required.

Notes

BEGIN performs the same function as START TRANSACTION.

Examples

This example shows how to start a transaction.

```
= > START TRANSACTION ISOLATION LEVEL READ COMMITTED READ WRITE;
START TRANSACTION
=> CREATE TABLE sample_table (a INT);
CREATE TABLE
=> INSERT INTO sample_table (a) VALUES (1);
OUTPUT
--------
1
(1 row)
```

See Also

- Transactions
- Creating Transactions
- COMMIT
- END
- ROLLBACK
**TRUNCATE TABLE**

Removes all storage associated with a table, while leaving the table definition intact. TRUNCATE TABLE auto-commits the current transaction after statement execution and cannot be rolled back.

TRUNCATE TABLE removes all table history preceding the current epoch, regardless of where that data resides (WOS or ROS) or how it is segmented. Immediately after TRUNCATE TABLE returns, AT EPOCH queries on the truncated table return nothing.

**Syntax**

```
TRUNCATE TABLE [[database.]schema.]table-name
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example: <code>myschema.thisDbObject</code> If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>table-name</code></td>
<td>The name of the anchor table or temporary table to truncate. You cannot truncate an external table.</td>
</tr>
</tbody>
</table>

**Privileges**

One of the following privileges is required:

- Superuser
- Table owner
- User with USAGE privileges on the table's schema—see GRANT (Schema)

A schema owner can drop a table but cannot truncate a table.
Examples

See Truncating Tables in the Administrator's Guide.

See Also

- DELETE
- DROP TABLE
- Best Practices for DELETE and UPDATE

**UPDATE**

Replaces the values of the specified columns in all rows for which a specific condition is true. All other columns and rows in the table are unchanged. If successful, UPDATE returns the number of rows updated. A count of 0 indicates no rows matched the condition.

UPDATE inserts new records into the WOS and marks the old records for deletion. If the WOS fills up, the operation overflows to the ROS.

**Syntax**

```
... SET set-expression [, ... ]
... [ FROM from-list ]
... [ where-clause ]
```

**Parameters**

<table>
<thead>
<tr>
<th>/*+ hint [, hint] */</th>
<th>One or both of the following hints:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A load hint, one of the following: AUTO, DIRECT, or TRICKLE</td>
</tr>
<tr>
<td></td>
<td>LABEL</td>
</tr>
</tbody>
</table>
| **database.**schema | Specifies a schema, by default public. If **schema** is any schema other than public, you must supply the schema name. For example:
| | | `myschema.thisDbObject`
| If you specify a database, it must be the current database. |
| **table-reference** | Specifies a table, one of the following:
| | - An optionally qualified table name with optional table aliases, column aliases, and outer joins.
| | - An outer join table.
| You cannot update a projection. |
| **alias** | A temporary name used to reference the table. |
| **SET** | Specifies the columns to update. Each **set-expression** in the SET clause specifies a target column and its new value as follows:
| **set-expression** [,....] | `column-name = { expression | DEFAULT }`
| where:
| | - **column-name** is any column that does not have primary key or foreign key referential integrity constraints.
| | - **expression** specifies a value to assign to the column. The expression can use the current values of this and other table columns. For example:
| | | `UPDATE T1 SET C1 = C1+1`
| | UPDATE only modifies the columns specified by the SET clause. Unspecified columns remain unchanged. |
| **FROM from-list** | A list of table expressions, allowing columns from other tables to appear in the WHERE condition and the UPDATE expressions. This is similar to the list of tables that can be specified in the **FROM Clause** of a SELECT command.
| **Important:** from-list must not include the target table. |
Privileges

Table owner or user with GRANT OPTION is grantor.

- UPDATE privilege on table
- USAGE privilege on schema that contains the table
- SELECT privilege on the table when executing an UPDATE statement that references table column values in a WHERE or SET clause

Subqueries and Joins

UPDATE supports subqueries and joins, which is useful for updating values in a table based on values that are stored in other tables. For details, see Subqueries in UPDATE and DELETE Statements in Analyzing Data.

Restrictions

- The table you specify in the UPDATE list cannot also appear in the FROM list (no self joins); for example, the following UPDATE statement is not allowed:

```sql
BEGIN;
UPDATE result_table
SET address='new' || r2.address
FROM result_table r2
WHERE r2.cust_id = result_table.cust_id + 10;
ERROR: Self joins in UPDATE statements are not allowed
DETAIL: Target relation result_table also appears in the FROM list
```

- If the joins specified in the WHERE predicate produce more than one copy of the row in the table to be updated, the new value of the row in the table is chosen arbitrarily.

- If any primary key, unique key, or check constraints are enabled for automatic enforcement, Vertica enforces those constraints when you insert values into a table. If a violation occurs, Vertica rolls back the SQL statement and returns an error. This behavior occurs for INSERT, UPDATE, COPY, and MERGE SQL statements.
Note: Automatic constraint enforcement requires that you have SELECT privileges on the table containing the constraint.

Examples

In the fact table, modify the price column value for all rows where the cost column value is greater than 100:

=> UPDATE fact SET price = price - cost * 80 WHERE cost > 100;

In the retail.customer table, set the state column to NH when the CID column value is greater than 100:

=> UPDATE retail.customer SET state = 'NH' WHERE CID > 100;

To use table aliases in UPDATE queries, consider the following two tables:

<table>
<thead>
<tr>
<th>cust_id</th>
<th>address</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>Lincoln Street</td>
</tr>
<tr>
<td>30</td>
<td>Beach Avenue</td>
</tr>
<tr>
<td>30</td>
<td>Booth Hill Road</td>
</tr>
<tr>
<td>40</td>
<td>Mt. Vernon Street</td>
</tr>
<tr>
<td>50</td>
<td>Hillside Avenue</td>
</tr>
</tbody>
</table>

(5 rows)

<table>
<thead>
<tr>
<th>new_cust_id</th>
<th>new_address</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>Infinite Loop</td>
</tr>
<tr>
<td>30</td>
<td>Loop Infinite</td>
</tr>
<tr>
<td>60</td>
<td>New Addresses</td>
</tr>
</tbody>
</table>

(3 rows)

The following query and subquery use table aliases to update the address column in result_table (alias r) with the new address from the corresponding column in the new_addresses table (alias n):

=> UPDATE result_table r
   SET address=n.new_address
   FROM new_addresses n
   WHERE r.cust_id = n.new_cust_id;

result_table shows the address field updates made for customer IDs 20 and 30:

<table>
<thead>
<tr>
<th>cust_id</th>
<th>address</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)
<table>
<thead>
<tr>
<th></th>
<th>Infinite Loop</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>Loop Infinite</td>
</tr>
<tr>
<td>30</td>
<td>Loop Infinite</td>
</tr>
<tr>
<td>40</td>
<td>Mt. Vernon Street</td>
</tr>
<tr>
<td>50</td>
<td>Hillside Avenue</td>
</tr>
</tbody>
</table>

(5 rows)
Vertica System Tables

Vertica provides system tables that let you monitor your database. Query these tables the same way you perform query operations on base or temporary tables—by using SELECT statements.

For more information, see the following sections in the Administrator's Guide:

- Using System Tables
- Monitoring Vertica
V_CATALOG Schema

The system tables in this section reside in the v_catalog schema. These tables provide information (metadata) about the objects in a database; for example, tables, constraints, users, projections, and so on.

ACCESS_POLICY

Provides information about access policies associated with specific tables.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS_POLICY_OID</td>
<td>INTEGER</td>
<td>A unique identifier for the access policy.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the table with which the access policy is assigned.</td>
</tr>
<tr>
<td>IS_POLICY_ENABLED</td>
<td>BOOLEAN</td>
<td>Indicates whether or not you have enabled the access policy.</td>
</tr>
<tr>
<td>POLICY_TYPE</td>
<td>VARCHAR</td>
<td>The type of access policy assigned to the table, valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Column Policy</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Row Policy</td>
</tr>
<tr>
<td>EXPRESSION</td>
<td>VARCHAR</td>
<td>The expression used when creating the access policy.</td>
</tr>
<tr>
<td>TRIGGERED_BY</td>
<td>VARCHAR</td>
<td>The SQL statement that triggers the access policy.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column to which the access policy is assigned.</td>
</tr>
</tbody>
</table>

ALL_TABLES

Provides summary information about tables in a Vertica database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema that contains the table.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name.</td>
</tr>
<tr>
<td>TABLE_TYPE</td>
<td>VARCHAR</td>
<td>The type of table, which can be one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SYSTEM TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• VIEW</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GLOBAL TEMPORARY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOCAL TEMPORARY</td>
</tr>
<tr>
<td>REMARKS</td>
<td>VARCHAR</td>
<td>A brief comment about the table. You define this field by using the <code>COMMENT ON TABLE</code> and <code>COMMENT ON VIEW</code> commands.</td>
</tr>
</tbody>
</table>

**Example**

```sql
onenode=> SELECT DISTINCT table_name, table_type FROM all_tables
             WHERE table_name ILIKE 't%';
    table_name | table_type
--------------------------
types | SYSTEM TABLE
trades | TABLE
tuple_mover_operations | SYSTEM TABLE
tables | SYSTEM TABLE
tuning_recommendations | SYSTEM TABLE
testid | TABLE
table_constraints | SYSTEM TABLE
transactions | SYSTEM TABLE
(8 rows)
onenode=> SELECT table_name, table_type FROM all_tables
             WHERE table_name ILIKE 'my%';
   table_name | table_type
--------------------------
mystocks | VIEW
(1 row)
=> SELECT * FROM all_tables LIMIT 4;
[ RECORD 1 ]----------------------------------
schema_name | v_catalog
table_id | 10206
table_name | all_tables```
### CLIENT_AUTH

Provides information about the client authentication methods that you created.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTH_OID</td>
<td>INTEGER</td>
<td>Unique identifier for the authentication method.</td>
</tr>
<tr>
<td>AUTH_NAME</td>

</tbody>
</table>

Examples

This example shows how to get information about each client authentication method that you created:

```sql
=> SELECT auth_name, is_auth_enabled, auth_host_type, auth_host_address, auth_method FROM CLIENT.AUTH;
```

<table>
<thead>
<tr>
<th>auth_name</th>
<th>is_auth_enabled</th>
<th>auth_host_type</th>
<th>auth_host_address</th>
<th>auth_method</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_ident</td>
<td>True</td>
<td>LOCAL</td>
<td></td>
<td>IDENT</td>
</tr>
<tr>
<td>v_gss</td>

CLIENT_AUTH_PARAMS

Provides information about client authentication methods that have parameter values assigned.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTH_OID</td>
<td>INTEGER</td>
<td>A unique identifier for the authentication method.</td>
</tr>
<tr>
<td>AUTH_NAME</td>
<td>VARCHAR</td>
<td>Name that you defined for the authentication method.</td>
</tr>
<tr>
<td>AUTH_PARAMETER_NAME</td>
<td>VARCHAR</td>
<td>Parameter name required by the authentication method. Some examples are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- system_users</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- binddn_prefix</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- host</td>
</tr>
<tr>
<td>AUTH_PARAMETER_VALUE</td>
<td>VARCHAR</td>
<td>Value of the specified parameter.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows how to retrieve parameter names and values for all authentication methods that you created. The authentication methods that have parameters are:

- **v_ident**
- **v_ldap**
- **v_ldap1**

```sql
=> SELECT * FROM CLIENT_AUTH_PARAMS;

<table>
<thead>
<tr>
<th>auth_oid</th>

(17 rows)
CLUSTER_LAYOUT

Shows the relative position of the actual arrangement of the nodes participating in the cluster and the fault groups that affect them. Ephemeral nodes are not shown in the cluster layout ring because they hold no resident data.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLUSTER_POSITION</td>
<td>INTEGER</td>
<td>Position of the node in the cluster ring, counting forward from 0.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> An output value of 0 has no special meaning other than there are no nodes in position before the node assigned 0.</td>
</tr>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the node.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node in the cluster ring. Only permanent nodes participating in database activity appear in the cluster layout. Ephemeral nodes are not shown in the output.</td>
</tr>
<tr>
<td>FAULT_GROUP_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the fault group.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> This value matches the FAULT_GROUP.MEMBER_ID value, but only if this node is in a fault group; otherwise the value is NULL.</td>
</tr>
<tr>
<td>FAULT_GROUP_NAME</td>
<td>VARCHAR</td>
<td>The name of the fault group for the node.</td>
</tr>
<tr>
<td>FAULT_GROUP_TIER</td>
<td>INTEGER</td>
<td>The node's depth in the fault group tree hierarchy. For example is the node:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>* Is not in a fault group, output is null</td>
</tr>
<tr>
<td></td>
<td></td>
<td>* Is in the top level fault group, output is 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>* Is in a fault group's child, output is 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>* Is a fault group's grandchild, output is 2</td>
</tr>
</tbody>
</table>
### COLUMNS

Provides table column information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the table.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Schema name for which information is listed in the database.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Table name for which information is listed in the database.</td>
</tr>
<tr>
<td>IS_SYSTEM_TABLE</td>
<td>BOOLEAN</td>
<td>Specifies whether the table is a system table.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>VARCHAR</td>
<td>A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in a table.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column name for which information is listed in the database.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>VARCHAR</td>
<td>Column's data type, for example VARCHAR(16), INTEGER, or FLOAT.</td>
</tr>
<tr>
<td>DATA_TYPE_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the data type.</td>
</tr>
<tr>
<td>DATA_TYPE_LENGTH</td>
<td>INTEGER</td>
<td>Maximum allowable length of the data type.</td>
</tr>
<tr>
<td>CHARACTER_MAXIMUM_LENGTH</td>
<td>VARCHAR</td>
<td>Maximum allowable length of the column.</td>
</tr>
<tr>
<td>NUMERIC_PRECISION</td>
<td>INTEGER</td>
<td>Number of significant decimal digits.</td>
</tr>
<tr>
<td>NUMERIC_SCALE</td>
<td>INTEGER</td>
<td>Number of fractional digits.</td>
</tr>
<tr>
<td>DATETIME_PRECISION</td>
<td>INTEGER</td>
<td>For TIMESTMP data type, returns the declared precision; returns NULL if no precision was declared.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INTERVAL_PRECISION</td>
<td>INTEGER</td>
<td>Number of fractional digits retained in the seconds field.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>INTEGER</td>
<td>Column position respective to other columns in the table.</td>
</tr>
<tr>
<td>IS_NULLABLE</td>
<td>BOOLEAN</td>
<td>Specifies whether the column can contain NULL values.</td>
</tr>
<tr>
<td>COLUMN_DEFAULT</td>
<td>VARCHAR</td>
<td>Expression set on a column with the constraint DEFAULT.</td>
</tr>
<tr>
<td>COLUMN_SET_USING</td>
<td>VARCHAR</td>
<td>Expression set on a column with the constraint SET USING.</td>
</tr>
<tr>
<td>IS_IDENTITY</td>
<td>BOOLEAN</td>
<td>Specifies whether the column is an identity column. See Column-Constraint.</td>
</tr>
</tbody>
</table>

### Examples

Retrieve table and column information from the COLUMNS table:

```sql
=> SELECT table_schema, table_name, column_name, data_type, is_nullable
    FROM columns WHERE table_schema = 'store'
    AND data_type = 'Date';
```

<table>
<thead>
<tr>
<th>table_schema</th>
<th>table_name</th>
<th>column_name</th>
<th>data_type</th>
<th>is_nullable</th>
</tr>
</thead>
<tbody>
<tr>
<td>store</td>
<td>store_dimension</td>
<td>first_open_date</td>
<td>Date</td>
<td>f</td>
</tr>
<tr>
<td>store</td>
<td>store_dimension</td>
<td>last_remodel_date</td>
<td>Date</td>
<td>f</td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>date_ordered</td>
<td>Date</td>
<td>f</td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>date_shipped</td>
<td>Date</td>
<td>f</td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>expected_delivery_date</td>
<td>Date</td>
<td>f</td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>date_delivered</td>
<td>Date</td>
<td>f</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

6 rows)

DATETIME_PRECISION is NULL because the table definition declares no precision:

```sql
=> CREATE TABLE c (c TIMESTAMP);
CREATE TABLE c
=> SELECT table_name, column_name, datetime_precision FROM columns
    WHERE table_name = 'c';
```

<table>
<thead>
<tr>
<th>table_name</th>
<th>column_name</th>
<th>datetime_precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>c</td>
<td></td>
</tr>
</tbody>
</table>

1 row)

DATETIME_PRECISION is 4 because the table definition declares precision as 4:
An identity column is a sequence available only for numeric column types. To identify what column in a table, if any, is an identity column, search the COLUMNS table to find the identity column in a table testid:

```
=> CREATE TABLE testid (c1 IDENTITY(1, 1, 1000), c2 INT);
=> \x
Expanded display is on.
=> SELECT * FROM COLUMNS WHERE is_identity='t' AND table_name='testid';
- RECORD 1 ]------------------------
table_id | 45035996273719486
table_schema | public
table_name | testid
is_system_table | f
column_id | 45035996273719486-1
column_name | c1
data_type | int
data_type_id | 6
data_type_length | 8
character_maximum_length | 
text | 
numeric_precision | 
numeric_scale | 
datetime_precision | 
interval_precision | 
ordinal_position | 1
is_nullable | f
column_default | 
is_identity | t
```

Use the SEQUENCES table to get detailed information about the sequence in testid:

```
=> SELECT * FROM sequences WHERE identity_table_name='testid';
- RECORD 1 ]------------------------
sequence_schema | public
sequence_name | testid_c1_seq
owner_name | dbadmin
identity_table_name | testid
session_cache_count | 1000
allow_cycle | f
output_ordered | f
increment_by | 1
minimum | 1
maximum | 9223372036854775807
current_value | 0
sequence_schema_id | 45035996273704976
sequence_id | 45035996273719488
owner_id | 45035996273704962
identity_table_id | 45035996273719486
```

For more information about sequences and identity columns, see Sequence Types.
COMMENTS

Returns information about comments associated with objects in the database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMENT_ID</td>
<td>INTEGER</td>
<td>The comment's internal ID number</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>The internal ID number of the object associated with the comment</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>VARCHAR</td>
<td>The type of object associated with the comment. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- COLUMN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CONSTRAINT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- FUNCTION</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- LIBRARY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- NODE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- PROJECTION</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- SCHEMA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- SEQUENCE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- VIEW</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema containing the object.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the object associated with the comment.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>VARCHAR</td>
<td>The internal ID of the owner of the object.</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>VARCHAR</td>
<td>The object owner's name.</td>
</tr>
<tr>
<td>CREATION_TIME</td>
<td>TIMESTAMPTZ</td>
<td>When the comment was created.</td>
</tr>
</tbody>
</table>
### LAST_MODIFIED_TIME
- **Data Type**: TIMESTAMPTZ
- **Description**: When the comment was last modified.

### COMMENT
- **Data Type**: VARCHAR
- **Description**: The text of the comments.

## CONSTRAINT_COLUMNS
Records information about table column constraints.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the constraint.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the schema that contains this table.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the table in which the column resides.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>Name of the column that is constrained. For check constraints, if more than one column is referenced, each appears as a separate row.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR</td>
<td>Constraint name for which information is listed.</td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td>CHAR</td>
<td>Indicates the constraint type. Valid Values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- c — check</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- f — foreign</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- n — not null</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- p — primary</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- u — unique</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>Indicates if a constraint for a primary key, unique key, or check constraint is currently enabled. Can be t (True) or f (False).</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
REFERENCE_TABLE_ID | INTEGER | A unique numeric ID assigned by the Vertica catalog that identifies the referenced table.
REFERENCE_TABLE_SCHEMA | VARCHAR | Schema name for which information is listed.
REFERENCE_TABLE_NAME | VARCHAR | References the TABLE_NAME column in the PRIMARY_KEY table.
REFERENCE_COLUMN_NAME | VARCHAR | References the COLUMN_NAME column in the PRIMARY_KEY table.

### Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

### DATABASES

Provides information about the databases in this Vertica installation.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE_ID</td>
<td>INTEGER</td>
<td>The database's internal ID number</td>
</tr>
<tr>
<td>DATABASE_NAME</td>
<td>VARCHAR</td>
<td>The database's name</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>The database owner's ID</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>INTEGER</td>
<td>The database owner's name</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The date and time the database last started</td>
</tr>
<tr>
<td>COMPLIANCE_MESSAGE</td>
<td>VARCHAR</td>
<td>Message describing the current state of the database's license compliance.</td>
</tr>
<tr>
<td>EXPORT_SUBNET</td>
<td>VARCHAR</td>
<td>Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The subnet (on the public network) used by the database for import/export.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The public address of the subnet that the</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
| | | Vertica native load balancing uses for load balancing.
| LOAD_BALANCE_POLICY | VARCHAR | The current native connection load balance policy, which controls whether client connection requests are redirected to other hosts in the database. See [About Native Connection Load Balancing](#) in the Administrator's Guide.

#### Example

```sql
=> SELECT * FROM DATABASES;
```

<table>
<thead>
<tr>
<th>database_id</th>
<th>database_name</th>
<th>owner_id</th>
<th>owner_name</th>
<th>start_time</th>
<th>compliance_message</th>
<th>export_subnet</th>
<th>load_balance_policy</th>
<th>backend_address_family</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996273704976</td>
<td>VMart</td>
<td>45035996273704962</td>
<td>dbadmin</td>
<td>2017-10-22 05:16:22.066961-04</td>
<td>The database is in compliance with respect to raw data size.</td>
<td>0</td>
<td>none</td>
<td>ipv4</td>
</tr>
</tbody>
</table>

**DIRECTED_QUERIES**

Returns information about directed queries.

| Column Name | Data Type | Description
---|---|---
| query_name | VARCHAR | This directed query's unique identifier, used by statements such as [ACTIVATE DIRECTED QUERY](#).
| is_active | BOOLEAN | Specifies whether the directed query is active.
| vertica_version | VARCHAR | The Vertica version used when this directed query was created.
| comment | VARCHAR | A user-supplied comment specified on creation of the directed query, up to 128 characters.
| creation_ | TIMESTAMPTZ | Specifies when the directed query was created.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td></td>
<td></td>
</tr>
<tr>
<td>input_query</td>
<td>VARCHAR</td>
<td>The input query that is associated with this directed query. Multiple directed queries can map to the same input query.</td>
</tr>
<tr>
<td>annotated_query</td>
<td>VARCHAR</td>
<td>The directed query that was saved with <code>CREATE DIRECTED QUERY</code>.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**Truncated Query Results**

Query results for the fields `input_query` and `annotated_query` are truncated after 8192 characters. You can get the full content of both fields in two ways:

- Use the statement `GET DIRECTED QUERY`.
- Use `EXPORT_CATALOG` to export directed queries.

**DUAL**

DUAL is a single-column "dummy" table with one record whose value is X; for example:

```sql
=> SELECT * FROM DUAL;
  dummy
  ------
  X
(1 row)
```

You can write the following types of queries:

```sql
=> SELECT 1 FROM dual;
?column?
-------
1
(1 row)
=> SELECT current_timestamp, current_user FROM dual;
?column? | current_user
--------- |----------
```
Restrictions

You cannot create projections for DUAL.

ELASTIC_CLUSTER

Returns information about cluster elasticity, such as whether Elastic Cluster is running.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCALING_FACTOR</td>
<td>INTEGER</td>
<td>This value is only meaningful when you enable local segments. SCALING_FACTOR influences the number of local segments on each node. Initially—before a rebalance runs—there are scaling_factor number of local segments per node. A large SCALING_FACTOR is good for rebalancing a potentially wide range of cluster configurations quickly. However, too large a value could lead to ROS pushback, particularly in a database with a table with a large number of partitions. See SET_SCALING_FACTOR for more details.</td>
</tr>
<tr>
<td>MAXIMUM_SKEW_PERCENT</td>
<td>INTEGER</td>
<td>This value is only meaningful when you enable local segments. MAXIMUM_SKEW_PERCENT is the maximum amount of skew a rebalance operation tolerates, which preferentially redistributes local segments; however, if after doing so the segment ranges of any two nodes differs by more than this amount, rebalance will separate and distribute storage to even the distribution.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SEGMENT_LAYOUT</td>
<td>VARCHAR</td>
<td>Current, offset=0, segment layout. New segmented projections will be created with this layout, with segments rotated by the corresponding offset. Existing segmented projections will be rebalanced into an offset of this layout.</td>
</tr>
<tr>
<td>LOCAL_SEGMENT_LAYOUT</td>
<td>VARCHAR</td>
<td>Similar to SEGMENT_LAYOUT but includes details that indicate the number of local segments, their relative size and node assignment.</td>
</tr>
<tr>
<td>VERSION</td>
<td>INTEGER</td>
<td>Number that gets incremented each time the cluster topology changes (nodes added, marked ephemeral, marked permanent, etc). Useful for monitoring active and past rebalance operations.</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>True if Elastic Cluster is enabled, otherwise false.</td>
</tr>
<tr>
<td>IS_LOCAL_SEGMENT_ENABLED</td>
<td>BOOLEAN</td>
<td>True if local segments are enabled, otherwise false.</td>
</tr>
<tr>
<td>IS_REBALANCE_RUNNING</td>
<td>BOOLEAN</td>
<td>True if rebalance is currently running, otherwise false.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**See Also**

- ENABLE_ELASTIC_CLUSTER
- DISABLE_ELASTIC_CLUSTER
- Elastic Cluster

**EPOCHS**

For all epochs, provides the date and time of the close and the corresponding epoch number of the closed epoch. This information lets you determine which time periods pertain to which
epochs.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPOCH_CLOSE_TIME</td>
<td>DATETIME</td>
<td>The date and time of the close of the epoch.</td>
</tr>
<tr>
<td>EPOCH_NUMBER</td>
<td>INTEGER</td>
<td>The corresponding epoch number of the closed epoch.</td>
</tr>
</tbody>
</table>

See Also

- Epoch Management Parameters
- Epoch Management Functions

FAULT_GROUPS

View the fault groups and their hierarchy in the cluster.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMBER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the fault group.</td>
</tr>
<tr>
<td>MEMBER_TYPE</td>
<td>VARCHAR</td>
<td>The type of fault group. Values can be either NODE or FAULT GROUP.</td>
</tr>
<tr>
<td>MEMBER_NAME</td>
<td>VARCHAR</td>
<td>Name associated with this fault group. Values will be the node name or the fault group name.</td>
</tr>
<tr>
<td>PARENT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the parent fault group. The parent fault group can contain:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Nodes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Other fault groups</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Nodes and other fault groups</td>
</tr>
<tr>
<td>PARENT_TYPE</td>
<td>VARCHAR</td>
<td>The type of parent fault group, where the default/root parent is the DATABASE object. Can be one of the following objects:</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
| | | • FAULT GROUP  
| | | • DATABASE  

**PARENT_NAME** | VARCHAR | The name of the fault group that contains nodes or other fault groups or both nodes and fault groups.  
**IS AUTOMATICALLY GENERATED** | BOOLEAN | If true, denotes whether Vertica Analytic Database created fault groups for you to manage the fault tolerance of control nodes in large cluster configurations. If false, denotes that you created fault groups manually. See [Fault Groups](#) for more information

### Examples

**Show the current hierarchy of fault groups in the cluster:**

```sql
vmartdb=> SELECT member_type, member_name, parent_type, CASE WHEN parent_type = 'DATABASE' THEN '' ELSE parent_name END FROM fault_groups ORDER BY member_name;
```

<table>
<thead>
<tr>
<th>member_type</th>
<th>member_name</th>
<th>parent_type</th>
<th>parent_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE</td>
<td>v_vmart_node0001</td>
<td>FAULT GROUP</td>
<td>two</td>
</tr>
<tr>
<td>NODE</td>
<td>v_vmart_node0002</td>
<td>FAULT GROUP</td>
<td>two</td>
</tr>
<tr>
<td>NODE</td>
<td>v_vmart_node0003</td>
<td>FAULT GROUP</td>
<td>three</td>
</tr>
<tr>
<td>FAULT GROUP</td>
<td>one</td>
<td>DATABASE</td>
<td></td>
</tr>
<tr>
<td>FAULT GROUP</td>
<td>three</td>
<td>DATABASE</td>
<td></td>
</tr>
<tr>
<td>FAULT GROUP</td>
<td>two</td>
<td>FAULT GROUP</td>
<td>one</td>
</tr>
</tbody>
</table>

**View the distribution of the segment layout:**

```sql
vmartdb=> SELECT segment_layout from elastic_cluster;
```

```
 v_vmart_node0001[33.3%]  v_vmart_node0003[33.3%]  v_vmart_node0004[33.3%]
(1 row)
```

### FOREIGN_KEYS

Provides foreign key information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR</td>
<td>The constraint name for which information is listed.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The name of the column that is constrained.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>VARCHAR</td>
<td>The position of the column within the key. The numbering of columns starts at 1.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name for which information is listed.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_NAME</td>
<td>VARCHAR</td>
<td>References the TABLE_NAME column in the PRIMARY_KEY table.</td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td>VARCHAR</td>
<td>The constraint type, f, for foreign key.</td>
</tr>
<tr>
<td>REFERENCE_COLUMN_NAME</td>
<td>VARCHAR</td>
<td>References the COLUMN_NAME column in the PRIMARY_KEY table.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>References the TABLE_SCHEMA column in the PRIMARY_KEY table.</td>
</tr>
</tbody>
</table>
Example

mydb=> SELECT constraint_name, table_name, ordinal_position, reference_table_name FROM foreign_keys ORDER BY 3;

<table>
<thead>
<tr>
<th>constraint_name</th>
<th>table_name</th>
<th>ordinal_position</th>
<th>reference_table_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>fk_store_sales_date</td>
<td>store_sales_fact</td>

<tr>
<td>fk_store_sales_promotion</td>
<td>online_sales_fact</td>
<td>10</td>
<td>promotion_dimension</td>
</tr>
</tbody>
</table>

(26 rows)

GRANTS

Provides information about privileges granted on various objects, the granting user, and grantee user. The order of columns in the table corresponds to the order in which they appear in the GRANT command. The GRANTS table does not retain the role grantor.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Datatype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td>VARCHAR</td>
<td>The user being granted permission.</td>
</tr>
<tr>
<td>GRANTEE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GRANT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the user granted permissions.</td>
</tr>
<tr>
<td>GRANTOR</td>
<td>VARCHAR</td>
<td>The user granting the permission.</td>
</tr>
<tr>
<td>GRANTOR_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the user who performed the grant operation.</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the object granted.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the object that is being granted privileges. Note that for schema privileges, the schemaname appears in the OBJECT_NAME column instead of the OBJECT_SCHEMA column.</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of the schema that is being granted privileges.</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>VARCHAR</td>
<td>The object type on which the grant was applied; for example, ROLE, SCHEMA, DATABASE, RESOURCEPOOL. Output from this column is useful in cases where a schema, resource pool, or user share the same name.</td>
</tr>
<tr>
<td>PRIVILEGES_DESCRIPTION</td>
<td>VARCHAR</td>
<td>A readable description of the privileges being granted; for example INSERT, SELECT. An asterisk in PRIVILEGES_DESCRIPTION output indicates a privilege WITH GRANT OPTION.</td>
</tr>
</tbody>
</table>

**Notes**

The `vsql` commands `\dp` and `\z` both include the schema name in the output. For example:

```sql
=> \dp
Access privileges for database "vmartdb"
Grantee | Grantor | Privileges | Schema | Name          
---------|---------|------------|--------|---------------
dbadmin | USAGE   |            | public          ```
The `vsql` command `\dp *.tablename` displays table names in all schemas. This command lets you distinguish grants for same-named tables in different schemas:

```
=> \dp *.events

<table>
<thead>
<tr>
<th>Grantee</th>
<th>Grantor</th>
<th>Privileges</th>
<th>Schema</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>user2</td>
<td>dbadmin</td>
<td>INSERT, SELECT, UPDATE, DELETE, REFERENCES</td>
<td>schema1</td>
<td>events</td>
</tr>
<tr>
<td>user1</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>schema1</td>
<td>events</td>
</tr>
<tr>
<td>user2</td>
<td>dbadmin</td>
<td>INSERT, SELECT, UPDATE, DELETE, REFERENCES</td>
<td>schema2</td>
<td>events</td>
</tr>
<tr>
<td>user1</td>
<td>dbadmin</td>
<td>INSERT, SELECT</td>
<td>schema2</td>
<td>events</td>
</tr>
</tbody>
</table>
```

(4 rows)

The `vsql` command `\dp schemaname.*` displays all tables in the named schema:

```
=> \dp schema1.*

<table>
<thead>
<tr>
<th>Grantee</th>
<th>Grantor</th>
<th>Privileges</th>
<th>Schema</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>user2</td>
<td>dbadmin</td>
<td>INSERT, SELECT, UPDATE, DELETE, REFERENCES</td>
<td>schema1</td>
<td>events</td>
</tr>
<tr>
<td>user1</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>schema1</td>
<td>events</td>
</tr>
</tbody>
</table>
```

(2 rows)

### Examples

This example shows `CREATE` and `USAGE` privileges granted to Bob in the fictitious apps database:

```
=> SELECT grantor, privileges_description, object_schema, object_name, grantee
FROM grants;

<table>
<thead>
<tr>
<th>grantor</th>
<th>privileges_description</th>
<th>object_schema</th>
<th>object_name</th>
<th>grantee</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbadmin</td>
<td>USAGE</td>
<td></td>
<td></td>
<td>Bob</td>
</tr>
<tr>
<td>dbadmin</td>
<td>CREATE</td>
<td></td>
<td></td>
<td>Bob</td>
</tr>
</tbody>
</table>
```

(2 rows)

This next query looks for privileges granted to a particular set of grantees. The asterisk in privileges_description column for User1 means that user has WITH GRANT OPTION privileges.

```
=> SELECT grantor, privileges_description, object_schema, object_name, grantee
FROM grants WHERE grantee ILIKE 'User%';
```
In the following example, `online_sales` is the schema that first gets privileges, and then inside that schema the anchor table gets SELECT privileges:

```sql
=> SELECT grantee, grantor, privileges_description, object_schema, object_name
    FROM grants
    WHERE grantee='u1' ORDER BY object_name;
```

The following statement shows all grants for user Bob:

```sql
=> SELECT * FROM grants WHERE grantee = 'Bob';
```

<table>
<thead>
<tr>
<th>grantor</th>
<th>privileges_description</th>
<th>object_schema</th>
<th>object_name</th>
<th>grantees</th>
</tr>
</thead>
<tbody>
<tr>
<td>release</td>
<td>USAGE</td>
<td>general</td>
<td>User1</td>
<td></td>
</tr>
<tr>
<td>release</td>
<td>USAGE</td>
<td>general</td>
<td>User2</td>
<td></td>
</tr>
<tr>
<td>release</td>
<td>USAGE</td>
<td>general</td>
<td>User3</td>
<td></td>
</tr>
<tr>
<td>release</td>
<td>USAGE</td>
<td>s1</td>
<td>User1</td>
<td></td>
</tr>
<tr>
<td>release</td>
<td>USAGE</td>
<td>s1</td>
<td>User2</td>
<td></td>
</tr>
<tr>
<td>release</td>
<td>USAGE</td>
<td>s1</td>
<td>User3</td>
<td></td>
</tr>
<tr>
<td>User1</td>
<td>INSERT*, SELECT*, UPDATE*</td>
<td>s1</td>
<td>t1</td>
<td>User1</td>
</tr>
</tbody>
</table>

7 rows

```sql
(7 rows)
```

HCATALOG_COLUMNS

Describes the columns of all tables available through the HCatalog Connector. Each row in this table corresponds to a column in a table accessible through the HCatalog Connector. See Using the HCatalog Connector in Integrating with Apache Hadoop for more information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR (128)</td>
<td>The name of the Vertica Analytic Database schema that contains the table containing this column</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HCATALOG_SCHEMA</td>
<td>VARCHAR (128)</td>
<td>The name of the Hive schema or database that contains the table containing this column</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the table that contains the column</td>
</tr>
<tr>
<td>IS_PARTITION_COLUMN</td>
<td>BOOLEAN</td>
<td>Whether the table is partitioned on this column</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the column</td>
</tr>
<tr>
<td>HCATALOG_DATA_TYPE</td>
<td>VARCHAR (128)</td>
<td>The Hive data type of this column</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>VARCHAR (128)</td>
<td>The Vertica Analytic Database data type of this column</td>
</tr>
<tr>
<td>DATA_TYPE_ID</td>
<td>INTEGER</td>
<td>Numeric ID of the column's Vertica Analytic Database data type</td>
</tr>
<tr>
<td>DATA_TYPE_LENGTH</td>
<td>INTEGER</td>
<td>The number of bytes used to store this data type</td>
</tr>
<tr>
<td>CHARACTER_MAXIMUM_LENGTH</td>
<td>INTEGER</td>
<td>For string data types, the maximum number of characters it can hold</td>
</tr>
<tr>
<td>NUMERIC_PRECISION</td>
<td>INTEGER</td>
<td>For numeric types, the precision of the values in the column</td>
</tr>
<tr>
<td>NUMERIC_SCALE</td>
<td>INTEGER</td>
<td>For numeric data types, the scale of the values in the column</td>
</tr>
<tr>
<td>DATETIME_PRECISION</td>
<td>INTEGER</td>
<td>For datetime data types, the precision of the values in the column</td>
</tr>
<tr>
<td>INTERVAL_PRECISION</td>
<td>INTEGER</td>
<td>For interval data types, the precision of the values in the column</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>INTEGER</td>
<td>The position of the column within the table</td>
</tr>
</tbody>
</table>
Privileges

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

Notes

If you are using WebHCat instead of HiveServer2, querying this table results in one web service call to the WebHCat server for each table in each HCatalog schema. If you need to perform multiple queries on this table in a short period of time, consider creating a copy of the table using a CREATE TABLE AS statement to improve performance. The copy does not reflect any changes made to the schema of the Hive tables after it was created, but it is much faster to query.

Example

The following example demonstrates finding the column information for a specific table:

```sql
=> SELECT * FROM HCATALOG_COLUMNS WHERE table_name = 'hcatalogtypes' -> ORDER BY ordinal_position;
-[ RECORD 1 ]----------------------------------------
table_schema | hcat
hcatalog_schema | default
table_name | hcatalogtypes
is_partition_column | f
column_name | intcol
hcatalog_data_type | int
data_type | int
data_type_id | 6
data_type_length | 8
character_maximum_length |
numeric_precision |
numeric_scale |
datetime_precision |
interval_precision |
ordinal_position | 1
-[ RECORD 2 ]----------------------------------------
table_schema | hcat
hcatalog_schema | default
table_name | hcatalogtypes
is_partition_column | f
column_name | floatcol
hcatalog_data_type | float
data_type | float
data_type_id | 7
data_type_length | 8
character_maximum_length |
```
<table>
<thead>
<tr>
<th>Numeric precision</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric scale</td>
<td></td>
</tr>
<tr>
<td>Datetime precision</td>
<td></td>
</tr>
<tr>
<td>Interval precision</td>
<td></td>
</tr>
<tr>
<td>Ordinal position</td>
<td>2</td>
</tr>
</tbody>
</table>

- [ RECORD 3 ]---------------------------------------------------

- HCATALOG_TABLE_LIST

HCATALOG_SCHEMATA

Lists all of the schemas defined using the HCatalog Connector. See Using the HCatalog Connector in Integrating with Apache Hadoop.

Unlike other HCatalog Connector-related system tables, this table makes no calls to Hive, so querying incurs very little overhead.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_ID</td>
<td>INTEGER</td>
<td>The Vertica Analytic Database ID number for the schema</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the schema defined in the Vertica Analytic Database catalog</td>
</tr>
<tr>
<td>SCHEMA_OWNER_ID</td>
<td>INTEGER</td>
<td>The ID number of the user who owns the Vertica Analytic Database schema</td>
</tr>
<tr>
<td>SCHEMA_OWNER</td>
<td>VARCHAR(128)</td>
<td>The username of the Vertica Analytic Database schema's owner</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The date and time the schema as created</td>
</tr>
<tr>
<td>HOSTNAME</td>
<td>VARCHAR(128)</td>
<td>The host name or IP address of the database server that holds the Hive metadata</td>
</tr>
<tr>
<td>PORT</td>
<td>INTEGER</td>
<td>The port number on which the metastore database listens for connections</td>
</tr>
<tr>
<td>HIVESERVER2_HOSTNAME</td>
<td>VARCHAR(128)</td>
<td>The host name or IP address of the HiveServer2 server for the Hive database</td>
</tr>
<tr>
<td>WEBSERVICE</td>
<td>VARCHAR(128)</td>
<td>The host name or IP address of the WebHCat server</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HOSTNAME</td>
<td></td>
<td>for the Hive database, if used</td>
</tr>
<tr>
<td>WEBSERVICE_PORT</td>
<td>INTEGER</td>
<td>The port number on which the WebHCat server listens for connections</td>
</tr>
<tr>
<td>WEBHDFS_ADDRESS</td>
<td>VARCHAR (128)</td>
<td>The host and port (&quot;host:port&quot;) for the WebHDFS service, used for reading ORC and Parquet files</td>
</tr>
<tr>
<td>HCATALOG_SCHEMA_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the schema or database in Hive to which the Vertica Analytic Database schema is mapped</td>
</tr>
<tr>
<td>HCATALOG_USER_NAME</td>
<td>VARCHAR(128)</td>
<td>The username the HCatalog Connector uses to authenticate itself to the Hive database.</td>
</tr>
<tr>
<td>HCATALOG_CONNECTION_TIMEOUT</td>
<td>INTEGER</td>
<td>The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer or WebHCat server. A value of 0 means wait indefinitely.</td>
</tr>
<tr>
<td>HCATALOG_SLOW_TRANSFER_LIMIT</td>
<td>INTEGER</td>
<td>The lowest data transfer rate (in bytes per second) from the HiveServer2 or WebHCat server that the HCatalog Connector accepts.</td>
</tr>
<tr>
<td>HCATALOG_SLOW_TRANSFER_TIME</td>
<td>INTEGER</td>
<td>The number of seconds the HCatalog Connector waits before enforcing the data transfer rate lower limit by breaking the connection and terminating the query.</td>
</tr>
<tr>
<td>SSL_CONFIG</td>
<td>VARCHAR(128)</td>
<td>The path of the Hadoop ssl-client.xml configuration file, if using HiveServer2 with SSL wire encryption.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

<td>The file size of the table's smallest data file, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>TOTAL_NUMBER_FILES</td>
<td>INTEGER</td>
<td>The number of files used to store this table's data in HDFS</td>
</tr>
<tr>
<td>LOCATION</td>
<td>VARCHAR(8192)</td>
<td>The URI for the directory containing this table's data, normally an HDFS URI</td>
</tr>
<tr>
<td>LAST_UPDATE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The last time data in this table was updated, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>OUTPUT</td>
<td>VARCHAR(128)</td>
<td>The Hive SerDe class used to output data from this table</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FORMAT</td>
<td></td>
<td>table</td>
</tr>
<tr>
<td>LAST_ACCESS_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The last time data in this table was accessed, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>MAX_FILE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The size of the largest data file for this table, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>IS_PARTITIONED</td>
<td>BOOLEAN</td>
<td>Whether this table is partitioned</td>
</tr>
<tr>
<td>PARTITION_EXPRESSION</td>
<td>VARCHAR(128)</td>
<td>The expression used to partition this table</td>
</tr>
<tr>
<td>TABLE_OWNER</td>
<td>VARCHAR(128)</td>
<td>The Hive user that owns this table in the Hive database, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>INPUT_FORMAT</td>
<td>VARCHAR(128)</td>
<td>The SerDe class used to read the data from this table</td>
</tr>
<tr>
<td>TOTAL_FILE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>Total number of bytes used by all of this table's data files</td>
</tr>
<tr>
<td>HCATALOG_GROUP</td>
<td>VARCHAR(128)</td>
<td>The permission group assigned to this table, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>PERMISSION</td>
<td>VARCHAR(128)</td>
<td>The Unix file permissions for this group, as shown by the ls -l command, if using WebHCat; null if using HiveServer2</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

Vertica Analytic Database (9.0.x)
HCATALOG_TABLE_LIST

A concise list of all tables contained in all Hive schemas and databases available through the HCatalog Connector. See Using the HCatalog Connector in Integrating with Apache Hadoop.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>Internal ID number for the schema containing the table</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the Vertica Analytic Database schema through which the table is available</td>
</tr>
<tr>
<td>HCATALOG_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>Name of the Hive schema or database containing the table</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the table</td>
</tr>
<tr>
<td>HCATALOG_USER_NAME</td>
<td>VARCHAR(128)</td>
<td>Name of Hive user used to access the table</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

**Notes**

- Querying this table results in one call to HiveServer2 for each Hive schema defined using the HCatalog Connector. This means that the query usually takes longer than querying other system tables.

- Querying this table is faster than querying HCATALOG_TABLES. Querying HCATALOG_TABLE_LIST only makes one HiveServer2 call per HCatalog schema versus one call per table for HCATALOG_TABLES.
Example

The following example demonstrates defining a new HCatalog schema then querying HCATALOG_TABLE_LIST. Note that one table defined in a different HCatalog schema also appears. HCATALOG_TABLE_LIST lists all of the tables available in any of the HCatalog schemas:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost'
- HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> \
Expanded display is on.
=> SELECT * FROM v_catalog.hcatalog_table_list;
- [ RECORD 1 ]------------------------
table_schema_id       | 45035996273748980
table_schema          | hcat
hcatalog_schema       | default
table_name            | weblogs
hcatalog_user_name    | hcatuser
- [ RECORD 2 ]------------------------
table_schema_id       | 45035996273748980
table_schema          | hcat
hcatalog_schema       | default
table_name            | tweets
hcatalog_user_name    | hcatuser
- [ RECORD 3 ]------------------------
table_schema_id       | 45035996273748980
table_schema          | hcat
hcatalog_schema       | default
table_name            | messages
hcatalog_user_name    | hcatuser
- [ RECORD 4 ]------------------------
table_schema_id       | 45035996273864948
table_schema          | hiveschema
hcatalog_schema       | default
table_name            | weblogs
hcatalog_user_name    | hcatuser
```

KEYWORDS

Identifies Vertica reserved and non-reserved keywords.
### Keywords

Vertica reserved or non-reserved keyword.

**Reserved**

Indicates whether a keyword is reserved or non-reserved:

- **R**: reserved
- **N**: non-reserved

### LARGE_CLUSTER_CONFIGURATION_STATUS

Shows the current cluster nodes and control node (spread hosts) designations in the Catalog so you can see if they match.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node in the cluster.</td>
</tr>
<tr>
<td>SPREAD_HOST_NAME</td>
<td>VARCHAR</td>
<td>The host name of the control node (the host that manages control message responsibilities)</td>
</tr>
<tr>
<td>CONTROL_NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the control node</td>
</tr>
</tbody>
</table>

**Large Cluster** in the Administrator's Guide

### LICENSE_AUDITS

Lists the results of Vertica's license automatic compliance audits. See How Vertica Calculates Database Size in the Administrator's Guide.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The estimated raw data size of the database</td>
</tr>
<tr>
<td>LICENSE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The licensed data allowance</td>
</tr>
<tr>
<td>USAGE_PERCENT</td>
<td>FLOAT</td>
<td>Percentage of the licensed allowance used</td>
</tr>
<tr>
<td>AUDIT_START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>When the audit started</td>
</tr>
<tr>
<td>AUDIT_END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>When the audit finished</td>
</tr>
<tr>
<td>CONFIDENCE_LEVEL_PERCENT</td>
<td>FLOAT</td>
<td>The confidence level of the size estimate</td>
</tr>
<tr>
<td>ERROR_TOLERANCE_PERCENT</td>
<td>FLOAT</td>
<td>The error tolerance used for the size estimate</td>
</tr>
<tr>
<td>USED_SAMPLING</td>
<td>BOOLEAN</td>
<td>Whether data was randomly sampled (if false, all of the data was analyzed)</td>
</tr>
<tr>
<td>CONFIDENCE_INTERVAL_LOWER_BOUNDgetBytes</td>
<td>INTEGER</td>
<td>The lower bound of the data size estimate within the confidence level</td>
</tr>
<tr>
<td>CONFIDENCE_INTERVAL_UPPER_BOUNDgetBytes</td>
<td>INTEGER</td>
<td>The upper bound of the data size estimate within the confidence level</td>
</tr>
<tr>
<td>SAMPLE_COUNT</td>
<td>INTEGER</td>
<td>The number of data samples used to generate the estimate</td>
</tr>
<tr>
<td>CELL_COUNT</td>
<td>INTEGER</td>
<td>The number of cells in the database</td>
</tr>
<tr>
<td>AUDITED_DATA</td>
<td>VARCHAR</td>
<td>The type of data audited, which includes regular (non-flex), flex, and total data</td>
</tr>
</tbody>
</table>

**LICENCES**

For all licenses, provides information on license types, the dates for which licenses are valid, and the limits the licenses impose.
### Column Name | Data Type | Description
---|---|---
LICENSE_ID | INTEGER | Unique numeric ID assigned by the Vertica catalog, which identifies the license.
NAME | VARCHAR | The license’s name. (The license name in this column could be represented by a long license key.)
LICENSEE | VARCHAR | The entity to which the product is licensed.
START_DATE | VARCHAR | The start date for which the license is valid.
END_DATE | VARCHAR | The end date until which the license is valid (or "Perpetual" if the license has no expiration).
LICENSETYPE | VARCHAR | The type of the license (for example, Premium Edition).
PARENT | VARCHAR | The parent license (field is blank if there is no parent).
SIZE | VARCHAR | The size limit for data on the license.
IS_SIZE_LIMIT_ENFORCED | BOOLEAN | Indicates whether the license includes enforcement of data and node limits, where t is true and f is false.
NODE_RESTRICTION | VARCHAR | The node limit the license imposes.
CONFIGURED_ID | INTEGER | A long license key.

### MATERIALIZE_FLEXTABLE_COLUMNS_RESULTS

Returns the results after you run the flex table function, **MATERIALIZE_FLEXTABLE_COLUMNS**. The system table includes the following information:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the license.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The license’s name.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The Vertica product toward which the license is applied.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>CREATION_TIME</td>
<td>VARCHAR</td>
<td>The start date for which the license is valid.</td>
</tr>
<tr>
<td>KEY_NAME</td>
<td>VARCHAR</td>
<td>The end date until which the license is valid (or &quot;Perpetual&quot; if the license has no expiration).</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>The function status, which can be one of these values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ADDED</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• EXISTS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ERROR</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>BOOLEAN</td>
<td>The message associated with the status in the previous column, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Added successfully</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Column of same name already exists in table definition</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Add operation failed</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• No data type guess provided to add column</td>
</tr>
</tbody>
</table>

Example

```sql
=> SELECT table_name, creation_time, key_name, status, message
FROM v_catalog.materialize_flextable_columns_results WHERE table_name = 'twitter_r';
```

```
table_name | creation_time | key_name | status | message
----------|--------------|----------|--------|-------------------------
twitter_r | 2013-11-20 17:00:27.945484-05 | contributors | ADDED | Added successfully
twitter_r | 2013-11-20 17:00:27.945511-05 | entities.hashtags | ADDED | Added successfully
twitter_r | 2013-11-20 17:00:27.945519-05 | entities.urls | ADDED | Added successfully
twitter_r | 2013-11-20 17:00:27.945532-05 | created_at | EXISTS | Column of same name already exists in table definition
(4 rows)
```
MODELS

Lists details about the machine-learning models in the database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MODEL_ID</td>
<td>INTEGER</td>
<td>The model's internal ID.</td>
</tr>
<tr>
<td>MODEL_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the model.</td>
</tr>
<tr>
<td>SCHEMA_ID</td>
<td>INTEGER</td>
<td>The schema's internal ID.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the schema.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>The model owner's ID.</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>VARCHAR(128)</td>
<td>The user who created the model.</td>
</tr>
<tr>
<td>CATEGORY</td>
<td>VARCHAR(128)</td>
<td>The type of model. By default, models created in Vertica are assigned to the Vertica_Models category.</td>
</tr>
<tr>
<td>MODEL_TYPE</td>
<td>VARCHAR(128)</td>
<td>The type of algorithm used to create the model.</td>
</tr>
<tr>
<td>IS_COMPLETE</td>
<td>VARCHAR(128)</td>
<td>Denotes whether the model is complete and ready for use in machine learning functions. This field is usually false when the model is being trained. Once the training is complete, the field is set to true.</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The time the model was created.</td>
</tr>
<tr>
<td>SIZE</td>
<td>INTEGER</td>
<td>The size of the model in bytes.</td>
</tr>
</tbody>
</table>

Example

```sql
=> SELECT * FROM models;
- [ RECORD 1 ]-------------------------
model_id | 45035996273714020
model_name | myLinearRegModel
schema_id | 45035996273704980
schema_name | public
owner_id | 45035996273704962
owner_name | dbadmin
category | VERTICA_MODELS
model_type | LINEAR_REGRESSION
is_complete | t
```
NODES

Lists details about the nodes in the database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the node.</td>
</tr>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the node.</td>
</tr>
<tr>
<td>NODE_STATE</td>
<td>VARCHAR(128)</td>
<td>The node's current state (up, down, recovering, etc.).</td>
</tr>
<tr>
<td>NODE_ADDRESS</td>
<td>VARCHAR(80)</td>
<td>The host address of the node.</td>
</tr>
<tr>
<td>NODE_ADDRESS_FAMILY</td>
<td>VARCHAR(10)</td>
<td>The IP Version of the node_address. For example, ipv4.</td>
</tr>
<tr>
<td>EXPORT_ADDRESS</td>
<td>VARCHAR(8192)</td>
<td>The IP address of the node (on the public network) used for import/export operations and native load-balancing.</td>
</tr>
<tr>
<td>EXPORT_ADDRESS_FAMILY</td>
<td>VARCHAR(10)</td>
<td>The IP Version of the export_address. For example, ipv4.</td>
</tr>
<tr>
<td>CATALOG_PATH</td>
<td>VARCHAR(8192)</td>
<td>The absolute path to the catalog on the node.</td>
</tr>
<tr>
<td>NODE_TYPE</td>
<td>VARCHAR(9)</td>
<td>The type of the node. For more information on the types of nodes, refer to Setting Node Type.</td>
</tr>
<tr>
<td>IS_EPHEMERAL</td>
<td>BOOLEAN</td>
<td>(Deprecated) True if this node has been marked as ephemeral. (in preparation for removing it from the cluster).</td>
</tr>
<tr>
<td>STANDING_IN_FOR</td>
<td>VARCHAR(128)</td>
<td>The name of the node that this node is currently replacing.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LAST_MSG_FROM_NODE_AT</td>
<td>TIMESTAMPZ</td>
<td>The date and time the last message was received from this node.</td>
</tr>
<tr>
<td>NODE_DOWN_SINCE</td>
<td>TIMESTAMPZ</td>
<td>The amount of time that the replaced node has been unavailable.</td>
</tr>
</tbody>
</table>

**ODBC_COLUMNS**

Provides table column information. The format is defined by the ODBC standard for the ODBC SQLColumns metadata. Details on the ODBC SQLColumns format are available in the ODBC specification: http://msdn.microsoft.com/en-us/library/windows/desktop/ms711683%28v=vs.85%29.aspx.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema in which the column resides. If the column does not reside in a schema, this field is empty.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table in which the column resides.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The name of the column.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>INTEGER</td>
<td>The data type of the column. This can be an ODBC SQL data type or a driver-specific SQL data type. This column corresponds to the ODBC_TYPE column in the TYPES table.</td>
</tr>
<tr>
<td>DATA_TYPE_NAME</td>
<td>VARCHAR</td>
<td>The driver-specific data type name.</td>
</tr>
<tr>
<td>COLUMN_SIZE</td>
<td>INTEGER</td>
<td>The ODBC-defined data size of the column.</td>
</tr>
<tr>
<td>BUFFER_LENGTH</td>
<td>INTEGER</td>
<td>The transfer octet length of a column is the maximum number of bytes returned to the application when data is transferred to its default C data type. See <a href="http://msdn.microsoft.com/en-us/library/windows/desktop/ms713979%28v=vs.85%29.aspx">http://msdn.microsoft.com/en-us/library/windows/desktop/ms713979%28v=vs.85%29.aspx</a></td>
</tr>
<tr>
<td>DECIMAL_DIGITS</td>
<td>INTEGER</td>
<td>The total number of significant digits to the right of the decimal point. This value has no meaning for non-decimal data types.</td>
</tr>
</tbody>
</table>
## NUM_PREC_RADIX

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>The radix Vertica reports decimal_digits and columns_size as. This value is always 10, because it refers to a number of decimal digits, rather than a number of bits.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>Indicates whether the column can contain null values. Values are 0 or 1.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR</td>
<td>The textual remarks for the column.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR</td>
<td>The default value of the column.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>The SQL data type of the column.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR</td>
<td>The subtype for a datetime data type. This value has no meaning for non-datetime data types.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>The maximum length of a string or binary data column.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>Indicates the position of the column in the table definition.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR</td>
<td>Values can be YES or NO, determined by the value of the NULLABLE column.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>Indicates whether the column is a sequence, for example, an auto-increment column.</td>
</tr>
</tbody>
</table>

## PASSWORD_AUDITOR

Stores information about individual users and their password information. This table also indicates if users are using hash authentication, which is the associated security algorithm.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique ID for the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user.</td>
</tr>
<tr>
<td>ACCTEXPIRED</td>
<td>BOOLEAN</td>
<td>Indicates if the user’s password expires. 'f' indicates that it does not expire. 't' indicates that it does expire.</td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.0.x)
### Column Name | Data Type | Description
---|---|---
SECURITY_ALGORITHM | VARCHAR | User-level security algorithm for hash authentication. **Valid values:**
- 'NONE' (Default. System-level security algorithm is used.)
- 'MD5'
- 'SHA512'

SYSTEM_SECURITY_ALGORITHM | VARCHAR | System-level security algorithm for hash authentication. **Default value:**
- 'NONE' (Uses MD5 algorithm.) **Valid values:**
- 'MD5'
- 'SHA512'

EFFECTIVE_SECURITY_ALGORITHM | VARCHAR | The resulting security algorithm, depending on the values of SECURITY_ALGORITHM and SYSTEM_SECURITY_ALGORITHM.

---

## PASSWORDS
Contains user passwords information. This table stores current passwords and past passwords if any Profiles have PASSWORD_REUSE_TIME or PASSWORD_REUSE_MAX parameters set. See CREATE PROFILE for details.

### Column Name | Data Type | Description
---|---|---
USER_ID | INTEGER | The ID of the user who owns the password.
USER_NAME | VARCHAR | The name of the user who owns the password.
PASSWORD | VARCHAR | The encrypted password.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PASSWORD_CREATE_TIME</td>
<td>DATETIME</td>
<td>The date and time when the password was created.</td>
</tr>
<tr>
<td>IS_CURRENT_PASSWORD</td>
<td>BOOLEAN</td>
<td>Denotes whether this is the user's current password. Non-current passwords are retained to enforce password reuse limitations.</td>
</tr>
<tr>
<td>PROFILE_ID</td>
<td>INTEGER</td>
<td>The ID number of the profile to which the user is assigned.</td>
</tr>
<tr>
<td>PROFILE_NAME</td>
<td>VARCHAR</td>
<td>The name of the profile to which the user is assigned.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_MAX</td>
<td>VARCHAR</td>
<td>The number password changes that must take place before an old password can be reused.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_TIME</td>
<td>VARCHAR</td>
<td>The amount of time that must pass before an old password can be reused.</td>
</tr>
</tbody>
</table>

**PRIMARY_KEYS**

Provides primary key information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR</td>
<td>The constraint name for which information is listed.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column name for which information is listed.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>VARCHAR</td>
<td>The position of the column within the key. The numbering of columns starts at 1.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name for which information is listed.</td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td>VARCHAR</td>
<td>The constraint type, p, for primary key.</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>Indicates if a table column constraint for a PRIMARY KEY is enabled by default. Can be t (True) or f (False).</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
</tbody>
</table>
# PROFILE_PARAMETERS

Defines what information is stored in profiles.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROFILE_ID</td>
<td>INTEGER</td>
<td>The ID of the profile to which this parameter belongs.</td>
</tr>
<tr>
<td>PROFILE_NAME</td>
<td>VARCHAR</td>
<td>The name of the profile to which this parameter belongs.</td>
</tr>
<tr>
<td>PARAMETER_TYPE</td>
<td>VARCHAR</td>
<td>The policy type of this parameter (password_complexity, password_security, etc.)</td>
</tr>
<tr>
<td>PARAMETER_NAME</td>
<td>VARCHAR</td>
<td>The name of the parameter.</td>
</tr>
<tr>
<td>PARAMETER_LIMIT</td>
<td>VARCHAR</td>
<td>The parameter's value.</td>
</tr>
</tbody>
</table>

# PROFILES

Provides information about password policies that you set using the CREATE PROFILE statement.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROFILE_ID</td>
<td>INTEGER</td>
<td>Unique identifier for the profile.</td>
</tr>
<tr>
<td>PROFILE_NAME</td>
<td>VARCHAR</td>
<td>Profile name.</td>
</tr>
<tr>
<td>PASSWORD_LIFE_TIME</td>
<td>VARCHAR</td>
<td>Number of days before the user's password expires. After expiration, the user is forced to change passwords during login or warned that their password has expired if password_grace_time is set to a value other than zero or unlimited.</td>
</tr>
<tr>
<td>PASSWORD_GRACE_TIME</td>
<td>VARCHAR</td>
<td>Number of days users are allowed to log in after their passwords expire. During the grace time, users are warned about their expired passwords when they log in. After the grace period, the user is forced to change passwords if he or she hasn't already.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PASSWORD_REUSE_MAX</td>
<td>VARCHAR</td>
<td>Number of password changes that must occur before the current password can be reused.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_TIME</td>
<td>VARCHAR</td>
<td>Number of days that must pass after setting a password before it can be used again.</td>
</tr>
<tr>
<td>FAILED_LOGIN_ATTEMPTS</td>
<td>VARCHAR</td>
<td>Number of consecutive failed login attempts that triggers Vertica to lock the account.</td>
</tr>
<tr>
<td>PASSWORD_LOCK_TIME</td>
<td>VARCHAR</td>
<td>Number of days an account is locked after being locked due to too many failed login attempts.</td>
</tr>
<tr>
<td>PASSWORD_MAX_LENGTH</td>
<td>VARCHAR</td>
<td>Maximum number of characters allowed in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_LENGTH</td>
<td>VARCHAR</td>
<td>Minimum number of characters required in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_LETTERS</td>
<td>VARCHAR</td>
<td>The minimum number of letters (either uppercase or lowercase) required in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_LOWERCASE_LETTERS</td>
<td>VARCHAR</td>
<td>The minimum number of lowercase.</td>
</tr>
<tr>
<td>PASSWORD_MIN_UPPERCASE_LETTERS</td>
<td>VARCHAR</td>
<td>The minimum number of uppercase letters required in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_DIGITS</td>
<td>VARCHAR</td>
<td>The minimum number of digits required in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_SYMBOLS</td>
<td>VARCHAR</td>
<td>The minimum of symbols (for example, !, #, $, etc.) required in a password.</td>
</tr>
</tbody>
</table>

**Notes**

Non-superusers querying this table see only the information for the profile to which they are assigned.

### PROJECTION_CHECKPOINT_EPOCHS

Provides details on when checkpoint epochs are.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>Unique numeric identifier of this projection's node.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of this projection's node.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA_ID</td>
<td>INTEGER</td>
<td>Unique numeric identifier of the projection schema.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the projection schema.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric identifier of this projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Name of this projection.</td>
</tr>
<tr>
<td>IS_UP_TO_DATE</td>
<td>BOOLEAN</td>
<td>Specifies whether the projection is <strong>up to date</strong> and available to participate in query execution.</td>
</tr>
<tr>
<td>CHECKPOINT_EPOCH</td>
<td>INTEGER</td>
<td>Checkpoint epoch of the projection on the corresponding node. Data up to and including this epoch is in persistent storage, and can be recovered in the event of node failure.</td>
</tr>
<tr>
<td>WOULD_RECOVER</td>
<td>BOOLEAN</td>
<td>Determines whether data up to and including CHECKPOINT_EPOCH can be used to <strong>recover from an unclean shutdown</strong>:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- t: CHECKPOINT_EPOCH is less than or equal to the cluster's Last Good Epoch, so data up to and including this epoch can be used during recovery.</td>

## PROJECTION_COLUMNS

Provides information about projection columns, such as encoding type, sort order, type of statistics, and the time at which columns statistics were last updated.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The projection name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The projection column name.</td>
</tr>
<tr>
<td>COLUMN_POSITION</td>
<td>INTEGER</td>
<td>The ordinal position of a projection's column used in the <code>CREATE_PROJECTION</code> statement.</td>
</tr>
<tr>
<td>SORT_POSITION</td>
<td>INTEGER</td>
<td>The projection's column sort specification, as specified in <code>CREATE_PROJECTION</code> .. ORDER BY clause. If the column is not included in the projection's sort order, <code>SORT_POSITION</code> output is NULL.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>INTEGER</td>
<td>A unique numeric object ID (OID) that identifies the associated projection column object and is assigned by the Vertica catalog. This field is helpful as a key to other system tables.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>VARCHAR</td>
<td>Matches the corresponding table column data type (see <code>V_CATALOG.COLUMNS</code>). <code>DATA_TYPE</code> is provided as a complement to <code>ENCODING_TYPE</code>.</td>
</tr>
</tbody>
</table>
| ENCODING_TYPE          | VARCHAR   | The encoding type defined on the

PROJECTION_DELETE_CONCERNS

Lists projections whose design may cause performance issues when deleting data. This table is generated by calling the EVALUATE_DELETE_PERFORMANCE function. See DELETE and UPDATE Optimization in the Administrator's Guide for more information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>The ID number of the projection</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema containing the projection</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The projection's name</td>
</tr>
<tr>
<td>CREATION_TIME</td>
<td>TIMESTAMPTZ</td>
<td>When the projection was created</td>
</tr>
<tr>
<td>LAST_MODIFIED_TIME</td>
<td>TIMESTAMPTZ</td>
<td>When the projection was last modified</td>
</tr>
<tr>
<td>COMMENT</td>
<td>VARCHAR</td>
<td>A comment describing the potential delete performance issue.</td>
</tr>
</tbody>
</table>

PROJECTIONS

Provides information about projections.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROJECTION_SCHEMA_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the specific schema that contains the projection and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of the schema that contains the projection.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the projection and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The projection name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_BASENAME</td>
<td>VARCHAR</td>
<td>The base name used for other projections. For auto-created projections, <code>projection_basename</code> is identical to the <code>anchor_table_name</code>. For a manually-created projection, <code>projection_basename</code> is the name you supply.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the projection owner and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>VARCHAR</td>
<td>The name of the projection's owner.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_ID</td>
<td>INTEGER</td>
<td>For pre-join projections, the unique numeric identification (OID) of the anchor table. If the projection is not a pre-join projection, this value is the OID of the table from which the projection was created. A projection has only one anchor (fact) table.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_NAME</td>
<td>VARCHAR</td>
<td>For pre-join projections, the name of the anchor table. If the projection is not a pre-join projection, the name of the table from which the projection was created.</td>
</tr>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID (OID) for any nodes that contain any unsegmented projections.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The names of any nodes that contain the projection. This column returns information for unsegmented projections only.</td>
</tr>
<tr>
<td>IS_PREJOIN</td>
<td>BOOLEAN</td>
<td>Specifies whether the projection is a pre-join projection.</td>
</tr>
<tr>
<td>CREATED_EPOCH</td>
<td>INTEGER</td>
<td>The epoch in which the projection was created.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>

</tr>
<tr>
<td></td>
<td></td>
<td>• Projections that have no data never have full statistics. Use system table <strong>PROJECTION_STORAGE</strong> to determine whether your projection contains data.</td>
</tr>
<tr>
<td>IS_SEGMENTED</td>
<td>BOOLEAN</td>
<td>Specifies whether the projection is segmented.</td>
</tr>
<tr>
<td>SEGMENT_EXPRESSION</td>
<td>VARCHAR</td>
<td>The segmentation expression used for the projection. In the following example for the clicks_agg projection, the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hash(clicks.user_id, (clicks.click_time)::date)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>indicate that the projection was created with the following expression:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SEGMENTED BY HASH( clicks.user_id, (clicks.click_time)::date)</td>
</tr>
<tr>
<td>SEGMENT_RANGE</td>
<td>VARCHAR</td>
<td>The percentage of projection data stored on each node, according to the segmentation expression. For example, segmenting a projection by the <strong>HASH</strong> function on all nodes results in a SEGMENT_RANGE value such as the following:</td>
</tr>
</tbody>
</table>
|                             |                 | implicit range: v_testcr_node0005[33.3%]  
v_testcr_node0006[33.3%]  
v_testcr_node0004[33.3%]                                                                                                       |
<p>| IS_SUPER_PROJECTION         | BOOLEAN         | Specifies whether a projection is a superprojection.                                                                                           |
| IS_KEYCONSTRAINT_PROJECTION | BOOLEAN         | Indicates whether a projection is a key constraint projection:                                                                               |
|                             |                 | • t: A key constraint projection that validates a key constraint. (Vertica uses the projection to efficiently enforce at least one enabled key constraint.) |</p>
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HAS_EXPRESSIONS</td>
<td>BOOLEAN</td>
<td>Specifies whether this projection has expressions that define the column values. HAS_EXPRESSIONS is always true for live aggregate projections.</td>
</tr>
<tr>
<td>IS_AMBERATE_PROJECTION</td>
<td>BOOLEAN</td>
<td>Specifies whether this projection is a live aggregate projection.</td>

PROJECTION_COLUMNS

RESOURCE_POOL_DEFAULTS

Provides information about the default parameter values for built-in and user-defined resource pools. You can use ALTER RESOURCE_POOL to restore default parameter values for any resource pool by setting that parameter to DEFAULT. To see the default values for the built-in resource pools, refer to Built-In Pool Configuration.

Privileges

None

See Also

- RESOURCE_POOLS

RESOURCE_POOLS

Displays information about the parameters specified for the resource pool by CREATE RESOURCE_POOL or ALTER RESOURCE_POOL.

Note: Column names in the RESOURCE_POOL table mirror syntax in the CREATE RESOURCE POOL statement. Therefore, column names do not use underscores.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>The name of the resource pool.</td>
</tr>
<tr>
<td>IS_INTERNAL</td>
<td>BOOLEAN</td>
<td>Denotes whether a pool is one of the Built-In Pools.</td>
</tr>
<tr>
<td>MEMORYSIZE</td>
<td>VARCHAR</td>
<td>Value of the amount of memory</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>allocated to the resource pool.</td>
</tr>
<tr>
<td>MAXMEMORYSIZE</td>
<td>VARCHAR</td>
<td>Value assigned as the maximum size the resource pool could grow by borrowing memory from the GENERAL pool.</td>
</tr>
<tr>
<td>EXECUTIONPARALLELISM</td>
<td>INTEGER</td>
<td>Limits the number of threads used to process any single query issued in this resource pool.</td>
</tr>
<tr>
<td>PRIORITY</td>
<td>INTEGER</td>
<td>Value of PRIORITY parameter specified when defining the pool.</td>
</tr>
</tbody>
</table>
| RUNTIMEPRIORITY         | VARCHAR         | Value that indicates the amount of run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool. Valid values are:  
  - HIGH  
  - MEDIUM (default)  
  - LOW  
These values are relative to each other. Queries with a HIGH run-time priority are given more CPU and I/O resources than those with a MEDIUM or LOW run-time priority. |
<p>| RUNTIMEPRIORITYTHRESHOLD| INTEGER         | Limits in seconds how soon a query must finish before the Resource Manager assigns to it the resource pool's RUNTIMEPRIORITY setting.                                                                 |
| QUEUETIMEOUT            | INTEGER or INTERVAL | The interval or value in seconds of the QUEUETIMEOUT parameter specified when defining the pool. Represents the maximum amount of time the request is allowed to wait for resources to become available before being rejected. |</p>
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLANNEDCONCURRENCY</td>
<td>INTEGER</td>
<td>Value of PLANNEDCONCURRENCY parameter specified when defining the pool, which represents the preferred number of concurrently executing queries in the resource pool.</td>
</tr>
<tr>
<td>MAXCONCURRENCY</td>
<td>INTEGER</td>
<td>Value of MAXCONCURRENCY parameter specified when defining the pool, which represents the maximum number of concurrent execution slots available to the resource pool.</td>
</tr>
<tr>
<td>RUNTIMECAP</td>
<td>INTERVAL</td>
<td>The maximum time a query in the pool can execute.</td>
</tr>
<tr>
<td>SINGLEINITIATOR</td>
<td>BOOLEAN</td>
<td>Specifies whether all requests using this pool are issued against the same initiator node or multiple initiator nodes can be used. Included for backwards compatibility. For all built-in resource pools, this must be set to false for all user-defined pools.</td>
</tr>
<tr>
<td>CPUAFFINITYSET</td>
<td>VARCHAR</td>
<td>Value which represents the set of CPUs on which queries associated with this pool are executed. For example, '0, 2-4' for the 0, 2, 3, and 4 CPUs, or '25%' for a percentage of available CPUs. Percentage values are rounded down to whole CPUs.</td>
</tr>
<tr>
<td>CPUAFFINITYMODE</td>
<td>VARCHAR</td>
<td>The mode of the CPU affinity. If CPUAFFINITYSET is set to a CPU percentage or index/index list, then its value is one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHARED: Pool is pinned to the CPU indexes or percentage defined in CPUAFFINITYSET, and other pools can share the same CPUs</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
**EXCLUSIVE** | | EXCLUSIVE: Pool is pinned to the CPU indexes or percentage defined in CPUAFFINITYSET, but other pools cannot use the same CPUs.
**ANY** | | ANY: Pool has no affinity for a specific CPU or percentage of available CPUs.
**CASCADETO** | VARCHAR | The name of the secondary resource pool, if one exists.

#### See Also
- CREATE RESOURCE POOL
- ALTER RESOURCE POOL

### ROLES
Contains the names of all roles the user can access, along with any roles that have been assigned to those roles.

**Tip:** You can also use the function HAS_ROLE to see if a role is available to a user.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ASSIGNED_ROLES</strong></td>
<td>VARCHAR</td>
<td>The names of any roles that have been granted to this role. By enabling the role, the user also has access to the privileges of these additional roles.</td>
</tr>
<tr>
<td><strong>NAME</strong></td>
<td>VARCHAR</td>
<td>The name of a role that the user can access.</td>
</tr>
<tr>
<td><strong>ROLE_ID</strong></td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the role.</td>
</tr>
</tbody>
</table>

**Note:** If you see an asterisk in the ASSIGNED_ROLES column output, it means the user has roles WITH ADMIN OPTION.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAP_DN</td>
<td>VARCHAR</td>
<td>Indicates whether or not the Vertica Analytic Database role maps to an LDAP Link group. When the column is set to dn, the Vertica role maps to LDAP Link.</td>
</tr>
<tr>
<td>LDAP_URI_HASH</td>
<td>VARCHAR</td>
<td>The URI hash number for the LDAP role.</td>
</tr>
<tr>
<td>IS_ORPHANED_FROM_LDAP</td>
<td>VARCHAR</td>
<td>Indicates if the role is disconnected (orphaned) from LDAP, valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>t - role is orphaned</td>
</tr>
<tr>
<td></td>
<td></td>
<td>f - role is not orphaned</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For more information see <a href="#">Troubleshooting LDAP Link Issues</a></td>

### SCHEMATA

Provides information about schemas in the database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the specific schema.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>Schema name for which information is listed.</td>
</tr>
<tr>
<td>SCHEMA_OWNER_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the owner who created the schema.</td>
</tr>
<tr>
<td>SCHEMA_OWNER</td>
<td>VARCHAR</td>
<td>Name of the owner who created the schema.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SYSTEM_SCHEMA_CREATOR</td>
<td>VARCHAR</td>
<td>Creator information for system schema or NULL for non-system schema.</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Time when the schema was created.</td>
</tr>
<tr>
<td>IS_SYSTEM_SCHEMA</td>
<td>BOOLEAN</td>
<td>Indicates whether the schema was created for system use, where t is true and f is false.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

**SEQUENCES**

Displays information about the parameters specified for a sequence using the CREATE SEQUENCE statement.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEQUENCE_SCHEMA</td>
<td>VARCHAR</td>
<td>Schema in which the sequence was created.</td>
</tr>
<tr>
<td>SEQUENCE_NAME</td>
<td>VARCHAR</td>
<td>Name of the sequence defined in the CREATE SEQUENCE statement.</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>VARCHAR</td>
<td>Name of the owner.</td>
</tr>
<tr>
<td>IDENTITY_TABLE_NAME</td>
<td>VARCHAR</td>
<td>If created by an auto_increment or identity column, the name of the table to which it belongs. See column constraints in the CREATE TABLE statement.</td>
</tr>
<tr>
<td>SESSION_CACHE_COUNT</td>
<td>INTEGER</td>
<td>Count of values cached in a session.</td>
</tr>
<tr>
<td>ALLOW_CYCLE</td>
<td>BOOLEAN</td>
<td>Values allowed to cycle when a sequence reaches its minimum or maximum value. See CYCLE</td>
</tr>
<tr>
<td>OUTPUT_ORDERED</td>
<td>BOOLEAN</td>
<td>Values guaranteed to be ordered (always false).</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INCREMENT_BY</td>
<td>INTEGER</td>
<td>Sequence values are incremented by this number (negative for reverse sequences).</td>
</tr>
<tr>
<td>MINIMUM</td>
<td>INTEGER</td>
<td>Minimum value the sequence can generate.</td>
</tr>
<tr>
<td>MAXIMUM</td>
<td>INTEGER</td>
<td>Maximum value the sequence can generate.</td>
</tr>
<tr>
<td>CURRENT_VALUE</td>
<td>INTEGER</td>
<td>Specifies how many sequence numbers Vertica has distributed to the nodes in your cluster. Includes all nodes.</td>
</tr>
<tr>
<td>SEQUENCE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the schema.</td>
</tr>
<tr>
<td>SEQUENCE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the sequence.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the user who created the sequence.</td>
</tr>
<tr>
<td>IDENTITY_TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the table to which the column belongs (if created by an auto_increment or identity column).</td>
</tr>
</tbody>
</table>

**Examples**

Create a simple sequence:

```sql
=> CREATE SEQUENCE my_seq MAXVALUE 5000 START 150;
CREATE SEQUENCE
```

Return information about the sequence you just created:

```sql
=> \x
Expanded display is on.
=> SELECT * FROM sequences;
- [ RECORD 1 ]------------------------------------
  sequence_schema | public
  sequence_name   | my_seq
  owner_name      | dbadmin
  identity_table_name |
  session_cache_count | 250000
  allow_cycle     | f
```
An identity column is a sequence available only for numeric column types. To identify what column in a table, if any, is an identity column, search the COLUMNS table to find the identity column in a table:

```
=> CREATE TABLE testid (c1 IDENTITY(1, 1, 1000), c2 INT);
=> \x
Expanded display is on.
=> SELECT * FROM COLUMNS WHERE is_identity='t' AND table_name='testid';
```

<table>
<thead>
<tr>
<th>table_id</th>
<th>45035996274150730</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_schema</td>
<td>public</td>
</tr>
<tr>
<td>table_name</td>
<td>testid</td>
</tr>
<tr>
<td>is_system_table</td>
<td>f</td>
</tr>
<tr>
<td>column_name</td>
<td>c1</td>
</tr>
<tr>
<td>data_type</td>
<td>int</td>
</tr>
<tr>
<td>data_type_id</td>
<td>6</td>
</tr>
<tr>
<td>data_type_length</td>
<td>8</td>
</tr>
<tr>
<td>character_maximum_length</td>
<td></td>
</tr>
<tr>
<td>numeric_precision</td>
<td></td>
</tr>
<tr>
<td>numeric_scale</td>
<td></td>
</tr>
<tr>
<td>datetime_precision</td>
<td></td>
</tr>
<tr>
<td>interval_precision</td>
<td></td>
</tr>
<tr>
<td>ordinal_position</td>
<td>1</td>
</tr>
<tr>
<td>is_nullable</td>
<td>f</td>
</tr>
<tr>
<td>column_default</td>
<td></td>
</tr>
<tr>
<td>is_identity</td>
<td>t</td>
</tr>
</tbody>
</table>

Use the SEQUENCES table to get detailed information about the sequence in testid:

```
=> SELECT * FROM sequences WHERE identity_table_name='testid';
```

<table>
<thead>
<tr>
<th>sequence_schema</th>
<th>public</th>
</tr>
</thead>
<tbody>
<tr>
<td>sequence_name</td>
<td>testid_c1_seq</td>
</tr>
<tr>
<td>owner_name</td>
<td>dbadmin</td>
</tr>
<tr>
<td>identity_table_name</td>
<td>testid</td>
</tr>
<tr>
<td>session_cache_count</td>
<td>1000</td>
</tr>
<tr>
<td>allow_cycle</td>
<td>f</td>
</tr>
<tr>
<td>output_ordered</td>
<td>f</td>
</tr>
<tr>
<td>increment_by</td>
<td>1</td>
</tr>
<tr>
<td>minimum</td>
<td>1</td>
</tr>
<tr>
<td>maximum</td>
<td>9223372036854775807</td>
</tr>
<tr>
<td>current_value</td>
<td>0</td>
</tr>
<tr>
<td>sequence_schema_id</td>
<td>45035996273704960</td>
</tr>
<tr>
<td>sequence_id</td>
<td>45035996273844996</td>
</tr>
<tr>
<td>owner_id</td>
<td>45035996273704962</td>
</tr>
<tr>
<td>identity_table_id</td>
<td>45035996274150768</td>
</tr>
</tbody>
</table>
Use the vsq1 command \ds to return a list of sequences. The following results show the two sequences created in the preceding examples. If more sequences existed, the table would list them.

The CurrentValue of the new sequence is one less than the start number you specified in the CREATE SEQUENCE and IDENTITY commands, because you have not yet used NEXTVAL to instantiate the sequences to assign their cache or supply their first start values.

```sql
=> \ds
List of Sequences
-[ RECORD 1 ]---------------------
| Schema | public |
| Sequence | my_seq |
| CurrentValue | 149 |
| IncrementBy | 1 |
| Minimum | 1 |
| Maximum | 5000 |
| AllowCycle | f |
| Comment | |
-[ RECORD 2 ]---------------------
| Schema | public |
| Sequence | testid_c1_seq |
| CurrentValue | 0 |
| IncrementBy | 1 |
| Minimum | 1 |
| Maximum | 922372036854775807 |
| AllowCycle | f |
| Comment | |
```

**STORAGE_LOCATIONS**

Provides information about storage locations, their IDs labels, and status.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCATION_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the storage location.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name on which the storage location exists.</td>
</tr>
<tr>
<td>LOCATION_PATH</td>
<td>VARCHAR</td>
<td>The path where the storage location is mounted.</td>
</tr>
<tr>
<td>LOCATION_USAGE</td>
<td>VARCHAR</td>
<td>The type of information stored in the location:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DATA: Only data is stored in the location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TEMP: Only temporary files that are created during loads or queries are stored in the location.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| DATA,TEMP        |           | • DATA,TEMP: Both types of files are stored in the location.  
|                  |           | • USER: The storage location can be used by non-dbadmin users, who are granted access to the storage location  
|                  |           | • CATALOG: The area is used for the Vertica catalog. This usage is set internally and cannot be removed or changed. |
| SHARING_TYPE     | VARCHAR   | How this location is shared among database nodes, if it is:  
|                  |           | • SHARED: The path used by the storage location is used by all nodes. See the SHARED parameter to CREATE LOCATION.  
|                  |           | • COMMUNAL: the location is used for communal storage in Eon Mode Beta.  
|                  |           | • NONE: The location is not shared among nodes. |
| IS RETIRED       | BOOLEAN   | Whether the storage location has been retired. This column has a value of t (true) if the location is retired, or f (false) if it is not. |
| LOCATION_LABEL   | VARCHAR   | The label associated with a specific storage location, added with the ALTER_LOCATION_LABEL function. |
| RANK             | INTEGER   | The Access Rank value either assigned or supplied to the storage location, as described in Prioritizing Column Access Speed. |
| THROUGHPUT       | INTEGER   | The throughput performance of the storage location, measured in MB/sec. You can get location performance values using MEASURE_LOCATION_PERFORMANCE, and set them with the SET_LOCATION_PERFORMANCE function. |
| LATENCY          | INTEGER   | The measured latency of the storage location as number of data seeks per second. You can get location performance values using MEASURE_LOCATION_PERFORMANCE, and set them with the SET_LOCATION_PERFORMANCE function. |
Privileges

Must be a superuser.

SYSTEM_COLUMNS

Provides table column information for SYSTEM_TABLES.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the table.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name for which information is listed.</td>
</tr>
<tr>
<td>IS_SYSTEM_TABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether the table is a system table, where t is true and f is false.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>VARCHAR</td>
<td>A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in a table.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column name for which information is listed in the database.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>VARCHAR</td>
<td>The data type assigned to the column; for example</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>VARCHAR</td>
<td>VARCHARG(16).</td>
</tr>
<tr>
<td>DATA_TYPE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the data type.</td>
</tr>
<tr>
<td>DATA_TYPE_LENGTH</td>
<td>INTEGER</td>
<td>The maximum allowable length of the data type.</td>
</tr>
<tr>
<td>CHARACTER_MAXIMUM_LENGTH</td>
<td>INTEGER</td>
<td>The maximum allowable length of the column.</td>
</tr>
<tr>
<td>NUMERIC_PRECISION</td>
<td>INTEGER</td>
<td>The number of significant decimal digits.</td>
</tr>
<tr>
<td>NUMERIC_SCALE</td>
<td>INTEGER</td>
<td>The number of fractional digits.</td>
</tr>
<tr>
<td>DATETIME_PRECISION</td>
<td>INTEGER</td>
<td>For TIMESTAMP data type, returns the declared precision; returns null if no precision was declared.</td>
</tr>
<tr>
<td>INTERVAL_PRECISION</td>
<td>INTEGER</td>
<td>The number of fractional digits retained in the seconds field.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>INTEGER</td>
<td>The position of the column respective to other columns in the table.</td>
</tr>
<tr>
<td>IS_NULLABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether the column can contain null values, where t is true and f is false.</td>
</tr>
<tr>
<td>COLUMN_DEFAULT</td>
<td>VARCHARG</td>
<td>The default value of a column, such as empty or expression.</td>
</tr>
</tbody>
</table>

**SYSTEM_TABLES**

Returns a list of all system table names.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the schema.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name in which the system table resides. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• V_CATALOG</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• V_MONITOR.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the system table.</td>
</tr>
<tr>
<td>TABLE_DESCRIPTION</td>
<td>VARCHAR</td>
<td>A description of the system table's purpose.</td>
</tr>
<tr>
<td>IS_SUPERUSER_ONLY</td>
<td>BOOLEAN</td>
<td>Indicates if the table is accessible only by a user with superuser privileges. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>t - table is accessible by superuser only</td>
</tr>
<tr>
<td></td>
<td></td>
<td>f - table is accessible by other users</td>
</tr>
<tr>
<td>IS_MONITORABLE</td>
<td>BOOLEAN</td>
<td>Indicates if the table is accessible by a user with the SYSMONITOR role enabled. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>t - table is accessible by SYSMONITOR role</td>
</tr>
<tr>
<td></td>
<td></td>
<td>f - table is not accessible by SYSMONITOR role</td>
</tr>
<tr>
<td></td>
<td></td>
<td>See SYSMONITOR Role.</td>
</tr>
<tr>
<td>IS_ACCESSIBLE_DURING_LOCKDOWN</td>
<td>BOOLEAN</td>
<td>Indicates if the table is restricted. See System Table Restriction and Access.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When you use the RESTRICT_SYSTEM_TABLES_ACCESS() function, the following conditions take affect:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• System tables with built-in restrictions that determine who can access information remain accessible. For example, the SESSIONS table allows a user to see only information on that user's current session.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• System tables that contain settings that a user should be allowed to see are accessible. For example, the TYPES system table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• System tables that contain information about other users are restricted.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• System tables that contain information</td>
</tr>
</tbody>
</table>
The behavior of the SYSMONITOR Role does not change.

About database settings are restricted.

### TABLE_CONSTRAINTS

Provides information about table constraints.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR</td>
<td>The name of the constraint, if specified as UNIQUE, FOREIGN KEY, NOT NULL, PRIMARY KEY, or CHECK.</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the schema containing the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_KEY_COUNT</td>
<td>INTEGER</td>
<td>The number of constraint keys.</td>
</tr>
<tr>
<td>FOREIGN_KEY_COUNT</td>
<td>INTEGER</td>
<td>The number of foreign keys.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table that contains the UNIQUE, FOREIGN KEY, NOT NULL, or PRIMARY KEY constraint.</td>
</tr>
<tr>
<td>FOREIGN_TABLE_ID</td>
<td>INTEGER</td>
<td>The unique object ID of the foreign table referenced in a foreign key constraint (zero if not a foreign key constraint).</td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td>CHAR</td>
<td>Indicates the constraint type.</td>
</tr>
<tr>
<td>Valid Values:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>● c — check</td>
<td></td>
<td></td>
</tr>
<tr>
<td>● f — foreign</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### TABLES

Provides information about all tables in the database.

**Tip:** Columns `TABLE_SCHEMA` and `TABLE_NAME` are case sensitive. To query `TABLES` on these columns, use the case-insensitive `ILIKE` predicate. For example:

```sql
SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema ILIKE 'Store%';
```

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>TABLE_SCHEMA_ID</code></td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the schema and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td><code>TABLE_SCHEMA</code></td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td><code>TABLE_ID</code></td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the table and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td><code>TABLE_NAME</code></td>
<td>VARCHAR</td>
<td>The table name for which information is listed.</td>
</tr>
<tr>
<td><code>OWNER_ID</code></td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the owner and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td><code>OWNER_NAME</code></td>
<td>VARCHAR</td>
<td>The name of the user who created the table.</td>
</tr>
<tr>
<td><code>IS_TEMP_TABLE</code></td>
<td>BOOLEAN</td>
<td>Indicates whether this table is a temporary table.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IS_SYSTEM_TABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether table is a system table.</td>
</tr>
<tr>
<td>FORCE_OUTER</td>
<td>INTEGER</td>
<td>Specifies whether this table is joined to another as an inner or outer input. For details, see Controlling Join Inputs in Analyzing Data.</td>
</tr>
<tr>
<td>IS_FLEXTABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether the table is a Flex table.</td>
</tr>
<tr>
<td>IS_SHARED</td>
<td>BOOLEAN</td>
<td>Indicates whether the table is located on shared storage.</td>
</tr>
<tr>
<td>HAS_AGgregate_PROJECTION</td>
<td>BOOLEAN</td>
<td>Indicates whether the table has live aggregate projections.</td>
</tr>
<tr>
<td>SYSTEM_TABLE_CREATOR</td>
<td>VARCHAR</td>
<td>The name of the process that created the table, such as Designer.</td>
</tr>
<tr>
<td>PARTITION_EXPRESSION</td>
<td>VARCHAR</td>
<td>The table's partition expression.</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>TIMESTAMP</td>
<td>Returns the timestamp, indicating when the table was created.</td>
</tr>
<tr>
<td>TABLE_DEFINITION</td>
<td>VARCHAR</td>
<td>The COPY statement table definition. This column is applicable only to external tables.</td>
</tr>
<tr>
<td>RECOVER_PRIORITY</td>
<td>INTEGER</td>
<td>The priority rank for the table for a Recovery By Table.</td>
</tr>
<tr>
<td>STORAGE_MODE</td>
<td>INTEGER</td>
<td>Specifies the load method a table uses, set to one of the following integer values: 0: The initial value for all tables that pre-date Vertica 9.0.x 1: Direct 5: Trickle 6: Auto (default)</td>
</tr>
<tr>
<td>PARTITION_GROUP_EXPRESSION</td>
<td>VARCHAR</td>
<td>The expression of a GROUP BY clause that qualifies a table's partition clause.</td>
</tr>
</tbody>
</table>
Examples

Find when tables were created:

```sql
=> SELECT table_schema, table_name, create_time FROM tables;

<table>
<thead>
<tr>
<th>table_schema</th>
<th>table_name</th>
<th>create_time</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>customer_dimension</td>
<td>2011-08-15 11:18:25.784203-04</td>
</tr>
<tr>
<td>public</td>
<td>promotion_dimension</td>
<td>2011-08-15 11:18:25.850592-04</td>
</tr>
<tr>
<td>public</td>
<td>date_dimension</td>
<td>2011-08-15 11:18:25.892347-04</td>
</tr>
<tr>
<td>public</td>
<td>vendor_dimension</td>
<td>2011-08-15 11:18:25.942805-04</td>
</tr>
<tr>
<td>public</td>
<td>employee_dimension</td>
<td>2011-08-15 11:18:25.966985-04</td>
</tr>
<tr>
<td>public</td>
<td>shipping_dimension</td>
<td>2011-08-15 11:18:25.999394-04</td>
</tr>
<tr>
<td>online_sales</td>
<td>online_page_dimension</td>
<td>2011-08-15 11:18:27.007329-04</td>
</tr>
<tr>
<td>online_sales</td>
<td>call_center_dimension</td>
<td>2011-08-15 11:18:27.476844-04</td>
</tr>
<tr>
<td>online_sales</td>
<td>online_sales_fact</td>
<td>2011-08-15 11:18:27.49749-04</td>
</tr>
</tbody>
</table>

(15 rows)
```

Find out whether certain tables are temporary and flex tables:

```sql
=> SELECT distinct table_name, table_schema, is_temp_table, is_flextable FROM v_catalog.tables
   WHERE table_name ILIKE 't%';

<table>
<thead>
<tr>
<th>table_name</th>
<th>table_schema</th>
<th>is_temp_table</th>
<th>is_flextable</th>
</tr>
</thead>
<tbody>
<tr>
<td>t2_temp</td>
<td>public</td>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>tt_keys</td>
<td>public</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>t2_temp_keys</td>
<td>public</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>t3</td>
<td>public</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>t1</td>
<td>public</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>t9_keys</td>
<td>public</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>t2_keys</td>
<td>public</td>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>t6</td>
<td>public</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>t5</td>
<td>public</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>t2</td>
<td>public</td>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>t8</td>
<td>public</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>t7</td>
<td>public</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>tt</td>
<td>public</td>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>t2_keys_keys</td>
<td>public</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>t9</td>
<td>public</td>
<td>t</td>
<td>t</td>
</tr>
</tbody>
</table>

(15 rows)
```

TEXT_INDICES

Provides summary information about the text indices in Vertica.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDEX_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the index and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>VARCHAR</td>
<td>The name of the text index.</td>
</tr>
<tr>
<td>INDEX_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name of the text index.</td>
</tr>
<tr>
<td>SOURCE_TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the table and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>SOURCE_TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the source table used to build the index.</td>
</tr>
<tr>
<td>SOURCE_TABLE_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name of the source table.</td>
</tr>
<tr>
<td>TOKENIZER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the tokenizer and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>TOKENIZER_NAME</td>
<td>VARCHAR</td>
<td>The name of the tokenizer used when building the index.</td>
</tr>
<tr>
<td>TOKENIZER_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name of the tokenizer.</td>
</tr>
<tr>
<td>STEMMER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the stemmer and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>STEMMER_NAME</td>
<td>VARCHAR</td>
<td>The name of the stemmer used when building the index.</td>
</tr>
<tr>
<td>STEMMER_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name of the stemmer.</td>
</tr>
<tr>
<td>TEXT_COL</td>
<td>VARCHAR</td>
<td>The text column used to build the index.</td>
</tr>
</tbody>
</table>

**TYPES**

Provides information about supported data types.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the specific data type.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ODBC_TYPE</td>
<td>INTEGER</td>
<td>The numerical ODBC type.</td>
</tr>
<tr>
<td>ODBC_SUBTYPE</td>
<td>INTEGER</td>
<td>The numerical ODBC subtype, used to differentiate types such as time and interval that have multiple subtypes.</td>
</tr>
<tr>
<td>MIN_SCALE</td>
<td>INTEGER</td>
<td>The minimum number of digits supported to the right of the decimal point for the data type.</td>
</tr>
<tr>
<td>MAX_SCALE</td>
<td>INTEGER</td>
<td>The maximum number of digits supported to the right of the decimal point for the data type. A value of 0 is used for types that do not use decimal points.</td>
</tr>
<tr>
<td>COLUMN_SIZE</td>
<td>INTEGER</td>
<td>The number of characters required to display the type. See: <a href="http://msdn.microsoft.com/en-us/library/windows/desktop/ms711786%28v=VS.85%29.aspx">http://msdn.microsoft.com/en-us/library/windows/desktop/ms711786%28v=VS.85%29.aspx</a> for the details on COLUMN_SIZE for each type.</td>
</tr>
<tr>
<td>INTERVAL_MASK</td>
<td>INTEGER</td>
<td>For data types that are intervals, the bitmask to determine the range of the interval from the Vertica TYPE_ID. Details are available in the Vertica SDK.</td>
</tr>
<tr>
<td>TYPE_NAME</td>
<td>VARCHAR</td>
<td>The data type name associated with a particular data type ID.</td>
</tr>
<tr>
<td>CREATION_PARAMETERS</td>
<td>VARCHAR</td>
<td>A list of keywords, separated by commas, corresponding to each parameter that the application may specify in parentheses when using the name that is returned in the TYPE_NAME field. The keywords in the list can be any of the following: length, precision, or scale. They appear in the order that the syntax requires them to be used.</td>
</tr>
</tbody>
</table>

**USER_AUDITS**

Lists the results of database and object size audits generated by users calling the AUDIT function. See Monitoring Database Size for License Compliance in the Administrator's Guide for more information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIZE_BYTES</td>
<td>INTEGER</td>
<td>The estimated raw data size of the database</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>The ID of the user who generated the audit</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user who generated the audit</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>The ID of the object being audited</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>VARCHAR</td>
<td>The type of object being audited (table, schema, etc.)</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema containing the object being audited</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the object being audited</td>
</tr>
<tr>
<td>AUDITED_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema on which you want to query HISTORICAL data. After running audit on a table, you can drop the table. In this case, object_schema becomes NULL.</td>
</tr>
<tr>
<td>AUDITED_OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the object on which you want to query HISTORICAL data. After running audit on a table, you can drop the table. In this case, object_name becomes NULL.</td>
</tr>
<tr>
<td>LICENSE_NAME</td>
<td>VARCHAR</td>
<td>The name of the license. After running a compliance audit, the value for this column is always vertica.</td>
</tr>
<tr>
<td>AUDIT_START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>When the audit started</td>
</tr>
<tr>
<td>AUDIT_END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>When the audit finished</td>
</tr>
<tr>
<td>CONFIDENCE_LEVEL_PERCENT</td>
<td>FLOAT</td>
<td>The confidence level of the size estimate</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
ERROR_TOLERANCE_PERCENT | FLOAT | The error tolerance used for the size estimate
USED_SAMPLING | BOOLEAN | Whether data was randomly sampled (if false, all of the data was analyzed)
CONFIDENCE_INTERVAL_LOWER_BOUND_BYTES | INTEGER | The lower bound of the data size estimate within the confidence level
CONFIDENCE_INTERVAL_UPPER_BOUND_BYTES | INTEGER | The upper bound of the data size estimate within the confidence level
SAMPLE_COUNT | INTEGER | The number of data samples used to generate the estimate
CELL_COUNT | INTEGER | The number of cells in the database

### USER_CLIENT_AUTH

Provides information about the client authentication methods that are associated with database users. You associate an authentication method with a user using `GRANT (Authentication)`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_OID</td>
<td>INTEGER</td>
<td>A unique identifier for that user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user.</td>
</tr>
<tr>
<td>AUTH_OID</td>
<td>INTEGER</td>
<td>A unique identifier for the authentication method you are using.</td>
</tr>
<tr>
<td>AUTH_NAME</td>
<td>VARCHAR</td>
<td>Name that you gave to the authentication method.</td>
</tr>
</tbody>
</table>
| GRANTED_TO | BOOLEAN | Name of the user with whom you have associated the authentication method using `GRANT (Authentication)`.
USER_FUNCTION_PARAMETERS

Provides information about the parameters of a C++ user-defined function (UDx). You can only view parameters that have the Properties.visible parameter set to TRUE.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR (128)</td>
<td>The schema to which the function belongs.</td>
</tr>
<tr>
<td>FUNCTION_NAME</td>
<td>VARCHAR (128)</td>
<td>The name assigned by the user to the User-Defined Function.</td>
</tr>
<tr>
<td>FUNCTION_TYPE</td>
<td>VARCHAR (128)</td>
<td>The type of user-defined function. For example, 'User Defined Function'.</td>
</tr>
<tr>
<td>FUNCTION_ARGUMENT_TYPE</td>
<td>VARCHAR (8192)</td>
<td>The number and data types of input arguments for the function.</td>
</tr>
<tr>
<td>PARAMETER_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the parameter for the user-defined function.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>VARCHAR (128)</td>
<td>The data type of the parameter.</td>
</tr>
<tr>
<td>DATA_TYPE_ID</td>
<td>INTEGER</td>
<td>A number specifying the ID for the parameter's data type.</td>
</tr>
<tr>
<td>DATA_TYPE_LENGTH</td>
<td>INTEGER</td>
<td>The maximum length of the parameter's data type.</td>
</tr>
<tr>
<td>IS_REQUIRED</td>
<td>BOOLEAN</td>
<td>Indicates whether the parameter is required or not.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If set to TRUE, and you don't provide the parameter, Vertica throws an error.</td>
</tr>
<tr>
<td>CAN_BE_NULL</td>
<td>BOOLEAN</td>
<td>Indicates whether the parameter can be passed as a NULL value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If set to FALSE, you pass the parameter with a NULL value, Vertica throws an error.</td>
</tr>
<tr>
<td>COMMENT</td>
<td>VARCHAR (128)</td>
<td>A user-supplied description of the parameter.</td>
</tr>
</tbody>
</table>
Privileges

Any user can query the USER_FUNCTION_PARAMETERS table. However, users can only see table information about those UDx functions which the user has permission to use.

- Developing User-Defined Extensions (UDxs)
- UDx Parameters

USER_FUNCTIONS

Returns metadata about user-defined SQL functions (which store commonly used SQL expressions as a function in the Vertica catalog) and User-Defined Functions (UDx).

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema in which this function exists.</td>
</tr>
<tr>
<td>FUNCTION_NAME</td>
<td>VARCHAR</td>
<td>The name assigned by the user to the SQL function or User-Defined Function.</td>
</tr>
<tr>
<td>PROCEDURE_TYPE</td>
<td>VARCHAR</td>
<td>The type of user-defined function. For example, 'User Defined Function'.</td>
</tr>
<tr>
<td>FUNCTION_RETURN_TYPE</td>
<td>VARCHAR</td>
<td>The data type name that the SQL function returns.</td>
</tr>
<tr>
<td>FUNCTION_ARGUMENT_TYPE</td>
<td>VARCHAR</td>
<td>The number and data types of parameters for the function.</td>
</tr>
<tr>
<td>FUNCTION_DEFINITION</td>
<td>VARCHAR</td>
<td>The SQL expression that the user defined in the SQL function's function body.</td>
</tr>
<tr>
<td>VOLATILITY</td>
<td>VARCHAR</td>
<td>The SQL function's volatility (whether a function returns the same output given the same input). Can be immutable, volatile, or stable.</td>
</tr>
<tr>
<td>IS STRICT</td>
<td>BOOLEAN</td>
<td>Indicates whether the SQL function is strict, where t is true and f is false.</td>
</tr>
</tbody>
</table>
## Notes

- The volatility and strictness of a SQL function are automatically inferred from the function definition in order that Vertica determine the correctness of usage, such as where an immutable function is expected but a volatile function is provided.

- The volatility and strictness of a UDx is defined by the UDx's developer.

## Example

Create a SQL function called `myzeroifnull` in the public schema:

```sql
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
       RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
   END;
```

Now query the USER_FUNCTIONS table. The query returns just the `myzeroifnull` macro because it is the only one created in this schema:

```sql
=> SELECT * FROM user_functions;
```

<table>
<thead>
<tr>
<th>schema_name</th>
<th>public</th>
</tr>
</thead>
<tbody>
<tr>
<td>function_name</td>
<td>myzeroifnull</td>
</tr>
<tr>
<td>procedure_type</td>
<td>User Defined Function</td>
</tr>
<tr>
<td>function_return_type</td>
<td>Integer</td>
</tr>
<tr>
<td>function_argument_type</td>
<td>x Integer</td>
</tr>
<tr>
<td>function_definition</td>
<td>RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END</td>
</tr>
<tr>
<td>volatility</td>
<td>immutable</td>
</tr>
<tr>
<td>is_strict</td>
<td>f</td>
</tr>
<tr>
<td>is_fenced</td>
<td>f</td>
</tr>
<tr>
<td>comment</td>
<td></td>
</tr>
</tbody>
</table>
See Also

- CREATE FUNCTION (SQL Functions)
- ALTER FUNCTION (UDF)
- DROP FUNCTION

**USER_PROCEDURES**

Provides information about external procedures that have been defined for Vertica. User sees only the procedures they can execute.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCEDURE_NAME</td>
<td>VARCHAR</td>
<td>The name given to the external procedure through the CREATE PROCEDURE statement.</td>
</tr>
<tr>
<td>PROCEDURE_ARGUMENTS</td>
<td>VARCHAR</td>
<td>Lists arguments for the external procedure.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>Indicates the schema in which the external procedure is defined.</td>
</tr>
</tbody>
</table>

**Example**

```sql
g=> SELECT * FROM user_procedures;
procedure_name | procedure_arguments | schema_name
---------------|---------------------|---------------------
helloplanet    | arg1 VARCHAR       | public              
(1 row)
```

**USER_TRANSFORMS**

Lists the currently-defined user-defined transform functions (UDTFs).

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the schema containing the UDTF.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FUNCTION_NAME</td>
<td>VARCHAR(128)</td>
<td>The SQL function name assigned by the user.</td>
</tr>
<tr>
<td>FUNCTION_RETURN_TYPE</td>
<td>VARCHAR(128)</td>
<td>The data types of the columns the UDTF returns.</td>
</tr>
<tr>
<td>FUNCTION_ARGUMENT_TYPE</td>
<td>VARCHAR(8192)</td>
<td>The data types of the columns that make up the input row.</td>
</tr>
<tr>
<td>FUNCTION_DEFINITION</td>
<td>VARCHAR(128)</td>
<td>A string containing the name of the factory class for the UDTF, and the name of the library that contains it.</td>
</tr>
<tr>
<td>IS_FENCED</td>
<td>BOOLEAN</td>
<td>Whether the UDTF runs in fenced mode.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only UDTFs contained in schemas to which they have read access.

**See Also**

- Transform Functions (UDTFs)
- CREATE TRANSFORM FUNCTION

**USERS**

Provides information about all users in the database.

**Tip**: To see if a role has been assigned to a user, call the function `HAS_ROLE`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>

<td>VARCHAR</td>
<td>The event logging mechanisms that are configured for Vertica. These can include vertica.log, (configured by default) syslog, and SNMP.</td>
</tr>
<tr>
<td>EVENT_POSTED_COUNT</td>
<td>INTEGER</td>
<td>Tracks the number of times an event occurs. Rather than posting the same event multiple times, Vertica posts the event once and then counts the number of additional instances in which the event occurs.</td>
</tr>
</tbody>
</table>

**ALLOCATOR_USAGE**

Provides real-time information on the allocation and reuse of memory pools for a Vertica node.

There are two memory pools in Vertica, global and SAL. The global memory pool is related to Vertica catalog objects. The SAL memory pool is related to the system storage layer. These memory pools are physical structures from which Vertica allocates and reuses portions of memory.

Within the memory pools, there are two allocation types. Both global and SAL memory pools include chunk and object memory allocation types.

- *Chunk* allocations are from tiered storage, and are grouped into sizes, in bytes, that are powers of 2.
- *Object* allocations are object types, for example, a table or projection. Each object assumes a set size.
The table provides detailed information on these memory pool allocations.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node from which Vertica has collected this allocator information.</td>
</tr>
<tr>
<td>POOL_NAME</td>
<td>VARCHAR</td>
<td>One of two memory pools:</td>
</tr>
<tr>
<td>ALLOCATION_TYPE</td>
<td>VARCHAR</td>
<td>One of two memory allocation types:</td>
</tr>
<tr>
<td>UNIT_SIZE</td>
<td>INTEGER</td>
<td>The size, in bytes, of the memory allocation. For example, if the allocation type is a table (an object type), then Vertica allots 8 bytes.</td>
</tr>
<tr>
<td>FREE_COUNT</td>
<td>INTEGER</td>
<td>Indicates the count of blocks of freed memory that Vertica has reserved for future memory needs. For example, if you delete a table, Vertica reserves the 8 bytes originally allotted for the table. The 8 bytes freed become 1 unit of memory that Vertica adds to this column.</td>
</tr>
<tr>
<td>FREE_BYTES</td>
<td>INTEGER</td>
<td>Indicates the number of freed memory bytes. For example, with a table deletion, Vertica adds 8 bytes to this column.</td>
</tr>
<tr>
<td>USED_COUNT</td>
<td>INTEGER</td>
<td>Indicates the count of in-use blocks for this allocation.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, if your database includes two table objects, Vertica adds 2 to this column.</td>
</tr>
<tr>
<td>USED_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes of in-use blocks of memory. For example, if your database includes two table objects, each of which assume 8 bytes, Vertica adds 16 to this column.</td>
</tr>
<tr>
<td>TOTAL_SIZE</td>
<td>INTEGER</td>
<td>Indicates the number of bytes that is the sum of all free and used memory.</td>
</tr>
<tr>
<td>CAPTURE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Indicates the current timestamp for when Vertica collected the for this table.</td>
</tr>
<tr>
<td>ALLOCATION_NAME</td>
<td>VARCHAR</td>
<td>Provides the name of the allocation type.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If the allocation is an object type, provides the name of the object. For example, CAT::Schema. Object types can also have the name internal, meaning that the object is an internal data structure.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Those object types that are not internal are prefaced with either CAT or SAL. Those prefaced with CAT indicate memory from the global memory pool. SAL indicates memory from the system storage memory pool.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If the allocation type is chunk, indicates a power of 2 in this field to represent the number of bytes assumed by the chunk. For example, $2^5$.</td>
</tr>
</tbody>
</table>

**Sample: How Memory Pool Memory is Allotted, Retained, and Freed**

The following table shows sample column values based upon a hypothetical example. The sample illustrates how column values change based upon addition or deletion of a table object.
When you add a table object (t1), Vertica assumes a UNIT_SIZE of 8 bytes, with a USED_COUNT of 1.

When you add a second table object (t2), the USED_COUNT increases to 2. Since each object assumes 8 bytes, USED_BYTES increases to 16.

When you delete one of the two table objects, Vertica USED_COUNT decreases to 1, and USED_BYTES decreases to 8. Since Vertica retains the memory for future use, FREE_BYTES increases to 8, and FREE_COUNT increases to 1.

Finally, when you create a new table object (t3), Vertica frees the memory for reuse. FREE_COUNT and FREE_BYTES return to 0.

allocation_name    | SAL::WOSAlloc

```

CATALOG_SUBSCRIPTION_CHANGES

Lists the changes made to catalog subscriptions.
### Column Name | Data Type | Description
---|---|---
EVENT_TIMESTAMP | TIMESTAMP | The time a catalog subscription changed.
SESSION_ID | VARCHAR | A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
USER_ID | INTEGER | A unique numeric ID assigned by the Vertica catalog, which identifies the user.
USER_NAME | VARCHAR | The user who made changes to the subscriptions.
TRANSACTION_ID | INTEGER | Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.
SHARD_NAME | VARCHAR | The name of the shard.
SHARD_OID | INTEGER | The OID of the shard.
SUBSCRIBER_NODE_NAME | VARCHAR | The node name or names subscribed to the shard.
SUBSCRIBER_NODE_OID | INTEGER | The OID of the subscribing node or nodes.
OLD_STATE | VARCHAR | The previous state of the node subscription.
NEW_STATE | VARCHAR | The current state of the node subscription.
WAS_PRIMARY | BOOLEAN | Defines whether the node was the primary subscriber.
IS_PRIMARY | BOOLEAN | Defines whether the node is currently the primary subscriber.
CATALOG_VERSION | INTEGER | The version of the catalog at the time of the subscription change.

**CATALOG_SYNC_STATE**

Indicates the last time a node synchronized its catalog.
### Column Name | Data Type | Description
--- | --- | ---
**NODE_OID** | INTEGER | The OID of the node.
**SYNC_CATALOG_VERSION** | INTEGER | The version number of the catalog being synchronized.
**LAST_CONFIG_CHANGE_VERSION** | INTEGER | The version number of the catalog before the next synchronization.
**SYNC_TRAILING_INTERVAL** | INTEGER | The difference between the global catalog version and the synchronized catalog version for a node.
**LAST_SYNC_AT** | DATE/TIME | The date and time the last time the catalog was synchronized.
**SYNC_QUEUE_SIZE** | INTEGER | The size, in bytes, of the synchronization queue.

### Example

```sql
=> SELECT * FROM CATALOG_SYNC_STATE;
```

<table>
<thead>
<tr>
<th>node_oid</th>
<th>45035996273704980</th>
</tr>
</thead>
<tbody>
<tr>
<td>sync_catalog_version</td>
<td>99</td>
</tr>
<tr>
<td>last_config_change_version</td>
<td>99</td>
</tr>
<tr>
<td>sync_trailing_interval</td>
<td>0</td>
</tr>
<tr>
<td>last_sync_at</td>
<td>2017-10-02 00:01:08.012556-04</td>
</tr>
<tr>
<td>sync_queue_size</td>
<td>0</td>
</tr>
</tbody>
</table>

### CATALOG_TRUNCATION_STATUS

Indicates how far behind a catalog version may be after you revive a cluster.

### Column Name | Data Type | Description
--- | --- | ---
**NODE_OID** | INTEGER | The OID of the node.
**CURRENT_CATALOG_VERSION** | INTEGER | The version number of the catalog currently on the cluster.
**TRUNCATION_CATALOG_VERSION** | INTEGER | The version number of the catalog after the next synchronization.
Example

```sql
=> SELECT * FROM CATALOG_TRUNCATION_STATUS;
- [ RECORD 1 ]---------------------------------------
node_oid | 45035996273704980
current_catalog_version | 99
truncation_catalog_version | 99
```

### COLUMN_STORAGE

Returns the amount of disk storage used by each column of each projection on each node. WOS data is stored by row, so per-column byte counts are not available.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the column.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column name for which information is listed.</td>
</tr>
<tr>
<td>ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows in the column.</td>
</tr>
<tr>
<td>USED_BYTES</td>
<td>INTEGER</td>
<td>The disk storage allocation of the column in bytes.</td>
</tr>
<tr>
<td>ENCODINGS</td>
<td>VARCHAR</td>
<td>The encoding type for the column.</td>
</tr>
<tr>
<td>COMPRESSION</td>
<td>VARCHAR</td>
<td>The compression type for the column. You can compare ENCODINGS and COMPRESSION columns to see how different encoding types affect column storage when optimizing for compression.</td>
</tr>
<tr>
<td>WOS_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of WOS rows in the column.</td>
</tr>
<tr>
<td>ROS_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of ROS rows in the column.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ROS_USED_BYTES</td>
<td>INTEGER</td>
<td>The number of ROS bytes in the column.</td>
</tr>
<tr>
<td>ROS_COUNT</td>
<td>INTEGER</td>
<td>The number of ROS containers.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The associated projection name for the column.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of the schema associated with the projection.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the anchor table.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_NAME</td>
<td>VARCHAR</td>
<td>The associated table name.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The associated table's schema name.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_COLUMN_ID</td>
<td>VARCHAR</td>
<td>A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in a table.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The name of the anchor table.</td>
</tr>
</tbody>
</table>

**CONFIGURATION_CHANGE**

Records the change history of system configuration parameters. This information is useful for identifying:

- Who changed the configuration parameter value
- When the configuration parameter was changed
- Whether nonstandard settings were in effect in the past

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when the row was recorded.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifier of the user who changed configuration parameters.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who changed configuration parameters at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>PARAMETER</td>
<td>VARCHAR</td>
<td>Name of the changed parameter. See Configuration Parameters in the Administrator's Guide for a detailed list of supported parameters.</td>
</tr>
<tr>
<td>VALUE</td>
<td>VARCHAR</td>
<td>New value of the configuration parameter.</td>
</tr>
</tbody>
</table>

### Privileges

Superuser

### CONFIGURATION_PARAMETERS

Provides information about configuration parameters currently in use by the system that are configurable at the database, node, or session level.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node names on the cluster for which information is listed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ALL indicates that all the nodes have the same value.</td>
</tr>
<tr>
<td>PARAMETER_NAME</td>
<td>VARCHAR</td>
<td>The name of the configurable parameter.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For names of supported parameters, see Configuration Parameter Categories in the Administrator's Guide.</td>
</tr>
<tr>
<td>CURRENT_VALUE</td>
<td>VARCHAR</td>
<td>The value of the current setting for the</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RESTART_VALUE</td>
<td>VARCHAR</td>
<td>The value of the parameter after the next restart.</td>
</tr>
<tr>
<td>DATABASE_VALUE</td>
<td>VARCHAR</td>
<td>The value that is set at the database level. If no database-level value is set, the value reflects the default value.</td>
</tr>
<tr>
<td>DEFAULT_VALUE</td>
<td>VARCHAR</td>
<td>The default value for the parameter.</td>
</tr>
<tr>
<td>CURRENT_LEVEL</td>
<td>VARCHAR</td>
<td>Level at which CURRENT_VALUE is set.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Valid values:</strong> Node, database, session, or default.</td>
</tr>
<tr>
<td>RESTART_LEVEL</td>
<td>VARCHAR</td>
<td>Level at which the parameter will be set after the next restart.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Valid values:</strong> Node, database, or default.</td>
</tr>
<tr>
<td>IS_MISMATCH</td>
<td>BOOLEAN</td>
<td>A <code>t</code> (true) setting indicates CURRENT_VALUE and RESTART_VALUE do not match.</td>
</tr>
<tr>
<td>GROUPS</td>
<td>VARCHAR</td>
<td>Any group to which the parameter belongs (for example, Security Parameters).</td>
</tr>
<tr>
<td>ALLOWED_LEVELS</td>
<td>VARCHAR</td>
<td>Indicates level or levels at which the specified parameter can be set.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Valid values:</strong> Node, database, or session.</td>
</tr>
<tr>
<td>SUPERUSER_ONLY</td>
<td>BOOLEAN</td>
<td>Indicates if the parameter settings are viewable by the superuser only. If true, the following columns will be masked if viewed by a non-superuser:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• current_value</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• restart_value</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• database_value</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• default_value</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CHANGE_UNDER_SUPPORT_GUIDANCE</td>
<td>BOOLEAN</td>
<td>A t (true) setting indicates parameters intended for use only by Vertica.</td>
</tr>
<tr>
<td>CHANGEQUIRES_RESTART</td>
<td>BOOLEAN</td>
<td>Indicates whether the configuration change requires a restart, where t is true and f is false.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>A description of the parameter's purpose.</td>
</tr>
</tbody>
</table>

**Example**

The following example shows a case where the parameter requires a restart for the new setting to take effect:

```sql
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'EnableSSL';
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>ALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameter_name</td>
<td>EnableSSL</td>
</tr>
<tr>
<td>current_value</td>
<td>0</td>
</tr>
<tr>
<td>restart_value</td>
<td>1</td>
</tr>
<tr>
<td>database_value</td>
<td>0</td>
</tr>
<tr>
<td>default_value</td>
<td>0</td>
</tr>
<tr>
<td>current_level</td>
<td>DEFAULT</td>
</tr>
<tr>
<td>restart_level</td>
<td>NODE</td>
</tr>
<tr>
<td>is_mismatch</td>
<td>t</td>
</tr>
<tr>
<td>groups</td>
<td></td>
</tr>
<tr>
<td>allowed_levels</td>
<td>NODE, DATABASE</td>
</tr>
<tr>
<td>superuser_only</td>
<td>f</td>
</tr>
<tr>
<td>change_under_support_guidance</td>
<td>f</td>
</tr>
<tr>
<td>change_requires_restart</td>
<td>t</td>
</tr>
<tr>
<td>description</td>
<td>Enable SSL for the server</td>
</tr>
</tbody>
</table>

The following example shows a case where a non-superuser is viewing a parameter where superuser_only is true.

```sql
=> \c VMart nonSuperuser
You are now connected to database "VMart" as user "nonSuperuser".
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE where superuser_only = 't';
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>ALL</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameter_name</td>
<td>LDAPLinkDryRun</td>
</tr>
<tr>
<td>current_value</td>
<td>******</td>
</tr>
<tr>
<td>restart_value</td>
<td>******</td>
</tr>
<tr>
<td>database_value</td>
<td>******</td>
</tr>
<tr>
<td>default_value</td>
<td>******</td>
</tr>
<tr>
<td>current_level</td>
<td>DEFAULT</td>
</tr>
<tr>
<td>restart_level</td>
<td>DEFAULT</td>
</tr>
</tbody>
</table>

CPU_USAGE

Records CPU usage history on the system.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Beginning of history interval.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMP</td>
<td>End of history interval.</td>
</tr>
<tr>
<td>AVERAGE_CPU_USAGE_PERCENT</td>
<td>FLOAT</td>
<td>Average CPU usage in percent of total CPU time (0-100) during history interval.</td>
</tr>
</tbody>
</table>

Privileges

Superuser

CRITICAL_HOSTS

Lists the critical hosts whose failure would cause the database to become unsafe and force a shutdown.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOST_NAME</td>
<td>VARCHAR</td>
<td>Name of a critical host</td>

None

CRITICAL_NODES

Lists the critical nodes whose failure would cause the database to become unsafe and force a shutdown.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the node.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of a critical node.</td>
</tr>
</tbody>
</table>

CURRENT_SESSION

Returns information about the current active session. Use this table to find out the current session's sessionID and get the duration of the previously-run query.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node for which information is listed</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name used to log into the database, NULL if the session is internal</td>
</tr>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>Host name and port of the TCP socket from which the client connection was made, NULL if the session is internal</td>
</tr>
<tr>
<td>TYPE</td>
<td>INTEGER</td>
<td>Identifies the session type, one of the following integer values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: Client 8: Shutdown</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>

</tr>
<tr>
<td></td>
<td></td>
<td>6 Recovery Sub-session</td>
</tr>
<tr>
<td></td>
<td></td>
<td>7 Refresh Repartition table</td>
</tr>
<tr>
<td>CLIENT_PID</td>
<td>INTEGER</td>
<td>Process identifier of the client process that issued this connection. This process might be on a different machine than the server.</td>
</tr>
<tr>
<td>LOGIN_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>When the user logged into the database or the internal session was created. This column can help identify open sessions that are idle.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier required to close or interrupt a session. This identifier is unique within the cluster at any point in time, but can be reused when the session closes.</td>
</tr>
<tr>
<td>CLIENT_LABEL</td>
<td>VARCHAR</td>
<td>User-specified label for the client connection that can be set when using ODBC. See Label in Data Source Name (DSN) Connection Properties in Connecting to Vertica.</td>
</tr>
<tr>
<td>TRANSACTION_START</td>
<td>TIMESTAMP</td>
<td>When the current transaction started, NULL if no transaction is running.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>VARCHAR</td>
<td>Hexadecimal identifier of the current transaction, NULL if no transaction is in progress.</td>
</tr>
</tbody>
</table>
| TRANSACTION_DESCRIPTION | VARCHAR | Description of the current transaction.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATEMENT_START</td>
<td>TIMESTAMP</td>
<td>When the current statement started execution, NULL if no statement is running</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>VARCHAR</td>
<td>Unique numeric ID for the currently-running statement, NULL if no statement is being processed. Combined, TRANSACTION_ID and STATEMENT_ID uniquely identify a statement within a session.</td>
</tr>
<tr>
<td>LAST_STATEMENT_DURATION_US</td>
<td>INTEGER</td>
<td>Duration in microseconds of the last completed statement</td>
</tr>
<tr>
<td>CURRENT_STATEMENT</td>
<td>VARCHAR</td>
<td>The currently-running statement, if any. NULL indicates that no statement is currently being processed.</td>
</tr>
<tr>
<td>LAST_STATEMENT</td>
<td>VARCHAR</td>
<td>NULL if the user has just logged in, otherwise the currently running statement or most recently completed statement.</td>
</tr>

</tr>
<tr>
<td>CLIENT_VERSION</td>
<td>VARCHAR</td>
<td>Client version</td>
</tr>
</tbody>
</table>

Profiling Settings:
- EXECUTION_ENGINE_PROFLING_CONFIGURATION
- QUERY_PROFLING_CONFIGURATION
- SESSION_PROFLING_CONFIGURATION
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT_OS</td>
<td>VARCHAR</td>
<td>Client operating system</td>
</tr>
<tr>
<td>CLIENT_OS_USER_NAME</td>
<td>VARCHAR</td>
<td>Identifies the user that logged into the database, also set for unsuccessful login attempts.</td>
</tr>
<tr>
<td>REQUESTED_PROTOCOL</td>
<td>VARCHAR</td>
<td>Communication protocol version that the ODBC client driver sends to Vertica server, used to support backward compatibility with earlier server versions.</td>
</tr>
<tr>
<td>EFFECTIVE_PROTOCOL</td>
<td>VARCHAR</td>
<td>Minimum protocol version supported by client and driver.</td>
</tr>
</tbody>
</table>

### Profiling Settings

The following columns show settings for different profiling categories:

- EXECUTIONENGINE_PROFILING_CONFIGURATION
- QUERY_PROFILING_CONFIGURATION
- SESSION_PROFILING_CONFIGURATION

These are set to one of the following:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Empty</td>
<td>No profiling is set</td>
</tr>
<tr>
<td>Session</td>
<td>On for current session</td>
</tr>
<tr>
<td>Global</td>
<td>On by default for all sessions</td>
</tr>
<tr>
<td>Session, Global</td>
<td>On by default for all sessions, including current session.</td>
</tr>
</tbody>
</table>

For information about controlling profiling settings, see Enabling and Disabling Profiling in the Administrator's Guide.

### DATA_COLLECTOR

Shows the Data Collector components, their current retention policies, and statistics about how much data is retained and how much has been discarded for various reasons. DATA_
COLLECTOR also calculates approximate collection rate, to aid in sizing calculations.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name on which information is retained.</td>
</tr>
<tr>
<td>COMPONENT</td>
<td>VARCHAR</td>
<td>The name of the component and its policy.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The data collector (dc) table name for which information is listed.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>A short description about the component.</td>
</tr>
<tr>
<td>IN_DB_LOG</td>
<td>BOOLEAN</td>
<td>Denotes if monitoring information is retained in the dbLog file.</td>
</tr>
<tr>
<td>IN_VERTICA_LOG</td>
<td>BOOLEAN</td>
<td>Denotes if monitoring information is retained in the vertica.log file.</td>
</tr>
<tr>
<td>MEMORY_BUFFER_SIZE_KB</td>
<td>INTEGER</td>
<td>The size of the memory buffer in kilobytes.</td>
</tr>
<tr>
<td>DISK_SIZE_KB</td>
<td>INTEGER</td>
<td>The on-disk size of the table in kilobytes.</td>
</tr>
<tr>
<td>SET_INTERVAL</td>
<td>BOOLEAN</td>
<td>A t (true) setting indicates time-based retention is set.</td>
</tr>
<tr>
<td>INTERVAL_TIME_S</td>
<td>INTERVAL</td>
<td>The time of retention expressed as an INTERVAL type. To turn time-based retention off, set the value to 0.</td>
</tr>
<tr>
<td>RECORD_TOO_BIG_ERRORS</td>
<td>INTEGER</td>
<td>A number that increments by one each time an error is thrown because data did not fit in memory (based on the data collector retention policy).</td>
</tr>
<tr>
<td>LOST_BUFFERS</td>
<td>INTEGER</td>
<td>The number of buffers lost.</td>
</tr>
<tr>
<td>LOST_RECORDS</td>
<td>INTEGER</td>
<td>The number of records lost.</td>
</tr>
<tr>
<td>RETIRED_FILES</td>
<td>INTEGER</td>
<td>The number of retired files.</td>
</tr>
<tr>
<td>RETIRED_RECORDS</td>
<td>INTEGER</td>
<td>The number of retired records.</td>
</tr>
<tr>
<td>CURRENT_MEMORY_RECORDS</td>
<td>INTEGER</td>
<td>The current number of rows in memory.</td>
</tr>
<tr>
<td>CURRENT_DISK_RECORDS</td>
<td>INTEGER</td>
<td>The current number of rows stored on disk.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>CURRENT_MEMORY_BYTES</td>
<td>INTEGER</td>
<td>Total current memory used in kilobytes.</td>
</tr>
<tr>
<td>CURRENT_DISK_BYTES</td>
<td>INTEGER</td>
<td>Total current disk space used in kilobytes.</td>
</tr>
<tr>
<td>FIRST_TIME</td>
<td>TIMESTAMP</td>
<td>Timestamp of the first record.</td>
</tr>
<tr>
<td>LAST_TIME</td>
<td>_TIMESTAMP</td>
<td>Timestamp of the last record</td>
</tr>
<tr>
<td>KB_PER_DAY</td>
<td>FLOAT</td>
<td>Total kilobytes used per day.</td>
</tr>
</tbody>
</table>

**Notes**

- Data Collector is on by default. To turn it off, see [Enabling and Disabling Data Collector](#).
- You can configure monitoring information retention policies. See [Data Collector Functions](#) and [Configuring Data Retention Policies](#) for more information.

**Examples**

The following example shows how to return all component names and their descriptions. This is a useful query if you want to change the retention policy for a particular component and don't remember its name:

```sql
=> SELECT DISTINCT component, description FROM data_collector ORDER BY 1 ASC;
```

<table>
<thead>
<tr>
<th>component</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllocationPoolStatistics</td>
<td>Information about global memory pools ...</td>
</tr>
<tr>
<td>AllocationPoolStatisticsByDay</td>
<td>Information about global memory pools, ... (historical, by day)</td>
</tr>
<tr>
<td>AllocationPoolStatisticsByHour</td>
<td>Information about global memory pools, ... (historical, by hour)</td>
</tr>
<tr>
<td>AllocationPoolStatisticsByMinute</td>
<td>Information about global memory pools, ... (historical, by minute)</td>
</tr>
<tr>
<td>AllocationPoolStatisticsBySecond</td>
<td>Information about global memory pools, ... (historical, by second)</td>

- SET_DATA_COLLECTOR_POLICY

DATABASE_BACKUPS

Lists historical information for each backup that successfully completed after running the vbr utility. This information is useful for determining whether to create a new backup before you advance the AHM. Because this system table displays historical information, its contents do not always reflect the current state of a backup repository. For example, if you delete a backup from a repository, the DATABASE_BACKUPS system table continues to display information about it.

To list existing backups, run vbr as described in Viewing Backups in the Administrator's Guide.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACKUP_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The timestamp of the backup.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the initiator node that performed the backup logging.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
SNAPSHOT_NAME | VARCHAR | The name of the backup, as specified in the snapshotName parameter of the vbr configuration file.
BACKUP_EPOCH | INTEGER | The database epoch at which the backup was saved.
NODE_COUNT | INTEGER | The number of nodes backed up in the completed backup, and as listed in the [Mappingn] sections of the configuration file.
OBJECTS | VARCHAR | The name of the object(s) contained in an object-level backup. This column is empty if the record is for a full cluster backup.
FILE_SYSTEM_TYPE | VARCHAR | The type of file system, such as Linux.

### Privileges
Superuser

## DATABASE_CONNECTIONS

Lists the connections to other databases for importing and exporting data. See Importing and Exporting Data Across Databases in the Administrator's Guide.

### Column Name | Data Type | Description
--- | --- | ---
DATABASE | VARCHAR | The name of the connected database
USERNAME | VARCHAR | The username used to create the connection
HOST | VARCHAR | The host name used to create the connection
PORT | VARCHAR | The port number used to create the connection
ISVALID | BOOLEAN | Whether the connection is still open and usable or not
Example

```sql
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD '' ON '10.10.20.150',5433;
CONNECT
=> SELECT * FROM DATABASE_CONNECTIONS;
```

<table>
<thead>
<tr>
<th>database</th>
<th>username</th>
<th>host</th>
<th>port</th>
<th>isvalid</th>
</tr>
</thead>
<tbody>
<tr>
<td>vmart</td>
<td>dbadmin</td>
<td>10.10.20.150</td>
<td>5433</td>
<td>t</td>
</tr>
</tbody>
</table>

(1 row)

### DELETE_VECTOR

Holds information on deleted rows to speed up the delete process.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node storing the deleted rows.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema where the deleted rows are located.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The name of the projection where the deleted rows are located.</td>
</tr>
<tr>
<td>STORAGE_TYPE</td>
<td>VARCHAR</td>
<td>The type of storage containing the delete vector (WOS or ROS).</td>
</tr>
<tr>
<td>DV_OID</td>
<td>INTEGER</td>
<td>The unique numeric ID (OID) that identifies this delete vector.</td>
</tr>
<tr>
<td>STORAGE_OID</td>
<td>INTEGER</td>
<td>The unique numeric ID (OID) that identifies the storage container that holds the delete vector.</td>
</tr>
<tr>
<td>SAL_STORAGE_ID</td>
<td>VARCHAR</td>
<td>Unique hexadecimal numeric ID assigned by the Vertica catalog, which identifies the storage.</td>
</tr>
<tr>
<td>DELETED_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows deleted.</td>
</tr>
<tr>
<td>USED_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes used to store the deletion.</td>
</tr>
<tr>
<td>START_EPOCH</td>
<td>INTEGER</td>
<td>The start epoch of the data in the delete vector.</td>
</tr>
<tr>
<td>END_EPOCH</td>
<td>INTEGER</td>
<td>The end epoch of the data in the delete vector.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IS_SORTED</td>
<td>BOOLEAN</td>
<td>Whether the storage container's data is sorted (WOS containers only).</td>
</tr>
</tbody>
</table>

**DEPLOY_STATUS**

Records the history of deployed Database Designer designs and their deployment steps.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIME</td>
<td>TIMESTAMP</td>
<td>Time when the row recorded the event.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who deployed a design at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>DEPLOY_NAME</td>
<td>VARCHAR</td>
<td>Name the deployment, same as the user-specified design name.</td>
</tr>
<tr>
<td>DEPLOY_STEP</td>
<td>VARCHAR</td>
<td>Steps in the design deployment.</td>
</tr>
<tr>
<td>DEPLOY_STEP_STATUS</td>
<td>VARCHAR</td>
<td>Textual status description of the current step in the deploy process.</td>
</tr>
<tr>
<td>DEPLOY_STEP_COMPLETE_PERCENT</td>
<td>FLOAT</td>
<td>Progress of current step in percentage (0–100).</td>
</tr>
<tr>
<td>DEPLOY_COMPLETE_PERCENT</td>
<td>FLOAT</td>
<td>Progress of overall deployment in percentage (0–100).</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>VARCHAR</td>
<td>Error or warning message during deployment.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.
DEPLOYMENT_PROJECTION_STATEMENTS

Contains information about `CREATE PROJECTION` statements used to deploy a database design. Each row contains information about a different `CREATE PROJECTION` statement. The function `DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY` populates this table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEPLOYMENT_ID</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the deployment.</td>
</tr>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Unique name that the user assigned to the design.</td>
</tr>
<tr>
<td>DEPLOYMENT_PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique ID assigned to the output projection by Database Designer.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique ID assigned to the statement type that creates the projection.</td>
</tr>
<tr>
<td>STATEMENT</td>
<td>VARCHAR</td>
<td>Text for the statement that creates the projection.</td>
</tr>
</tbody>
</table>

DEPLOYMENT_PROJECTIONS

Contains information about projections created and dropped during the design. Each row contains information about a different projection. Database Designer populates this table after the design is deployed.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deployment_id</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the deployment.</td>
</tr>
<tr>
<td>deployment_projection_id</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the output projection.</td>
</tr>
<tr>
<td>design_name</td>
<td>VARCHAR</td>
<td>Name of the design being deployed.</td>
</tr>
<tr>
<td>deployment_projection_id</td>
<td>VARCHAR</td>
<td>Name that Database Designer assigned to the projection.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td></td>
</tr>
<tr>
<td>anchor_table_schema</td>
<td>VARCHAR</td>
<td>Name of the schema that contains the table the projection is based on.</td>
</tr>
<tr>
<td>anchor_table_name</td>
<td>VARCHAR</td>
<td>Name of the table the projection is based on.</td>
</tr>
<tr>
<td>deployment_operation</td>
<td>VARCHAR</td>
<td>Action being taken on the projection, for example, add or drop.</td>
</tr>
</tbody>
</table>
| deployment_projection_type          | VARCHAR     | Indicates whether Database Designer has proposed new projections for this design (DBD) or is using the existing catalog design (CATALOG). The REENCODED suffix indicates that the projection sort order and segmentation are the same, but the projection columns have new encodings:  
  - DBD  
  - CATALOG  
  - DBD_REENCODED  
  - CATALOG_REENCODED |
| deploy_weight                       | INTEGER     | Weight of this projection in creating the design. This field is always 0 for projections that have been dropped. |
| estimated_size_on_disk              | INTEGER     | Approximate size of the projection on disk, in MB.                          |

**DEPOT_EVICTIONS**

Lists the details of the files that have been evicted from the depot when the database is in Eon Mode Beta.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVICTION_TIME</td>
<td>TIMESTAMP</td>
<td>The time a catalog subscription changed.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of a node where an eviction occurred.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The user who made changes to the depot.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session; these columns are useful for creating joins with other system tables.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>STORAGE_ID</td>
<td>VARCHAR</td>
<td>The OID of the evicted file.</td>
</tr>
<tr>
<td>FILE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The size of the file in bytes that was evicted.</td>
</tr>
<tr>
<td>NUMBER_HITS</td>
<td>INTEGER</td>
<td>The number of times the file was accessed.</td>
</tr>
<tr>
<td>LAST_ACCESS_TIME</td>
<td>TIMESTAMP</td>
<td>The last time the file was read.</td>
</tr>
</tbody>
</table>

**DEPOT_FETCHES**

Lists the details about files the depot fetched when the database is in Eon Mode Beta.
### Table 1: DEPOT_UPLOADED Columns

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Timestamp from the beginning of the fetch.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMP</td>
<td>Timestamp from the completion of the fetch.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that fetched from the depot.</td>
</tr>
<tr>
<td>PLAN_ID</td>
<td>VARCHAR</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>STORAGE_ID</td>
<td>VARCHAR</td>
<td>The OID of the fetched file.</td>
</tr>
<tr>
<td>FILE_SIZE(Bytes)</td>
<td>INTEGER</td>
<td>The fetch size in bytes.</td>
</tr>
<tr>
<td>SOURCE_FILE</td>
<td>VARCHAR</td>
<td>The source file path used.</td>
</tr>
<tr>
<td>DESTINATION_PATH</td>
<td>VARCHAR</td>
<td>The destination file path.</td>
</tr>
<tr>
<td>SOURCE_NODE</td>
<td>VARCHAR</td>
<td>The source node used.</td>
</tr>
</tbody>
</table>

### DEPOT_UPLOADED

Lists the details about uploads to communal storage from the depot.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Timestamp from the beginning of the upload.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMP</td>
<td>Timestamp from the completion of the upload.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of a node where an upload occurred.</td>
</tr>
<tr>
<td>PLAN_ID</td>
<td>VARCHAR</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>FILE_SIZE(Bytes)</td>
<td>INTEGER</td>
<td>The size of the file in bytes that was uploaded.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>SOURCE_FILE</td>
<td>VARCHAR</td>
<td>The source file path used.</td>
</tr>
<tr>
<td>DESTINATION_FILE</td>
<td>VARCHAR</td>
<td>The destination file path.</td>
</tr>
</tbody>
</table>

**DESIGN_QUERIES**

Contains info about design queries for a given design. The following functions populate this table:

- **DESIGNER_ADD DESIGN QUERIES**
- **DESIGNER_ADD DESIGN QUERIES FROM RESULTS**
- **DESIGNER_ADD DESIGN_QUERY**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESIGN_ID</td>
<td>INTEGER</td>
<td>Unique id that Database Designer assigned to the design.</td>
</tr>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Name that you specified for the design.</td>
</tr>
<tr>
<td>DESIGN_QUERY_ID</td>
<td>INTEGER</td>
<td>Unique id that Database Designer assigned to the design query.</td>
</tr>
<tr>
<td>DESIGN_QUERY_ID_INDEX</td>
<td>INTEGER</td>
<td>Database Designer chunks the query text if it exceeds the maximum attribute size before storing it in this table. Database Designer stored all chunks stored under the same value of DESIGN_QUERY_ID. DESIGN_QUERY_ID_INDEX keeps track of the order of the chunks, starting with 0 and ending in n, the index of the final chunk.</td>
</tr>
<tr>
<td>QUERY_TEXT</td>
<td>VARCHAR</td>
<td>Text of the query chunk, or the entire query text if it does not exceed the maximum attribute size.</td>
</tr>
<tr>
<td>WEIGHT</td>
<td>FLOAT</td>
<td>A value from 0 to 1 that indicates the importance of that query in creating the</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DESIGN_QUERY_SEARCH_PATH</td>
<td>VARCHAR</td>
<td>The search path with which the query is to be parsed.</td>
</tr>
<tr>
<td>DESIGN_QUERY_SIGNATURE</td>
<td>INTEGER</td>
<td>Categorizes queries that affect the design that Database Designer creates in the same way. Database Designer assigns a signature to each query, weights one query for each signature group, depending on how many queries there are with that signature, and Database Designer considers that query when creating the design.</td>
</tr>
</tbody>
</table>

design. Assign a higher weight to queries that you run frequently so that Database Designer prioritizes those queries in creating the design. Default: 1.

---

**Example**

Add queries to VMART_DESIGN and query the DESIGN_QUERIES table:

```sql
=> SELECT DESIGNER_ADD DESIGN QUERIES ('VMART_DESIGN', '/tmp/examples/vmart_queries.sql', 'true');
DESIGNER_ADD DESIGN QUERIES

Number of accepted queries = 9
Number of queries referencing non-design tables = 0
Number of unsupported queries = 0
Number of illegal queries = 0

=> \x
Expanded display is on.
=> SELECT * FROM V_MONITOR.DESIGN.QUERIES

<table>
<thead>
<tr>
<th>RECORD 1</th>
<th>-----------------------------</th>
</tr>
</thead>
<tbody>
<tr>
<td>design_id</td>
<td>45035996273705090</td>
</tr>
<tr>
<td>design_name</td>
<td>vmart_design</td>
</tr>
<tr>
<td>design_query_id</td>
<td>1</td>
</tr>
<tr>
<td>design_query_id_index</td>
<td>0</td>
</tr>
<tr>
<td>query_text</td>
<td>SELECT fat_content FROM (SELECT DISTINCT fat_content FROM product_dimension WHERE department_description IN ('Dairy') ) AS food ORDER BY fat_content LIMIT 5;</td>
</tr>
<tr>
<td>weight</td>
<td>1</td>
</tr>
<tr>
<td>design_query_search_path</td>
<td>v_dbd_vmart_design_vmart_design_ltt, &quot;$user&quot;, public, v_catalog, v_monitor, v_internal</td>
</tr>
<tr>
<td>design_query_signature</td>
<td>45035996273724651</td>
</tr>
</tbody>
</table>
```
### DESIGN_STATUS

Records the progress of a running Database Designer design or history of the last Database Designer design executed by the current user.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIME</td>
<td>TIMESTAMP</td>
<td>Time when the row recorded the event.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who ran a design at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Name of the user-specified design.</td>
</tr>
<tr>
<td>DESIGN_PHASE</td>
<td>VARCHAR</td>
<td>Phase of the design.</td>
</tr>
<tr>
<td>PHASE_STEP</td>
<td>VARCHAR</td>
<td>Substep in each design phase.</td>
</tr>
<tr>
<td>PHASE_STEP_COMPLETE_PERCENT</td>
<td>FLOAT</td>
<td>Progress of current substep in percentage (0–100).</td>
</tr>
<tr>
<td>PHASE_COMPLETE_PERCENT</td>
<td>FLOAT</td>
<td>Progress of current design phase in percentage (0–100).</td>
</tr>
</tbody>
</table>
Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

Example

The following example shows the content of the DESIGN_STATUS table of a complete Database Designer run:

```
=> SELECT event_time, design_name, design_phase, phase_complete_percent
    FROM v_monitor.design_status;

  event_time | design_name | design_phase                      | phase_complete_percent |
  -------------------+-------------+-----------------------------------+------------------------
   2012-02-14 10:31:20 | design1     | Design started                    |                        |
   2012-02-14 10:31:21 | design1     | Design in progress: Analyze statistics phase | 33.33                 |
   2012-02-14 10:31:22 | design1     | Analyzing data statistics         | 66.67                 |
   2012-02-14 10:31:24 | design1     | Analyzing data statistics         | 100                   |
   2012-02-14 10:31:25 | design1     | Design in progress: Query optimization phase |                        |
   2012-02-14 10:31:25 | design1     | Optimizing query performance      | 37.5                  |
   2012-02-14 10:31:31 | design1     | Optimizing query performance      | 62.5                  |
   2012-02-14 10:31:36 | design1     | Optimizing query performance      | 75                    |
   2012-02-14 10:31:39 | design1     | Optimizing query performance      | 87.5                  |
   2012-02-14 10:31:41 | design1     | Optimizing query performance      | 87.5                  |
   2012-02-14 10:31:42 | design1     | Design in progress: Storage optimization phase |                        |
   2012-02-14 10:31:44 | design1     | Optimizing storage footprint      | 4.17                  |
   2012-02-14 10:31:44 | design1     | Optimizing storage footprint      | 16.67                 |
   2012-02-14 10:32:04 | design1     | Optimizing storage footprint      | 29.17                 |
   2012-02-14 10:32:04 | design1     | Optimizing storage footprint      | 31.25                 |
   2012-02-14 10:32:05 | design1     | Optimizing storage footprint      | 33.33                 |
   2012-02-14 10:32:05 | design1     | Optimizing storage footprint      | 35.42                 |
   2012-02-14 10:32:05 | design1     | Optimizing storage footprint      | 37.5                  |
   2012-02-14 10:32:05 | design1     | Optimizing storage footprint      | 62.5                  |
   2012-02-14 10:32:05 | design1     | Optimizing storage footprint      | 87.5                  |
   2012-02-14 10:32:39 | design1     | Optimizing storage footprint      | 87.5                  |
   2012-02-14 10:32:41 | design1     | Optimizing storage footprint      | 100                   |
(24 rows)
```

**DESIGN_TABLES**

Contains information about all the design tables for all the designs for which you are the owner. Each row contains information about a different design table. Vertica creates this table when you run **DESIGNER_CREATE_DESIGN**.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Unique name that the user specified for the design.</td>
</tr>
<tr>
<td>DESIGN_TABLE_ID</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the design table.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the schema that contains the design table.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>System object identifier (OID) assigned to the design table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the design table.</td>
</tr>
</tbody>
</table>

**Example**

Add all the tables from the VMart database to the design VMART_DESIGN. This operation populates the DESIGN_TABLES table:

```sql
=> SELECT DESIGNER_ADD DESIGN_TABLES('VMART_DESIGN', 'online_sales.*');
DESIGNER_ADD DESIGN_TABLES
-------------------------------
3
(1 row)
=> SELECT DESIGNER_ADD DESIGN_TABLES('VMART_DESIGN', 'public.*');
DESIGNER_ADD DESIGN_TABLES
-------------------------------
9
(1 row)
=> SELECT DESIGNER_ADD DESIGN_TABLES('VMART_DESIGN', 'store.*');
DESIGNER_ADD DESIGN_TABLES
-------------------------------
3
(1 row)
=> SELECT * FROM DESIGN_TABLES;
design name    | design table id | table schema | table id | table name                                 |
----------------|-----------------|-------------|----------|-------------------------------------------|
VMART_DESIGN   | 1   | online_sales | 45035996373718754 | online_page_dimension    |
VMART_DESIGN   | 2   | online_sales | 45035996373718758 | call_center_dimension    |
VMART_DESIGN   | 3   | online_sales | 45035996373718762 | online_sales_fact        |
VMART_DESIGN   | 4   | public       | 45035996373718766 | customer_dimension       |
VMART_DESIGN   | 5   | public       | 45035996373718770 | product_dimension        |
VMART_DESIGN   | 6   | public       | 45035996373718774 | promotion_dimension      |
VMART_DESIGN   | 7   | public       | 45035996373718778 | date_dimension           |
VMART_DESIGN   | 8   | public       | 45035996373718782 | vendor_dimension         |
VMART_DESIGN   | 9   | public       | 45035996373718786 | employee_dimension       |
VMART_DESIGN   | 10  | public       | 45035996373718822 | shipping_dimension       |
VMART_DESIGN   | 11  | public       | 45035996373718826 | warehouse_dimension      |
VMART_DESIGN   | 12  | public       | 45035996373718830 | inventory_face           |
VMART_DESIGN   | 13  | store        | 45035996373718794 | store_dimension          |
```
**DESIGNS**

Contains information about a Database Designer design. After you create a design and specify certain parameters for Database Designer, `DESIGNER_CREATE_DESIGN` creates this table in the `V_MONITOR` schema.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESIGN_ID</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigns to this design.</td>
</tr>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Name that the user specifies for the design.</td>
</tr>
<tr>
<td>KSAFETY_LEVEL</td>
<td>INTEGER</td>
<td>K-safety level for the design. Database Designer assigns a K-safety value of 0 for clusters with 1 or 2 nodes, and assigns a value of 1 for clusters with 3 or more nodes.</td>
</tr>
<tr>
<td>OPTIMIZATION_OBJECTIVE</td>
<td>VARCHAR</td>
<td>Name of the optimization objective for the design. Valid values are:.Query, Load, Balanced (default).</td>
</tr>
<tr>
<td>DESIGN_TYPE</td>
<td>VARCHAR</td>
<td>Name of the design type. Valid values are: COMPREHENSIVE (default), INCREMENTAL.</td>
</tr>
<tr>
<td>PROPOSE_SUPER_FIRST</td>
<td>BOOLEAN</td>
<td>Specifies to propose superprojections before projections, by default false. If DESIGN_MODE is COMPREHENSIVE, this field has no impact.</td>
</tr>
<tr>
<td>DESIGN_AVAILABLE</td>
<td>BOOLEAN</td>
<td>t if the design is currently available, otherwise, f (default).</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>COLLECTED_STATISTICS</td>
<td>BOOLEAN</td>
<td><code>t</code> if statistics are to be collected when creating the design, otherwise, <code>f</code> (default).</td>
</tr>
<tr>
<td>POPULATE_DESIGN_TABLES_FROM_QUERIES</td>
<td>BOOLEAN</td>
<td><code>t</code> if you want to populate the design tables from the design queries, otherwise, <code>f</code> (default).</td>
</tr>
<tr>
<td>ENCODING_DESIGN</td>
<td>BOOLEAN</td>
<td><code>t</code> if the design is an encoding optimization design on pre-existing projections, otherwise, <code>f</code> (default).</td>
</tr>
<tr>
<td>DEPLOYMENT_PARALLELISM</td>
<td>INTEGER</td>
<td>Number of tables to be deployed in parallel when the design is complete. Default: 0</td>
</tr>
<tr>
<td>PROPOSE_UNSEGMENTED_PROJECTIONS</td>
<td>BOOLEAN</td>
<td><code>t</code> if you specify unsegmented projections, otherwise, <code>f</code> (default).</td>
</tr>
<tr>
<td>ANALYZE_CORRELATIONS_MODE</td>
<td>INTEGER</td>
<td>Specifies how Database Designer should handle existing column correlations in a design and whether or not Database Designer should reanalyze existing column correlations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 0—(default) Ignore column correlations when creating the design.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 1—Consider the existing correlations in the tables when creating the design.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 2—Analyze column correlations if not previously performed, and consider the column correlations when creating the design.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 3—Analyze all column correlations in the tables and consider them when creating the design, even if they have been analyzed previously.</td>
</tr>
</tbody>
</table>
DISKRESOURCE_REJECTIONS

Returns requests for resources that are rejected due to disk space shortages. Output is aggregated by both RESOURCE_TYPE and REJECTED_REASON to provide more comprehensive information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>RESOURCE_TYPE</td>
<td>VARCHAR</td>
<td>The resource request requester (example: Temp files).</td>
</tr>
<tr>
<td>REJECTED_REASON</td>
<td>VARCHAR</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Insufficient disk space</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Failed volume</td>
</tr>
<tr>
<td>REJECTED_COUNT</td>
<td>INTEGER</td>
<td>Number of times this REJECTED_REASON has been given for this RESOURCE_TYPE.</td>
</tr>
<tr>
<td>FIRST_REJECTED_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time of the first rejection for this REJECTED_REASON and RESOURCE_TYPE.</td>
</tr>
<tr>
<td>LAST_REJECTED_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time of the most recent rejection for this REJECTED_REASON and RESOURCE_TYPE.</td>
</tr>
<tr>
<td>LAST_REJECTED_VALUE</td>
<td>INTEGER</td>
<td>The value of the most recent rejection for this REJECTED_REASON and RESOURCE_TYPE.</td>
</tr>
</tbody>
</table>

**DISK_STORAGE**

Returns the amount of disk storage used by the database on each node. Each node can have one or more storage locations, and the locations can be on different disks with separate properties, such as free space, used space, and block size. The information in this system table is useful in determining where data files reside.

All returned values for this system table are in the context of the file system of the host operating system, and are not specific to Vertica-specific space.

The storage usage annotation called CATALOG indicates that the location is used to store the catalog. Each CATALOG location is specified only when creating a new database. You cannot add a CATALOG location annotation using CREATE LOCATION, nor remove an existing CATALOG annotation.

**Storage Location Performance**

The performance of a storage location is measured with two values:

- Throughput in MB/sec
- Latency in seeks/sec

These two values are converted to a single number (Speed) with the following formula:

\[
\text{ReadTime (time to read 1MB)} = \frac{1}{\text{throughput}} + \frac{1}{\text{latency}}
\]

- \(1/\text{throughput}\) is the time taken to read 1MB of data
- \(1/\text{latency}\) is the time taken to seek to the data.
- ReadTime is the time taken to read 1MB of data.

A disk is faster than another disk if its ReadTime is less.

<table>
<thead>
<tr>
<th>Column Name</th>

<td>The number of free disk blocks available.</td>
</tr>
<tr>
<td>DISK_SPACE_FREE_MB</td>
<td>INTEGER</td>
<td>The number of megabytes of free storage available.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
**DISK_SPACE_FREE_PERCENT** | VARCHAR | The percentage of free disk space remaining.

### ERROR_MESSAGES

Lists system error messages and warnings Vertica encounters while processing queries. Some errors occur when no transaction is in progress, so the transaction identifier or statement identifier columns might return NULL.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>EVENT_TIMESTAMP</strong></td>
<td>TIMESTAMPTZ</td>
<td>Time when the row recorded the event.</td>
</tr>
<tr>
<td><strong>NODE_NAME</strong></td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td><strong>USER_ID</strong></td>
<td>INTEGER</td>
<td>Identifier of the user who received the error message.</td>
</tr>
<tr>
<td><strong>USER_NAME</strong></td>
<td>VARCHAR</td>
<td>Name of the user who received the error message at the time Vertica recorded the session.</td>
</tr>
<tr>
<td><strong>SESSION_ID</strong></td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td><strong>REQUEST_ID</strong></td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td><strong>TRANSACTION_ID</strong></td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td><strong>STATEMENT_ID</strong></td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td><strong>ERROR_LEVEL</strong></td>
<td>VARCHAR</td>
<td>Severity of the error, can be one of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOG</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• INFO</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
| NOTICE | | 
| WARNING | | 
| ERROR | | 
| ROLLBACK | | 
| INTERNAL | | 
| FATAL | | 
| PANIC | | 

**ERROR_CODE** INTEGER Error code that Vertica reports.

**MESSAGE** VARCHAR Textual output of the error message.

**DETAIL** VARCHAR Additional information about the error message, in greater detail.

**HINT** VARCHAR Actionable hint about the error. For example:

HINT: Set the locale in this session to en_US@collation=binary using the command "\locale en_US@collation=binary"

### Privileges
No explicit privileges are required. You only see the records for tables that you have privileges to view.

### EVENT_CONFIGURATIONS
Monitors the configuration of events.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_ID</td>
<td>VARCHAR</td>
<td>The name of the event.</td>
</tr>
<tr>
<td>EVENT_DELIVERY_</td>
<td>VARCHAR</td>
<td>The delivery channel on which the event</td>
</tr>
</tbody>
</table>
EXECUTION_ENGINE_PROFILES

Provides profiling information about query execution runs. The hierarchy of IDs, from highest level to actual execution is:

- PATH_ID
- BASEPLAN_ID
- LOCALPLAN_ID
- OPERATOR_ID

Counters (output from the COUNTER_NAME column) are collected for each actual Execution Engine (EE) operator instance.

The following columns combine to form a unique key for rows in EXECUTION_ENGINE_PROFILES:

- TRANSACTION_ID
- STATEMENT_ID
- NODE_NAME
- OPERATOR_ID
- COUNTER_NAME
- COUNTER_TAG

For more about profiling and debugging, see Profiling Database Performance in the Administrator's Guide.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node name for which information is listed.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>

<td>VARCHAR</td>
<td>Identifier of the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed.</td>
</tr>
<tr>
<td>OPERATOR_NAME</td>
<td>VARCHAR</td>
<td>Name of the Execution Engine (EE) component; for example, NetworkSend.</td>
</tr>
<tr>
<td>OPERATOR_ID</td>
<td>INTEGER</td>
<td>Identifier assigned by the EE operator instance that performs the work. OPERATOR_ID is different from LOCALPLAN_ID because each logical operator, such as Scan, may be executed by multiple threads concurrently. Each thread operates on a different operator instance, which has its own ID.</td>
</tr>
<tr>
<td>BASEPLAN_ID</td>
<td>INTEGER</td>
<td>Assigned by the optimizer on the initiator to EE operators in the original base (EXPLAIN) plan. Each EE operator in the base plan gets a unique ID.</td>
</tr>
<tr>
<td>PATH_ID</td>
<td>INTEGER</td>
<td>Identifier that Vertica assigns to a query operation or path; for example to a logical grouping operation that might be performed by multiple execution engine operators.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For each path, the same PATH ID is shared between the query plan (using EXPLAIN output) and in error messages that refer to joins.</td>
</tr>
<tr>
<td>LOCALPLAN_ID</td>
<td>INTEGER</td>
<td>Identifier assigned by each local executor while preparing for plan execution (local planning). Some operators in the base plan, such as the Root operator, which is connected to the client, do not run on all nodes. Similarly, certain operators, such as ExprEval, are</td>
</tr>
<tr>

<tr>
<td>ACTIVITY_ID</td>
<td>INTEGER</td>
<td>Identifier of the plan activity.</td>
</tr>
<tr>
<td>RESOURCE_ID</td>
<td>INTEGER</td>
<td>Identifier of the plan resource.</td>
</tr>
<tr>
<td>COUNTER_NAME</td>
<td>VARCHAR</td>
<td>Name of the counter. See the &quot;COUNTER_NAME Values&quot; section below this table.</td>
</tr>
<tr>
<td>COUNTER_TAG</td>
<td>VARCHAR</td>
<td>String that uniquely identifies the counter for operators that might need</td>
</tr>
<tr>
<td></td>
<td></td>
<td>to distinguish between different instances. For example, COUNTER_TAG is</td>
</tr>
<tr>
<td></td>
<td></td>
<td>used to identify to which of the node bytes are being sent to or received</td>
</tr>
<tr>
<td></td>
<td></td>
<td>from for the NetworkSend operator.</td>
</tr>
<tr>
<td>COUNTER_VALUE</td>
<td>INTEGER</td>
<td>Value of the counter.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Indicates whether the profile is active or completed, where t is active and</td>
</tr>
<tr>
<td></td>
<td></td>
<td>f is completed.</td>
</tr>
</tbody>
</table>

Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

COUNTER_NAME Values

The value of COUNTER_NAME can be any of the following:

<table>
<thead>
<tr>
<th>COUNTER_NAME</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active threads</td>
<td>A counter of the LoadUnion operator, which indicates the number of input</td>
</tr>
<tr>
<td>blocks analyzed by SIPS</td>
<td>The number of data blocks analyzed by SIPS expression from the Scan operator.</td>
</tr>
<tr>
<td>expression</td>
<td></td>
</tr>
<tr>
<td>COUNTER_NAME</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>blocks filtered by SIPS expression</td>
<td>The number of data blocks filtered by SIPS expression from the Scan operator.</td>
</tr>
<tr>
<td>blocks filtered by SIPS value lists</td>
<td>The number of data blocks filtered by SIPS sorted value lists from the Scan operator.</td>
</tr>
<tr>
<td>buffers spilled</td>
<td>[NetworkSend] Buffers spilled to disk by NetworkSend.</td>
</tr>
<tr>
<td>bytes read from cache</td>
<td>[DataSource] The number of bytes read from Vertica cache when an EE DataSource operator is reading from ROS containers.</td>
</tr>
<tr>
<td>bytes read from disk</td>
<td>[DataSource] The number of bytes read from disk when an EE DataSource operator is reading from ROS containers.</td>
</tr>
<tr>
<td>bytes received</td>
<td>[NetworkRecv] The number of bytes received over the network for query execution.</td>
</tr>
<tr>
<td>bytes sent</td>
<td>[NetworkSend] Size of data after encoding and compression sent over the network (actual network bytes).</td>
</tr>
<tr>
<td>bytes spilled</td>
<td>[NetworkSend] Bytes spilled to disk by NetworkSend.</td>
</tr>
<tr>
<td>bytes total</td>
<td>Only relevant to SendFiles operator (that is, recover-by-container plan) total number of bytes to send / receive.</td>
</tr>
<tr>
<td>clock time (us)</td>
<td>Real-time clock time spent processing the query, in microseconds.</td>
</tr>
<tr>
<td>completed merge phases</td>
<td>Number of merge phases already completed by an LSort or DataTarget operator. Compare to the total merge phases. Variants on this value include join inner completed merge phases.</td>
</tr>
<tr>
<td>cumulative size of raw temp data (bytes)</td>
<td>Total amount of temporary data the operator has written to files. Compare to cumulative size of temp files (bytes) to understand impact of</td>
</tr>
<tr>
<td>COUNTER_NAME</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>encoding and compression in an externalizing operator. Variants on this value include join inner cumulative size of raw temp files (bytes).</td>
<td></td>
</tr>
<tr>
<td>cumulative size of temp files (bytes)</td>
<td>For externalizing operators only, the total number of encoded and compressed temp data the operator has written to files. A sort operator might go through multiple merge phases, where at each pass sorted chunks of data are merged into fewer chunks. This counter remembers the cumulative size of all temp files past and present. Variants on this value include join inner cumulative size of temp files (bytes).</td>
</tr>
<tr>
<td>current allocated rid memory (bytes)</td>
<td>Per-rid memory tracking: current allocation amount under this rid.</td>
</tr>
<tr>
<td>current file handles</td>
<td>Number of files open.</td>
</tr>
<tr>
<td>current memory allocations (count)</td>
<td>Number of actual allocator calls made.</td>
</tr>
<tr>

<td>The total number of rows being put into the sort facility</td>
</tr>
</tbody>
</table>
### COUNTER_NAME | Description
--- | ---
sort | in Join.
total rows read in sort | The total number of rows ingested into the sort by the SortManager. This counter and the counter rows written in sort are typically equal.
total rows written in sort | See the counter, rows written in sort.
total sources | Total number of distinct input sources processed in a load.
unpacked (bytes) | The number of bytes produced by a compressed source in a load (for example, for a gzip file, the size of the file when decompressed).
wait clock time (us) | StorageUnion wait time in microseconds.
WOS bytes acquired | Number of bytes acquired from the WOS by a DataTarget operator.  
  **Note:** This is usually more but can be less than WOS bytes written if an earlier statement in the transaction acquired some WOS memory.
WOS bytes written | Number of bytes written to the WOS by a DataTarget operator.
written rows | [DataTarget] Number of rows written when an EE DataTarget operator writes to ROS containers

### Examples

The two queries below show the contents of the `EXECUTION_ENGINE_PROFILES` table:

```sql
=> SELECT operator_name, operator_id, counter_name, counter_value  
    FROM EXECUTION_ENGINE_PROFILES WHERE operator_name = 'Scan'  
    ORDER BY counter_value DESC;
```

<table>
<thead>
<tr>
<th>operator_name</th>
<th>operator_id</th>
<th>counter_name</th>
<th>counter_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan</td>
<td>12</td>
<td>end time</td>
<td>397916465478595</td>
</tr>
<tr>
<td>Scan</td>
<td>9</td>
<td>end time</td>
<td>397916465478510</td>
</tr>
<tr>
<td>Scan</td>
<td>12</td>
<td>start time</td>
<td>397916465462098</td>
</tr>
</tbody>
</table>
```sql
SELECT DISTINCT counter_name FROM execution_engine_profiles;
```

<table>
<thead>
<tr>
<th>operator_name</th>
<th>path_id</th>
<th>counter_name</th>
<th>counter_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Join</td>
<td>1</td>
<td>estimated rows produced</td>
<td>10000</td>
</tr>
<tr>
<td>Join</td>
<td>1</td>
<td>file handles</td>
<td>0</td>
</tr>
<tr>
<td>Join</td>
<td>1</td>
<td>memory allocated (bytes)</td>
<td>2405824</td>
</tr>
<tr>
<td>Join</td>
<td>1</td>
<td>memory reserved (bytes)</td>
<td>1769472</td>
</tr>
<tr>
<td>Join</td>
<td>1</td>
<td>rle rows produced</td>
<td>3</td>
</tr>
<tr>
<td>Join</td>
<td>1</td>
<td>rows produced</td>
<td>3</td>
</tr>
<tr>
<td>Join</td>
<td>1</td>
<td>clock time (us)</td>
<td>24105</td>
</tr>
<tr>
<td>Join</td>
<td>1</td>
<td>execution time (us)</td>
<td>235</td>
</tr>
</tbody>
</table>

(24 rows)

The following query includes the `path_id` column, which links the path that the query optimizer takes (via the EXPLAIN command’s textual output) with join error messages.

```sql
SELECT operator_name, path_id, counter_name, counter_value FROM execution_engine_profiles;
```
EXTERNAL_TABLE_DETAILS

Returns the amount of disk storage used by the source files backing external tables in the database. The information in this system table is useful in determining Hadoop license compliance.

When computing the size of an external table, Vertica counts all data found in the location specified by the COPY FROM clause. If you have a directory that contains ORC and delimited files, for example, and you define your external table with "COPY FROM *" instead of "COPY FROM *.orc", this table includes the size of the delimited files. (You would probably also encounter errors when querying that external table.) When you query this system table Vertica does not validate your table definition; it just uses the path to find files to report.

Restrict your queries to filter by schema, table, or format to avoid expensive queries. Vertica calculates the values in this table at query time, so "SELECT *" accesses every input file contributing to every external table.

Predicates in queries may use only the TABLE_SCHEMA, TABLE_NAME, and SOURCE_FORMAT columns. Values are case-sensitive.

This table includes TEMP external tables.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_OID</td>
<td>INTEGER</td>
<td>The unique identification number of the schema in which the external table resides.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of the schema in which the external table resides.</td>
</tr>
<tr>
<td>TABLE_OID</td>
<td>VARCHAR</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>INTEGER</td>
<td>The table name.</td>
</tr>
<tr>
<td>SOURCE_FORMAT</td>
<td>VARCHAR</td>
<td>The data format the source file used, one of ORC, PARQUET, DELIMITED, USER DEFINED, or NULL if another format.</td>
</tr>
<tr>
<td>TOTAL_FILE_COUNT</td>
<td>INTEGER</td>
<td>The number of files used to store this table's data, expanding globs and partitions.</td>
</tr>

</tr>
<tr>
<td>threads_limit</td>
<td>INTEGER</td>
<td>The amount of physical RAM, in bytes, left unused by the system.</td>
</tr>
<tr>
<td>core_file_limit_max_size_bytes</td>
<td>INTEGER</td>
<td>The amount of physical RAM, in bytes, used for file buffers on the system.</td>
</tr>
<tr>
<td>processor_count</td>
<td>INTEGER</td>
<td>The amount of physical RAM, in bytes, used as cache memory on the system.</td>
</tr>
<tr>
<td>total_swap_memory_bytes</td>
<td>INTEGER</td>
<td>The total amount of swap memory available, in bytes, on the system.</td>
</tr>
<tr>
<td>total_swap_memory_free_bytes</td>
<td>INTEGER</td>
<td>The total amount of swap memory free, in bytes, on the system.</td>
</tr>
<tr>
<td>disk_space_free_mb</td>
<td>INTEGER</td>
<td>The free disk space available, in megabytes, for all storage location file systems (data directories).</td>
</tr>
<tr>
<td>disk_space_used_mb</td>
<td>INTEGER</td>
<td>The disk space used, in megabytes, for all storage location file systems.</td>
</tr>
<tr>
<td>disk_space_total_mb</td>
<td>INTEGER</td>
<td>The total free disk space available, in megabytes, for all storage location file systems.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**LDAP_LINK_EVENTS**

Monitors events that occurred during an LDAP Link synchronization.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time the event occurred.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node or nodes for which the information is listed.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The identification number of the LDAP Link session.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>The unique, system-generated user identification number.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user for which the information is listed.</td>
</tr>
</tbody>
</table>
| TRANSACTION_ID   | INTEGER     | The system-generated transaction identification number.  
Is NULL if a transaction id does not exist. |
<p>| EVENT_TYPE       | VARCHAR     | The type of event being logged, for example USER CREATED and PROCESSING_STARTED. |</p>
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENTRY_NAME</td>
<td>VARCHAR</td>
<td>The name of the object on which the event occurred, if applicable. For example, the event SYNC-STARTED does not use an object.</td>
</tr>
<tr>
<td>ENTRY_OID</td>
<td>INTEGER</td>
<td>The unique identification number for the object on which the event occurred, if applicable.</td>
</tr>
<tr>
<td>LDAPURIHASH</td>
<td>INTEGER</td>
<td>The URI hash number for the LDAP user.</td>
</tr>
</tbody>
</table>

**LOAD_SOURCES**

Like LOAD_STREAMS, monitors active and historical load metrics on each node. The LOAD_SOURCES table breaks information down by source and portion. Rows appear in this table only for COPY operations that are profiled or run for more than one second. LOAD_SOURCES does not record information about loads from ORC or Parquet files or COPY LOCAL.

A row is added to this table when the loading of a source or portion begins. Column values related to the progress of the load are updated during the load operation.

The columns uniquely identifying the load source (the various ID and name columns) and IS_EXECUTING always have non-NULL values.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier of the session for which Vertica captures load stream information. This identifier is unique within the cluster for the current session but can be reused in a subsequent session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within a session. If a session is active, but no transaction has begun, this value is NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| STREAM_NAME  | VARCHAR   | Load stream identifier. If the user does not supply a specific name, the STREAM_NAME default value is `tablename-ID`, where:
|              |           | - `tablename` is the table into which data is being loaded.  
|              |           | - `ID` is an integer value. `ID` is guaranteed to be unique within the current session on a node.  
|              |           | This system table includes stream names for every COPY statement that takes more than 1 second to run. The 1-second duration includes the time to plan and execute the statement. |
| SCHEMA_NAME  | VARCHAR   | Schema name for which load information is listed. Lets you identify two streams that are targeted at tables with the same name in different schemas. NULL, if selecting from an external table. |
| TABLE_OID    | INTEGER   | A unique numeric ID assigned by the Vertica catalog that identifies the table. NULL, if selecting from an external table. |
| TABLE_NAME   | VARCHAR   | Name of the table being loaded. NULL, if selecting from an external table. |
| NODE_NAME    | VARCHAR   | Name of the node loading the source. |
| SOURCE_NAME  | VARCHAR   | - Full file path if copying from a file.  
|              |           | - Value returned by `getUri()` if the source is a user-defined source.  
<p>|              |           | - STDIN if loading from standard input. |
| PORTION_OFFSET | INTEGER | Offset of the source portion, or NULL if not apportioned. |
| PORTION_SIZE | INTEGER   | Size of the source portion, or NULL if not apportioned. |</p>
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Whether this source is currently being parsed, where t is true and f is false.</td>
</tr>
<tr>
<td>READ_BYTES</td>

<td>Number of bytes read from the input file.</td>
</tr>
<tr>
<td>ROWS_PROroduced</td>
<td>INTEGER</td>
<td>Number of rows produced from parsing the source.</td>
</tr>
<tr>
<td>ROWS_REJECTED</td>
<td>INTEGER</td>
<td>Number of rows rejected from parsing the source. If CopyFaultTolerantExpressions is true, also includes rows rejected during expression evaluation.</td>
</tr>
<tr>
<td>INPUT_SIZE</td>
<td>INTEGER</td>
<td>Size of the input source in bytes, or NULL for unsized sources. For UDSources, this value is the value returned by getSize().</td>
</tr>
<tr>
<td>PARSE_COMPLETE_PERCENT</td>
<td>INTEGER</td>
<td>Percent of rows from the input file that have been parsed.</td>
</tr>
<tr>
<td>FAILURE_REASON</td>
<td>VARCHAR</td>
<td>For load failures, error message indicating why loading from this source failed or was cancelled:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• In cases of a node failure, exception, or cancellation, this column contains the associated error message.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If ERROR TOLERANCE was not used and a failure occurred, &quot;Source aborted due to exception while loading from (name)&quot;.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For any other failure, &quot;Exception occurred during load&quot;.</td>
</tr>
<tr>
<td>PEAK_COOPERATING_THREADS</td>
<td>INTEGER</td>
<td>The peak number of threads parsing this source in parallel.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.
Examples

The following example shows the values you would see in the LOAD_SOURCES table after some loads with various errors.

```sql
=> CREATE TABLE tt (i int);
=> COPY tt FROM '/tmp/load_sources_large.dat';
^CCancel request sent
ERROR 3322: Execution canceled by operator

=> COPY tt FROM '/tmp/load_sources_large.dat' ON ANY NODE;
  Rows Loaded
     ----------

LOAD_STREAMS

Monitors active and historical load metrics for load streams. This is useful for obtaining statistics about how many records got loaded and rejected from the previous load. Vertica maintains system table metrics until they reach a designated size quota (in kilobytes). This quota is set through internal processes, which you cannot set or view directly.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier of the session for which Vertica captures load stream information. This identifier is unique within the cluster for the current session, but can be reused in a subsequent session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within a session. If a session is active but no transaction has begun, this is NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
</tbody>
</table>
| STREAM_NAME    | VARCHAR   | Load stream identifier. If the user does not supply a
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>specific name, the STREAM_NAME default value is: tablename-ID where tablename is the table into which data is being loaded, and ID is an integer value, guaranteed to be unique with the current session on a node. This system table includes stream names for every COPY statement that takes more than 1-second to run. The 1-second duration includes the time to plan and execute the statement.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>Schema name for which load stream information is listed. Lets you identify two streams that are targeted at tables with the same name in different schemas</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the table being loaded.</td>
</tr>
<tr>
<td>LOAD_START</td>
<td>VARCHAR</td>
<td>Linux system time when the load started.</td>
</tr>
<tr>
<td>LOAD_DURATION_MS</td>
<td>NUMERIC (54,0)</td>
<td>Duration of the load stream in milliseconds.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Indicates whether the load is executing, where t is true and f is false.</td>
</tr>
<tr>
<td>ACCEPTED_ROW_COUNT</td>
<td>INTEGER</td>
<td>Number of rows loaded.</td>
</tr>
<tr>
<td>REJECTED_ROW_COUNT</td>
<td>INTEGER</td>
<td>Number of rows rejected.</td>
</tr>
<tr>
<td>READBYTES</td>
<td>INTEGER</td>
<td>Number of bytes read from the input file.</td>
</tr>
<tr>
<td>INPUT_FILE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>Size of the input file in bytes. Note: When using STDIN as input, the input file size is zero (0).</td>
</tr>
<tr>
<td>PARSE_COMPLETE_PERCENT</td>
<td>INTEGER</td>
<td>Percent of rows from the input file that have been parsed.</td>
</tr>
<tr>
<td>UNSORTED_ROW_COUNT</td>
<td>INTEGER</td>
<td>Cumulative number rows not sorted across all</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>projections.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> UNSORTED_ROW_COUNT could be greater than ACCEPTED_ROW_COUNT because data is copied and sorted for every projection in the target table.</td>
</tr>
<tr>
<td>SORTED_ROW_COUNT</td>
<td>INTEGER</td>
<td>Cumulative number of rows sorted across all projections.</td>
</tr>
<tr>
<td>SORT_COMPLETE_PERCENT</td>
<td>INTEGER</td>
<td>Percent of rows from the input file that have been sorted.</td>
</tr>
</tbody>
</table>

**Privileges**

If you have the SYSMONITOR role or are the dbadmin user, this table shows all loads. Otherwise it shows only your loads.

**LOCK_USAGE**

Provides aggregate information about lock requests, releases, and attempts, such as wait time/count and hold time/count. Vertica records:

- Lock attempts at the end of the locking process
- Lock releases after lock attempts are released

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information on which lock interaction occurs.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>Name of object being locked; can be a table or an internal structure (projection, global catalog, or local catalog).</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MODE</td>
<td>VARCHAR</td>
<td>Intended operations of the transaction. Otherwise, this value is NONE. For a list of lock modes and compatibility, see Lock Modes.</td>
</tr>
<tr>
<td>AVG_HOLD_TIME</td>
<td>INTERVAL</td>
<td>Average time (measured in intervals) that Vertica holds a lock.</td>
</tr>
<tr>
<td>MAX_HOLD_TIME</td>
<td>INTERVAL</td>
<td>Maximum time (measured in intervals) that Vertica holds a lock.</td>
</tr>
<tr>
<td>HOLD_COUNT</td>
<td>INTEGER</td>
<td>Total number of times the lock was granted in the given mode.</td>
</tr>
<tr>
<td>AVG_WAIT_TIME</td>
<td>INTERVAL</td>
<td>Average time (measured in intervals) that Vertica waits on the lock.</td>
</tr>
<tr>
<td>MAX_WAIT_TIME</td>
<td>INTERVAL</td>
<td>Maximum time (measured in intervals) that Vertica waits on a lock.</td>
</tr>
<tr>
<td>WAIT_COUNT</td>
<td>INTEGER</td>
<td>Total number of times lock was unavailable at the time it was first requested.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

**See Also**

- DUMP_LOCKTABLE
- LOCKS
- PROJECTION_REFRESHES
- SELECT
- SESSION_PROFILES
# LOCKS

Monitors lock grants and requests for all nodes. A table call with no results indicates that no locks are in use.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAMES</td>
<td>VARCHAR</td>
<td>Nodes on which lock interaction occurs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Node Rollup:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>NODE_NAMES are separated by commas. A transaction can have the same lock in the same mode in the same scope on multiple nodes. However, the transaction gets only one (1) line in the table.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>Name of object being locked; can be a table or an internal structure (projection, global catalog, or local catalog).</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog that identifies the object being locked.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>VARCHAR</td>
<td>Identification of transaction within the session, if any; otherwise NULL. Useful for creating joins to other system tables.</td>
</tr>
<tr>
<td>TRANSACTION_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Identification of transaction and associated description. Typically this query caused the transaction's creation.</td>
</tr>
<tr>
<td>LOCK_MODE</td>
<td>VARCHAR</td>
<td>Intended operation of the transaction. For a list of lock modes and compatibility, see <a href="#">Lock Modes</a>.</td>
</tr>
</tbody>
</table>
| LOCK_SCOPE     | VARCHAR     | Expected duration of the lock after it is granted. Before the lock is granted, Vertica lists the scope as REQUESTED. Once a lock has been granted, the following scopes are possible:  
  - STATEMENT_LOCALPLAN |
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATEMENT_COMPILE</td>
<td></td>
<td>• STATEMENT_COMPILE</td>
</tr>
<tr>
<td>STATEMENT_EXECUTE</td>
<td></td>
<td>• STATEMENT_EXECUTE</td>
</tr>
<tr>
<td>TRANSACTION_POSTCOMMIT</td>
<td></td>
<td>• TRANSACTION_POSTCOMMIT</td>
</tr>
<tr>
<td>TRANSACTION</td>
<td></td>
<td>• TRANSACTION</td>
</tr>
</tbody>
</table>

All scopes, other than TRANSACTION, are transient and are used only as part of normal query processing.

<table>
<thead>
<tr>
<th>REQUEST_TIMESTAMP</th>
<th>TIMESTAMP</th>
<th>Time when the transaction began waiting on the lock.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>Time the transaction acquired or upgraded the lock:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return values are NULL until the grant occurs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If the grant occurs immediately, values might be the same as REQUEST_TIMESTAMP.</td>
</tr>
</tbody>
</table>

LOGIN_FAILURES

This system table lists failures for each failed login attempt. This information helps you determine if a user is having difficulty getting into the database or identify a possible intrusion attempt.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGIN_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica recorded the login.</td>
</tr>
<tr>
<td>DATABASE_NAME</td>
<td>VARCHAR</td>
<td>The name of the database for the login attempt.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user whose login failed at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>Host name and port of the TCP socket from which the client connection was made. NULL if the session is internal.</td>
</tr>
<tr>
<td>CLIENT_PID</td>
<td>INTEGER</td>
<td>Identifier of the client process that issued this connection. In some cases, the client process is on a different machine from the server.</td>
</tr>
<tr>
<td>CLIENT_VERSION</td>
<td>VARCHAR</td>
<td>Unused.</td>
</tr>
<tr>
<td>CLIENT_OS_USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.</td>
</tr>
<tr>
<td>AUTHENTICATION_METHOD</td>
<td>VARCHAR</td>
<td>Name of the authentication method used to validate the client application or user who is trying to connect to the server using the database user name provided</td>
</tr>
</tbody>
</table>

**Valid values:**

- Trust
<table>

### Privileges

Superuser
MEMORY_USAGE

Records system resource history for memory usage. This is useful for comparing memory that Vertica uses versus memory in use by the entire system.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Beginning of history interval.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMP</td>
<td>End of history interval.</td>
</tr>
<tr>
<td>AVERAGE_MEMORY_USAGE_PERCENT</td>
<td>FLOAT</td>
<td>Records the average memory usage in percent of total memory (0-100) during the history interval.</td>
</tr>
</tbody>
</table>

Privileges

Superuser

MONITORING_EVENTS

Reports significant events that can affect database performance and functionality if you do not address their root causes.

See Monitoring Events in the Administrator's Guide for details.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>EVENT_CODE</td>
<td>INTEGER</td>
<td>Numeric identifier that indicates the type of event. See Event Types in Monitoring Events in the Administrator's Guide for a list of event type codes.</td>
</tr>
<tr>
<td>EVENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID that identifies the specific event.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| EVENT_SEVERITY              | VARCHAR     | Severity of the event from highest to lowest. These events are based on standard syslog severity types:  
0  – Emergency  
1  – Alert  
2  – Critical  
3  – Error  
4  – Warning  
5  – Notice  
6  – Info  
7  – Debug |
| EVENT_POSTED_TIMESTAMP      | TIMESTAMPTZ | When this event was posted.                                                |
| EVENT_CLEARED_TIMESTAMP     | TIMESTAMPTZ | When this event was cleared.                                               |
|                             |             | **Note:** You can also query the ACTIVE_EVENTS system table to see events that have not been cleared. |
| EVENT_EXPIRATION            | TIMESTAMPTZ | Time at which this event expires. If the same event is posted again prior to its expiration time, this field gets updated to a new expiration time. |
| EVENT_CODE_DESCRIPTION      | VARCHAR     | Brief description of the event and details pertinent to the specific situation. |
| EVENT_PROBLEM_DESCRIPTION   | VARCHAR     | Generic description of the event.                                           |

<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>INTERFACE</td>
<td>VARCHAR</td>
<td>Network interface name.</td>
</tr>
<tr>
<td>IP_ADDRESS_FAMILY</td>
<td>VARCHAR</td>
<td>Network address protocol.</td>
</tr>
<tr>
<td>IP_ADDRESS</td>
<td>VARCHAR</td>
<td>IP address for this interface.</td>
</tr>
<tr>
<td>SUBNET</td>
<td>VARCHAR</td>
<td>IP subnet for this interface.</td>
</tr>
<tr>
<td>MASK</td>
<td>VARCHAR</td>
<td>IP network mask for this interface.</td>
</tr>
<tr>
<td>BROADCAST_ADDRESS</td>
<td>VARCHAR</td>
<td>IP broadcast address for this interface.</td>
</tr>
</tbody>
</table>

Privileges

None

NETWORK_USAGE

Provides network bandwidth usage history on the system. This is useful for determining if Vertica is using a large percentage of its available network bandwidth.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Beginning of history interval.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
END_TIME | TIMESTAMP | End of history interval.
TX_KBYTES_PER_SEC | FLOAT | Counter history of outgoing (transmitting) usage in kilobytes per second.
RX_KBYTES_PER_SEC | FLOAT | Counter history of incoming (receiving) usage in kilobytes per second.

### Privileges
Superuser

### NODE_EVICTIONS
Monitors node evictions on the system.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVICTION_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the eviction request was made.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name logging the information.</td>
</tr>
<tr>
<td>EVICTED_NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name of the evicted node.</td>
</tr>
<tr>
<td>EVICTED_NODE_ID</td>
<td>INTEGER</td>
<td>The evicted node ID.</td>
</tr>
<tr>
<td>NODE_STATE_BEFORE_EVICTION</td>
<td>VARCHAR</td>
<td>The previous node state at the time of eviction.</td>
</tr>
</tbody>
</table>

### NODE_RESOURCES
Provides a snapshot of the node. This is useful for regularly polling the node with automated tools or scripts.

<table>
<thead>

OUTPUT_DEPLOYMENT_STATUS

Contains information about the deployment status of all the projections in your design. Each row contains information about a different projection. Vertica populates this table when you deploy the database design by running the function DESIGNER_RUN_POPULATE DESIGN AND DEPLOY.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deployment_id</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the deployment.</td>
</tr>
<tr>
<td>design_name</td>
<td>VARCHAR</td>
<td>Unique name that the user assigned to the design.</td>
</tr>
<tr>
<td>deployment_projection_id</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the output projection.</td>
</tr>
<tr>
<td>deployment_projection_name</td>
<td>VARCHAR</td>
<td>Name that Database Designer assigned to the output projection or the name of the projection to be</td>
</tr>
</tbody>
</table>
### Column Name | Column Type | Description
---|---|---
name | | dropped.

**deployment_status** | VARCHAR | Status of the deployment:

- pending
- complete
- needs_refresh
- in_progress
- error

**error_message** | VARCHAR | Text of any error that occurred when creating or refreshing the specified projection.

---

**OUTPUT_EVENT_HISTORY**

Contains information about each stage that Database Designer performs to design and optimize your database design.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME_STAMP</td>
<td>TIMESTAMP</td>

</tbody>
</table>

| TABLE_ID   | INTEGER    | Unique id that Database Designer assigned to the design table. |

Example

The following example shows the steps that Database Designer performs while optimizing the VMart example database:

```sql
=> SELECT DESIGNER_CREATE_DESIGN('VMART_DESIGN');
=> SELECT DESIGNER_ADD DESIGN TABLES('VMART_DESIGN','public.*');
=> SELECT DESIGNER_ADD DESIGN QUERIES('VMART_DESIGN','/tmp/examples/vmart_queries.sql');;
...
=> \x
Expanded display is on.
=> SELECT * FROM OUTPUT_EVENT_HISTORY;
```

</table>
PARTITION_COLUMNS

For each projection of each partitioned table, shows the disk space used by each column on each node. The column disk_space_bytes shows how much disk space the partitioned data uses, including deleted data. So, if you delete rows but do not not purge them, the view's deleted_row_count column changes to show the number of deleted rows in each column; however, disk_space_bytes remains the same. After the deleted rows are purged, Vertica, reclaims the disk space: disk_space_bytes changes accordingly, and deleted_row_count is reset to 0.

For grouped partitions, PARTITION_COLUMNS shows the cumulative disk space used for each column per grouped partition. The column grouped_partition_key, if not null, identifies the partition in which a given column is grouped.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>Identifies a named column within the partitioned table.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica, which identifies the column.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the partitioned table.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Projection name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by Vertica, which identifies the projection.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node that hosts partitioned data.</td>
</tr>
<tr>
<td>PARTITION_KEY</td>
<td>VARCHAR</td>
<td>Identifies the table partition.</td>
</tr>
<tr>
<td>GROUPED_PARTITION_KEY</td>
<td>VARCHAR</td>
<td>Identifies the grouped partition to which a given column belongs.</td>
</tr>
<tr>
<td>ROW_COUNT</td>
<td>INTEGER</td>
<td>The total number of partitioned data rows for each column, including deleted rows.</td>
</tr>
<tr>
<td>DELETED_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of deleted partitioned data rows in each column.</td>
</tr>
</tbody>
</table>
Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

Example

Given the following table definition:

```sql
=> CREATE TABLE messages
(    time_interval timestamp NOT NULL,
    thread_id varchar(32) NOT NULL,
    unique_id varchar(53) NOT NULL,
    msg_id varchar(65),
    ...)
PARTITION BY ((messages.time_interval)::date);
```

A query on partition_columns might return the following (truncated) results:

```sql
=> SELECT * FROM partition_columns order by table_name, column_name;
```

<table>

**PARTITION_REORGANIZE_ERRORS**

new column `projection_id`

Monitors all background partitioning tasks, and if Vertica encounters an error, creates an entry in this table with the appropriate information. Does not log repartitioning tasks that complete successfully.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

**PARTITION_STATUS**

For each projection of each partitioned table, shows the fraction of its data that is actually partitioned according to the current partition expression. When the partitioning of a table is altered, the value in PARTITION_REORGANIZE_PERCENT for each of its projections drops to zero and goes back up to 100 when all the data is repartitioned.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the schema that contains the partitioned table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Table name that is partitioned.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica, which identifies the table.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>Schema containing the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Projection name for which information is listed.</td>
</tr>
<tr>
<td>PARTITION_REORGANIZE_PERCENT</td>
<td>INTEGER</td>
<td>For each projection, drops to zero and goes back up to 100 when all the data is repartitioned after the partitioning of a table has been altered. Ideally all rows will show 100 (%).</td>
</tr>
</tbody>
</table>
Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

PARTITIONS

Displays partition metadata, one row per partition key, per ROS container.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARTITION_KEY</td>
<td>VARCHAR</td>
<td>The partition value(s).</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The projection name for which information is listed.</td>
</tr>
<tr>
<td>ROS_ID</td>
<td>VARCHAR</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the ROS container.</td>
</tr>
<tr>
<td>ROS_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The ROS container size in bytes.</td>
</tr>
<tr>
<td>ROS_ROW_COUNT</td>
<td>INTEGER</td>
<td>Number of rows in the ROS container.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node where the ROS container resides.</td>
</tr>
<tr>
<td>DELETED_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows in the partition.</td>
</tr>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR</td>
<td>The location label of the default storage location.</td>
</tr>
</tbody>
</table>

Notes

- A many-to-many relationship exists between partitions and ROS containers. PARTITIONS displays information in a denormalized fashion.
To find the number of ROS containers having data of a specific partition, aggregate PARTITIONS over the partition_key column.

To find the number of partitions stored in a ROS container, aggregate PARTITIONS over the ros_id column.

Example

See Viewing Partition Storage Data in the Administrator's Guide.

**PROCESS SIGNALS**

Returns a history of signals that were received and handled by the Vertica process. For details about signals, see the Linux documentation.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGNAL_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica recorded the signal.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>SIGNAL_NUMBER</td>
<td>INTEGER</td>
<td>Signal number, refers to POSIX SIGNAL_NUMBER</td>
</tr>
<tr>
<td>SIGNAL_CODE</td>
<td>INTEGER</td>
<td>Signal code.</td>
</tr>
<tr>
<td>SIGNAL_PID</td>
<td>INTEGER</td>
<td>Linux process identifier of the signal.</td>
</tr>
<tr>
<td>SIGNAL_UID</td>
<td>INTEGER</td>
<td>Process ID of sending process.</td>
</tr>
<tr>
<td>SIGNAL_ADDRESS</td>
<td>INTEGER</td>
<td>Address at which fault occurred.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser
PROJECTION_RECOVERIES

Retains history about projection recoveries. Because Vertica adds an entry per recovery plan, a projection/node pair might appear multiple times in the output.

**Note:** You cannot query this or other system tables during cluster recovery; the cluster must be UP to accept connections.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is recovering or has recovered the corresponding projection.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Name of the projection that is being or has been recovered on the corresponding node.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any. TRANSACTION_ID initializes as NO_TRANSACTION with a value of 0. Vertica will ignore the recovery query and keep (0) if there's no action to take (no data in the table, etc). When no recovery transaction starts, ignored value appears in this table's STATUS column.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>METHOD</td>
<td>VARCHAR</td>
<td>Recovery method that Vertica chooses. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• incremental</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• incremental-replay-delete</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• split</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• recovery-by-container</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| STATUS      | VARCHAR   | Current projection-recovery status on the corresponding node. STATUS can be "queued," which indicates a brief period between the time the query is prepared and when it runs. Possible values are:  
  - queued  
  - running  
  - finished  
  - ignored  
  - error-retry  
  - error-fatal |
| PROGRESS    | INTEGER   | An estimate (value in the range [0,100]) of percent complete for the recovery task described by this information.  
  Note: The actual amount of time it takes to complete a recovery task depends on a number of factors, including concurrent workloads and characteristics of the data; therefore, accuracy of this estimate can vary.  
  The PROGRESS column value is NULL after the task completes. |
| DETAIL      | VARCHAR   | More detailed information about PROGRESS. The values returned for this column depend on the type of recovery plan:  
  - General recovery plans – value displays the estimated progress, as a percent, of the three primary parts of the plan: Scan, Sort, and Write.  
  - Recovery-by-container plans – value begins with CopyStorage: and is followed by the number of bytes copied over the total number of bytes to copy. |
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>replay</td>
<td></td>
<td>• Replay delete plans – value begins with Delete: and is followed by the number of deletes replayed over an estimate of the total number of deletes to replay. The DETAIL column value becomes NULL after the recovery plan completes.</td>
</tr>
<tr>
<td>start_time</td>
<td>TIMESTAMPTZ</td>
<td>Time the recovery task described by this information started.</td>
</tr>
<tr>
<td>end_time</td>
<td>TIMESTAMPTZ</td>
<td>Time the recovery task described by this information ended.</td>
</tr>
<tr>
<td>runtime_priority</td>
<td>VARCHAR</td>
<td>Determines the amount of runtime resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool. Valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HIGH</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MEDIUM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOW</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

**See Also**

*RECOVERY_STATUS*

**PROJECTION_REFRESHES**

System table PROJECTION_REFRESHES records information about refresh operations, successful and unsuccessful. PROJECTION_REFRESHES retains refresh data until one of the
following events occurs:

- **CLEAR_PROJECTION_REFRESHES** is called.
- The table's storage quota is exceeded.

Tables and projections can be dropped while a query runs against them. The query continues to run, even after the drop occurs. Only when the query finishes does it notice the drop, which might cause a rollback. The same is true for refresh queries. Thus, **PROJECTION_REFRESHES** might report that a projection failed to be refreshed before the refresh query completes. In this case, the **REFRESH_DURATION_SEC** column continues to increase until the refresh query completes.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node where the refresh was initiated.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the projection schema.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Name of the refreshed projection.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the projection's anchor table.</td>
</tr>
<tr>
<td>REFRESH_STATUS</td>
<td>VARCHAR</td>
<td>Status of refresh operations for this projection, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Queued : Projection is queued for refresh.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Refreshing: Projection refresh is in progress.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Refreshed: Projection refresh is complete.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Failed: Projection refresh failed.</td>
</tr>
<tr>
<td>REFRESH_PHASE</td>
<td>VARCHAR</td>
<td>Indicates how far the refresh has progressed:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Historical: Refresh reached the first phase and is refreshing data from historical data. This refresh phase requires the most amount of time.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Current: Refresh reached the final phase and is</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>attempting to refresh data from the current epoch. To complete this phase, refresh must obtain a lock on the table. If the table is locked by another transaction, refresh is blocked until that transaction completes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The LOCKS system table is useful for determining if a refresh is blocked on a table lock. To determine if a refresh has been blocked, locate the term &quot;refresh&quot; in the transaction description. A refresh has been blocked when the scope for the refresh is REQUESTED and other transactions acquired a lock on the table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field is NULL until the projection starts to refresh and is NULL after the refresh completes.</td>
</tr>
<tr>
<td>REFRESH_METHOD</td>
<td>VARCHAR</td>
<td>Method used to refresh the projection:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Buddy: Projection refreshed from the contents of a buddy projection. This method maintains historical data, so the projection can used for historical queries.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Scratch: Projection refreshed without using a buddy projection. This method does not generate historical data, so the projection cannot participate in historical queries on data that precedes the refresh.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Rebalance: If the projection is segmented, it is refreshed from scratch; if unsegmented, it is refreshed from a buddy projection.</td>
</tr>
<tr>
<td>REFRESH_FAILURE_COUNT</td>
<td>INTEGER</td>
<td>Number of times a refresh failed for the projection. REFRESH_FAILURE_COUNT does not indicate whether the projection was eventually refreshed. See REFRESH_STATUS to determine whether the refresh operation is progressing.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the refresh session.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>REFRESH_START</td>
<td>TIMESTAMPTZ</td>
<td>Time the projection refresh started.</td>
</tr>
<tr>
<td>REFRESH_DURATION_SEC</td>
<td>INTERVAL SECOND (0)</td>
<td>How many seconds the projection refresh ran.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Differentiates active and completed refresh operations.</td>
</tr>
</tbody>
</table>
| RUNTIME_PRIORITY         | VARCHAR         | Determines how many run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool, one of the following:  
  - HIGH  
  - MEDIUM  
  - LOW |
| TRANSACTION_ID           | INTEGER         | Identifier for the transaction within the session, if any; otherwise NULL. |

**Note:** The transaction_id is correlated with the execution plan only when refreshing from scratch. When refreshing from a buddy, multiple sub-transactions are created.

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

**PROJECTION_STORAGE**

Monitors the amount of disk storage used by each projection on each node.

**Note:** Projections that have no data never have full statistics. Querying this system table lets you see if your projection contains data.
<table>
<thead>
<tr>

**PROJECTION_USAGE**

Records information about projections Vertica used in each processed query.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY_START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Value of query at beginning of history interval.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>IO_TYPE</td>
<td>VARCHAR</td>
<td>Input/output.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>

<td>VARCHAR</td>
<td>Name of the projection's associated anchor table.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

**QUERY_EVENTS**

Returns information about query planning, optimization, and execution events.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica recorded the event.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifier of the user for the query event.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user for which Vertica lists query information at the time it recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EVENT_CATEGORY</td>
<td>VARCHAR</td>
<td>Category of event: OPTIMIZATION or EXECUTION.</td>
</tr>
<tr>
<td>EVENT_TYPE</td>
<td>VARCHAR</td>
<td>Type of event. For more information, refer to the Event Types table on this page.</td>
</tr>
<tr>
<td>EVENT_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Generic description of the event.</td>
</tr>
<tr>
<td>OPERATOR_NAME</td>
<td>VARCHAR</td>
<td>Name of the Execution Engine component that generated the event, if applicable; for example, NetworkSend. Values from the OPERATOR_NAME and PATH_ID columns let you tie a query event back to a particular operator in the query plan. If the event did not come from a specific operator, the OPERATOR_NAME column is NULL.</td>
</tr>
<tr>
<td>PATH_ID</td>
<td>INTEGER</td>
<td>Unique identifier that Vertica assigns to a query operation or path in a query plan. If the event did not come from a specific operator, the PATH_ID column is NULL. See EXECUTION ENGINE PROFILES for more information.</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>Object identifier (such as projection or table) to which the event refers.</td>
</tr>
<tr>
<td>EVENT_DETAILS</td>
<td>VARCHAR</td>
<td>Free-form text describing the specific event.</td>
</tr>
<tr>
<td>SUGGESTED_ACTION</td>
<td>VARCHAR</td>
<td>Suggested user action, if any is available.</td>
</tr>
</tbody>
</table>

The following table lists informational event types.

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIP_FALLBACK</td>
<td>This optimization did not apply to this query type.</td>
</tr>
<tr>
<td>SMALL_MERGE_REPLACED</td>
<td>Vertica has chosen a more efficient way to access the data by replacing a merge.</td>
</tr>
<tr>
<td>STORAGE_CONTAINERS_ELIMINATED</td>
<td>Vertica has performed partition pruning for the purpose of optimization.</td>
</tr>
<tr>
<td>GROUPBY_PUSHDOWN</td>
<td>(Message is Internal to Vertica.)</td>
</tr>
<tr>
<td>Event Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NO GROUPBY PUSHDOWN</td>
<td>(Message is Internal to Vertica.)</td>
</tr>
<tr>
<td>VALUE_TRUNCATED</td>
<td>A character value is too long.</td>
</tr>
<tr>
<td>GROUP_BY_PREPASS_FALLBACK</td>
<td>Vertica could not run an optimization. In-memory prepass is disabled. The projection may not be optimal.</td>
</tr>
<tr>
<td>MERGE_CONVERTED_TO_UNION</td>
<td>Vertica has converted a merge operator to a union operator due to the sort order of the multi-threaded storage access stream.</td>
</tr>
<tr>
<td>TRANSITIVE PREDICATE</td>
<td>Vertica has optimized by adding predicates to joins where it makes logical sense to do so.</td>
</tr>
<tr>
<td></td>
<td>For example, for the statement, SELECT * FROM A, B WHERE A.a = B.a AND A.a = 1; Vertica may add a predicate B a = 1 as a filter for better storage access of table B.</td>
</tr>
<tr>
<td>NODE PRUNING</td>
<td>Vertica has performed node pruning, which is similar to partition pruning, but at the node level.</td>
</tr>
<tr>
<td>SEQUENCE CACHE REFILLED</td>
<td>Vertica has refilled sequence cache.</td>
</tr>
<tr>
<td>OUTER OVERRIDE USED</td>
<td>For efficiency and optimization, Vertica has swapped the inner/outer tables in a join. Vertica used the smaller table as the inner table.</td>
</tr>
<tr>
<td>OUTER OVERRIDE NOT USED</td>
<td>Vertica found swapping inner/outer tables in a join unnecessary because the inner/outer tables were in good order. (For example, a smaller table was used in an inner join.)</td>
</tr>
<tr>
<td>EXTERNAL_PREDICATE_PUSHDOWN_NOT_SUPPORTED</td>
<td>Predicate pushdown for older Hive versions may not be supported. For more information, see Improving Query Performance for Data Stored in HDFS.</td>
</tr>
<tr>
<td>LibHDFS++ UNSUPPORTED OPERATION</td>
<td>Vertica accessed HDFS using the hdfs URL scheme, but the HDFS cluster uses an unsupported feature such as wire encryption or HTTPS_ONLY. Vertica fell back to WebHDFS.</td>
</tr>
</tbody>
</table>
Vertica attempted to contact a Name Node on an HDFS cluster that uses High Availability Name Node and did not receive a response. Vertica retried with a different Name Node.

The following table lists event types that you should review for possible corrective action.

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP_BY_SPIPPED</td>
<td>This event type is typically related to a specific type of query, which you may need to adjust.</td>
<td>Identify the type of query and make adjustments accordingly. You may need to adjust resource pools, projections, or the amount of RAM available. Try running the query on a cluster with no additional workload.</td>
</tr>
<tr>
<td>RESEGMENTED_MANY_ROWS</td>
<td>This event type is typically related to a specific type of query, which you may need to adjust.</td>
<td>Do projections need to be segmented in a different way to allow for join locality? Can you rewrite the query to filter out more rows at storage access time? (Typically, Vertica does so automatically through predicate pushdown.) Review your explain plan.</td>
</tr>
<tr>
<td>RLE_OVERRIDDEN</td>
<td>The average run counts are not large enough for Run Length Encoding (RLE). This event occurs with queries where the filtered results for certain columns do not work with RLE because cardinality is less than 10.</td>
<td>Review and rewrite your query, if necessary.</td>
</tr>
<tr>
<td>PREDICATE OUTSIDE HISTOGRAM</td>
<td>A predicate value you are trying to match does not exist in a set</td>
<td>Review and rewrite your query, if necessary.</td>
</tr>
</tbody>
</table>
of possible values for a specific column. For example, you try to match a VARCHAR value WHERE mystring = "ABC\newline". In this case, the newline character throws off the predicate matching optimizations.

The following table lists more critical event types, and recommends actions you can take to resolve issues.

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>WOS_SPILL</td>
<td>WOS ran out of memory, and began spilling to ROS.</td>
<td>Try one or more of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Adjust the load process to run bigger batches less frequently.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Give the WOS resource pool more memory.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Increase how often the Tuple Mover moveout and mergeout processes run for high ingest rates. (Adjustment of the moveout process helps avoid ROS issues.)</td>
</tr>
<tr>
<td>NO HISTOGRAM</td>
<td>Indicates a table does not have an updated column histogram.</td>
<td>Running the function ANALYZE_STATISTICS most often corrects this issue.</td>
</tr>
<tr>
<td>MEMORY LIMIT HIT</td>
<td>Indicates query complexity or, possibly, lack of available system memory.</td>
<td>Consider adjusting the MAXMEMORYSIZE and PLANNEDCONCURRENCY resource pools so that the optimizer has sufficient memory. On a heavily used system, this event may occur more frequently.</td>
</tr>
<tr>
<td>Event Type</td>
<td>Description</td>
<td>Action</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DELETE WITH NON OPTIMIZED PROJECTION</td>
<td>One or more projections do not have your delete filter column in their sort order, causing Vertica difficulty identifying rows to mark as deleted.</td>
<td>Add the delete filter column to the end of every projection sort order for your target delete table.</td>
</tr>
<tr>
<td>JOIN_SPILLED</td>
<td>Vertica has spilled a join to disk. A join spill event slows down the subject query and all other queries as it consumes resources while using disk as virtual memory.</td>
<td>Try the following (in sequence):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Review the explain plan. The query could be too ambitious, for example, cross joining two large tables.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Consider adding the query to a lower priority pool to reduce impact on other queries.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Create projections that allow for a merge join instead of a hash join.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Adjust the PLANNEDCONCURRENCY resource pool so that queries have more memory to execute.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

<td>EXECUTED_QUERY_COUNT</td>
<td>INTEGER</td>
<td>The total number of queries that ran.</td>
</tr>
</tbody>
</table>

**QUERY_PLAN_PROFILES**

Provides detailed execution status for queries that are currently running in the system. Output from the table shows the real-time flow of data and the time and resources consumed for each path in each query plan.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>An identifier for the transaction within the session if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session; these columns are useful for creating joins with other system tables.</td>
</tr>
<tr>
<td>PATH_ID</td>
<td>INTEGER</td>
<td>Unique identifier that Vertica assigns to a query operation or path in a query plan. Textual representation for this path is output in the PATH_LINE column.</td>
</tr>
<tr>
<td>PATH_LINE_INDEX</td>
<td>INTEGER</td>
<td>Each plan path in QUERY_PLAN_PROFILES could be represented with multiple rows. PATH_LINE_INDEX returns the relative line order. You should include the PATH_LINE_INDEX column in the QUERY_PLAN_PROFILES ... ORDER BY clause so rows in the result set appear as they do in EXPLAIN-generated query plans.</td>
</tr>
<tr>
<td>PATH_IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Status of a path in the query plan. True (t) if the path has started running, otherwise false.</td>
</tr>
<tr>
<td>PATH_IS_COMPLETE</td>
<td>BOOLEAN</td>
<td>Status of a path in the query plan. True (t) if the path has finished running, otherwise false.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Status of a running query. True if the query is currently active (t), otherwise false (f).</td>
</tr>
<tr>
<td>RUNNING_TIME</td>
<td>INTERVAL</td>
<td>The amount of elapsed time the query path took to execute.</td>
</tr>
<tr>
<td>MEMORY_ALLOCATED_BYTES</td>
<td>INTEGER</td>
<td>The amount of memory the path used, in bytes.</td>
</tr>
<tr>
<td>READ_FROM_DISK_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes the path read from disk (or the disk cache).</td>
</tr>
<tr>
<td>RECEIVED_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes received over the network.</td>
</tr>
<tr>
<td>SENT_BYTES</td>
<td>INTEGER</td>
<td>Size of data sent over the network by the path.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PATH_LINE</td>
<td>VARCHAR</td>
<td>The query plan text string for the path, associated with the PATH ID and PATH_LINE_INDEX columns.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only the records that correspond to tables they have permissions to view.

**Best Practices**

Table results can be very wide. For best results when you query the QUERY_PLAN_PROFILES table, sort on these columns:

- TRANSACTION_ID
- STATEMENT_ID
- PATH_ID
- PATH_LINE_INDEX

For example:

```
=> SELECT ... FROM query_plan_profiles
   WHERE ...
   ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

**Example**

See [Profiling Query Plans](#) in the Administrator's Guide

- [EXPLAIN](#)
### QUERY_PROFILES

Provides information about executed queries.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The identification of the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>An identifier for the transaction within the session if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>IDENTIFIER</td>
<td>VARCHAR</td>
<td>A string to identify the query in system tables.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> You can query the IDENTIFIER column to quickly identify queries you have labeled for profiling and debugging. See Labeling Queries in the Administrator’s Guide for details.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>QUERY</td>
<td>VARCHAR</td>
<td>The query string used for the query.</td>
</tr>
<tr>
<td>QUERY_SEARCH_PATH</td>
<td>VARCHAR</td>
<td>A list of schemas in which to look for tables.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name in which the query is being profiled, set only for load operations.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name in the query being profiled, set only for load operations.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------</td>
<td>------------------------------------------------------------------</td>
</tr>
<tr>
<td>QUERY_DURATION_US</td>
<td>NUMERIC (18, 0)</td>
<td>The duration of the query in microseconds.</td>
</tr>
<tr>
<td>QUERY_START_EPOCH</td>
<td>INTEGER</td>
<td>The epoch number at the start of the given query.</td>
</tr>
<tr>
<td>QUERY_START</td>
<td>VARCHAR</td>
<td>The Linux system time of query execution in a format that can be used as a DATE/TIME expression.</td>
</tr>
<tr>
<td>QUERY_TYPE</td>
<td>VARCHAR</td>
<td>Is one of INSERT, SELECT, UPDATE, DELETE, UTILITY, or UNKNOWN.</td>
</tr>
<tr>
<td>ERROR_CODE</td>
<td>INTEGER</td>
<td>The return error code for the query.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user who ran the query.</td>
</tr>
<tr>
<td>PROCESSED_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows returned by the query.</td>
</tr>
<tr>
<td>RESERVED_EXTRA_MEMORY_B</td>
<td>INTEGER</td>
<td>Shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator. This is the memory from which unbounded operators pull first.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Displays information about actively running queries, regardless of whether profiling is enabled.</td>
</tr>
</tbody>
</table>

**QUERY_REQUESTS**

Returns information about user-issued query requests.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who issued the query at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>REQUEST_TYPE</td>
<td>VARCHAR</td>
<td>Type of the query request. Examples include, but are not limited to: QUERY, DDL, LOAD, UTILITY, TRANSACTION, PREPARE, EXECUTE, SET, SHOW</td>
</tr>
<tr>
<td>REQUEST</td>
<td>VARCHAR</td>
<td>Query statement.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
REQUEST_LABEL | VARCHAR | Label of the query, if available.
SEARCH_PATH | VARCHAR | Contents of the search path.
MEMORY_ACQUIRED_MB | FLOAT | Memory acquired by this query request in megabytes.
SUCCESS | BOOLEAN | Value returned if the query successfully executed.
ERROR_COUNT | INTEGER | Number of errors encountered in this query request (logged in ERROR_MESSAGES table).
START_TIMESTAMP | TIMESTAMPTZ | Beginning of history interval.
END_TIMESTAMP | TIMESTAMPTZ | End of history interval.
REQUEST_DURATION | TIMESTAMPTZ | Length of time the query ran in days, hours, minutes, second, and milliseconds.
REQUEST_DURATION_MS | INTEGER | Length of time the query ran in milliseconds.
IS_EXECUTING | BOOLEAN | Distinguishes between actively-running (t) and completed (f) queries.

### Privileges
No explicit privileges are required. You can only see the records for requests associated with your user name. Users with SYSMONITOR Role or DBADMIN Role can see all records from all users.

### Example

```sql
=> SELECT * FROM QUERY_REQUESTS;
```

```
node_name | v_vmart_node0001
user_name | dbadmin
session_id | v_vmart_node0001-321039:0x3a
request_id | 404
transaction_id | 45035996274380645
statement_id | 1
request_type | DDL
request | GRANT EXECUTE ON FUNCTION public.STV_SetExportShapefileDirectory() TO dbadmin;
request_label |
search_path | "$user", public, v_catalog, v_monitor, v_internal
```

REPARENTED_ON_DROP

Lists re-parenting events of objects dropped from their original owner but still remain in Vertica. For example, a user may leave the organization and needs to be removed from the database. When the dbadmin drops the user from the database that user's objects are re-parented to another user.

In some cases a Vertica user's objects are reassigned based on the GlobalHeirUserName parameter. In this case a user's objects are re-parented to the user indicated by this parameter.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPARENT_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time the re-parenting event occurred.</td>
</tr>
<tr>

<td>- Acquire: [Internal] related to the optimizer and other internal services, such as the Database Designer</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Acquire additional: [Internal] related to size adjustment of acquisitions obtained through the first two methods; unusual, outside the WOS</td>
</tr>
<tr>
<td>POOL_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the resource pool. The ID represents the initial pool, even if the request has been moved to a new pool due to cascade. For more information about cascade events, see RESOURCE_POOL_MOVE.</td>
</tr>
<tr>
<td>POOL_NAME</td>
<td>VARCHAR</td>
<td>Name of the resource pool. The name represents the initial pool, even if the request has been moved to a new pool due to cascade. For more information about cascade events, see RESOURCE_POOL_MOVE.</td>
</tr>
<tr>
<td>THREAD_COUNT</td>
<td>INTEGER</td>
<td>Number of threads in use by this request.</td>
</tr>
<tr>
<td>OPEN_FILE_HANDLE_COUNT</td>
<td>INTEGER</td>
<td>Number of open file handles in use by this request.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MEMORY_INUSE_KB</td>
<td>INTEGER</td>
<td>Total amount of memory in kilobytes acquired by this query. Column RESERVED_EXTRA_MEMORY_B in system table QUERY_PROFILES shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator. If operators for a query acquire all memory specified by MEMORY_INUSE_KB, the plan must request more memory from the Vertica resource manager.</td>
</tr>
<tr>
<td>QUEUE_ENTRY_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the request was queued at the Resource Manager.</td>
</tr>
<tr>
<td>ACQUISITION_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the request was admitted to run. See the Notes section below for the difference between these two timestamps.</td>
</tr>
<tr>
<td>RELEASE_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica released this resource acquisition.</td>
</tr>
<tr>
<td>DURATION_MS</td>
<td>INTEGER</td>
<td>Duration of the resource request in milliseconds.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Denotes if the query holding the resource is still executing (t).</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

**Notes**

When monitoring resource pools and resource usage by queries, the “queue wait” time is the difference between ACQUISITION_TIMESTAMP and QUEUE_ENTRY_TIMESTAMP. For example, to determine how long a query waits in the queue before it is admitted to run, you
can get the difference between the ACQUISITION_TIMESTAMP and the QUEUE_ENTRY_TIMESTAMP using a query like the following:

```sql
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp, 
   (acquisition_timestamp - queue_entry_timestamp) AS 'queue wait'
FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE 'node0001';
```

RESOURCE_REJECTION

RESOURCE_POOL_STATUS

Provides configuration settings of the various resource pools in the system, including internal pools. For detailed information about resource parameters, see CREATE RESOURCE POOL or ALTER RESOURCE POOL.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node for which information is provided.</td>
</tr>
<tr>
<td>POOL_OID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the pool and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>POOL_NAME</td>
<td>VARCHAR</td>
<td>The name of the resource pool.</td>
</tr>
<tr>
<td>IS_INTERNAL</td>
<td>BOOLEAN</td>
<td>Denotes whether a pool is one of the Built-In Pools.</td>
</tr>
<tr>
<td>MEMORY_SIZE_KB</td>
<td>INTEGER</td>
<td>Value of MEMORYSIZE setting of the pool in kilobytes.</td>
</tr>
</tbody>
</table>
| MEMORY_SIZE_ACTUAL_KB | INTEGER | Current amount of memory, in kilobytes, allocated to the pool by the resource manager. The actual size can be less than specified in the DDL, if both the following conditions exist:
  - The pool has been recently altered in a running system.
  - The request to shuffle memory is pending. |
<p>| MEMORY_INUSE_KB  | INTEGER   | Amount of memory, in kilobytes, acquired by requests running against this pool. |
| GENERAL_MEMORY_BORROWED_KB | INTEGER | Amount of memory, in kilobytes, borrowed from the GENERAL pool by requests running against this pool. The sum of MEMORY_INUSE_KB and GENERAL_MEMORY_BORROWED_KB should be less than MAX_MEMORY_SIZE_KB. |</p>
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUEUEING_THRESHOLD_KB</td>
<td>INTEGER</td>
<td>Calculated as MAX_MEMORY_SIZE_KB * 0.95. When the amount of memory used by all requests against this resource pool exceeds the QUEUEING_THRESHOLD_KB, new requests against the pool are queued until memory becomes available.</td>
</tr>
<tr>
<td>MAX_MEMORY_SIZE_KB</td>
<td>INTEGER</td>
<td>Value, in kilobytes, of the MAXMEMORYSIZE parameter specified when defining the pool. After this threshold is reached, new requests against this pool are rejected or queued until memory becomes available.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MAX_MEMORY_SIZE_KB might not reflect the set MAXMEMORYSIZE parameter value if the specified value cannot be reached.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>If MAXMEMORYSIZE = 10G, but less than 2G is available, MAX_MEMORY_SIZE_KB will not reflect the original value in KB, but will instead reflect 2G in KB, since that is the highest value that can be reached.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Ordinarily, the ALTER RESOURCE POOL and CREATE RESOURCE POOL statements provide error messages to prevent setting the MAXMEMORYSIZE to a value greater than available, but making system changes or other configuration changes can cause this scenario.</td>
</tr>
<tr>
<td>RUNNING_QUERY_COUNT</td>
<td>INTEGER</td>
<td>Number of queries actually running using this pool.</td>
</tr>
<tr>

<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LOCK_REJECTION_COUNT</td>
<td>INTEGER</td>
<td>The number of times a lock was rejected during a session.</td>
</tr>
<tr>
<td>LOCK_ERROR_COUNT</td>
<td>INTEGER</td>
<td>The number of lock errors encountered during the session.</td>
</tr>
<tr>
<td>CLIENT_TYPE</td>
<td>VARCHAR</td>
<td>The type of client from which the connection was made. Possible client type values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ADO.NET Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ODBC Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• JDBC Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• vsql</td>
</tr>
<tr>
<td>CLIENT_VERSION</td>
<td>VARCHAR</td>
<td>Returns the client version.</td>
</tr>
<tr>
<td>CLIENT_OS</td>
<td>VARCHAR</td>
<td>Returns the client operating system.</td>
</tr>
<tr>
<td>CLIENT_OS_USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.</td>
</tr>
</tbody>
</table>

**See Also**

LOCKS

**SESSION_SUBSCRIPTIONS**

Lists the session subscriptions in the database. Shows the session’s view of the node subscriptions. Session subscriptions are used when running queries within the session.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_OID</td>
<td>INTEGER</td>
<td>The OID of the node.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
NODE_NAME | VARCHAR | The name of the subscribed node.
SHARD_OID | INTEGER | The OID of the shard.
SHARD_NAME | VARCHAR | The name of the shard the node is subscribed to.
IS_PARTICIPATING | BOOLEAN | Defines whether or not the subscription is participating in the session.

```sql
=> SELECT * FROM SESSION_SUBSCRIPTIONS;

| node_oid    | 45035996273704978 |
| node_name   | v_eon_db_node0001 |
| shard_oid   | 45035996273704980 |
| shard_name  | replica           |
| is_participating | t                 |
```

### SESSIONS

Monitors external sessions. Use this table to perform the following tasks:

- Identify users who are running lengthy queries.
- Identify users who hold locks because of an idle but uncommitted transaction.
- Determine the details of the database security used for a particular session, either Secure Socket Layer (SSL) or client authentication.
- Identify client-specific information, such as client version.

**Note:** During session initialization and termination, you might see sessions running only on nodes other than the node on which you ran the virtual table query. This is a temporary situation that corrects itself when session initialization and termination complete.

| Column Name | Data Type | Description
--- | --- | ---
NODE_NAME | VARCHAR | The node name for which information is listed.
USER_NAME | VARCHAR | The name used to log in to the database or NULL if the session is internal.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal. Vertica accepts either IPv4 or IPv6 connections from a client machine. If the client machine contains mappings for both IPv4 and IPv6, the server randomly chooses one IP address family to make a connection. This can cause the CLIENT_HOSTNAME column to display either IPv4 or IPv6 values, based on which address family the server chooses.</td>
</tr>
<tr>
<td>CLIENT_PID</td>
<td>INTEGER</td>
<td>The process identifier of the client process that issued this connection. Remember that the client process could be on a different machine than the server.</td>
</tr>
<tr>
<td>LOGIN_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The date and time the user logged into the database or when the internal session was created. This field can help you identify sessions that have been left open for a period of time and could be idle.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The identifier required to close or interrupt a session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>IDLE_SESSION_TIMEOUT</td>
<td>VARCHAR</td>
<td>Specifies how long this session can remain idle before timing out, set by <code>SET SESSION IDLESESSIONTIMEOUT</code>.</td>
</tr>
<tr>
<td>GRACE_PERIOD</td>
<td>VARCHAR</td>
<td>Specifies how long a session socket remains blocked while awaiting client input or output for a given query, set by <code>SET SESSION GRACEPERIOD</code>. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT_LABEL</td>
<td>VARCHAR</td>
<td>A user-specified label for the client connection that can be set when using ODBC. See Label in Data Source Name (DSN) Connection Properties in Connecting to Vertica. An MC output value means there is a client connection to an MC-managed database for that USER_NAME.</td>
</tr>
<tr>
<td>TRANSACTION_START</td>
<td>DATE</td>
<td>The date/time the current transaction started or NULL if no transaction is running.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>A string containing the hexadecimal representation of the transaction ID, if any; otherwise, NULL.</td>
</tr>
<tr>
<td>TRANSACTION_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Description of the current transaction.</td>
</tr>
<tr>
<td>STATEMENT_START</td>
<td>TIMESTAMP</td>
<td>The timestamp the current statement started execution, or NULL if no statement is running.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the currently-executing statement. A value of NULL indicates that no statement is currently being processed.</td>
</tr>
<tr>
<td>LAST_STATEMENT_DURATION_US</td>
<td>INTEGER</td>
<td>The duration of the last completed statement in microseconds.</td>
</tr>
<tr>
<td>RUNTIME_PRIORITY</td>
<td>VARCHAR</td>
<td>Specifies how many run-time resources (CPU, I/O bandwidth) are allocated to queries that are running in the resource pool.</td>
</tr>
<tr>
<td>CURRENT_STATEMENT</td>
<td>VARCHAR</td>
<td>The currently executing statement, if any. NULL indicates that no statement is currently being processed.</td>
</tr>
<tr>
<td>LAST_STATEMENT</td>
<td>VARCHAR</td>
<td>NULL if the user has just logged in; otherwise the currently running statement or the most recently completed statement.</td>
</tr>
<tr>
<td>SSL_STATE</td>
<td>VARCHAR</td>
<td>Indicates if Vertica used Secure Socket Layer (SSL).</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AUTHENTICATION_METHOD</td>
<td>VARCHAR</td>
<td>The type of client authentication used for a particular session, if known. Possible values are: \n  • Unknown \n  • Trust \n  • Reject \n  • Hash \n  • Ident \n  • LDAP \n  • GSS \n  • TLS \n  See <a href="#">Security and Authentication</a> and <a href="#">TLS/SSL Server Authentication</a>.</td>
</tr>
<tr>
<td>CLIENT_TYPE</td>
<td>VARCHAR</td>
<td>The type of client from which the connection was made. Possible client type values: \n  • ADO.NET Driver \n  • ODBC Driver \n  • JDBC Driver</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• vsql</td>
</tr>
<tr>
<td>CLIENT_VERSION</td>
<td>VARCHAR</td>
<td>Client version.</td>
</tr>
<tr>
<td>CLIENT_OS</td>
<td>VARCHAR</td>
<td>Client operating system.</td>
</tr>
<tr>
<td>CLIENT_OS_USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.</td>
</tr>
<tr>
<td>CLIENT_AUTHENTICATION_NAME</td>
<td>VARCHAR</td>
<td>User-assigned name of the authentication method.</td>
</tr>
<tr>
<td>CLIENT_AUTHENTICATION</td>
<td>INTEGER</td>
<td>Object identifier of the client authentication method.</td>
</tr>
<tr>
<td>REQUESTED_PROTOCOL</td>
<td>INTEGER</td>
<td>The requested protocol to be used when connecting.</td>
</tr>
<tr>
<td>EFFECTIVE_PROTOCOL</td>
<td>INTEGER</td>
<td>The protocol used when connecting.</td>
</tr>
<tr>
<td>EXTERNAL_MEMORY_KB</td>
<td>INTEGER</td>
<td>Amount of memory consumed by the Java Virtual Machines associated with the session.</td>
</tr>
</tbody>
</table>

**Privileges**

A superuser has unrestricted access to all session information. Users can view information only about their own, current sessions.

**See Also**

- `CLOSE_SESSION`

<td>SCHEMA_NAME*</td>
<td>VARCHAR</td>
<td>Schema name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_ID*</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME*</td>
<td>VARCHAR</td>
<td>Projection name for which information is listed on that node.</td>
</tr>
<tr>
<td>STORAGE_TYPE*</td>
<td>VARCHAR</td>
<td>Type of storage container: ROS or WOS.</td>
</tr>
<tr>
<td>STORAGE_OID*</td>
<td>INTEGER</td>
<td>Numeric ID assigned by the Vertica catalog, which identifies the storage.</td>
</tr>
<tr>
<td>SAL_STORAGE_ID</td>
<td>VARCHAR</td>
<td>Unique hexadecimal numeric ID assigned by the Vertica catalog, which identifies the storage.</td>
</tr>
<tr>
<td>TOTAL_ROW_COUNT*</td>
<td>VARCHAR</td>
<td>Total rows in the storage container listed for that projection.</td>
</tr>
<tr>
<td>DELETED_ROW_COUNT*</td>
<td>INTEGER</td>
<td>Total rows in the storage container deleted for that projection.</td>
</tr>
<tr>
<td>USED_BYTES*</td>
<td>INTEGER</td>
<td>Total bytes in the storage container listed for that projection.</td>
</tr>
<tr>
<td>START_EPOCH*</td>
<td>INTEGER</td>
<td>Number of the start epoch in the storage container for which information is listed.</td>
</tr>
<tr>
<td>END_EPOCH*</td>
<td>INTEGER</td>
<td>Number of the end epoch in the storage container for which information is listed.</td>
</tr>
<tr>
<td>GROUPING</td>
<td>VARCHAR</td>
<td>The group by which columns are stored:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ALL: All columns are grouped</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- PROJECTION: Columns grouped according to projection definition</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- NONE: No columns grouped, despite grouping in the projection definition</td>
</tr>
</tbody>
</table>

* Column values cached for faster query performance
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>

<td>INTEGER</td>
<td>Lower bound of the segment range spanned by the storage container or NULL if the corresponding projection is not elastic.</td>
</tr>
<tr>
<td>SEGMENT_UPPER_BOUND</td>
<td>INTEGER</td>
<td>Upper bound of the segment range spanned by the storage container or NULL if the corresponding projection is not elastic.</td>
</tr>
<tr>
<td>IS_SORTED</td>
<td>BOOLEAN</td>
<td>Whether the storage container’s data is sorted (WOS containers only).</td>
</tr>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR (128)</td>
<td>The location label (if any) for the storage container is stored.</td>
</tr>
<tr>
<td>DELETE_VECTOR_COUNT</td>
<td>INTEGER</td>
<td>The number of delete vectors in the storage container.</td>
</tr>
</tbody>
</table>

* Column values cached for faster query performance, continued

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

**STORAGE_POLICIES**

Monitors the current storage policies in effect for one or more database objects.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>Schema name for which information is listed.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the database object associated through the storage policy.</td>
</tr>
<tr>
<td>POLICYDETAILS</td>
<td>VARCHAR</td>
<td>The object type of the storage policy.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR</td>
<td>The label for this storage location.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR</td>
<td>The label associated with a specific storage location. The storage_tiers system table includes data totals for unlabeled locations, which are considered labeled with empty strings ('').</td>
</tr>
<tr>
<td>NODE_COUNT</td>
<td>INTEGER</td>
<td>The total number of nodes that include a storage location named location_label.</td>
</tr>
<tr>
<td>LOCATION_COUNT</td>
<td>INTEGER</td>
<td>The total number of storage locations named location_label. This value can differ from node_count if you create</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
| | | labeled locations with the same name at different paths on different nodes. For example: 
| | | vVmart_node0001: Create one labeled location, FAST 
| | | VVmart_node0002: Create two labeled locations, FAST, at different directory paths 
| | | In this case, node_count value = 2, while location_count value = 3. 
| ROS_CONTAINER_COUNT | INTEGER | The total number of ROS containers stored across all cluster nodes for location_label. 
| TOTAL_OCCUPIED_SIZE | INTEGER | The total number of bytes that all ROS containers for location_label occupy across all cluster nodes. 

### Privileges
None

STRATA

Contains internal details of how the Tuple Mover combines ROS containers in each projection, broken down by stratum and classifies the ROS containers by size and partition. The related STRATA_STRUCTURES table provides a summary of the strata values.

Mergeout in the Administrator's Guide describes how the Tuple Mover combines ROS containers.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The projection name for which information is listed on that node.</td>
</tr>
<tr>
<td>PARTITION_KEY</td>
<td>VARCHAR</td>
<td>References the partition or partition group for which information is listed.</td>
</tr>
<tr>
<td>STRATA_COUNT</td>
<td>INTEGER</td>
<td>The total number of strata for this projection partition.</td>
</tr>
<tr>
<td>MERGING_STRATA_COUNT</td>
<td>INTEGER</td>
<td>The number of strata the Tuple Mover can merge out.</td>
</tr>
<tr>
<td>STRATUM_CAPACITY</td>
<td>INTEGER</td>
<td>The maximum number of ROS containers for the stratum before they must be merged.</td>
</tr>
<tr>
<td>STRATUM_HEIGHT</td>
<td>FLOAT</td>
<td>The size ratio between the smallest and largest ROS container in this stratum.</td>
</tr>
<tr>
<td>STRATUM_NO</td>
<td>INTEGER</td>
<td>The stratum number. Strata are numbered starting at 0, for the stratum containing the smallest ROS containers.</td>
</tr>
<tr>
<td>STRATUM_LOWER_SIZE</td>
<td>VARCHAR</td>
<td>The smallest ROS container size allowed in this stratum.</td>
</tr>
<tr>
<td>STRATUM_UPPER_SIZE</td>
<td>VARCHAR</td>
<td>The largest ROS container size allowed in this stratum.</td>
</tr>
<tr>
<td>ROS_CONTAINER_COUNT</td>
<td>INTEGER</td>
<td>The current number of ROS containers in the projection partition.</td>
</tr>
</tbody>
</table>

**STRATA_STRUCTURES**

This table provides an overview of Tuple Mover internal details. It summarizes how the ROS containers are classified by size. A more detailed view can be found in the STRATA virtual table.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>

**TABLE_RECOVERIES**

Provides detailed information about recovered and recovering tables during a recovery by table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is performing the recovery.</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>The status of the table. Tables can have the following status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• recovered - The table is fully recovered</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• recovering - The table is in the process of recovery</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• error_retry - Vertica has attempted to recover the table, but the recovery failed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tables that have not yet begun the recovery process do not have a status.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table being recovered.</td>
</tr>
<tr>
<td>TABLE_OID</td>
<td>INTEGER</td>
<td>The object ID of the table being recovered.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMPZ</td>
<td>The date and time that the table began recovery.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMPZ</td>
<td>The date and time that the table completed recovery.</td>
</tr>
<tr>
<td>PHASE</td>
<td>VARCHAR</td>
<td>The phase of the recovery.</td>
</tr>
<tr>
<td>RECOVER_PRIORITY</td>
<td>INTEGER</td>
<td>The recovery priority of the table being recovered.</td>
</tr>
<tr>
<td>THREAD_ID</td>
<td>VARCHAR</td>
<td>The ID of the thread that performed the recovery.</td>
</tr>
</tbody>
</table>

**Privileges**

None
TABLE_RECOVERY_STATUS

Provides node recovery information during a Recovery By Table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is performing the recovery.</td>
</tr>
<tr>
<td>NODE_RECOVERY_START_TIME</td>
<td>TIMESTAMPZ</td>
<td>The timestamp for when the node began recovering.</td>
</tr>
<tr>
<td>IS_RUNNING</td>
<td>BOOLEAN</td>
<td>Indicates if the recovery process is still running.</td>
</tr>
<tr>
<td>RECOVER_EPOCH</td>
<td>INTEGER</td>
<td>The epoch that the recovery operation is trying to recover to.</td>
</tr>
<tr>
<td>RECOVERING_TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table currently recovering.</td>
</tr>
<tr>
<td>RECOVERED_TABLE_COUNT</td>
<td>INTEGER</td>
<td>Indicates how many tables on the node have already recovered.</td>
</tr>
<tr>
<td>TABLE_COUNT</td>
<td>INTEGER</td>
<td>The total number of tables on the node.</td>
</tr>
</tbody>
</table>

Privileges

None

TRANSACTIONS

Records the details of each transaction.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Beginning of history interval.</td>
</tr>
<tr>
<td>END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>End of history interval.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user for which transaction information is listed.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>Textual description of the transaction.</td>
</tr>
<tr>
<td>START_EPOCH</td>
<td>INTEGER</td>
<td>Number of the start epoch for the transaction.</td>
</tr>
<tr>
<td>END_EPOCH</td>
<td>INTEGER</td>
<td>Number of the end epoch for the transaction</td>
</tr>
<tr>
<td>NUMBER_OF_STATEMENTS</td>
<td>INTEGER</td>
<td>Number of query statements executed in this transaction.</td>
</tr>
<tr>
<td>ISOLATION</td>
<td>VARCHAR</td>
<td>Denotes the transaction mode as &quot;READ COMMITTED&quot; or &quot;SERIALIZABLE&quot;.</td>
</tr>
<tr>
<td>IS_READ_ONLY</td>
<td>BOOLEAN</td>
<td>Denotes &quot;READ ONLY&quot; transaction mode.</td>
</tr>
<tr>
<td>IS_COMMITTED</td>
<td>BOOLEAN</td>
<td>Determines if the transaction was committed. False means ROLLBACK.</td>
</tr>
<tr>
<td>IS_LOCAL</td>
<td>BOOLEAN</td>
<td>Denotes transaction is local (non-distributed).</td>
</tr>
<tr>
<td>IS_INITIATOR</td>
<td>BOOLEAN</td>
<td>Denotes if the transaction occurred on this node (t).</td>
</tr>
<tr>
<td>IS_DDL</td>
<td>BOOLEAN</td>
<td>Distinguishes between a DDL transaction (t) and non-DDL transaction (f).</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit privileges are required. You only see the records for tables that you have privileges to view.

TRUNCATED_SCHEMA

Lists the original names of restored schemas that were truncated due to name lengths exceeding 128 characters.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESTORE_TIME</td>
<td>TIMESTAMPZ</td>
<td>The time that the table was restored.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for the restoring session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifier of the user for the restore event.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user for which Vertica lists restore information at the time it recorded the session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>ORIGINAL_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The original name of the schema prior to the restore.</td>
</tr>
<tr>
<td>NEW_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema after it was truncated.</td>
</tr>
</tbody>
</table>

Privileges

None

TUNING_RECOMMENDATIONS

Returns tuning recommendation results from the last ANALYZE_WORKLOAD call. This information is useful for letting you build filters on the Workload Analyzer result set.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>observation_count</td>
<td>INTEGER</td>
<td>Integer for the total number of events observed for this tuning recommendation. For example, if you see a return value of 1, WLA is making its first tuning recommendation for the event in 'scope'.</td>
</tr>
<tr>
<td>first_observation_time</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the event first occurred. If this column returns a null value, the tuning recommendation is from the current status of the system instead of from any prior event.</td>
</tr>
<tr>
<td>last_observation_time</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the event last occurred. If this column returns a null value, the tuning recommendation is from the current status of the system instead of from any prior event.</td>
</tr>
<tr>
<td>tuning_parameter</td>
<td>VARCHAR</td>
<td>Objects on which you should perform a tuning action. For example, a return value of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• public.t informs the DBA to run Database Designer on table t in the public schema</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• bsmith notifies a DBA to set a password for user bsmith</td>
</tr>
<tr>
<td>tuning_description</td>
<td>VARCHAR</td>
<td>Textual description of the tuning recommendation from the Workload Analyzer to perform on the tuning_parameter object. Examples of some of the returned values include, but are not limited to:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Run database designer on table schema.table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Create replicated projection for table schema.table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Consider incremental design on query</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Reset configuration parameter with ALTER DATABASE dbName SET parameter = value;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Re-segment projection projection-name on high-cardinality column(s)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Drop the projection projection-name</td>

<tr>
<td></td>
<td></td>
<td>• Alter a table's partition expression</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Reorganize data in partitioned table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Decrease the MoveOutInterval configuration parameter setting</td>
</tr>
<tr>
<td>tuning_command</td>
<td>VARCHAR</td>
<td>Command string if tuning action is a SQL command. For example, the following example statements recommend that the DBA:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Update statistics on a particular schema's table.column:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SELECT ANALYZE_STATISTICS('public.table.column');</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Resolve mismatched configuration parameter 'LockTimeout':</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'LockTimeout';</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set the password for user bsmith:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ALTER USER (user) IDENTIFIED BY ('new_password');</td>
</tr>
<tr>
<td>tuning_cost</td>
<td>VARCHAR</td>
<td>Cost is based on the type of tuning recommendation and is one of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOW—minimal impact on resources from running the tuning command</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MEDIUM—moderate impact on resources from running the tuning command</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HIGH—maximum impact on resources from running the tuning command</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Depending on the size of your database or table, consider running high-cost operations after hours instead of during peak load times.</td>
</tr>
</tbody>
</table>

### UDFS_EVENTS

Records information about events involving the S3 file system.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Starting timestamp of the event.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Ending time of the event.</td>
</tr>
<tr>
<td>FILESYSTEM</td>
<td>VARCHAR</td>
<td>Name of the file system, such as S3.</td>
</tr>
<tr>
<td>PATH</td>
<td>VARCHAR</td>
<td>Complete file path.</td>
</tr>
<tr>
<td>EVENT</td>
<td>VARCHAR</td>
<td>The function call that was made, for example &quot;virtual size_t SAL::S3FileOperator::read(void*, size_t)&quot;.</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>Status of the event: OK, CANCEL, or FAIL.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>Other details of the event. For example, a read event reports the size of what was read.</td>
</tr>
</tbody>
</table>

### UDFS_STATISTICS

Records aggregate information about operations on the S3 file system.

An operation can be made up of many individual read, write, or retry requests. SUCCESSFUL_OPERATIONS and FAILED_OPERATIONS count operations; the other counters count individual
requests. When an operation finishes, one of the OPERATIONS counters is incremented once, but several other counters could be incremented several times each.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILESYSTEM</td>
<td>VARCHAR</td>
<td>Name of the file system, such as S3.</td>
</tr>
<tr>
<td>SUCCESSFUL_OPERATIONS</td>
<td>INTEGER</td>
<td>Number of successful file-system operations.</td>
</tr>
<tr>
<td>FAILED_OPERATIONS</td>
<td>INTEGER</td>
<td>Number of failed file-system operations.</td>
</tr>
<tr>
<td>RETRIES</td>
<td>INTEGER</td>
<td>Number of retry events.</td>
</tr>
<tr>
<td>METADATA_READS</td>
<td>INTEGER</td>
<td>Number of requests to read metadata. For example, S3 list bucket and HEAD requests are metadata reads.</td>
</tr>
<tr>
<td>METADATA_WRITES</td>
<td>INTEGER</td>
<td>Number of requests to write metadata. For example, S3 POST and DELETE requests are metadata writes.</td>
</tr>
<tr>
<td>DATA_READS</td>
<td>INTEGER</td>
<td>Number of read operations, such as S3 GET requests to download files.</td>
</tr>
<tr>
<td>DATA_WRITES</td>
<td>INTEGER</td>
<td>Number of write operations, such as S3 PUT requests to upload files.</td>
</tr>
<tr>
<td>DOWNSTREAM_BYTES</td>
<td>INTEGER</td>
<td>Number of bytes received.</td>
</tr>
<tr>
<td>UPSTREAM_BYTES</td>
<td>INTEGER</td>
<td>Number of bytes sent.</td>
</tr>
</tbody>
</table>

**UDX_FENCED_PROCESSES**

Provides information about processes Vertica uses to run user-defined extensions in fenced mode.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>PROCESS_TYPE</td>
<td>VARCHAR</td>
<td>Indicates what kind of side process this row is for and can be one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- UDxZygoteProcess — Master process that creates worker side processes, as needed, for queries. There</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
 | | will be, at most, 1 UP UDxZygoteProcess for each Vertica instance.
 | | UDxSideProcess — Indicates that the process is a worker side process. There could be many UDxSideProcesses, depending on how many sessions there are, how many queries, and so on.

| SESSION_ID | VARCHAR | Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
| LANGUAGE | VARCHAR | The language of the UDx. For example 'R' or 'C++';
| MAX_MEMORY_JAVA_KB | INTEGER | The maximum amount of memory in KB that can be used for the Java heap file on the node.
| PID | INTEGER | Linux process identifier of the side process (UDxSideProcess).
| PORT | VARCHAR | For Vertica internal use. The TCP port that the side process is listening on.
| STATUS | VARCHAR | Set to UP or DOWN, depending on whether the process is alive or not.

After a process fails, Vertica restarts it only on demand. So after a process failure, there might be periods of time when no side processes run.

### Privileges
None

### USER_LIBRARIES

Lists the user libraries that are currently loaded. These libraries contain user-defined extensions (UDxs) that provide additional analytic functions.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR (8192)</td>
<td>The name of the schema containing the library.</td>
</tr>
<tr>
<td>LIB_NAME</td>
<td>VARCHAR (8192)</td>
<td>The name of the library.</td>
</tr>
<tr>
<td>LIB_OID</td>
<td>INTEGER</td>
<td>The object ID of the library.</td>
</tr>
<tr>
<td>AUTHOR</td>
<td>VARCHAR (8192)</td>
<td>The creator of the library file.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>The object ID of the library's owner.</td>
</tr>
<tr>
<td>LIB_FILE_NAME</td>
<td>VARCHAR (8192)</td>
<td>The name of the shared library file.</td>
</tr>
<tr>
<td>MD5_SUM</td>
<td>VARCHAR (8192)</td>
<td>The MD5 checksum of the library file, used to verify that the file was correctly copied to each node. Note: This use of MD5 is not for cryptographic or authentication purposes. For information on authenticating with MD5 see Hash Authentication.</td>
</tr>
<tr>
<td>SDK_VERSION</td>
<td>VARCHAR (8192)</td>
<td>The version of the Vertica SDK used to compile the library.</td>
</tr>
<tr>
<td>REVISION</td>
<td>VARCHAR (8192)</td>
<td>The revision of the Vertica SDK used to compile the library.</td>
</tr>
<tr>
<td>LIB_BUILD_TAG</td>
<td>VARCHAR (8192)</td>
<td>Internal information set by library developer to track the when the library was compiled.</td>
</tr>
<tr>
<td>LIB_VERSION</td>
<td>VARCHAR (8192)</td>
<td>The version of the library.</td>
</tr>
<tr>
<td>LIB_SDK_VERSION</td>
<td>VARCHAR (8192)</td>
<td>The version of the Vertica SDK intended for use with the library. The developer sets this value manually. This value may differ from the values in the SDK_VERSION and REVISION, which are set automatically during compilation.</td>
</tr>
<tr>
<td>SOURCE_URL</td>
<td>VARCHAR (8192)</td>
<td>A URL that contains information about the library.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR (8192)</td>
<td>A description of the library.</td>
</tr>
<tr>
<td>LICENSES_REQUIRED</td>
<td>VARCHAR (8192)</td>
<td>The licenses required to use the library.</td>
</tr>
<tr>
<td>SIGNATURE</td>
<td>VARCHAR (8192)</td>
<td>The signature used to sign the library for validation.</td>
</tr>
<tr>
<td>DEPENDENCIES</td>
<td>VARCHAR (8192)</td>
<td>External libraries on which this library depends. These libraries are</td>
</tr>
<tr>
<td></td>
<td></td>
<td>maintained by Vertica, just like the user libraries themselves.</td>
</tr>
</tbody>
</table>

**USER_LIBRARY_MANIFEST**

Lists user-defined functions contained in all loaded user libraries.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema containing the function.</td>
</tr>
<tr>
<td>LIB_NAME</td>
<td>VARCHAR</td>
<td>The name of the library containing the UDF.</td>
</tr>
<tr>
<td>LIB_OID</td>
<td>INTEGER</td>
<td>The object ID of the library containing the function.</td>
</tr>
<tr>
<td>OBJ_NAME</td>
<td>VARCHAR</td>
<td>The name of the constructor class in the library for a function.</td>
</tr>
<tr>
<td>OBJ_TYPE</td>
<td>VARCHAR</td>
<td>The type of user defined function (scalar function, transform function)</td>
</tr>
<tr>
<td>ARG_TYPES</td>
<td>VARCHAR</td>
<td>A comma-delimited list of data types of the function's parameters.</td>
</tr>
<tr>
<td>RETURN_TYPE</td>
<td>VARCHAR</td>
<td>A comma-delimited list of data types of the function's return values.</td>
</tr>
</tbody>
</table>
Privileges

None

USER_SESSIONS

Returns user session history on the system.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>

Appendix: Compatibility with Other RDBMS

This section describes compatibility of Vertica with other relational database management systems.

Information in this appendix is intended to simplify database migration to Vertica.

Data Type Mappings Between Vertica and Oracle

Oracle uses proprietary data types for all main data types (for example, VARCHAR, INTEGER, FLOAT, DATE), if you plan to migrate your database from Oracle to Vertica, [[[Undefined variable _Branding_Variables._Company_Acronym]]] strongly recommends that you convert the schema—a simple and important exercise that can minimize errors and time lost spent fixing erroneous data issues.

The following table compares the behavior of Oracle data types to Vertica data types.

<table>
<thead>
<tr>
<th>Oracle</th>
<th>Vertica</th>
<th>Notes</th>
</tr>
</thead>
</table>
| NUMBER (no explicit precision)  | INTEGER, NUMERIC or FLOAT | In Oracle, the NUMBER data type with no explicit precision stores each number N as an integer M, together with a scale S. The scale can range from -84 to 127, while the precision of M is limited to 38 digits. So \( N = M \times 10^S \).

When precision is specified, precision/scale applies to all entries in the column. If omitted, the scale defaults to 0.

For the common case where Oracle’s NUMBER with no explicit precision data type is used to store only integer values, INTEGER is the best suited and the fastest Vertica data type. However, INTEGER (the same as BIGINT) is limited to a little less than 19 digits, with a scale of 0; if the Oracle column contains integer values outside of the range \([-9223372036854775807, +9223372036854775807]\), use the Vertica data type NUMERIC\((p,0)\) where \(p\) is the maximum number of digits required to represent the
<table>
<thead>
<tr>
<th>Oracle</th>
<th>Vertica</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{NUMBER (P,0),} \hspace{1cm} P \leq 18</td>
<td>\texttt{INTEGER}</td>
<td>In Oracle, when precision is specified the precision/scale applies to all entries in the column. If omitted the scale defaults to 0. For the Oracle \texttt{NUMBER} data type with 0 scale, and a precision less than or equal to 18, use \texttt{INTEGER} in Vertica.</td>
</tr>
<tr>
<td>\texttt{NUMBER (P,0),} \hspace{1cm} P &gt; 18</td>
<td>\texttt{NUMERIC (p,0)}</td>
<td>An Oracle column precision greater than 18 is often more than an application really needs. If all values in the Oracle column are within the INT range ([-9223372036854775807,+9223372036854775807]), use \texttt{INTEGER} for best performance. Otherwise, use the Vertica data type \texttt{NUMERIC(p,0)}, where \texttt{p = P}.</td>
</tr>
<tr>
<td>\texttt{NUMBER (P,S)} \hspace{1cm} all cases other than previous</td>
<td>\texttt{NUMERIC (p,s)} or \texttt{FLOAT}</td>
<td>When \texttt{P} \geq \texttt{S} and \texttt{S} \geq 0, use \texttt{p = P} and \texttt{s = S}, unless the data allows reducing \texttt{P} or using \texttt{FLOAT} as discussed above. If \texttt{S} &gt; \texttt{P}, use \texttt{p = S}, \texttt{s = S}. If \texttt{S} &lt; 0, use \texttt{p = P - S}, \texttt{s = 0}.</td>
</tr>
</tbody>
</table>

values of \textit{N}.

Even though no explicit scale is specified for an Oracle \texttt{NUMBER} column, Oracle allows non-integer values, each with its own scale. If the data stored in the column is approximate, Vertica recommends using the Vertica data type \texttt{FLOAT}, which is standard IEEE floating point, like \texttt{ORACLE BINARY\_DOUBLE}. If the data is exact with fractional places, for example dollar amounts, Vertica recommends \texttt{NUMERIC(p,s)} where \texttt{p} is the precision (total number of digits) and \texttt{s} is the maximum scale (number of decimal places).

Vertica conforms to standard SQL, which requires that \texttt{p} \geq \texttt{s} and \texttt{s} \geq 0. Vertica’s \texttt{NUMERIC} data type is most effective for \texttt{p=18}, and increasingly expensive for \texttt{p=37, 58, 67, etc.}, where \texttt{p} \leq 1024.

Vertica recommends against using the data type \texttt{NUMERIC (38,s)} as a default "failsafe" mapping to guarantee no loss of precision. \texttt{NUMERIC (18,s)} is better, and \texttt{INTEGER} or \texttt{FLOAT} are better yet, if one of these data types will do the job.

</table>
Vertica provides tools and features that allow you to ensure your system is secure as well as to prevent unauthorized users from accessing sensitive information.

Client Authentication establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server.
Client Authentication

Implementing strong security programs provides Vertica users the assurance that access to sensitive information is closely guarded. Vertica uses several approaches to manage data access.

The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.

Encrypting Client-Server Communication

Vertica uses Secure Socket Layer (SSL) and Transport Layer Security (TLS) to establish a secure connection between the client machine and the server. Configure SSL/TLS to:

- Authenticate the server so the client can confirm the server's identity. Vertica supports mutual authentication in which the server can also confirm the identity of the client. This authentication helps prevent "man-in-the-middle" attacks.

- Encrypt data sent between the client and database server to significantly reduce the likelihood that the data can be read if the connection between the client and server is compromised.

- Verify that data sent between the client and server has not been altered during transmission.

For details see TLS/SSL Server Authentication.

Authentication Management

Users with the DBADMIN Role can manage the following authentication tasks:

- Create authentication records using CREATE AUTHENTICATION.
Important: Configure client authentication so that the DBADMIN user can always access the database locally. If a problem occurs with the authentication that blocks all users from logging in, the DBADMIN user needs access to correct the problem.

- Assign a specific authentication method to a user using GRANT (Authentication).
- Use ALTER AUTHENTICATION to:
  - Enable/disable authentication methods.
  - Define a default authentication method to be used if a user has not been assigned a specific authentication method.
- Define parameters required by LDAP, Ident, and Kerberos authentication methods.
- Revoke a user's authentication record using REVOKE Authentication. This user now uses the default authentication.
- Delete an authentication record from the database using DROP AUTHENTICATION. Any users assigned the dropped record now use the default authentication method.

For details about managing authentication records, see:

- DBADMIN Authentication Access
- Creating Authentication Records
- Enabling and Disabling Authentication Methods
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

See Implementing Client Authentication.

User Authorization

Database users should have access to just the database resources they need to perform their required tasks. For example, some users need to query only specific sets of data. To prevent unauthorized access to additional data, you can limit their access to just the data that they need to run their queries. Other users should be able to read the data but not be able to modify or insert new data. Still other users might need more permissive access, including the
right to create and modify schemas, tables, and views, or grant other users access to database resources.

For information on controlling data access, see the following:

- About Database Users in Managing Users and Privileges
- About Database Roles to grant users access to a set of privileges.
- Access Policies to limit user's from viewing data from a specific table.

**Implementing Client Authentication**

Vertica restricts which database users can connect through client authentication. The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.

When a user or client application connect to the Vertica database server, it supplies a unique user name and password to gain access.

Vertica offers several client authentication methods. You can configure Vertica to require just a user name for connections, you likely require more secure means of authentication, such as a password at a minimum.

**Note:** Topics in this section describe authentication methods supported at the database server layer. For information on authentication between server and client, see TLS/SSL Server Authentication.

**How Client Authentication Works**

When connecting to a Vertica database, a user or client application must supply the name of a valid user account. In addition, the application usually includes a means of authentication, such as a password or security certificate.

There are two types of client authentication:

- LOCAL—Authenticating users or applications that are trying to connect from the same node that the database is running on.
HOST—Authenticating users or applications that are trying to connect from a node that has a different IPv4 or IPv6 address than the database.

The DBADMIN user manages the client authentication information that the database uses to authenticate users.

Vertica takes the following steps to authenticate users:

1. When a user or application attempts to connect to a Vertica database, the system checks to see if the user is a DBADMIN user. If so, authentication occurs using the assigned authentication method, local trust or local hash authentication.

2. For non-DBADMIN users, the database checks to see if the user is associated with an authentication method through a GRANT statement. If so, the database allows the user to log in if they match the parameters required for that authentication method.

   Note: For detailed information on how authentication priorities work, see Priorities for Client Authentication Methods.

The DBADMIN user can grant an authentication method to users or user roles. The DBADMIN user can also create a default authentication method that Vertica uses when no authentication has been associated with a user or role.

3. If the user has not been granted an authentication method, the database checks to see if the DBADMIN has established a default authentication method.

4. If the DBADMIN has specified a default authentication method, the database authenticates the user using that default method.

5. If you have not specified a default authentication method, the database checks to see if the DBADMIN user has defined any authentication methods. If not, no authentication information exists in the database. However, if a password exists, the DBADMIN user can log in.

6. If authentication information exists, Vertica rejects the user request to connect to the database. The DBADMIN has not granted an authentication method for that user nor has the DBADMIN defined a default authentication method for all users ('public').

7. If no authentication records exist in the database, Vertica uses implicit trust/implicit password to authenticate the user.

The following image illustrates the steps involved in client authentication:
IPv4 and IPv6 for Client Authentication

Vertica supports clients using either the IPv4 or the IPv6 protocol to connect to the database server. Internal communication between database servers must consistently use one address.
family (IPv4 or IPv6). The client, however, can connect to the database from either type of IP address.

If the client will be connecting from either IPv4 or IPv6, you must create two authentication methods, one for each address. Any authentication method that uses HOST authentication requires an IP address.

For example, the first statement allows users to connect from any IPv4 address. The second statement allows users to connect from any IPv6 address:

```sql
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '::/0'; --IPv6
```

If you are using a literal IPv6 address in a URL, you must enclose the IPv6 address in square brackets as shown in the following examples:

```sql
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb:dbfa:0:65::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[:1]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]:5678';
```

If you are working with a multi-node cluster, any IP/netmask settings in (HOST, HOST TLS, HOST NO TLS) must match all nodes in the cluster. This setup allows the database owner to authenticate with and administer every node in the cluster. For example, specifying 10.10.0.8/30 allows a CIDR address range of 10.10.0.8–10.10.0.11.

For detailed information about IPv6 addresses, see RFC 1924 and RFC 2732.

**Supported Client Authentication Methods**

Vertica supports the following types of authentication to prove a client's identity.

- **Trust**—Authorizes any user that connects to the database using a valid user name, no password is required and authentication is not performed.

- **Reject**—Rejects the connection attempt when a user with an invalid user name attempts to connect to the database.

- **Kerberos (GSS)**—Authorizes connecting to the database using a MIT Kerberos implementation. The KDC must support Kerberos 5 using GSS-API. This API also provides compatibility with non-MIT Kerberos implementations, such as Java and Windows clients.
- Hash—Sends encrypted passwords hashed by the MD5 algorithm or the more secure SHA-512 method over the network. The server provides the client with salt.

- LDAP—Works like password authentication except the LDAP method authenticates the client against a Lightweight Directory Access Protocol or Active Directory server.

- Ident—Authenticates the client against the username in an Ident server.

- TLS authentication—Authenticates the client using digital certificates that contain a public key. Transport Layer Security (TLS) is the successor to Secure Sockets Layer (SSL) authentication.

## Local and Host Authentication

You can define a client authentication method as:

- Local: Local connection to the database.

- Host: Remote connection to the database from different hosts, each with their own IPv4 or IPv6 address and host parameters. For more information see IPv4 and IPv6 for Client Authentication above.

Some authentication methods cannot be designated as local, as listed in this table:

<table>
<thead>
<tr>
<th>Authentication Method</th>
<th>Local?</th>
<th>Host?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kerberos (GSS)</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Ident</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>LDAP</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Hash</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Reject</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Trust</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Authentication for Chained Users and Roles

Vertica supports creating chained users and roles, where you can grant ROLE2 privileges to ROLE1. All users in ROLE1 use the same authentication assigned to ROLE2. For example:

```sql
=> CREATE USER user1;
=> CREATE ROLE role1;
=> CREATE ROLE role2;
=> CREATE AUTHENTICATION h1 method 'hash' local;
=> GRANT AUTHENTICATION h1 to role2;
=> GRANT role2 to role1;
=> GRANT role1 to user1;
```

The user and role chain in the example above can be illustrated as follows:

auth1 -> role2 -> role1 -> user1

In this example, since role2 privileges are granted to role1 you only need to grant authentication to role2 to also enable it for role1.

DBADMIN Authentication Access

The DBADMIN user must have access to the database at all times.

The DBADMIN account must authenticate against the database using local trust or local hash authentication.

Vertica recommends that you create an authentication method (LOCAL TRUST or LOCAL PASSWORD) with a very high priority, say, 10,000. Grant this method to the DBADMIN user and set the priority using ALTER AUTHENTICATION.

With the high priority, this new authentication method supersedes any authentication methods you create for PUBLIC (which includes the DBADMIN user). Even if you make changes to PUBLIC authentication methods, the DBADMIN user can now connect to the database at any time.

This example shows how you configure local trust authentication for the DBADMIN user. As a result, the user can use vsql with the -h option and does not need to enter a password:

```sql
=> CREATE AUTHENTICATION v_dbadmin_trust METHOD 'trust' LOCAL;
=> GRANT AUTHENTICATION v_dbadmin_trust TO dbadmin;
=> ALTER AUTHENTICATION v_dbadmin_trust PRIORITY 10000;
```
The next example shows how you configure host hash authentication for DBADMIN. They allow the user to access the Vertica database using the assigned password from any IPv4 address. The DBADMIN user can access the database using vsq1 -h --host, the Administration Tools, or any other tools that connects to Vertica:

```sql
=> CREATE AUTHENTICATION v_dbadmin_hash METHOD 'hash' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION v_dbadmin_hash TO dbadmin;
=> ALTER AUTHENTICATION v_dbadmin_hash PRIORITY 10000;
=> SELECT SET_CONFIG_PARAMETER('SecurityAlgorithm', 'SHA512');
```

Note: Vertica supports IPv4 and IPv6 addresses. For more information, see IPv4 and IPv6 for Client Authentication.

## Creating Authentication Records

You can manage client authentication records using vsq1 commands. To use these statements, you must be connected to the database.

**Important:** You cannot modify client authentication records using the Administration Tools. The Administration Tools interface allows you to modify the contents of the `vertica.conf` file. However, Vertica ignores any client authentication information stored in that file.

You create authentication records with `CREATE AUTHENTICATION`, which Vertica stores in the catalog and automatically enables.

### Examples

The following examples show how to create authentication records.

Create authentication method `localpwd` to authenticate users who are trying to log in from a local host using a password:

```sql
=> CREATE AUTHENTICATION localpwd METHOD 'hash' LOCAL;
```

Create authentication method `v_ldap` that uses LDAP over TLS to authenticate users logging in from the host with the IPv4 address 10.0.0.0/23:

```sql
=> CREATE AUTHENTICATION v_ldap METHOD 'ldap' HOST TLS '10.0.0.0/23';
```

Create authentication method `v_kerberos` to authenticate users who are trying to connect from any host in the networks 2001:0db8:0001:12xx:
CREATE AUTHENTICATION v_kerberos METHOD 'gss' HOST '2001:db8:1::1200/56';

Create authentication method RejectNoSSL that rejects users from any IP address that are trying to authenticate without SSL/TLS:

CREATE AUTHENTICATION RejectNoSSL_IPv4 METHOD 'reject' HOST NO TLS '0.0.0.0/0'; --IPv4
CREATE AUTHENTICATION RejectNoSSL_IPv6 METHOD 'reject' HOST NO TLS '::/0'; --IPv6

- Deleting Authentication Records
- Enabling and Disabling Authentication Methods
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

Modifying Authentication Records

To modify existing authentication records, you must first be connected to your database. The following examples show how to make changes to your authentication records. For more information see ALTER AUTHENTICATION.

Rename an Authentication Method

Rename the v_kerberos authentication method to K5, and enable it. All users who have been associated with the v_kerberos authentication method are now associated with the K5 method granted instead.

ALTER AUTHENTICATION v_kerberos RENAME TO K5 ENABLE;
Specify a Priority for an Authentication Method

Specify a priority of 10 for K5 authentication:

```sql
=> ALTER AUTHENTICATION K5 PRIORITY 10;
```

For more information see Priorities for Client Authentication Methods.

Change a Parameter

Set the `system_users` parameter for `ident1` authentication to `root`:

```sql
=> CREATE AUTHENTICATION ident1 METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION ident1 SET system_users='root';
```

Change the IP address and specify the parameters for an LDAP authentication method named Ldap1.

In this example, you specify the bind parameters for the LDAP server. Vertica connects to the LDAP server, which authenticates the Vertica client. If the authentication succeeds, Vertica authenticates any users who have been granted the Ldap1 authentication method on the designated LDAP server:

```sql
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
    binddn_prefix='cn=', binddn_suffix=',dc=qa_domain,dc=com';
```

Change the IP address, and specify the parameters for an LDAP authentication method named Ldap1. Assume that Vertica does not have enough information to create the distinguished name (DN) for a user attempting to authenticate. Therefore, in this case, you must specify to use LDAP search and bind:

```sql
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
    basedn='dc=qa_domain,dc=com', binddn='cn=Manager,dc=qa_domain,dc=com',
    search_attribute='cn', bind_password='secret';
```
Change the Associated Method

Change the localpwd authentication from trust to hash:

```
=> CREATE AUTHENTICATION localpwd METHOD 'trust' LOCAL;
=> ALTER AUTHENTICATION localpwd METHOD 'hash';
```

ALTER AUTHENTICATION validates the parameters you enter. If there are errors, it disables the authentication method that you are trying to modify.

Using the Administration Tools

The advantages of using the Administration Tools are:

- You do not have to connect to the database
- The editor verifies that records are correctly formed
- The editor maintains records so they are available to you to edit later

**Note:** You must restart the database to implement your changes.

For information about using the Administration Tools to create and edit authentication records, see [Creating Authentication Records](#).

Using the Client Authentication Configuration Parameter

The advantage of using the ClientAuthentication configuration parameter is that the changes are implemented immediately across all nodes within the database cluster. You do not need to restart the database.

However, all the database nodes must be up and you must [connect to the database](#) before you set this parameter. Most importantly, this method does not verify that records are correctly formed and it does not maintain the records so you can modify them later.
New authentication records are appended to the list of existing authentication records. Because Vertica scans the list of records from top to bottom and uses the first record that matches the incoming connection, you might find your newly-added record does not have an effect if Vertica used an earlier record instead.

To configure client authentication through a connection parameter, use the `ALTER DATABASE` statement:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'connection type user name address method';
```

When you specify authentication records, make sure to adhere to the following guidelines:

- Fields that make up the record can be separated by white space or tabs
- Other than IP addresses and mask columns, field values cannot contain white space

### Examples

The following example creates an authentication record for the trust method:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'hostssl dbadmin 0.0.0.0/0 trust';
```

The following example creates an authentication record for the LDAP method:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'host all 10.0.0.0/8
ldap "ldap://summit.vertica.com;cn=;,dc=vertica,dc=com"';
```

The following example specifies three authentication records. In a single command, separate each authentication record by a comma:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'hostssl dbadmin 0.0.0.0/0 trust, hostssl all 0.0.0.0/0 md5, local all trust';
```

### Deleting Authentication Records

To delete client authentication record, use `DROP AUTHENTICATION`. To use this approach, you have to be connected to your database.

To delete an authentication record for md5_auth use the following command:

```
=> DROP AUTHENTICATION md5_auth;
```

To delete an authentication record for a method that has been granted to a user, use the `CASCADE` keyword:
CREATE AUTHENTICATION localpwd METHOD 'password' LOCAL;
GRANT AUTHENTICATION localpwd TO jsmith;
DROP AUTHENTICATION localpwd CASCADE;

See Also

- Creating Authentication Records
- Granting and Revoking Authentication Methods

Priorities for Client Authentication Methods

You can associate one or more authentication methods to a connection or user. For a user who has multiple authentication methods, specify the order in which Vertica should try them. To do so, assign a priority to each authentication method using ALTER AUTHENTICATION. All priority values should be a non-negative INTEGER.

Higher values indicate higher priorities. Vertica tries to authenticate a user with an authentication method in order of priority from highest to lowest. For example:

- A priority of 10 is higher than a priority of 5.
- A priority 0 is the lowest possible value.

Important: Vertica does not support authentication chaining where you can configure multiple authentication modules to identify a specific user. For example, chaining to try a password authentication method after an LDAP authentication method failed is not supported.

Priority Order for Authentication Methods

When you associate multiple authentication methods with a connection, Vertica uses the following order to determine how to authenticate the client:

- Administrator-assigned priority for an individual method
- The most specific IP addresses have priority over the least specific IP addresses
For example, the IPv4 address 10.3.4.128/25 has priority over 10.3.0.0/24, which in turn has priority over 10.3.0.0/16. The IPv6 address 2001:db8:ab::123/128 has priority over 2001:db8:1::1200/56.

- Reject
- GSS | LDAP | Ident
- Hash
- Trust

**Authentication Attempts Using Multiple Methods**

If there is only one authentication method associated with a user, Vertica uses that method to authenticate the login attempt.

If the administrator has associated multiple authentication methods with a given user or IP address, Vertica tries to authenticate as follows:

- If the highest priority authentication method is Ident and authentication fails, Vertica tries the next highest priority authentication method, regardless of what method it uses.

  If the next attempt does not use Ident authentication and fails, the authentication process ends. However, if the next attempt uses Ident and fails, Vertica continues to the next highest priority method. This process continues until authentication is successful or a non-Ident authentication attempt fails.

- If the highest priority method is LDAP and authentication fails, Vertica searches for the next highest priority LDAP method. Authentication attempts continue until the authentication is successful, or there are no additional LDAP authentication methods that satisfy the connection criteria.

  Note that if a user not found error occurs during LDAP authentication, the retry connection attempt initiates only if you set the ldap_continue parameter to yes.

- For all other authentication types, Vertica tries the highest priority authentication method associated with that user. If that authentication fails, the authentication process stops.

For example, suppose there are two client authentication methods associated with a user, as follows:
When user tries to connect to the database, Vertica first tries auth_name2 to authenticate because it has a higher priority. If that fails, Vertica tries auth_name1. If that fails, authentication fails.

### Specifying Authentication Method Priority

To specify priorities for client authentication methods, use `ALTER AUTHENTICATION`. The priority value must be a non-negative INTEGER. Higher numbers indicate a higher priority. The default value, 0, is the lowest possible priority.

The syntax is:

```
ALTER AUTHENTICATION <name> ... PRIORITY <priority_value>;
```

If you do not specify a priority, or omit the `<priority_value>` when using `ALTER AUTHENTICATION`, Vertica sets the priority to 0.

### DBADMIN and Authentication Priority

To allow the DBADMIN user to connect to the database at any time, Vertica recommends that you create an authentication method (LOCAL TRUST or LOCAL PASSWORD) with a very high priority, such as 10,000. Grant this method to the DBADMIN user, and set the priority using `ALTER AUTHENTICATION`.

With the high priority, this new authentication method supersedes any authentication methods you create for PUBLIC (which includes the DBADMIN user). Even if you make changes to PUBLIC authentication methods, the DBADMIN still has access.

**Note:** For the DBADMIN user to be able to perform all Admintools functions, the DBADMIN must always be able to authenticate by LOCAL TRUST or LOCAL PASSWORD (the default for DBADMIN user). If you have changed DBADMIN user authentication from LOCAL TRUST or LOCAL PASSWORD, use the `ALTER AUTHENTICATION` statement to once again give the DBADMIN user LOCAL TRUST or LOCAL PASSWORD authentication.
Viewing Information About Client Authentication Records

For information about client authentication records that you have configured for your database, query the following system tables in the V_CATALOG schema:

- CLIENT_AUTH
- CLIENT_AUTH_PARAMS
- PASSWORD_AUDITOR
- USER_CLIENT_AUTH

To determine the details behind the client authentication used for a particular user session, query the following tables in the V_MONITOR schema:

- SESSIONS
- USER_SESSIONS

Enabling and Disabling Authentication Methods

When you create an authentication method, Vertica stores it in the catalog and enables it automatically. To enable or disable an authentication method, use the ALTER AUTHENTICATION statement. To use this approach, you must be connected to your database.

If an authentication method has not been enabled, Vertica cannot use it to authenticate users and clients trying to connect to the database.

To enable an authentication method:

```
ALTER AUTHENTICATION v_kerberos ENABLE;
```

To disable this authentication method:

```
ALTER AUTHENTICATION v_kerberos DISABLE;
```
See Also

- Creating Authentication Records
- Deleting Authentication Records
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

Granting and Revoking Authentication Methods

Before Vertica can validate a user or client through an authentication method, you must first associate that authentication method with the user or role that requires it. To do this, use GRANT AUTHENTICATION. When that user or role no longer needs to connect to Vertica using that method, you can disassociate that authentication from that user with REVOKE AUTHENTICATION.

Grant Authentication Methods

You can grant an authentication method to a specific user or role. You can also specify the default authentication method by granting an authentication method to Public. Use the GRANT (Authentication) statement as follows:

This example uses a GRANT AUTHENTICATION statement to associate v_ldap authentication with user jsmith:

```sql
=> GRANT AUTHENTICATION v_ldap TO jsmith;
```

This example uses a GRANT AUTHENTICATION statement to associate v_gss authentication to the role DBprogrammer:

```sql
=> CREATE ROLE DBprogrammer;
=> GRANT AUTHENTICATION v_gss to DBprogrammer;
```

This example sets the default client authentication method to v_localpwd:
=> GRANT AUTHENTICATION v_localpwd TO Public;

Revoke Authentication Methods

If you no longer want to authenticate a user or client with a given authentication method, use the `REVOKE (Authentication)` statement as follows:

This example revokes `v_ldap` authentication from user `jsmith`:

=> REVOKE AUTHENTICATION v_ldap FROM jsmith;

This example revokes `v_gss` authentication from the role `DBprogrammer`:

=> REVOKE AUTHENTICATION v_gss FROM DBprogrammer;

This example removes `localpwd` as the default client authentication method:

=> REVOKE AUTHENTICATION localpwd from Public;

Hash Authentication

Vertica provides a hash authentication method that allows you to use the MD5 algorithm or the more secure algorithm, SHA-512, to store user passwords. SHA-512 is one of the industry-standard SHA-2 family of hash algorithms that address weaknesses in SHA-1 and MD5. For information on creating passwords to be hashed during authentication see Passwords

Note: Vertica strongly recommends that you use SHA-512 for hash authentication because it is more secure than MD5.

Before you perform hash authentication, review the following topics:

- **Hash Authentication Parameters**—Describes the two hash authentication parameters that specify which hashing algorithm to use.

- **Upgrade Considerations for Hash Authentication**—Before you implement the SHA-512 algorithm for one or more users, you must be aware of several issues. For details, review this topic before proceeding.

- **How to Configure Hash Authentication**—After you decide to implement hash authentication in your database, follow the steps described in this topic.
Hash Authentication Parameters

Two parameters control which algorithm hash authentication uses for hashing and storing user passwords:

- A user-level parameter, Security_Algorithm:

  => ALTER USER username SECURITY_ALGORITHM 'MD5' IDENTIFIED BY 'newpassword';
  => ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';

- A system-level configuration parameter, SecurityAlgorithm:

  => SELECT SET_CONFIG_PARAMETER('SecurityAlgorithm', 'MD5');
  => SELECT SET_CONFIG_PARAMETER('SecurityAlgorithm', 'SHA512');

Both parameters can have the following values:

- 'NONE'
- 'MD5'
- 'SHA512'

Note: If your current password is in the MD5 format you cannot rename a user with ALTER USER.

The user-level parameter usually has precedence over the system-level parameter. However, if the user-level parameter is 'NONE', Vertica hashes passwords with the algorithm assigned to the system-level parameter value. If both parameters are 'NONE', Vertica uses the MD5 algorithm.

These values, which are stored in the PASSWORD_AUDITOR system table, affect the security algorithm that is actually used for hash authentication.

How to Configure Hash Authentication

Follow these steps to configure hash authentication:

1. Create an authentication method that is based on hash encryption. When you create an authentication method, it is automatically enabled for use.

   The following example shows how to create an authentication method v_hash for users logging in from the IP address 10.0.0.0/0.

   ```
   => CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '10.0.0.0/0';
   ```

   If users are trying to connect from an IPv6 address, the statement might look like this example:

   ```
   => CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '2001:db8:ab::123/128';
   ```

2. Decide which password-hashing algorithm you want to use: MD5 or the more secure SHA-512.

3. Specify the security algorithm as follows:
At the system level, set the SecurityAlgorithm configuration parameter. This setting applies to all users, unless their user-level security is set to another value:

```sql
=> ALTER DATABASE mydb SET SecurityAlgorithm = 'MD5';
=> ALTER DATABASE mydb SET SecurityAlgorithm = 'SHA512';
```

If you want users to inherit the system-level security, set their passwords to expire immediately. Users must change their passwords before they log in again. Alternatively, you can ask users to change their passwords. Vertica hashes all new passwords using the system-level security algorithm.

At the user level, use `ALTER USER` to set the Security_Algorithm user parameter. Changing this parameter at the user level overrides the system-level value:

```sql
=> ALTER USER username SECURITY_ALGORITHM 'MD5' IDENTIFIED BY 'newpassword';
=> ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
```

4. Associate the `v_hash` authentication method with the desired users or user roles, using a `GRANT` statement:

```sql
=> GRANT AUTHENTICATION v_hash to user1, user2, ...;
```

For more information about how these parameters work, see [Hash Authentication Parameters](#).

### Upgrade Considerations for Hash Authentication

For Vertica releases before 7.1, MD5 is the only algorithm used for hashing passwords. In Vertica 7.1, you can use either the MDS algorithm or the more secure SHA-512 algorithm. Before you upgrade, you must consider the following behaviors to avoid problems.

### Upgrade the Client and Server

To implement the more secure SHA-512 algorithm for hashing passwords, you *must* upgrade BOTH the client and the server to Vertica 7.1 or higher. If you upgrade the server but not the client and specify that one or more users store their passwords using SHA-512, the client does not understand hashing with SHA-512. When it sends a message to the server, the server returns an error.
Change Existing Users to SHA-512 Hash Algorithm

When you upgrade from a pre-7.1 database, the user-level parameter Security_Algorithm, is set to 'NONE'. This allows all existing users to continue connecting to the Vertica server and their passwords are hashed using MD5.

If you want one or more users to use the SHA-512 algorithm, set the system-level parameter Security Algorithm to 'SHA512' and change the user passwords.

Use one of three methods to change the user password:

- Manually set the user's user-level security algorithm to 'SHA512'. Then, change the user’s password, as in the following statement:

  ```sql
  => ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
  ```

- Set the user's password to expire immediately as in the following statement. After the password expires, the user responds by changing it.

  ```sql
  => ALTER USER username PASSWORD EXPIRE;
  ```

- Ask the user to change the password.

All new passwords inherit the system-level security algorithm, which is SHA-512.

Passwords

Assign a password to a user to allow that user to connect to the database using password authentication. When the user supplies the correct password a connection to the database occurs.

Vertica stores passwords in an encrypted format to prevent potential theft. However, the transmission of the password to Vertica is in plain text. Thus, it is possible for a "man-in-the-middle" attack to intercept the password.

Implementing Hash Authentication ensures secure login using passwords.

About Password Creation and Modification

You must be a superuser to create passwords for user accounts using the CREATE USER statement. A superuser can set any user account's password.
To add a password, use the ALTER USER statement.

To change a password, use ALTER USER or the vsql \password command.

Users can also change their own passwords.

To make password authentication more effective, Vertica recommends that you enforce password policies that control how often users are forced to change passwords and the required content of a password. You set these policies using Profiles.

Default Password Authentication

When you have not specified any authentication methods, Vertica defaults to using password authentication for user accounts that have passwords.

If you create authentication methods, even for remote hosts, password authentication is disabled. In such cases, you must explicitly enable password authentication. The following commands create the local_pwd authentication method and make it the default for all users.

When you create an authentication method, Vertica enables it automatically:

```
=> CREATE AUTHENTICATION local_pwd METHOD hash' LOCAL;
=> GRANT AUTHENTICATION local_pwd To Public;
```

Profiles

You can set password policies for users by assigning them profiles. You can create multiple profiles to manage the password policies for several categories of users. For example, you might create one profile for interactive users, requiring them to frequently change their passwords. You might create another profile for user accounts that are not required to change passwords.

Defining Assigning Profiles

You create profiles with CREATE PROFILE statement, and change existing profiles with ALTER PROFILE. Both statements let you set one or more profile parameters.

Each profile can specify one or more of the following policies:

- How often users must change their passwords.
- How many times users must change their passwords before they can reuse an old password.
How many times a user can fail to log in before the account is locked.

The required length and content of the password:

- Maximum and minimum number of characters
- Minimum number of capital letters, lowercase letters, digits, and symbols required in a password.

Assigning Profiles

After you define a profile, you can assign it to new and existing users with `CREATE USER` and `ALTER USER`, respectively.

Changes to profile policies for password content—for example, `PASSWORD_MAX_LENGTH` and `PASSWORD_MIN_SYMBOLS`—affect users only when they change their passwords. Vertica does not test existing passwords to verify that they comply with new password requirements. To enforce immediate compliance with new profile requirements, use `ALTER USER...PASSWORD EXPIRE` to force immediate expiration of the user's current password. On the user’s next login, Vertica prompts this user to supply a new password, which must comply with the new policy.

Default Profile

Each database contains a profile named `DEFAULT`. Vertica assigns the default profile to users who are not explicitly assigned a profile. The default profile also sets parameters of non-default profiles in two cases:

- Profile parameters that are not explicitly set by `CREATE PROFILE`
- Parameters that `ALTER PROFILE` sets to `DEFAULT`

All parameters in the default profile are initially set to `unlimited`. You can use `ALTER PROFILE` to change these settings. For example, the following statement modifies the default profile parameter `PASSWORD_MIN_SYMBOLS`. The change requires passwords to contain at least one symbol, such as $, #, @. This change affects all profiles where `PASSWORD_MIN_SYMBOLS` is set to `default`:

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_MIN_SYMBOLS 1;
```

Profile Settings and Client Authentication

The following profile settings affect client authentication methods, such as LDAP or GSS:
- FAILED_LOGIN_ATTEMPTS
- PASSWORD_LOCK_TIME

All other profile settings are used only by Vertica to manage its passwords.

- PROFILES
- Creating a Database Name and Password

Password Guidelines

For passwords to be effective, they must be hard to guess. You need to protect passwords from:

- Dictionary-style, brute-force attacks
- Users who have knowledge of the password holder (family names, birth dates, etc.)

Use Profiles to enforce good password practices (password length and required content). Make sure database users know the password guidelines, and encourage them not to use personal information in their passwords.

For guidelines on creating strong passwords go to Microsoft Tips for Creating a Strong Password.

See Also

- Creating a Database Name and Password

Password Expiration

User profiles control how often users must change their passwords. Initially, the DEFAULT profile is set so that passwords never expire.

Important: Password expiration has no effect on any of the user's current sessions.
Set Password Expiration and Grace Period

You can change the default value to set a password expiration. Alternatively, you can create additional profiles that set time limits for passwords and assign users to them.

When a password expires, the user must change the password on the next login. However, you can set a PASSWORD_GRACE_TIME in any individual user's profile, allowing that user to log in after the expiration. After the password expires, Vertica issues a warning about the password expiration but continues to recognize the password.

After the grace period ends, users must change their passwords to log in, unless they have changed them already in response to the warning.

Expire a Password

You can expire a user's password immediately using the ALTER USER statement's PASSWORD EXPIRE parameter. By expiring a password, you can:

- Force users to comply with a change to password policy.
- Set a new password when a user forgets the old password.

Account Locking

In a profile, you can set a password policy for how many consecutive failed login attempts a user account is allowed before locking. This locking mechanism helps prevent dictionary-style brute-force attempts to guess users' passwords.

Set Account Locking

Set this value using the FAILED_LOGIN_ATTEMPTS parameter using the CREATE PROFILE or ALTER PROFILE statement.

Vertica locks any user account that has more consecutive failed login attempts than the value to which you set FAILED_LOGIN_ATTEMPTS. The user cannot log in to a locked account, even by supplying the correct password.

Unlock a Locked Account

You can unlock accounts in one of two ways, depending on your privileges.
• Manually: If you are a superuser, you can manually unlock the account using the ALTER USER command.

Note: A superuser account cannot be locked, because it is the only user that can unlock accounts. For this reason, choose a very secure password for a superuser account. See Password Guidelines for suggestions.

• Password Lock Time Setting: Specify the number of days until an account unlocks in the PASSWORD_LOCK_TIME parameter of the user's profile. Vertica automatically unlocks the account after the specified number of days has passed. If you set this parameter to UNLIMITED, the user's account is never automatically unlocked, and a superuser must manually unlock it.

Ident Authentication

The Ident protocol, defined in RFC 1413, authenticates a database user with a system user name. To see if that system user can log in without specifying a password, you configure Vertica client authentication to query an Ident server. With this feature, the DBADMIN user can run automated scripts to execute tasks on the Vertica server.

Caution: Ident responses can be easily spoofed by untrusted servers. Use Ident authentication only on local connections, where the Ident server is installed on the same computer as the Vertica database server.

Following the instructions in these topics to install, set up, and configure Ident authentication for your database:

• Installing and Setting Up an Ident Server
• Configuring Ident Authentication for Database Users

Examples

The following examples show several ways to configure Ident authentication.

Allow system_user1 to connect to the database as Vertica vuser1:

=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
=> GRANT AUTHENTICATION v_ident to vuser1;
ALTER AUTHENTICATION v_ident ENABLE;

Allow system_user1, system_user2, and system_user3 to connect to the database as vuser1. Use colons (:) to separate the user names:

```sql
-> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
-> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
-> GRANT AUTHENTICATION v_ident TO vuser1;
-> ALTER AUTHENTICATION v_ident ENABLE;
```

Associate the authentication with Public using a GRANT AUTHENTICATION statement. The users, system_user1, system_user2, and system_user3 can now connect to the database as any database user:

```sql
-> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
-> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
-> GRANT AUTHENTICATION v_ident to Public;
-> ALTER AUTHENTICATION v_ident ENABLE;
```

Set the system_users parameter to * to allow any system user to connect to the database as vuser1:

```sql
-> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
-> ALTER AUTHENTICATION v_ident SET system_users='*';
-> GRANT AUTHENTICATION v_ident TO vuser1;
-> ALTER AUTHENTICATION v_ident ENABLE;
```

Using a GRANT statement, associate the v_ident authentication with Public to allow system_user1 to log into the database as any database user:

```sql
-> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
-> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
-> GRANT AUTHENTICATION v_ident to Public;
-> ALTER AUTHENTICATION v_ident ENABLE;
```

### Installing and Setting Up an Ident Server

To use Ident authentication, you must install one or more packages, depending on your operating system, and enable the Ident server on your Vertica server. `oidentd` is an Ident daemon that is compatible with Vertica and compliant with RFC 1413.

**Note:** You can find the source code and installation instructions for `oidentd` at the [oidentd website](#).

To install and configure Ident authentication for use with your Vertica database, follow the appropriate steps for your operating system:
Red Hat 6.x/CentOS 6.x

Install oidentd on Red Hat 6.x or CentOS 6.x by running this command:

$ yum install oidentd

Depending on your configuration, you might receive the following error message:

No package oidentd available.

In this case, you must install the Red Hat/CentOS Extras Repository. Download and install the Extras Repository from the following location: https://dl.fedoraproject.org/pub/epel/epel-release-latest-6.noarch.rpm

Red Hat 7.x/CentOS 7.x

Install an Ident server on Red Hat 7.x or CentOS 7.x by installing the authd and xinetd packages:

$ yum install authd
$ yum install xinetd

Ubuntu/Debian

Install oidentd on Ubuntu or Debian by running this command:

$ sudo apt-get install oidentd

SUSE Linux Enterprise Server

Install the pidentd and xinetd RPMs from the following locations:

Post-Installation Steps for Red Hat 6.x/CentOS 6.x and Ubuntu/Debian

After you install `oidentd` on your Red Hat 6.x/CentOS 6.x or Ubuntu/Debian system, continue with the following steps:

1. Verify that the Ident server accepts IPv6 connections to prevent authentication failure. To do so, you must enable this capability. In the script `/etc/init.d/oidentd`, change the line from:

   ```
   exec="/usr/sbin/oidentd"
   ```

   to

   ```
   exec="/usr/sbin/oidentd -a ::"
   ```

   Then, at the Linux prompt, start `oidentd` with `-a ::`.

2. Restart the server with the following command:

   ```
   $ /etc/init.d/oidentd restart
   ```

Post-Installation Steps for Red Hat 7.x/CentOS 7.x and SUSE Linux Enterprise Server

After you install the required packages on your Red Hat 7.x/CentOS 7.x or SUSE Linux Enterprise Server system, continue with the following steps:

1. Enable the auth service in the configuration file located at the following location: `/etc/xinet.d/auth`

   Enter no for the disable option, as this sample configuration file shows.

   ```
   service auth
   {
       disable = no
       socket_type = stream
       wait = no
       user = ident
       cps = 4096 10
   }
   ```
instances = UNLIMITED
server = /usr/sbin/in.authd
server_args = -t60 --xerror --os
}

2. Restart the xinetd service with the following command:

$ service xinetd restart

### Configuring Ident Authentication for Database Users

To configure Ident authentication, take the following steps:

1. Create an authentication method that uses Ident.

   The Ident server must be installed on the same computer as your database, so specify the keyword LOCAL. Vertica requires that the Ident server and database always be on the same computer as the database.

   ```sql
   => CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
   ```

2. Set the Ident authentication parameters, specifying the system users who should be allowed to connect to your database.

   ```sql
   => ALTER AUTHENTICATION v_ident SET system_users='user1:user2:user3';
   ```

3. Associate the authentication method with the Vertica user. Use a GRANT statement that allows the system user `user1` to log in using Ident authentication:

   ```sql
   => GRANT AUTHENTICATION v_ident TO user1;
   ```

### Kerberos Authentication

Kerberos authentication uses the following components to perform user authentication.
Client Package

The Kerberos 5 client package communicates with the KDC server. This package is not included as part of the Vertica Analytics Platform installation. Kerberos software is built into Microsoft Windows. If you are using another operating system, you must obtain and install the client package.

If you do not already have the Kerberos 5 client package on your system, download it from the MIT Kerberos Distribution page. Install the package on each Vertica server and client used in Kerberos authentication, except the KDC itself.

Refer to the Kerberos documentation for installation instructions.

Service Principals

A service principal consists of a host name, a service name, and a realm to which a set of credentials gets assigned (service/hostname@REALM). These credentials connect to the service, which is a host that you connect to over your network and authenticate using the KDC.

See Specify KDC Information and Configure Realms to create the realm name. The host name must match the value supplied by the operating system. Typically this is the fully qualified host name. If the host name part of your principal does not match the value supplied by the operating system, Kerberos authentication fails.

Some systems use a hosts file (/etc/hosts or /etc/hostname) to define host names. A hosts file can define more than one name for a host. The operating system supplies the first entry, so use that in your principal. For example, if your hosts file contains:

```
192.168.1.101  v_vmart_node0001.example.com  v_vmart_node0001
```

then use v_vmart_node0001.example.com as the hostname value.

Note: Depending on your configuration it may be safer to use the fully qualified domain name rather than the hostname.

Configure the following as Kerberos principals:

- Each client (users or applications that connects to Vertica)
- The Vertica server

See the following topics for more information:
Configure Vertica for Kerberos Authentication

Configure Clients for Kerberos Authentication

### Keytab Files

Principals are stored in encrypted keytab files. The keytab file contains the credentials for the Vertica principal. The keytab allows the Vertica server to authenticate itself to the KDC. You need the keytab so that Vertica Analytic Database does not have to prompt for a password.

Create one service principal for each node in your cluster. You can then either create individual keytab files (one for each node containing only that node's principal) or create one keytab file containing all the principals.

- **Create one keytab file with all principals to simplify setup:** all nodes have the same file, making initial setup easier. If you add nodes later you either update (and redistribute) the global keytab file or make separate keytabs for the new nodes. If a principal is compromised it is compromised on all nodes where it is present in a keytab file.

- **Create separate keytab files on each node to simplify maintenance:** Initial setup is more involved as you must create a different file on each node, but no principals are shared across nodes. If you add nodes later you create keytabs on the new nodes. Each node's keytab contains only one principal, the one to use for that node.

### Ticket-Granting Ticket

The Ticket-Granting Ticket (TGT) retrieves service tickets that authenticates users to servers in the domain. Future login requests use the cached HTTP Service Ticket for authentication, unless it has expired as set in the ticket_lifetime parameter in krb5.conf.

### Multi-realm Support

Vertica provides multi-realm support for Kerberos authentication using the SET param=value parameter in `ALTER AUTHENTICATION` with REALM as the parameter:

```
=> ALTER AUTHENTICATION krb_auth_users set REALM='USERS.COM';
=> ALTER AUTHENTICATION krb_auth_realmad set REALM='REALM_AD.COM';
```

This allows you to assign a different realm so that users from another realm can authenticate to Vertica.
Multi-realm support applies to GSS authentication types only. You can have one realm per authentication method. If you have multiple authentication methods, each can have its own realm:

```sql
=> SELECT * FROM client_auth;
auth_oid | auth_name | is_auth_enabled | auth_host_type | auth_host_address | auth_method | auth_parameters | auth_priority
----------|-----------|----------------|----------------|------------------|-------------|----------------|----------------
45035996  | krb001    | True           | HOST           | 0.0.0.0/0        | GSS         |                 | 0              
realm=USERS.COM   | 0          |                |                |                  |             |                 |                
45035997  | user_auth | True           | HOST           | 0.0.0.0/0        | TRUST       |                 | 1000           
realm=REALM_AD.COM | 1          |                |                |                  |             |                 |                
```

Configure Vertica for Kerberos Authentication

Kerberos provides a strong cryptographic authentication against the devices which lets the client & servers to communicate in a more secured manner. It addresses network security problems.

Your system must have one or more Kerberos Key Distribution Centers (KDC) installed and configured. The KDCs must be accessible from every node in your Vertica Analytic Database cluster.

The KDC must support Kerberos 5 using GSS-API. For details, see the MIT Kerberos Distribution Page.

In This Section

Create the Vertica Principals and Keytabs on Linux KDC

Vertica uses service principals for system-level operations. These principals identify the Vertica service and are used as follows:
• Kerberized Vertica clients request access to this service when they authenticate to the database.

• System processes like the Tuple Mover use this identity when they authenticate to external services such as Hadoop.

Create principals and keys as follows:

1. Start the Kerberos 5 database administration utility (kadmin or kadmin.local) to create Vertica principals on a Linux KDC.

   ▶ Use kadmin if you are accessing the KDC on a remote server. If you have access to the Kerberos administrator password, you can use kadmin on any machine where the Kerberos 5 client package is installed. When you start kadmin, the utility prompts you for the Kerberos administrator's password. You might need root privileges on the client to run kadmin.

   ▶ Use kadmin.local if:
     ○ The KDC is on the machine that you are logging in to.
     ○ You have root privileges on that server.

   kadmin.local does not require the administrators login credentials.

   For more information about the kadmin and kadmin.local commands, see the kadmin documentation.

2. Create one service principal for Vertica on each node. The host name must match the value supplied by the operating system. The following example creates the service principal vertica for the node named v_vmart_node0001.example.com:

   ```bash
   $ sudo /usr/kerberos/sbin/kadmin.local
   kadmin.local add_principal vertica/v_vmart_node0001.example.com
   ```

   Repeat the ktadd command once per principal. You can create separate keytabs for each principal user or add them all to a single keytab file (such as krb5.keytab). If you are using a single file, see the documentation for the -glob option in the MIT Kerberos documentation.

   You must have a user principal for each Vertica Analytic Database user that uses Kerberos Authentication. For example:

   ```bash
   $ sudo /usr/kerberos/sbin/kadmin.local
   kadmin.local add_principal [options] VerticaUser1
   ```
3. Copy each keytab file to the /etc folder on the corresponding cluster node. Use the same path and file name on all nodes.

4. On each node, make the keytab file readable by the file owner who is running the database process (typically, the Linux dbadmin user). For example, you can change ownership of the files to dbadmin as follows:

```
$ sudo chown dbadmin *.keytab
```

**Important:** In a production environment, you must control who can access the keytab file to prevent unauthorized users from delegating your server. For more information about delegation (also known as impersonation), see [Technet.Microsoft.com](https://technet.microsoft.com).

After you create a keytab file, you can use the `klist` command to view keys stored in the file:

```
$ sudo /usr/kerberos/bin/klist -ke -t
Keytab name: FILE:/etc/krb5.keytab
KVNO Timestamp Principal
---------- ----------- --------------------------------------------
 4 08/15/2017 7:35:41 vertica/v_mart_node0001.example.com@EXAMPLE.COM (aes256-cts-hmac-sha1-96)
 4 08/15/2017 7:35:41 vertica/v_mart_node0001.example.com@EXAMPLE.COM (aes128-cts-hmac-sha1-96)
```

5. On Vertica run the following to ensure the Kerberos parameters are set correctly:

```
=> select parameter_name, current_value from configuration_parameters where parameter_name like 'Ker%';
```

```
parameter_name | current_value
--------------- | ----------------
KerberosHostname | glCentos5-04.glvpn.com
KerberosKeytabFile | /scratch_b/ga/krbTest/v_krbtest_node0001_catalog/krb5.keytab
KerberosRealm | GLVPN.COM
KerberosTicketDuration | 0
KerberosServiceName | vertica
(4 rows)
```

6. On Vertica, run `KERBEROS_CONFIG_CHECK` to verify the Kerberos configuration.

`KERBEROS_CONFIG_CHECK` verifies the following:

- The existence of the `kinit` and `kb5.conf` files.
- Whether the keytab file exists and is set.
The Kerberos configuration parameters set in the database:
- KerberosServiceName
- KerberosHostname
- KerberosRealm
- Vertica Principal

That Kerberos can read the Vertica keys
That Kerberos can get the tickets for the Vertica principal
That Vertica can initialize the keys with kinit

Creating the Principals and Keytab on Active Directory

Active Directory stores information about members of the Windows domain, including users and hosts.

Vertica uses the Kerberos protocol to access this information in order to authenticate windows users to the vertica database. The Kerberos protocol uses principals to identify users and keytab files to store their cryptographic information. You need to install the keytab files into Vertica to enable the Vertica database to cryptographically authenticate windows users.

This procedure describes:

- The creation of a Vertica service principal.
- Exporting the keytab files for these principals
- Installing the keytab files in the Vertica database. This allows Vertica to authenticate windows users and grant them access to the Vertica database.

1. Create a Windows account (principal) for the Vertica service and one Vertica host for each node/host in the cluster. This procedure creates windows accounts for host verticanode01 and service vertica running on this node.

When you create these accounts, select the following:

- User Cannot change password
- Password never expires
2. If you are using external tables on HDFS that are secured by kerberos authentication, you MUST enable Delegation. To do so, access the Active Directory Users and Computers dialog, right-click on the Windows account (principal) for the Vertica service, and select Delegation. Trust this user for delegation to any service.

3. Run the following command to create the keytab for the host verticanode01.dc.com node/host:

```bash
$ ktpass -out ./host.verticanode01.dc.com.keytab -princ host/verticanode01.dc.com@DC.COM -mapuser verticanode01 -mapop set -pass secret -ptype KRB5_NT_SRV_HST
```

4. Run the following command to create the keytab for the vertica service:

```bash
$ ktpass -out ./vertica.verticanode01dc.com.keytab -princ vertica/verticanode01.dc.com@DC.COM -mapuser vertica -mapop set -pass secret -ptype KRB5_NT_PRINCIPAL
```

For more information about keytab files, see [Technet.Microsoft.com](https://technet.microsoft.com).

5. Run the following commands to ensure the service principal name is mapped correctly. You must run these commands for each node in your cluster:

```bash
$ setspn -L vertica
  Registered ServicePrincipalNamefor CN=vertica,CN=Users,DC=dc,DC=com
  vertica/verticanode01.dc.com

$ setspn -L verticanode01
  Registered ServicePrincipalNamefor CN=verticanode01,CN=Users,DC=dc,DC=com
  host/verticanode01.dc.com
```

7. Combine the keytab files into a single keytab:

```bash
[release@vertica krbTest]$ /usr/kerberos/sbin/ktutil
ktutil:  rkt host.verticanode01.dc.com.keytab
ktutil:  rkt vertica.verticanode01.dc.com.keytab
ktutil:  list
slot KVNO Principal
```

**Note:** You can deselect Password never expires, but if you change these user passwords you must recreate the keytab files and reinstall them into Vertica. This includes repeating the entire procedure.
This creates a single keytab file that contains the server principal for authentication.

8. Copy the new keytab file to the catalog directory. For example:

```
$ cp verticanode01.dc.com.keytab /home/dbadmin/VMart/v_vmart_nodennnn_catalog
```

9. Test the keytab file’s ability to retrieve a ticket to ensure it works from the Vertica node:

```
$ kinit vertica/verticanode01.dc.com -k -t verticanode01.dc.com.keytab
$ klist
```

```
Ticket cache: KFILE:/tmp/krb_ccache_1003
Default principal: vertica/verticanode01.dc.com@DC.COM

Valid starting Expires Service principal
04/08/2017 13:35:25 04/08/2017 23:35:25 krbtgt/DC.COM@DC.COM
renew until 04/15/2017 14:35:25
```

When the ticket expires or not automatically retrieved you need to manually run the kinit command. See Get the Kerberos Ticket and Authenticate Vertica.

10. Set the right permissions and ownership on the keytab files:

```
$ chmod 600 verticanode01.dc.com.keytab
$ chown dbadmin:verticadba verticanode01.dc.com.keytab
```

11. Set the following Kerberos Configuration Parameters using ALTER DATABASE to inform Vertica about the Kerberos principal:

```
KerberosKeytabFile=<CATALOGDIR>/verticanode01.dc.com.keytab
KerberosRealm=DC.COM
KerberosServiceName=vertica
KerberosTicketDuration = 0
KerberosHostname=verticanode01.dc.com
```

12. Restart the Vertica server.

13. Test your Kerberos setup as follows to ensure that all clients use the gss authentication method.

   From Vertica:
CREATE USER windowsuser1;
CREATE USER v_kerberos method 'gss' host '0.0.0.0/0';
ALTER AUTHENTICATION v_kerberos enable;
GRANT AUTHENTICATION v_kerberos to windowsuser1;

From OS command line:

$ kinit windowsuser1
$ vsql -U windowsuser1 -k vertica -K verticanode01.dc.com -h verticanode01.dc.com -c "select client_authentication_name, authentication_method from sessions;"

14. Run KERBEROS_CONFIG_CHECK to verify the Kerberos configuration. KERBEROS_CONFIG_CHECK verifies the following:

- The existence of the kinit and kb5.conf files.
- Whether the keytab file exists and is set
- The Kerberos configuration parameters set in the database:
  - KerberosServiceName
  - KerberosHostname
  - KerberosRealm
  - Vertica Principal
- That Kerberos can read the Vertica keys
- That Kerberos can get the tickets for the Vertica principal
- That Vertica can initialize the keys with kinit
Get the Kerberos Ticket and Authenticate Vertica

If your organization uses Kerberos as part of the login process, Kerberos tickets are automatically retrieved upon login. Otherwise, you need to run `kinit` to retrieve the Kerberos ticket.

The following example shows how to retrieve the ticket and authenticate Vertica Analytic Database with the KDC using the `kinit` command. EXAMPLE.COM is the realm name. You must use the realm name with your username to retrieve a Kerberos ticket. See Specify KDC Information and Configure Realms.

```
$ kinit
Password for principal_user@EXAMPLE.COM: kpasswd
```

You are prompted for the password of the principal user name created when you created the principals and keytabs (see Create the Vertica Principals and Keytabs on Linux KDC).

The Kerberos ticket gets cached for a pre-determined length of time. See Ticket Management in the Kerberos documentation for more information on setting expiration parameters.

Upon expiration, you need to run the `kinit` command again to retrieve another Kerberos ticket.

Configure Clients for Kerberos Authentication

Each supported platform has a different security framework. Thus, the steps required to configure and authenticate against Kerberos differ among clients.

On the server side, you construct the Vertica Kerberos service name principal using this format:

```
Kerberos_Service_Name/Kerberos_Host_Name@Kerberos_REALM
```

For each client, the GSS libraries require the following format for the Vertica service principal:

```
Kerberos_Service_Name@Kerberos_Host_Name
```

You can omit the realm portion of the principal because GSS libraries use the realm name of the configured default (Kerberos_REALM) realm.

For information about client connection strings, see the following topics in Connecting to Vertica:
In This Section

- Configure ODBC and vsql Clients on Linux, HP-UX, AIX, MAC OSX, and Solaris
- Configure ODBC and vsql Clients on Windows and ADO.NET
- Configure JDBC Clients on all Platforms

Configure ODBC and vsql Clients on Non-Windows Platforms

To configure an ODBC or vsql client on Linux, HP-UX, AIX, MAC OSX, or Solaris, you must first install the Kerberos 5 client package. See Configuring Kerberos Authentication.

After you install the Kerberos 5 client package, you must provide clients with a valid Kerberos configuration file (krb5.conf). To communicate with the KDC, each client participating in Kerberos authentication must have a valid, identically configured krb5.conf file. The default location for the Kerberos configuration file is /etc/krb5.conf.

Tip: To enforce consistency among clients, Vertica Analytic Database, and the KDC, copy the /etc/krb5.conf file from the KDC to the client's/etc directory.

The Kerberos configuration (krb5.conf) file contains Kerberos-specific information, including:

- How to reach the KDC
- Default realm name
- Domain
- Path to log files

Note: A few scenarios exist in which the Vertica server principal name might not match the host name in the connection string. See Troubleshooting Kerberos Authentication for more information.
- DNS lookup
- Encryption types to use
- Ticket lifetime

The default location for the Kerberos configuration file is `/etc/krb5.conf`. When configured properly, the client can authenticate with Kerberos and retrieve a ticket through the `kinit` utility (see Acquire an ODBC Authentication Request and Connection below). Likewise, the server can then use `ktutil` to store its credentials in a keytab file.

Authenticating ODBC and vsql Clients Requests and Connections on Non-Windows Platforms

ODBC and vsql use the client's ticket established by `kinit` to perform Kerberos authentication. These clients rely on the security library's default mechanisms to find the ticket file and the Kerberos configuration file.

To authenticate against Kerberos, call the `kinit` utility to obtain a ticket from the Kerberos KDC server. The following two examples show how to send the ticket request using ODBC and vsql clients.

**Acquire an ODBC Authentication Request and Connection**

1. On an ODBC client, acquire a ticket for the `kuser` user by calling the `kinit` utility.

   ```
   $ kinit kuser@EXAMPLE.COM
   Password for kuser@EXAMPLE.COM:
   ```

2. Connect to Vertica, and provide the principals in the connection string:

   ```
   char outStr[100];
   SQLLEN len;
   SQLDriverConnect(handle, NULL, "Database=VMart;User=kuser;
   Server=myserver.example.com;Port=5433;KerberosHostname=vcluster.example.com",
   SQL_NT5, outStr, &len);
   ```

**Acquire a vsql Authentication Request Connection**

If the `vsql` client is on the same machine you are connecting to, `vsql` connects through a UNIX domain socket. This connection bypasses Kerberos authentication. When you authenticate
with Kerberos, especially if the client authentication method is configured as 'local', you must include the -h hostname option. See Command Line Options in Connecting to Vertica.

1. On the vsql client, call the `kinit` utility:

   ```bash
   $ kinit kuser@EXAMPLE.COM
   Password for kuser@EXAMPLE.COM:
   ```

2. Connect to Vertica, and provide the host and user principals in the connection string:

   ```bash
   $ ./vsql -K vcluster.example.com -h myserver.example.com -U kuser
   Welcome to vsql, the Vertica Analytic Database
   interactive terminal.
   Type: \h or \? for help with vsql commands
   \g or terminate with semicolon to execute query
   \q to quit
   ```

   In the future, when you log in to vsql as `kuser`, vsql uses your cached ticket without prompting you for a password.

Verify the Authentication Method

You can verify the authentication method by querying the SESSIONS system table:

```sql
=> SELECT authentication_method FROM sessions;
   authentication_method
   ---------------------
   GSS-Kerberos
   (1 row)
```

- Data Source Name (DSN) Connection Properties in Connecting to Vertica
- (vsql) Command-Line Options in Connecting to Vertica

Configure ADO.NET, ODBC, and vsql Clients on Windows

The Vertica client drivers support the Windows SSPI library for Kerberos authentication. Windows Kerberos configuration is stored in the registry.

You can choose between two different setup scenarios for Kerberos authentication on ODBC and vsql clients on Windows and ADO.NET:
Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica

Linux KDC with Windows Built-in Kerberos Client and Vertica

Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica

Kerberos authentication on Windows is commonly used with Active Directory, Microsoft’s enterprise directory service/Kerberos implementation. Typically your organization's network or IT administrator performs the setup.

Windows clients have Kerberos authentication built into the authentication process. You do not need any additional software.

Your login credentials authenticate you to the Kerberos server (KDC) when you:

- Log in to Windows from a client machine
- Use a Windows instance that has been configured to use Kerberos through Active Directory

To use Kerberos authentication on Windows clients, log in as REALM\user.

Important: When you use the ADO.NET driver to connect to Vertica, you can optionally specify IntegratedSecurity=true in the connection string. This informs the driver to authenticate the calling user against the user's Windows credentials. As a result, you do not need to include a user name or password in the connection string. Any user=<username> entry to the connection string is ignored.

Linux KDC with Windows Built-in Kerberos Client and Vertica

A simple, but less common scenario is to configure Windows to authenticate against a non-Windows KDC. In this implementation, you use the ksetup utility to point the Windows operating system native Kerberos capabilities at a non-Active Directory KDC. By logging in to Windows, you obtain a ticket-granting ticket, similar to the Active Directory implementation. However, in this case, Windows is internally communicating with a Linux KDC. See the Microsoft Windows Server Ksetup page for more information.

When a database/windows user logs into their Windows machine (or after performing a kinit on Windows) the Kerberos ticket MUST have ok_as_delegate and forwardable flag set to be able to access webhdfs based external tables as follows:

```bash
$ CMD \> klist
#2> Client: release @ VERTQA.LOCAL
Server: vertica/vqatest108.verticacorp.com @ VERTQA.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
```
Note: The Ticket Flags setting above must contain ok_as_delegate and forwardable entries. For information on these parameters see Kerberos documentation.

Configure Windows Clients for Kerberos Authentication

Depending on which implementation you want to configure, refer to one of the following pages on the Microsoft Server website:

- To set up Windows clients with Active Directory, refer to Step-by-Step Guide to Kerberos 5 (krb5 1.0) Interoperability.

- To set up Windows clients with the ksetup utility, refer to the Ksetup page.

Authenticate and Connect Clients

The KDC can authenticate both an ADO.NET and a vsql client.

Note: Use the fully-qualified domain name as the server in your connection string; for example, use host.example.com instead of just host. That way, if the server moves location, you do not have to change your connection string.

Verify an ADO.NET Authentication Request and Connection

This example shows how to use the IntegratedSecurity=true, setting to specify that the ADO.NET driver authenticate the calling user's Windows credentials:

```java
VerticaConnection conn = new VerticaConnection("Database=VMart;Server=host.example.com;Port=5433;IntegratedSecurity=true;KerberosServiceName=vertica;KerberosHostname=vcluster.example.com");
conn.open();
```
Verify a vsq1 Authentication Request and Connection

1. Log in to your Windows client, for example, as EXAMPLE\kuser.

2. Run the vsq1 client and supply the connection string to Vertica:

```bash
C:\Users\kuser\Desktop>vsql.exe -h host.example.com -K vcluster -U kuser
```

Welcome to vsq1, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsq1 commands
\g or terminate with semicolon to execute query
\q to quit

Configure JDBC Clients on All Platforms

Kerberos authentication on JDBC clients uses Java Authentication and Authorization Service (JAAS) to acquire the initial Kerberos credentials. JAAS is an API framework that hides platform-specific authentication details and provides a consistent interface for other applications.

You specify the client login process through the JAAS Login Configuration File. This file contains options that specify the authentication method and other settings to use for Kerberos. A class called the LoginModule defines valid options in the configuration file.

The JDBC client principal is crafted as jdbc-username@server-from-connection-string.

Implement the LoginModule

Vertica recommends that you use the JAAS public class com.sun.security.auth.module.Krb5LoginModul provided in the Java Runtime Environment (JRE).

The Krb5LoginModule authenticates users using Kerberos protocols and is implemented differently on non-Windows and Windows platforms:
On non-Windows platforms: The Krb5LoginModule defers to a native Kerberos client implementation. Thus, you can use the same /etc/krb5.conf setup as you use to configure ODBC and vsql clients on Linux, HP-UX, AIX, MAC OSX, and Solaris platforms.

On Windows platforms: The Krb5LoginModule uses a custom Kerberos client implementation bundled with the Java Runtime Environment (JRE). Windows settings are stored in a %WINDIR%\krb5.ini file, which has similar syntax and conventions to the non-Windows krb5.conf file. You can copy a krb5.conf from a non-Windows client to %WINDIR%\krb5.ini.

You can find documentation for the LoginModules in the com.sun.security.auth package, and on the Krb5LoginModule web page.

Create the JAAS Login Configuration

The JAASConfigName connection property identifies a specific configuration within a JAAS configuration that contains the Krb5LoginModule and its settings. The JAASConfigName setting lets multiple JDBC applications with different Kerberos settings coexist on a single host. The default configuration name is verticajdbc.

Important: Carefully construct the JAAS login configuration file. If syntax is incorrect, authentication fails.

You can configure JAAS-related settings in the java.security master security properties file. This file resides in the lib/security directory of the JRE. For more information, see Appendix A in the Java™ Authentication and Authorization Service (JAAS) Reference Guide.

Create a JDBC Login Context

The following example shows how to create a login context for Kerberos authentication on a JDBC client. The client uses the default JAASConfigName of verticajdbc and specifies that:

- The ticket-granting ticket will be obtained from the ticket cache
- The user will not be prompted for a password if credentials cannot be obtained from the cache, keytab file, or through a shared state.

```java
verticajdbc {
    com.sun.security.auth.module.Krb5LoginModule
        required
        useTicketCache=true
        doNotPrompt=true;
};
```
JDBC Authentication Request and Connection

You can configure the Krb5LoginModule to use a cached ticket or keytab. The driver can also acquire a ticket or keytab automatically if the calling user provides a password.

In the preceding example, the login process uses a cached ticket and does not prompt for a password because both useTicketCache and doNotPrompt are set to true. If doNotPrompt=false and you provide a user name and password during the login process, the driver provides that information to the LoginModule. The driver then calls the kinit utility on your behalf.

1. On a JDBC client, call the kinit utility to acquire a ticket:

   ```bash
   $ kinit kuser@EXAMPLE.COM
   ```

   If you prefer to use a password instead of calling the kinit utility, see the next section.

2. Connect to Vertica:

   ```java
   Properties props = new Properties();
   props.setProperty("user", "kuser");
   props.setProperty("KerberosServiceName", "vertica");
   props.setProperty("KerberosHostName", "vcluster.example.com");
   props.setProperty("JAASConfigName", "verticajdbc");
   Connection conn = DriverManager.getConnection("jdbc:vertica://myserver.example.com:5433/VMart", props);
   ```

Have the Driver Acquire a Ticket

Sometimes, you may want to bypass calling the kinit utility yourself but still use encrypted, mutual authentication. In such cases, you can optionally pass the driver a clear text password to acquire the ticket from the KDC. The password is encrypted when sent across the network. For example, useTicketCache and doNotPrompt are both false in the following example. Thus, the calling user's credentials are not obtained through the ticket cache or keytab.

```bash
$ verticajdbc {
   com.sun.security.auth.module.Krb5LoginModule
   required
   useTicketCache=false
   doNotPrompt=false;
};
```

The preceding example demonstrates the flexibility of JAAS. The driver no longer looks for a cached ticket, and you do not have to call kinit. Instead, the driver takes the password and user name and calls kinit on your behalf.

Troubleshooting Kerberos Authentication

These tips can help you avoid issues related to Kerberos authentication with Vertica Analytic Database and to troubleshoot any problems that occur.

JDBC Client Authentication Fails

If Kerberos authentication fails on a JDBC client, check the JAAS login configuration file for syntax issues. If syntax is incorrect, authentication fails.

Working Domain Name Service (DNS) Not Configured

Verify that the DNS entries and the system host file (/etc/hosts or /etc/hostname) on the network are all properly configured for your environment. If you are using a fully qualified domain name, ensure that is properly configured as well. Refer to the Kerberos documentation for your platform for details.

System Clocks Out of Sync

All Systems Except Red Hat 7/CentOS 7

System clocks in your network must remain in sync for Kerberos authentication to work properly. To do so:

1. Install NTP on the Kerberos server (KDC).
2. Install NTP on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other
Clock skew can be a problem on Linux virtual machines that need to sync with the Windows Time Service. Use the following steps to keep time in sync:

1. Using any text editor, open /etc/ntp.conf.

2. Under the Undisciplined Local Clock section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.

3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

   ```
   # 0 */2 * * * /etc/init.d/ntpd restart
   ```

4. Alternatively, run the following command to force clock sync immediately:

   ```
   $ sudo /etc/init.d/ntpd restart
   ```

For more information, see Enabling Network Time Protocol (NTP) in Installing Vertica and the Network Time Protocol website.

**Red Hat 7/CentOS 7 Systems**

In Red Hat 7/CentOS 7, ntpd is deprecated in favor of chrony. To keep system clocks in your network in sync for Kerberos authentication to work properly, do the following:

1. Install chrony on the Kerberos server (KDC).

2. Install chrony on each server in your network.

3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other.

**Clock Skew on Linux Virtual Machines**

Clock skew can be problematic on Linux virtual machines that need to sync with the Windows Time Service. Try the following to keep time in sync:

1. Using any text editor, open /etc/chrony.conf.

2. Under the Undisciplined Local Clock section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

```
# 0 */2 * * * systemctl start chronyd
```

4. Alternatively, run the following command to force clock sync immediately:

```
$ sudo systemctl start chronyd
```

For more information, see Set Up Time Synchronization in Installing Vertica and the Red Hat chrony guide.

**Kerberos Ticket Is Valid, But Hadoop Access Fails**

Vertica uses Kerberos tickets to obtain Hadoop tokens. It then uses the Hadoop tokens to access the Hadoop data. Hadoop tokens expire after a period of time, so Vertica periodically refreshes them. However, if your Hadoop cluster is set to expire tokens frequently, it is possible that tokens might not be refreshed in time. If the token expires, you cannot access data.

Setting the HadoopFSTokenRefreshFrequency configuration parameter allows you to specify how often Vertica should refresh the token. Specify this value, in seconds, to be smaller than the expiration period set for Hadoop. For example:

```
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

**Encryption Algorithm Choices**

Kerberos is based on symmetric encryption. Be sure that all Kerberos parties used in the Kerberos realm agree on the encryption algorithm to use. If they do not agree, authentication fails. You can review the exceptions in the vertica.log.

On a Windows client, be sure the encryption types match the types set on Active Directory. See Configure Vertica for Kerberos Authentication.

Be aware that Kerberos is used only for securing the login process. After the login process completes, by default, information travels between client and server without encryption. If you want to encrypt traffic, use SSL. For details, see Implementing SSL.
Kerberos Passwords Not Recognized

If you change your Kerberos password, you must re-create all of your keytab files.

Using the ODBC Data Source Configuration Utility

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica Analytic Database server.

Authentication Failure in Backup, Restore, or Admin Tools

This problem can arise in configurations where each Vertica node uses its own Kerberos principal. (This configuration is recommended.) When using vbr or admintools you might see an error such as the following:

```
$ vsql: GSSAPI continuation error: Miscellaneous failure
GSSAPI continuation error: Server not found in Kerberos database
```

Backup/restore and the admin tools use the value of KerberosHostname, if it is set, in the Kerberos principal used to authenticate. The same value is used on all nodes. If you have defined one Kerberos principal per node, as recommended, this value does not match. To correct this, unset the KerberosHostname parameter:

```
=> ALTER DATABASE mydb CLEAR KerberosHostname;
```

Server's Principal Name Does Not Match Host Name

This problem can arise in configurations where a single Kerberos principal is used for all nodes. OpenText recommends against using a single Kerberos principal for all nodes. Instead, use one principal per node and do not set the KerberosHostname parameter.

In some cases during client connection, the Vertica server's principal name might not match the host name in the connection string. (See also Using the ODBC Data Source Configuration Utility in this topic.)

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica Analytic Database server.
On ODBC, JDBC, and ADO.NET clients, set the host name portion of the server's principal using the KerberosHostName connection string.

Tip: On vsq1 clients, you set the host name portion of the server's principal name using the -K KRB HOST command-line option. The default value is specified by the -h switch, which is the host name of the machine on which the Vertica server is running. -K is equivalent to the drivers' KerberosHostName connection string value.

For details, see Command Line Options in Connecting to Vertica.

Principal/Host Mismatch Issues and Resolutions

This section lists potential issues that may occur if the principal and host are mismatched.

- The KerberosHostName configuration parameter has been overridden.

  For example, consider the following connection string:

  ```
  jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser
  ```

  Because the this connection string includes no explicit KerberosHostName parameter, the driver defaults to the host in the URL (v_vmart_node0001.example.com). If you overwrite the server-side KerberosHostName parameter as “abc”, the client generates an incorrect principal.

  To resolve this issue, explicitly set the client’s KerberosHostName to the connection string, as in this example:

  ```
  jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser&kerberoshostname=abc
  ```

- Connection load balancing is enabled, but the node against which the client authenticates might not be the node in the connection string.

  In this situation, consider changing all nodes to use the same KerberosHostName setting. When you use the default to the host that was originally specified in the connection string, load balancing cannot interfere with Kerberos authentication.

- You have a DNS name that does not match the Kerberos host name.

  For example, imagine a cluster of six servers, where you want hr-servers and finance-servers to connect to different nodes on the Vertica Analytic Database cluster. Kerberos
authentication, however, occurs on a single (the same) KDC. In the following example, the Kerberos service host name of the servers is server.example.com.

Suppose you have the following list of example servers:

<table>
<thead>
<tr>
<th>Server Name</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>server1.example.com</td>
<td>192.16.10.11</td>
</tr>
<tr>
<td>server2.example.com</td>
<td>192.16.10.12</td>
</tr>
<tr>
<td>server3.example.com</td>
<td>192.16.10.13</td>
</tr>
<tr>
<td>server4.example.com</td>
<td>192.16.10.14</td>
</tr>
<tr>
<td>server5.example.com</td>
<td>192.16.10.15</td>
</tr>
<tr>
<td>server6.example.com</td>
<td>192.16.10.16</td>
</tr>
</tbody>
</table>

Now, assume you have the following DNS entries:

<table>
<thead>
<tr>
<th>Name</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>finance-servers.example.com</td>
<td>192.168.10.11, 192.168.10.12, 192.168.10.13</td>
</tr>
<tr>
<td>hr-servers.example.com</td>
<td>192.168.10.14, 192.168.10.15, 192.168.10.16</td>
</tr>
</tbody>
</table>

When you connect to finance-servers.example.com, specify:

- Kerberos -h host name option as server.example.com
- -K host option for hr-servers.example.com

For example:

```
$ vsql -h finance-servers.example.com -K server.example.com
```

- You do not have DNS set up on the client machine, so you must connect by IP only.

To resolve this issue, specify:

- Kerberos -h host name option for the IP address
- -K host option for server.example.com

For example:

```
$ vsql -h 192.168.1.12 -K server.example.com
```

- There is a load balancer involved (Virtual IP), but there is no DNS name for the VIP.

Specify:
**Kerberos**

- **-h** host name option for the Virtual IP address
- **-K** host option for server.example.com

For example:

```
$ vsq1 -h <virtual IP> -K server.example.com
```

- You connect to Vertica using an IP address, but there is no host name to construct the Kerberos principal name.

  Provide the instance or host name for the Vertica as described in [Inform About the Kerberos Principal](#).

- You set the server-side **KerberosHostName** configuration parameter to a name other than the Vertica node's host name, but the client cannot determine the host name based on the host name in the connection string alone.

  **Rename the KerberosHostName**

  Rename the **KerberosHostName** to match the name of the Vertica node's host name. For more information, see the following topics in Connecting to Vertica:

  - **ODBC DSN Parameters**
  - **JDBC Connection Properties**
  - **ADO.NET Connection Properties**

**LDAP Authentication**

Lightweight Directory Access Protocol (LDAP) is an authentication method that works like password authentication. The main difference is that the LDAP method authenticates clients trying to access your Vertica database against an LDAP or Active Directory server. Use LDAP authentication when your database needs to authenticate a user with an LDAP or Active Directory server.

Before you configure LDAP authentication for your Vertica database, review the following information:
LDAP Prerequisites and Definitions

Prerequisites

Before you configure LDAP authentication for your Vertica database you must have:

- IP address and host name for the LDAP server. Vertica supports IPv4 and IPv6 addresses.
- Your organization's Active Directory information.
- A service account for search and bind.
- Administrative access to your Vertica database.
- open-ldap-tools package installed on at least one node. This package includes ldapsearch.

Definitions

The following definitions are important to remember for LDAP authentication:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>IP address or host name of the LDAP server. Vertica supports IPv4 and IPv6 addresses. For more information, see IPv4 and IPv6 for Client Authentication.</td>
</tr>
<tr>
<td>Common name (CN)</td>
<td>Depending on your LDAP environment, this value can be either the username or the first and last name of the user.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Domain component (DC)</td>
<td>Comma-separated list that contains your organization's domain component broken up into separate values, for example: dc=vertica, dc=com</td>
</tr>
<tr>
<td>Distinguished name (DN)</td>
<td>domain.com. A DN consists of two DC components, as in &quot;DC=example, DC= com&quot;.</td>
</tr>
<tr>
<td>Organizational unit (OU)</td>
<td>Unit in the organization with which the user is associated, for example, Vertica Users.</td>
</tr>
<tr>
<td>sAMAccountName</td>
<td>An Active Directory user account field. This value is usually the attribute to be searched when you use bind and search against the Microsoft Active Directory server.</td>
</tr>
<tr>
<td>UID</td>
<td>A commonly used LDAP account attribute used to store a username.</td>
</tr>
<tr>
<td>Bind</td>
<td>LDAP authentication method that allows basic binding using the DN.</td>
</tr>
<tr>
<td>Search and bind</td>
<td>LDAP authentication method that must log in to the LDAP server to search on the specified attribute.</td>
</tr>
<tr>
<td>Service account</td>
<td>An LDAP user account that can be used to log in to the LDAP server during bind and search. This account's password is usually shared.</td>
</tr>
<tr>
<td>Anonymous binding</td>
<td>Allows a client to connect and search the directory (search and bind) without needing to log in.</td>
</tr>
<tr>
<td>ldapsearch</td>
<td>A command-line utility to search the LDAP directory. It returns information that you use to configure LDAP search and bind.</td>
</tr>
<tr>
<td>basedn</td>
<td>Distinguished name where the directory search should begin.</td>
</tr>
<tr>
<td>binddn</td>
<td>Domain name to find in the directory search.</td>
</tr>
<tr>
<td>search_attribute</td>
<td>Text to search for to locate the user record. The default is UID.</td>
</tr>
</tbody>
</table>

**LDAP Parameters**

There are several parameters that you need to configure for LDAP authentication.
General LDAP Parameters

Use the following parameters to configure for either LDAP bind or LDAP bind and search:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
</table>
| host           | LDAP server URI in the following format: `schema://host:optional_port`  
`schema` is either `ldap` (for LDAP/Active Directory) or `ldaps` (for secure LDAP/Active Directory). |
| starttls       | Optional parameter that defines StartTLS behavior:  
- `soft`—If the server does not support TLS, continue authenticating the user in plain text. This value is equivalent to the `-Z` option in `ldapsearch`.  
- `hard`—If server does not support TLS, authentication should fail. This value is equivalent to the `-ZZ` in `ldapsearch`.  
  
Using ldaps is equivalent to `starttls='hard'`. However, if you use them together in the same connection string, authentication fails and the following error appears:  

```
FATAL 3846: LDAP authentication failed for user "<user_name>"
```

| 1dap_continue | When set to yes, this parameter allows a connection retry when a user not found error occurs during the previous connection attempt.  
For any other failure error, the system automatically retries the connection. |

LDAP Bind Parameters

Use the following parameters when authenticating with LDAP bind to create the bind name string. For more information see [Workflow for Configuring LDAP Bind](#).
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binddn_prefix</td>
<td>First half of the bind string.</td>
</tr>
</tbody>
</table>
| binddn_suffix  | Second half of bind string.  
You must use the binddn_prefix and binddn_suffix together. 
In the following example, the bind name becomes `cn=<user_login_name>;ou=vertica_users;dc=verticacorp;dc=com`.  
`=> ALTER AUTHENTICATION auth_method_name SET binddn_prefix='cn=',binddn_suffix=''; ou=vertica_users;dc=verticacorp;dc=com';` |
| domain_prefix | The domain where to find the user name. 
In the following example, the bind name is `verticacorp/<user_login_name>`  
`ALTER AUTHENTICATION auth_method_name SET domain_prefix='Example';` |
| email_suffix | The part of an email address that comes after the @ sign.  
In the following example, the bind name becomes `<user_login_name>@example.com`  
`=> ALTER AUTHENTICATION auth_method_name SET email_suffix='Example.com';` |

To create the bind name string, you must provide one of the following:

- Both binddn_prefix and binddn_suffix
- domain_name
- email_suffix

Otherwise, Vertica performs a bind and search operation instead of a bind operation.

### LDAP Search and Bind Parameters

Use the following parameters when authenticating with LDAP search and bind. For more information see [Workflow for Configuring LDAP Search and Bind](#).
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>basedn</td>
<td>Base DN for search.</td>
</tr>
<tr>
<td>binddn</td>
<td>Bind DN. Domain name to find in the directory search.</td>
</tr>
<tr>
<td>bind_password</td>
<td>Bind password. Required if you specify a binddn.</td>
</tr>
<tr>
<td>search_attribute</td>
<td>Optional attribute to search for on the LDAP server.</td>
</tr>
</tbody>
</table>

The following example shows how to set these three attributes. In this example, it sets:

- `binddn` to `cn=Manager,dc=example,dc=com`
- `bind_password` to `secret`
- `search_attribute` to `cn`

```
=> ALTER AUTHENTICATION auth_method_name SET host='ldap://example13', basedn='dc=example,dc=com', binddn='cn=Manager,dc=example,dc=com', bind_password='secret', search_attribute='cn';
```

The `binddn` and `bind_password` parameters are optional. If you omit them, Vertica performs an anonymous search.

**Using LDAP Over SSL/TLS**

Vertica supports Transport Layer Security (TLS) for client authentication. TLS uses OpenSSL 0.9.8za and SSL v3/Transport Layer Security (TLS) 1.0 protocol.

The terms SSL and TLS are often used interchangeably. TLS is the successor to SSL and offers greater security. The original SSL standard was renamed TLS at the time it became open source. The introduction of TLS began with version 1, which is essentially equal to SSL 3. You use openssl commands to create certificates and keys and TLS syntax to create an authentication method.

For more information see the [Information Security website](#).

You use `ALTER AUTHENTICATION` to specify LDAP and SSL/TLS parameters. If you specify a host URL that starts with `ldaps`, the Vertica server authenticates using SSL/TLS on the specified port or on the secure LDAPS port (636).
ldaps://abc.dc.com

If the LDAP server does not support SSL on that port, authentication fails.

If you specify a host URL that starts with ldap and set the LDAP starttls parameter, the Vertica server sends a StartTLS request. This request determines if the LDAP server supports TLS on the specified port or on the default LDAP port (389).

```sql
=> ALTER AUTHENTICATION Ldap1 SET host='ldaps://abc.dc.com', binddn_prefix='CN=',
   binddn_suffix=',OU=Unit2,DC=dc,DC=com', basedn='dc=dc,dc=com',
   tls_cacert='~/home/dc.com.ca.cer', tls_reqcert='never';
```

If the LDAP server does not support TLS on that port, the result depends on the value of the starttls parameter:

- **starttls = hard**: The Vertica server terminates the authentication process.
- **starttls = soft**: The Vertica server proceeds with the authentication but does not use TLS.

To configure LDAP over SSL/TLS, use the following configuration parameters:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS_REQCERT</td>
<td>hard—If the client does not provide a certificate, or provides an invalid certificate, it cannot connect. This is the default behavior. never—The client does not request or verify a certificate. allow—If the client does not provide a certificate or provides an invalid certificate, it can connect anyway. try—If the client does not provide a certificate, they can connect. If the client provides an invalid certificate, they cannot connect.</td>
</tr>
</tbody>
</table>
| TLS_CADIR      | Path to the folder with the CA certificates. For example: 
ALTER AUTHENTICATION Ldap1 SET TLS_CADIR ='/scratch_b/qa/vertica/QA/VT_Scenario/V_SEC/'; |
| TLS_CACERT     | Path to the CA certificate. For example: 
ALTER AUTHENTICATION Ldap1 SET TLS_CACERT ='/scratch_b/qa/vertica/QA/VT_Scenario/V_SEC/dc.com.ca.cer'; |

If you do not provide one or more of these parameters, the LDAP server checks to see if the LDAPNOINIT environment variable points to the ldap.conf file. If it does, the server uses the
parameters specified in the ldap.conf file. If the LDAP server cannot find the ldap.conf file, authentication fails.

The following example shows how to specify the TLS parameters and the LDAP parameters when configuring LDAP over SSL/TLS:

```sql
=> CREATE AUTHENTICATION LDAP1 METHOD 'ldap' HOST :clientIP = '172.16.65.177';
=> GRANT AUTHENTICATION ldap1 TO user1;
=> ALTER AUTHENTICATION Ldap1 SET host='ldaps://abc.dc.com', binddn_prefix='CN=', binddn_suffix=',OU=Unit2,DC=dc,DC=com', basedn='dc=DC,dc=com', tls_cacert='/home/dc.com.ca.cer', tls_reqcert='never';
```

**Configuring Multiple LDAP Servers**

If you need to configure multiple LDAP servers that have different URLs, create a separate authentication record for each server. Use the PRIORITY keyword to indicate which search the LDAP server performs first.

The following statements create two authentication methods, vldap1 and vldap2. They specify that the LDAP server first search the entire directory (basedn=dc=example,dc=com) for a DN with an OU attribute Sales. If the first search returns no results, or otherwise fails, the LDAP server next searches for a DN with the OU attribute Marketing:

```sql
=> CREATE AUTHENTICATION vldap1 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap1 SET
    host='ldap://ldap.example.com/search',
    basedn='dc=example,dc=com',
    search_attribute='Sales'
    PRIORITY 1;
=> GRANT AUTHENTICATION vldap1 to public;
=> CREATE AUTHENTICATION vldap2 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap2 SET
    host='ldap://ldap.example.com/search',
    basedn='dc=example,dc=com',
    search_attribute='Marketing'
    PRIORITY 0;
=> GRANT AUTHENTICATION vldap2 to public;
```

**LDAP Bind Methods**

There are two LDAP methods that you use to authenticate your Vertica database against an LDAP server.

- Bind—Use LDAP bind when Vertica connects to the LDAP server and binds using the CN and password. (These values are the username and password of the user logging into the
database). Use the bind method when your LDAP account's CN field matches that of the username defined in your database. For more information see Workflow for Configuring LDAP Bind.

- Search and Bind —Use LDAP search and bind when your LDAP account's CN field is a user's full name or does not match the username defined in your database. For search and bind, the username is usually in another field such as UID or sAMAccountName in a standard Active Directory environment. Search and bind requires your organization's Active Directory information. This information allows Vertica to log into the LDAP server and search for the specified field. For more information see Workflow for Configuring LDAP Search and Bind.

If you are using search and bind, having a service account simplifies your server side configuration. In addition, you do not need to store your Active Directory password.

**LDAP Anonymous Binding**

*Anonymous binding* is an LDAP server function. Anonymous binding allows a client to connect and search the directory (bind and search) without logging in because binddn and bindpasswd are not needed.

You also do not need to log in when you configure LDAP authentication using Management Console.

**Workflow for Configuring LDAP Bind**

To configure your Vertica database to authenticate clients using LDAP bind, follow these steps:

1. Obtain a service account. For information see the LDAP product documentation. You cannot use the service account in the connection parameters for LDAP bind.

2. Compare the user's LDAP account name to their Vertica username. For example, if John Smith's Active Directory (AD) sAMAccountName = jsmith, his Vertica username must also be jsmith.

   However, the LDAP account does not have to match the database user name, as shown in the following example:
CREATE USER r1 IDENTIFIED BY 'password';
CREATE AUTHENTICATION ldap1 METHOD 'ldap' HOST '172.16.65.177';
ALTER AUTHENTICATION ldap1 SET HOST='ldap://172.16.65.10',basedn='dc=dc,dc=com',binddn_suffix=',ou=unit2,dc=dc,dc=com',binddn_prefix='cn=use';
GRANT AUTHENTICATION ldap1 TO r1;

${TARGET}/bin/vsql -p $PGPORT -U r1 -w $LDAP_USER_PASSWD -h ${HOSTNAME} -c "select user_name, client_authentication_name from sessions;"

3. Run ldapsearch from a Vertica node against your LDAP or AD server. Verify the connection to the server and identify the values of relevant fields. Running ldapsearch helps you build the client authentication string needed to configure LDAP authentication.

In the following example, ldapsearch returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username jsmith. This search succeeds only for LDAP servers that allow anonymous binding:

$ ldapsearch -x -h 10.10.10.10 -b "ou=Vertica Users,dc=CompanyCorp,dc=com" '(cn=jsmith*)' cn dn uid sAMAccountName

ldapsearch returns the following results. The relevant information for LDAP bind is in bold:

# extended LDIF
#
# LDAPv3
# base <ou=Vertica Users,dc=CompanyCorp,dc=com> with scope subtree
# filter: (cn=jsmith*)
# requesting: cn dn uid sAMAccountName
#
# jsmith, Users, CompanyCorp.com
dn: cn=jsmith,ou=Vertica Users,dc=CompanyCorp,dc=com
cn: jsmith
uid: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1

4. Create a new authentication record based on the information from ldapsearch. In the ldapsearch entry, the CN is username jsmith, so you do not need to set it. Vertica automatically sets the CN to the username of the user who is trying to connect. Vertica uses that CN to bind against the LDAP server.
For more information see [LDAP Bind Parameters](#)

**Workflow for Configuring LDAP Search and Bind**

To configure your Vertica database to authenticate clients using LDAP search and bind, follow these steps:

1. Obtain a service account. For information see the [LDAP product documentation](#).

2. From a Vertica node, run `ldapsearch` against your LDAP or AD server. Verify the connection to the server, and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication.

   In the following example, `ldapsearch` returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username, John. This search succeeds only for LDAP servers that allow anonymous binding:

   ```
   $ ldapsearch -x -h 10.10.10.10 -b 'OU=Vertica Users,DC=CompanyCorp,DC=com' -s sub -D 'CompanyCorp\jsmith' -W '(cn=John*)' cn dn uid sAMAccountName
   ```

3. Review the results that `ldapsearch` returns. The relevant information for search and bind is in bold:

   ```
   # extended LDIF
   #
   # LDAPv3
   # base <OU=Vertica Users,DC=CompanyCorp,DC=com> with scope subtree
   # filter: (cn=John*)
   # requesting: cn dn sAMAccountName
   #
   # John Smith, Vertica Users, CompanyCorp.com
dn: CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com
   cn: Jsmith
   sAMAccountName: jsmith
   ```
4. Create the client authentication record. The `cn` attribute contains the username you want—`jsmith`. Set your search attribute to the `CN` field so that the search finds the appropriate account.

```sql
=> CREATE AUTHENTICATION v_ldap_bind_search METHOD 'ldap' HOST '10.10.10.10';
=> GRANT AUTHENTICATION v_ldap_bind_search TO public;
=> ALTER AUTHENTICATION v_ldap_bind_search SET
    host='ldap://10.10.10.10',
    basedn='OU=Vertica,DC=CompanyCorp,DC=com',
    binddn='CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com',
    bind_password='password',
    search_attribute='CN';
```

For more information see [LDAP Search and Bind Parameters](https://Documentation.Vertica.com/Security_and_Authentication/Vertica_Analytic_Database_(9.0.x)/Page_4061_of_6180).
TLS/SSL Server Authentication

The terms SSL and TLS are often used interchangeably. This document uses both terms. TLS is the successor to SSL and offers greater security. The original SSL standard was renamed TLS at the time it became open source. The introduction of TLS began with version 1, which is essentially equal to SSL 3. You use openssl commands to create certificates and keys and TLS syntax to create an authentication method.

SSL Authentication

To protect privacy and verify data integrity, you can configure Vertica and database clients to use Secure Socket Layer (SSL). SSL allows secure connection and communication between the client and the server. The SSL protocol uses a trusted third party called a Certificate Authority (CA). Both the owner of a certificate and the party that relies on the certificate trust the CA.

Vertica supports the following authentication methods under Transport Layer Security (TLS) v1.0, v1.1, and v1.2 protocol:

- **SSL server authentication** — Lets the client confirm the server's identity. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This authentication helps prevent man-in-the-middle attacks. See "Prerequisites for SSL Server Authentication and SSL Encryption" in SSL Overview and Configuring SSL.

- **SSL client authentication** — (Optional) Lets the server confirm the client's identity. The server verifies that the client's certificate and public key are valid and were issued by a certificate authority (CA) listed in the server's list of trusted CAs. Client authentication is optional because Vertica can authenticate the client at the application protocol level through user name and password credentials. See "Optional Prerequisites for SSL Server and Client Mutual Authentication" in SSL Overview.

- **Encryption** — Encrypts data sent between the client and database server. This method significantly reduces the likelihood that the data can be read if the connection between the client and server is compromised. Encryption works at both ends of a transaction, regardless of whether SSL Client Authentication is enabled. See "Prerequisites for SSL Server Authentication and SSL encryption" in SSL Overview and Configuring SSL.

- **Data integrity** — Verifies that data sent between the client and server has not been altered during transmission.
Note: For server authentication, Vertica supports using RSA encryption with ephemeral Diffie-Hellman (DH). DH is the key agreement protocol.

Certificate Authority

The CA issues electronic certificates to identify one or both ends of a transaction. These certificates to verify ownership of a public key by the name on the certificate.

Public and Private Keys

A CA issues digital certificates that contain a public key and the identity of the owner. The public key is available to all users through a publicly accessible directory. However, private keys are confidential to their respective owners. When you use a private/public key pair, the data is encrypted by one key and decrypted by its corresponding key.

- If encrypted with a public key, data can be decrypted by its corresponding private key only.
- If encrypted with a private key, data can be decrypted by its corresponding public key only.

For example, suppose Alice wants to send confidential data to Bob. Because she wants only Bob to read it, she encrypts the data with Bob's public key. Even if someone else gains access to the encrypted data, it remains protected. Because only Bob has access to his corresponding private key, he is the only person who can decrypt Alice's encrypted data back into its original form.

SSL Overview

Before you implement SSL security, including mutual mode, obtain the appropriate certificate signed by a certificate authority (CA) and private key files. Copy the certificate file to the database catalog directory. These files must use the Privacy-Enhanced Mail (PEM) format. PEM is the standard file format for Certificates and can be included in ascii or rich text documents. For reference information on SSL use the following links:

- OpenSSL Documentation
- OpenSSL Support
**OpenSSL FAQs**

**OpenSSL Release**

Use the following files for SSL authentication:

- **root.crt** - contains the top-level Certificate Authorities that are trusted for signing server certificates (server.crt).

- **server.crt** - must reside in the server’s data directory and contains the trusted server certificate. This file gets sent to the client where root.crt identifies the server.

- **server.key** - must reside in the server’s data directory and proves the server certificate was sent by the certificate owner. It does not indicate the certificate owner is trustworthy.

If you make changes to any of these files you must restart the server.

You can also implement SSL with LDAP authentication. For more information see [Using LDAP Over SSL/TLS](#).

**Using wildcards**

You can enter wildcard characters as part of the server names in root.crt. For example, server.crt contains server names called eng001.corptech.com, eng002.corptech.com, and eng003.corptech.com. You can enter *.corptech.com in root.crt and it locates the required server.

The wildcard must be the first character of the hostname followed by a period, for example:

```
*.hostname.com
```

**Set Up SSL Server Authentication and SSL Encryption**

Follow these steps to set up server SSL authentication:

**Important:** If you do not perform these steps, database operation may be compromised. If the client cannot authenticate the server, the database does not start.

1. Enable SSL authentication in one of the following ways:

   ```
   Set EnableSSL=1 in vertica.conf
   Enter ALTER DATABASE mydb SET EnableSSL = 1; in vsql.
   ```
2. Copy the server certificate file (server.crt) and private key (server.key) to one of your server hosts in the cluster, as follows:

3. Distribute these files to all server hosts using the instruction in Distributing Certificates and Keys.

   The public key contained in the certificate and the corresponding private key allow the SSL connection to encrypt the data to protect data integrity

4. SSL Server mode requires that the client verify the server's certificate. The client must be able to access certificate authority file (root.crt), and the server must be set with server certificate and private key. Also, SSL Mutual mode requires that the server verify the client’s certificate. The server should be set with CA file and the client must have the client certificate and its private key.

   For vsqI:

   If the VSQL_HOME environment variable is not set, copy the root.crt file to the .vsqI subdir of the login user’s home directory (for example, ~/.vsqI/root.crt).

   If the VSQL_HOME environment variable is set, copy the root.crt file to the .vsqI subdir of the target directory (for example, $vsql_home/.vsqI/root.crt)

   The root.crt file contains the Certificate Authority that issued the server certificate.

Set SSL Server for Mutual Mode Authentication

Use SSL Mutual Mode to have both server and client mutually authenticate themselves with SSL keys. With SSL Mutual Mode the server requests a certificate from the client and the client requests a certificate from the server. Set up SSL Mutual Mode as follows:

1. Enable SSL authentication in one of the following ways:

   Set EnableSSL=1 in vertica.conf

   Enter ALTER DATABASE mydb SET EnableSSL = 1; in vsqI.
2. Copy the root.crt file to one server host in the cluster. This file is distributed to all server hosts when you distribute certificates and keys. See Distributing Certificates and Keys.

   The root.crt file has the same name on the client and server though the file contents can differ. The contents are identical only if the client and server certificates were used by the same root certificate authority (CA).

3. Copy the client certificate file (client.crt) and private key (client.key) to each client. For vsql:

   - If the VSQL_HOME environment variable is set, copy the file to the .vsql subdirectory of the target directory set up in the environment variable (e.g., $vsql_home/.vsql/client.crt).

   - If the VSQL_HOME environment variable is not set, copy the two files to the .vsql subdir of the login user's home directory. (e.g., ~/.vsql/client.crt).

   If you are using either ODBC or JDBC, you can place the files anywhere on your system. Then, provide the location in the connection string (ODBC/JDBC) or ODBCINI (ODBC only). See Configuring SSL for ODBC Clients and Configuring SSL for JDBC Clients.

   Important: If you're using ODBC, the private key file (client.key) must have read and write permissions only for the dbadmin user. For example:

   ```
   chmod 600 client.key
   ```

   Do not provide any additional permissions or extend them to any other users.

### Generating SSL Certificates and Keys

Generating SSL certificates and keys, you must perform the following tasks:

- **Create a Certificate Authority Private Key and Public Certificate** that can then be used to sign server and client keys.

  Important: In a production environment, always use certificates signed by a Certificate Authority.

- **Create the Server Private key and Certificate**, and request a new server certificate that includes a public key.
Create the Client Private key and Certification, and request a new client certificate that includes a public key.

For more detailed information on creating signed certificates, refer to the OpenSSL documentation.

The documentation includes examples and sample procedures to show how to create certificates and keys. The commands shown allow many other possible options not used in these examples. Create commands based on your specific environment.

Create a Certificate Authority Private Key and Public Certificate

Create a Certificate Authority (CA) private key and public certificate. For more information on using the following commands. see the OpenSSL documentation.

1. Generate CA files serverca.crt and servercakey.pem. This allows the signing of server and client keys:

```
$ openssl genrsa -out new_servercakey.pem
$ openssl req -config openssl_req_CA.conf -new -x509 -key servercakey.pem -out serverca.crt
```

You can add multiple CA files to the .crt file with the following command:

```
$ cat serverca_new.crt >> serverca.crt
```

This concatenates the serverca_new.crt file to the original CA file serverca.crt. You can run this command multiple times to concatenate additional CA files.

2. Create the server private key (server.crt) and public key (server.key):

```
$ openssl genrsa -out server.key
$ openssl req -config openssl_req_server.conf -new -key server.key -out server_reqout.txt
$ openssl x509 -req -in server_reqout.txt -days 3650 -sha1 -CAcreateserial -CA serverca.crt -CAkey servercakey.pem -out server.crt
```

3. Create the client private key (client.crt) and public key (client.key):

```
$ openssl genrsa -out client.key
$ openssl req -config openssl_req_client.conf -new -key client.key -out client_reqout.txt
$ openssl x509 -req -in client_reqout.txt -days 3650 -sha1 -CAcreateserial -CA serverca.crt -CAkey servercakey.pem -out client.crt
```
4. Enter the following sample CA certificate values in response to openssl command line prompts. The actual values you enter here will be different than the sample values.

Rather than enter these values from command line prompts, you can optionally provide the same information in .conf files. For example, openssl_req_ca.conf in the preceding example.

- Country Name (2 letter code) [GB]: US
- State or Province Name (full name) [Berkshire]: Massachusetts
- Locality Name (e.g., city) [Newbury]: Cambridge
- Organization Name (e.g., company) [My Company Ltd]: CorpName
- Organizational Unit Name (e.g., section) []: TechSupport
- Common Name (e.g., your name or server hostname) []: myhost
- Email Address []: myhost@CorpName.com

5. Include one unique Distinguished Name (DN) for each certificate that you create. In the preceding examples, the DN is the Organizational Unit Name.

6. Set file permissions:

   $ chmod 700 server.crt server.key
   $ chmod 700 client.crt client.key

7. Rename the CA file serverca.crt to root.crt, and do one of the following:

   - copy it to VSQL_HOME or
   - point to it in ODBC DSN Configuration dialog

8. Create a trusted Certificate Authority for the client for server mutual mode:

   => ALTER DATABASE <mydb> SET SSLCA = '\content of root.crt';

You now have a CA private key, new_servercakey.pem. You also have a CA public certificate, new_serverca.crt. Use both the private key and the public certificate in the procedures that follow for creating server and client certificates.

**Generating Certificates and Keys for MC**

A certificate signing request (CSR) is a block of encrypted text generated on the server on which the certificate is used. You send the CSR to a certificate authority (CA) to apply for a digital identity certificate. The CA uses the CSR to create your SSL certificate from information in your certificate; for example, organization name, common (domain) name, city, and country.
Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the agents. Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the openssl package installed on your Linux environment first.

When you connect to MC through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol. See Set Up Time Synchronization in Installing Vertica.

Create a Certificate and Submit it for Signing

For production, you must use certificates signed by a certificate authority. You can create and submit a certificate and when the certificate returns from the CA, import the certificate into MC.

Use the openssl command to generate a new CSR:

```
$ sudo openssl req -new -key /opt/vconsole/config/keystore.key -out server.csr
```

When you press Enter, you are prompted to enter information to be incorporated into your certificate request. Some fields contain a default value, which you should change for security reasons. Other fields you can leave blank, such as password and optional company name. To leave the field blank, type ' . '.

Important: The keystore.key value for the -key option creates private key for the keystore. If you generate a new key and import it using the Management Console interface, the MC process does restart properly. You must restore the original keystore.jks file and restart Management Console.

This information is contained in the CSR and shows both the default and replacement values:

```
Country Name (2 letter code) [GB]:US
State or Province Name (full name) [GB]:Massachusetts
Locality Name (eg, city) [Newbury]: Cambridge
Organization Name (eg, company) [My Company Ltd]:Vertica
Organizational Unit Name (eg, section) []:Information Management
Common Name (eg, your name or your server's hostname) []:console.vertica.com
Email Address []:mcadmin@vertica.com
```
The Common Name field is the fully qualified domain name of your server. Your entry must exactly match what you type in your web browser, or you receive a name mismatch error.

Self-Sign a Certificate for Testing

To test your new SSL implementation, you can self-sign a CSR using either a temporary certificate or your own internal CA, if one is available.

Note: A self-signed certificate generates a browser-based error notifying you that the signing certificate authority is unknown and not trusted. For testing purposes, accept the risks and continue.

The following command generates a temporary certificate, which expires after 365 days:

```
$ sudo openssl x509 -req -days 365 -in server.csr -signkey /opt/vconsole/config/keystore.key -out server.crt
Enter passphrase for /opt/vconsole/config/keystore.key:
Enter same passphrase again:
```

The previous example prompts you for a passphrase. This is required for Apache to start. To implement a passphrase you must put the SSLPassPhraseDialog directive in the appropriate Apache configuration file. For more information see your Apache documentation.

This example shows the command's output to the terminal window:

```
Signature ok
subject=/C=US/ST=Massachusetts/L=Cambridge/O=Vertica/OU=IT/CN=console.vertica.com/emailAddress=mcadmin@vertica.com
Getting Private key
```

You can now import the self-signed key, server.crt, into Management Console.

See Also

- Configuring SSL
- Key and Certificate Management Tool

Importing a New Certificate to MC

Use this procedure to import a new certificate into Management Console.

Note: To generate a new certificate for Management Console, you must use the keystore.key file, which is located in /opt/vconsole/config on the server on which
you installed MC. Any other generated key/certificate pair causes MC to restart incorrectly. You will then have to restore the original keystore.jks file and restart Management Console. See Generating Certifications and Keys for Management Console.

1. Connect to Management Console, and log in as an administrator.

2. On the Home page, click MC Settings.

3. In the button panel on the left, click SSL certificates.

4. To the right of "Upload a new SSL certificate," click Browse to import the new key.

5. Click Apply.

6. Restart Management Console.

Configuring SSL

Configure SSL for each server in the cluster.

1. Verify that you have performed at least the minimum steps required in SSL Overview for server authentication and encryption and, optionally, for mutual authentication.

2. Verify that you have performed the steps in Distributing Certificates and Keys.

Important: Before you set the Security Parameters SSLCertificate and SSLPrivateKey, you must first set the EnableSSL parameter. Admintools sets these parameters for you when you perform the procedure steps listed in Distributing Certificates and Keys. Alternatively, you can use vsq1 to set the parameters using the ALTER DATABASE statement. For more information on setting configuration parameters see ALTER DATABASE.

These parameters are also automatically set during upgrade to 7.1 if you set EnableSSL=1 in the previous version.

3. Set the EnableSSL parameter to 1. By default, EnableSSL is set to 0 (disabled).

   => ALTER DATABASE mydb SET EnableSSL = 1;

4. Restart the database.

5. If you are using either ODBC or JDBC, configure SSL for the appropriate client:
Configuring SSL for ODBC Clients

Configuring SSL for JDBC Clients

vsql automatically tries to connect using SSL. If a connection fails, and your server is started in SSL Server Mode, vsql attempts to make a second connection over clear text. If you start the server in SSL Mutual Mode, the connection fails without vsql attempting to connect over clear text.

Configure JDBC for SSL Mutual Mode

In addition to the procedure above, you need to perform the following to configure SSL in Mutual Mode:

a. Edit openssl_req_server.conf as follows:

```
[req]
prompt = no
distinguished_name = CStore4Ever
req_extensions = v3_req

[CStore4Ever]
C = US
ST = Massachusetts
O = Corp Server
CN = engXXX
e-mailAddress = foo@bar.com

[v3_req]
basicConstraints = CA:FALSE
keyUsage = nonRepudiation, digitalSignature, keyEncipherment
subjectAltName = @alt_names

[alt_names]
DNS.1 = engXXX.corp.com
DNS.2 = engXXX
DNS.3 = *.corp.com
IP = 10.20.40.XX
```

b. Create the server private key (server.crt) and public key (server.key):

```
$ openssl genrsa -out server.key
$ openssl req -config openssl_req_server.conf -new -key server.key -out server_reqout.txt
$ openssl x509 -req -in server_reqout.txt -days 3650 -sha1 -CAcreateserial -CA serverca.crt
-CAkey servercakey.pem -extensions v3_req -extfile openssl_req_server.conf -out server.crt
```

Note: If you are using SSL mutual mode with JDBC, copy the root.crt file to a location on any one of the clients. After you copy the file to the client, root.crt is
Configuring SSL for ODBC Clients

Configuring SSL for ODBC clients requires that you set the SSLMode connection property. If you want to configure optional SSL client authentication, you must also configure the Security Parameters SSLKeyFile and SSLCertFile connection properties.

How you configure the DSN depends on your operating system:

- **Linux and UNIX** — Enter the connection properties in the odbc.ini file. See [Creating an ODBC DSN for Linux, Solaris, AIX, and HP-UX Clients](#).

- **Microsoft Windows** — Enter the connection properties in the Windows Registry. See [Creating an ODBC DSN for Windows Clients](#).

For Windows ODBC you can set connection string properties in the Client Settings tab on the ODBC DSN Configuration dialog. Connection string properties you can set are:

- **SSL CA file** - the location of the root certificate file, for example root.crt.

- **SSL cert file** - the location of the server certificate file, for example server.crt.

- **SSL key file** - the location of the server key file, for example, server.key.

Set SSLMode Connection Property

Set the SSLMode connection property to one of the following options for the DSN:

- Prefer
- Require
- Disable
- Auto
- VerifyOptional
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>verify_full</td>
<td>Encrypts data and connects to a user-specified trusted server.</td>
</tr>
<tr>
<td>verify_ca</td>
<td>Encrypts data and connects to a trusted server.</td>
</tr>
<tr>
<td>require</td>
<td>Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails.</td>
</tr>
<tr>
<td>prefer</td>
<td>(Default value) Indicates your preference that the server to use SSL. The first connection to the database tries to use SSL. If that connection fails, a second connection is attempted over a clear channel.</td>
</tr>
<tr>
<td>allow</td>
<td>Makes a connection to the server whether the server uses SSL or not. The first connection attempt to the database is made over a clear channel. If that connection fails, a second connection is attempted over SSL.</td>
</tr>
<tr>
<td>disable</td>
<td>Never connects to the server using SSL. This setting is typically used for troubleshooting.</td>
</tr>
</tbody>
</table>

Using verify_ca and verify_full

You can use the SSL Mode properties verify_ca and verify_full exclusively on client authentication. These properties require:

- The root.crt to allow the client to access the server’s authentication certificate. If root.crt does not exist, and verify_can or verify_full are set, the connection fails upon SSL initialization.

- A server.crt, which contains the authentication certificate.

- A server.key, which contains the server’s private key that prevents the server from accessing external systems.

- A server hostname that matches the hostname specified by the client, verify_full only.

- A certificateAll nodes in the cluster must either share the same certificate or each certificate must contain all the hostnames or IP addresses in the Subject Alternative Name (SAN).

SSL Workflow

The following diagram shows an example workflow for SSL authentication. Your actual workflow may differ depending on what SSLMode Connection Properties you use.
In this workflow:

1. **SSL Mode**
   - **SSLMode Connection Props prefer, require, verify_ca or verify_full**
2. **Has root.crt?**
   - **No**
     - **SSL Mode?**
       - **verify_ca or verify_full**
         - **Connection fails**
   - **prefer or require**
     - **SSL Request**
       - **Assuming SSL enabled**
         - **Get server certificate and public key**
           - **succeed**
             - **SSL Authentication**
               - **succeed**
                 - **Connection succeeds and session starts**
               - **fail**
                 - **Connection fails**
         - **fail**
           - **Connection fails**
         - **SSL Mode?**
           - **verify_full**
             - **Hostname check**
               - **fail**
                 - **Connection fails**
               - **succeed**
                 - **Connection succeeds and session starts**
If the SSLMode Connection Property is set to none or allow, the client connects without authentication.

If the SSLMode Connection Property is set to verify_ca or verify_full, and root.crt does not exist, the SSL authentication fails. If root.crt exists, the authentication process proceeds.

During SSL authentication if the SSLMode Connection Property is set to verify_full, and the server hostname is not the same as the hostname specified by the client, authentication fails.

Enable SSL Mutual Mode Authentication

You can optionally configure SSL mutual mode by setting the following database Security Parameters:

- SSLKeyFile — Set this connection property to the file path and name of the client's private key. This key can reside anywhere on the client.

- SSLCertFile — Set this connection property to the file path and name of the client's public certificate. This file can reside anywhere on the client.

Configuring SSL for JDBC Clients

Configuring SSL Authentication for JDBC clients involves the following tasks:

- Set required properties
- Optionally run the SSL Debug Utility
- Configure for SSL Mutual Mode (optional)

Set Required Properties

Set Properties When Location or the Keystore/Truststore Is Not the Default

If you are using a location or the keystore/truststore that is not the default, set the following system properties so that the JRE can find your keystore/truststore:

```
$ javax.net.ssl.keyStore
$ javax.net.ssl.trustStore
```
Set Properties When Keystore/Truststore Is Password Protected

If your keystore/truststore is password protected, set the following system properties so that the JRE has access to it:

```
$ javax.net.ssl.keyStorePassword
$ javax.net.ssl.trustStorePassword
```

Run the SSL Debug Utility

After configuring SSL for JDBC, optionally run the following command to enable the debug utility for SSL:

```
$ -Djavax.net.debug=ssl
```

You can use several debug specifiers (options) with the debug utility. The specifiers help narrow the scope of the debugging information that is returned. For example, you could specify one of the options that prints handshake messages or session activity.

For information on the debug utility and its options, see Debugging Utilities in the Oracle document, JSSE Reference Guide.

For information on interpreting debug information, refer to the Oracle document, Debugging SSL/TLS Connections.

Distributing Certificates and Keys

Before you can distribute certifications and keys to all hosts in a cluster, you must obtain the appropriate certificate signed by a certificate authority (CA) and private key files. See SSL Overview.

To distribute certifications and keys to all hosts in a cluster:

1. Log on to a host that contains the certifications and keys you want to distribute.

2. Start the Administration Tools, as described in Using the Administration Tools

   Note: The database does not need to be running when you distribute the certificates and key files.
3. On the Main Menu in the Administration Tools, select Configuration Menu, and click OK.

4. On the Configuration Menu:
   a. Select Distribute Config Files, and click OK.
   
   b. Select SSL Keys, and click OK.

5. Select the database on which you want to distribute the files and click OK. The following appears:

![Select files to install](image)

6. [Optional] Modify the fields in the previous screenshot to add the file locations for the `server.crt`, `server.key` and `root.crt` files, and click OK to distribute the files.

   Admintools sets the parameters SSLCertificate, SSLPrivateKey, and, if applicable, SSLCA. See Security Parameters.

   - If you are upgrading to 7.1, the SSLCertificate and SSLPrivateKey parameters are automatically set by Admintools if you set EnableSSL=1 in the previous version.
   - If your server.crt SSL certificate file includes certificate chain (more than one certificate), Admintools accepts the whole chained certificate.

7. Configure SSL.
**TLS Authentication**

Server authentication methods define how clients connect to a Vertica server. Before you define a TLS authentication method, you should understand what type of authentication methods your Vertica server supports. You should also perform any prerequisite tasks.

In regards to SSL, your server can operate with:

- No SSL
- SSL Server Mode —The client does not need certificate or key files.
- SSL Mutual Mode —The client needs certificate, key, and certificate authority files.

SSL modes are independent of authentication, except that the SSL client self-authentication method requires that your server be set-up in SSL Mutual Mode. Otherwise, if you are not implementing client self-authentication method, you can use TLS authentication with either SSL Server Mode or SSL Mutual Mode.

Before you create a TLS authentication method, perform the pre-requisite tasks necessary for your specific environment (for example, certificate creation). Refer to TLS/SSL Server Authentication and all subsections applicable to your environment.

To create a TLS authentication method, use the command `CREATE AUTHENTICATION` as documented in the SQL Reference Manual.

**Implementing Client Self-Authentication**

To use a client self-authentication method, your server must be in SSL Mutual Mode.

To create an authentication method for client self-authentication, use the `CREATE AUTHENTICATION` statement. Specify the `auth_type 'tls'` and with HOST TLS.

**Important:** You use the `tls` `auth_type` only when you want to create an authentication method for client self-authentication. You must use the `tls` `auth_type` with the HOST TLS syntax.
Create an Authentication Method with Client Self-Authentication Method

This section provides sample chronological steps for setting up a client for self-authentication, creating an authentication method, and associating the method with a user through a grant statement.

1. Follow all applicable procedures for implementing SSL and distributing certificates and keys. Refer to TLS/SSL Server Authentication as it applies to your environment.

   When you create a client key, make sure to include a Common Name (CN) that is the database user name you want to use with the target database.

   $ Common Name <server hostname> []:<database username>

2. Create the authentication method. Authentication methods are automatically enabled when you create them.

   => CREATE AUTHENTICATION myssltest METHOD 'tls' HOST TLS '10.0.0.0/23;

3. Associate the method with the user through a grant statement.

   => GRANT AUTHENTICATION myssltest TO mydatabaseusername;

Your client can now log on and be recognized.

For information on creating authentication methods, refer to the SQL Reference Manual topic, CREATE AUTHENTICATION.

Specify TLS for Client Connections

You can require clients to use TLS when connecting to Vertica. To do so, create a client authentication method for them that uses the HOST TLS syntax with the CREATE AUTHENTICATION statement.

Specific clients might connect through a network connection known to be insecure. In such cases, you can choose to limit specific users to connecting through TLS. You can also require all clients to use TLS.

See Creating Authentication Records for more information about creating client authentication methods.
LDAP Link Service

LDAP Link enables synchronization between the LDAP and Vertica servers. This eliminates the need for you to manage two sets of users and groups or roles, one on the LDAP server and another on the Vertica server. With LDAP synchronization, the Vertica server becomes a replication database for the LDAP server.

Automatic Synchronization

With LDAP Link the Vertica server closely integrates with an existing directory service such as MS Active Directory or OpenLDAP. The Vertica server automatically synchronizes:

- LDAP users to Vertica users
- LDAP groups to Vertica roles

You manage all user and group properties in the LDAP server. If you are the Vertica database administrator, you need only to set up permissions for Vertica Analytic Database access on the users and groups.

Configure LDAP Link with LDAP Link connection parameters that reside in the catalog. See Set LDAP Link Parameters for more information.

Enable LDAP Link

Enable LDAP Link as shown:

```sql
=> ALTER DATABASE dbname SET PARAMETER LDAPLinkURL='ldap://example.dc.com',
LDAPLinkSearchBase='dc=DC,dc=com', LDAPLinkBindDN='CN=jsmith,OU=QA,DC=dc,DC=com,
LDAPLinkBindPswd='password',LDAPLinkFilterUser='(objectClass=inetOrgPerson)',
LDAPLinkFilterGroup='(objectClass=group)', LDAPLinkOn=1;
=> SELECT ldap_link_sync_start();
```

See LDAP Link Parameters.

LDAP Link Workflow

After you enable LDAP Link, synchronization occurs according to this workflow:
1. The System Administrator creates users and user groups on the LDAP server.

2. The System Administrator sets up LDAP Link service parameters as required and enables the service.

3. Using the LDAP Link service, Vertica Analytic Database replicates the users and user groups from the Application LDAP to the Vertica database, creating Vertica users and roles.

4. The LDAP server uses Kerberos (KDC) to authenticate the user logging in to Vertica.
   - The LDAP user can log into Vertica if assigned the appropriate authentication type.
   - After login, you can grant users privileges using GRANT statements or as part of a Group.

Note: After synchronization the Vertica Analytic Database user does not have an associated authentication method. To allow the user to login, you must assign an authentication method to the user. See Implementing Client Authentication.
Using LDAP Link

When you implement LDAP Link the following are directly affected and help you manage and monitor the LDAP Link - Vertica Analytic Database synchronization:

- User and Group management
- LDAP Link User Flag
- Blocked Commands
- Client Authentication types

User and Group Management

Users and groups created on the LDAP server have a specific relationship with those users and roles replicated to the Vertica server:

- The user-group relationship on the LDAP server is maintained when those users and groups (roles) are synchronized with Vertica Analytic Database.

- If a user or group name exists on the Vertica database and a user or group with the same names is synchronized from the LDAP Server using LDAP Link, the users or groups become conflicted. Vertica can not support multiple users with the same name. For a resolution of this conflict, see User Conflicts.

LDAP Link uses the entries in the dn: section of the LDAP configuration file as the unique user identifier when synchronizing a user to the Vertica Analytic Database:

```
dn: cn=user1,ou=dev,dc=example,dc=com
  cn: user1
  ou: dev
  id: user1
```

The uid parameter in the LDAP configuration file indicates the LDAP user name.

```
uid: user1
```

Upon synchronization, the dn: entry gets mapped to the uid: to identify the Vertica Analytic Database user.
If you change a setting in the dn: and do not change the uid: LDAP Link interprets the user as a new user when re-synchronizing with the Vertica Analytic Database. In this case, the existing Vertica Analytic Database user with that uid: gets deleted from Vertica and a new Vertica Analytic Database user is created.

If you change the uid: and not the dn: on LDAP, the uid on the Vertica Analytic Database gets updated to the new uid. Since you did not change the dn: LDAP Link does not interpret the user as a new user.

### LDAP Link User Flag

As a dbadmin user, you can access the vs_users table to monitor user behavior on the Vertica Analytic Database. The users table contains an `ldap_dn` field that identifies whether or not the Vertica Analytic Database user is also an LDAP Link user. This example shows the `ldap_dn` field set to `dn` indicating the Vertica Analytic Database user is also an LDAP Link user:

```sql
=> SELECT * FROM vs_users;
- [ RECORD 1 ]-+-------------------------------+
| user_id       | 45035996273704962 |
| user_name     | dbadmin           |
| is_superuser  | t                 |
| profile_name  | default           |
| is_locked     | f                 |
| lock_time     |                  |
| resource_pool | general           |
| memory_cap_kb | unlimited         |
| temp_space_cap_kb | unlimited    |
| run_time_cap  | unlimited         |
| max_connections| unlimited        |
| connection_limit_mode | database     |
| idle_session_timeout | unlimited |
| all_roles     | dbuser*, dbadmin*, pseudosuperuser* |
| default_roles | dbuser*, dbadmin*, pseudosuperuser* |
| search_path   |                  |
| ldap_dn       | dn                |
| ldap_uri_hash | Ø                 |
| is_orphaned_from_ldap | f        |
```

### Blocked Commands

Be aware that the following SQL statements are blocked for Vertica Analytic Database users with `ldapdn` set to `dn` in the `vs_users` table:

- **DROP USER** and **DROP ROLE**
- **ALTER ROLE RENAME**
- `ALTER USER` name IDENTIFIED BY 'password' [REPLACE 'old_password']
- `ALTER USER` name PASSWORD EXPIRE
- `ALTER USER` name PROFILE
- `ALTER USER` name SECURITY_ALGORITHM...
- `ALTER USER` name DEFAULT ROLE role-name
- `GRANT (Role)`

### Client Authentication Types

LDAP user and groups cannot log into Vertica if client authentication is not assigned to the user or group. You can use the following valid authentication types for LDAP users and groups:

- GSS
- Ident
- LDAP
- Reject
- Trust

### LDAP Link Parameters

Use LDAP Link parameters to determine:

- LDAP Link operations, such as enabling or disabling LDAP Link and how often to perform replication
- Authentication parameters, including SSL authentication parameters
- Users and groups that inherit unowned objects
- How to resolve conflicts
Set LDAP Link Parameters

This example shows how you can set:

- The URL of the LDAP server (LDAPLinkURL) and
- The base DN from where to start replication (LDAPLinkSearchBase)

You also see how to set the LDAP Link Bind authentication parameters (LDAPLinkBindDN and LDAPLinkBindPswd) and enables LDAP Link (LDAPLinkOn).

```sql
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkURL='ldap://10.60.55.128',
   LDAPLinkSearchBase='dc=corp,dc=com',LDAPLinkBindDN='dc=corp,dc=com',LDAPLinkBindPswd='password';

=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkOn = '1';
```

General and Connection Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLinkOn</td>
<td>Enables or disables LDAP Link.</td>
</tr>
<tr>
<td><strong>Valid Values:</strong></td>

</tr>
<tr>
<td></td>
<td>using TLS.</td>
</tr>
<tr>
<td><strong>Valid Values:</strong></td>
<td></td>
</tr>
<tr>
<td>allow</td>
<td>connection is successful even if the client does not provide a certificate or provides an invalid certificate.</td>
</tr>
<tr>
<td>hard</td>
<td>connection is unsuccessful if the client does not provide a certificate or provides an invalid certificate.</td>
</tr>
<tr>
<td>try</td>
<td>connection is successful if the client does not provide a certificate. A connection is unsuccessful if the client provides an invalid certificate.</td>
</tr>
<tr>
<td>never</td>
<td>The client does not request or verify a certificate. For more information see <a href="#">Using LDAP Over SSL/TLS</a>.</td>
</tr>
<tr>
<td>Default Value:</td>
<td>allow</td>
</tr>
</tbody>
</table>

| LDAPLinkTLSCACert       | [Optional] The path to the CA certificates. |

### Miscellaneous Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLinkConflictPolicy</td>
<td>Determines how to resolve a user conflict.</td>
</tr>
<tr>
<td></td>
<td><strong>Valid Values:</strong></td>
</tr>
<tr>
<td>IGNORE</td>
<td>Ignores the incoming LDAP user and maintains the existing Vertica user.</td>
</tr>
<tr>
<td>MERGE</td>
<td>Converts the existing user to an LDAP user.</td>
</tr>
<tr>
<td>Default Value:</td>
<td>MERGE</td>
</tr>
</tbody>
</table>

| LDAPLinkStopIfZeroUsers | Enables or disables the shutdown of LDAPLink synchronization if no users are found in LDAP. |
|                         | **Valid values:** |
| 0                       | Disables the LDAPLink synchronization shutdown if no users are found. This may lead to inadvertent dropping of Vertica users. |
| 1                       | Enables the LDAPLink synchronization shutdown if no |
### Troubleshooting LDAP Link Issues

Various issues can arise with LDAP Link Service, including:

- Disconnected (Orphaned) Users and Roles
- Lost Objects
- User Conflicts

### Disconnected (Orphaned) Users and Roles

Vertica Analytic Database users and roles synchronized through LDAP Link can become disconnected, or *orphaned*, if an issue arises with the LDAP Link service. For example, users and roles become orphaned when you change the connection to the LDAP server as the following scenario describes:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>users</td>
<td>are found. This prevents inadvertent dropping of Vertica users.</td>
</tr>
</tbody>
</table>
| LDAPLinkDryRun  | [Optional] Tests the connection to the LDAP server and logs the response without doing a synchronization. Also tests if parameters are correctly set.  
|                 | **Valid Values:**  
|                 | 0 - Disables LDAPLinkDryRun  
|                 | 1 - Enables LDAPLinkDryRun  
|                 | **Default Value:** 0                                                      |

See [Managing Configuration Parameters: VSQL](#) for information on setting LDAP Link parameters.

**Note:** When you change any Connection or Authentication parameter, LDAP Link reconnects and re-initializes the synchronization.
1. Create an LDAP connection as follows:

```sql
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkURL='ldap://ebuser',
  LDAPLinkSearchBase='dc=example,dc=com', LDAPLinkBindDN='mega',
  LDAPLinkBindPswd='$megapassword$';
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkOn = '1';
```

2. Run an LDAP Link session to synchronize LDAP and Vertica users.

3. Change one or more connection parameters from Step 1. You can change the connection only if you change one of the LDAPLinkURL or LDAPLinkSearchBase parameters.

4. Run another LDAP Link session. The system attempts to re-synchronize LDAP and Vertica users. Since the connection has changed, the existing Vertica users cannot be synchronized with the LDAP users from the new connection. These Vertica users become orphaned.

As a dbadmin user, you can identify orphaned users by checking the field is_orphaned_from_ldap in the users system table:

```sql
=> SELECT is_orphaned_from_ldap FROM users;
```

A field value of t indicates that the user is an orphaned user. Orphaned Vertica users cannot connect to the LDAP server and cannot login to Vertica using LDAP authentication (however, other authentication methods assigned to the user work). In this case, you can delete the orphaned Vertica user and run the LDAP Link service to resynchronize users.

## Re-parented Objects

When you delete users or groups from linked LDAP, the LDAP Link service removes the same users and roles from Vertica Analytic Database. However, the service does not delete objects owned by the deleted user. Use the `GlobalHeirUserName` parameter to assign the objects to a new owner (re-parent).

**Example:**

```sql
=> ALTER DATABASE example_db SET PARAMETER GlobalHeirUserName=user1;
```

This creates a new user named user1, if it does not exist. The `GlobalHeirUserName` user serves as the new parent for all the objects owned by deleted users.

By default, this parameter is set to `<auto>` which re-parents the objects to the dbadmin user.

If you leave `GlobalHeirUserName` empty, the objects are not re-parented to another user.

For more information see `GlobalHeirUserName` in Security Parameters.
User Conflicts

Vertica Analytic Database users and roles synchronized using LDAP Link can become conflicted. Such conflicts can occur, for example, when you create a new user or group on the LDAP server and another user or role with the same name exists on the Vertica Analytic Database.

As a dbadmin user, use one of the following parameters to resolve user conflicts:

- LDAPLinkConflictPolicy
- LDAPLinkStopIfZeroUsers

**LDAPLinkConflictPolicy**

Use LDAPLinkConflictPolicy to resolve any user conflicts:

- LDAPLinkConflictPolicy=IGNORE - Ignores the incoming LDAP users and maintains the existing Vertica user
- LDAPLinkConflictPolicy=MERGE - Merges the incoming LDAP user with the Vertica user and converts the database user to an LDAP user retaining the database user's objects

Example:

```sql
=> ALTER DATABASE example_db SET PARAMETER LDAPLinkConflictPolicy='MERGE';
```

The default is MERGE. If you change LDAPLinkConflictPolicy, the change takes affect on the next synchronization.

**LDAPLinkStopIfZeroUsers**

Use LDAPLinkStopIfZeroUsers to prevent an accidental dropping of Vertica users if the LDAP Link synchronization does not find any LDAP users.

- LDAPLinkStopIfZeroUsers=0 - Does not stop the LDAP Link synchronization if no users are found in LDAP. This drops all Vertica users during synchronization.
- LDAPLinkStopIfZeroUsers=1 - Stops the LDAP Link synchronization if no users are found in LDAP and displays an error. This prevents the dropping of Vertica users due to some issue.
Monitoring LDAP Link

Use the ldap_link_events table to monitor events that occurred during an LDAP Link synchronization:

```sql
=> SELECT transaction_id, event_type, entry_name, entry_oid FROM ldap_link_events;
```

<table>
<thead>
<tr>
<th>transaction_id</th>
<th>event_type</th>
<th>entry_name</th>
<th>entry_oid</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996273705317</td>
<td>SYNC_STARTED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>4506696273253589</td>
<td>SYNC_FINISHED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>45066988112255317</td>
<td>PROCESSING_STARTED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>2341123456789765</td>
<td>USER_CREATED</td>
<td>tuser</td>
<td>234548899</td>
</tr>
</tbody>
</table>

(4 rows)
Connector Framework Service

The Connector Framework Service (CFS) allows secure indexing of documents from IDOL to the Vertica Analytic Database. Access Control Lists determine which users have permissions to access documents. Documents transferred from IDOL are stored in a Flex table (Using Flex Tables).

The dbadmin creates a view from this flex table (see Views). Users access the IDOL data from these views.

CFS Components

Use the following CFS components to implement the service on the Vertica:

- IDOL document metadata
- Security key and authorization functions
- SQL statement and Security Parameter
- CFS Configuration file

See Implementing CFS

Document Metadata

Vertica Analytic Database stores IDOL document metadata in a flex table. Set the name of the flex table with the TableName parameter in the CFS configuration file (see Modify the CFS Configuration File). The metadata includes the following:

- AUTONOMYMETADATA (Mandatory)—An alphanumeric designation for the ACL designated for the document.
- DREFIELD—Assigns permission levels to users and groups for accessing IDOL documents.
- DRETITLE—The document title.

For information see.
Security Key and Authorization Functions

As the dbadmin user you can assign each user a unique Security Information String (SIS). The strings are encrypted with a key stored in /idol/community/key. This key uses the following functions:

- INSTALL_COMMUNITY_KEY
- DESCRIBE_COMMUNITY_KEY
- DELETE_COMMUNITY_KEY

In addition to the preceding functions, the authorization function IDOL_CHECK_ACL verifies that the user has access to data in the view.

These functions reside in the v_idol schema contained in the idollib library installed with the CFS. When you run the functions, you must use v_idol in the command, for example:

```
=> SELECT v_idol.DELETE_COMMUNITY_KEY();
```

SQL Statement and Security Parameter

As the dbadmin user set the Security Information String for a specific user using:

- ALTER SESSION

- IdolSecurityInfo user-defined session parameter.

CFS Configuration File

You must index IDOL metadata in Vertica Analytic Database to be available for queries. See Implementing CFS
Implementing CFS

After Vertica Analytic Database ingests documents from IDOL, you can implement CFS to secure those documents. Implementing the security requires action from both the Vertica database administrator and the user who runs queries.

The database administrator must:

- **Modify the CFS Configuration File**
- **Create a View** from the flex table where the ingested IDOL data resides
- **Install the Security Key** used to decrypt the Security Information String
- **Verify CFS implementation success**

Upon CFS implementation, the user can **Query the IDOL Data**:

Modify the CFS Configuration File

Set the following in the CFS configuration file to have CFS automatically index the metadata:

1. In the `[Indexing]` section, set the `IndexerSections` parameter to `vertica`:

   ```
   [Indexing]
   IndexerSections=vertica
   IndexBatchSize=1
   IndexTimeInterval=30
   ```

2. Create a new section with the same name you entered in the `IndexerSections` parameter and enter the following parameters and keywords:

   ```
   [vertica]
   IndexerType=Library
   ConnectionString=Driver=Vertica;Server=123.456.478.900;Database=myDb;UID=dbadmin;PWD=password
   TableName=myFlexTable
   LibraryDirectory=./shared_library_indexers
   LibraryName=VerticaIndexer
   ```

The `VerticaIndexer` (LibraryName above) is part of CFS. To use this tool, you must install and configure the Vertica ODBC drivers on the same machine as CFS. CFS sends JSON-formatted data to the Flex table using ODBC. For more information, see Installing ODBC Drivers on Linux, Solaris, AIX, and HP-UX.
Create a View

The Vertica database administrator must create a view from the flex table where the ingested IDOL data resides. Users querying IDOL data do so using this view, thus preventing unauthorized access to the flex table.

This example creates a view from the idol_table:

```sql
=> CREATE VIEW idol_view as select * from idol_table where v_idol.idol_check_acl(acl, security_section, security_type);
```

You must then run GRANT privileges as follows:

1. Grant usage on the v_idol schema:

```sql
=> GRANT USAGE on schema v_idol to user1;
GRANT PRIVILEGE
```

2. Grant SELECT privileges on the view to any user who needs access:

```sql
=> GRANT SELECT on idol_view to user1;
GRANT PRIVILEGE
```

3. Grant usage on the library. This allows you to set UDSession parameters later:

```sql
=> GRANT USAGE on library v_idol.IdolLib to user1;
GRANT PRIVILEGE
```

4. Grant execute privileges on the acl-checking function.

```sql
=> GRANT EXECUTE on function v_idol.idol_check_acl(long varchar, long varchar, long varchar) to user1;
GRANT PRIVILEGE
```

Important: When granting EXECUTE privileges on a CFS function, ensure that you only grant the privilege to v_idol.idol_check_acl(). Never grant EXECUTE privileges to the following CFS functions:

- v_idol.install_community_key()
- v_idol.describe_community_key()
- v_idol.delete_community_key()
Install the Security Key

Before a user can access the view containing IDOL data, the database administrator must retrieve and install the security key. Store the security key in Vertica's Distributed File System (DFS) with the following command:

```
=> SELECT v_idol.install_community_key(USING PARAMETERS file_path='/home/user1/Downloads/IDOL/cli/aes.txt');
```

The Security Key is the same one used in IDOL. You can only install one key at a time. Installing another key overwrites the existing one.

The SecurityInfoKeys parameter in the following IDOL configuration files indicates the key you need to install:

- community/Community.cfg
- content/Content.cfg

After installing the key, run the following command to ensure it was correctly installed:

```
=> SELECT v_idol.describe_community_key();
```

```
daf3cc7d3c9368c2e78ed336aec6d8e75ee038c47aajc76f86a3bb5b197639ed43725a
(1 row)
```

See DELETE_COMMUNITY_KEY for information on deleting security keys.

Verify CFS implementation success

As a database administrator, do the following to verify the successful implementation of CFS:

1. Retrieve the Security Information String (SIS) from your organization's application. This is accomplished outside of Vertica.

2. Set the retrieved SIS for your current session:

```
=> ALTER SESSION set UDPARAMETER FOR v_idol.IdolLib IdolSecurityInfo = 'MzA0U08/+T59PHj6Pn64v/m8A';
```

3. Run the following ACL check function to see if it returns true only for rows to which you should have access:
Alternatively you can run the ACL check function and explicitly pass the SIS:

```sql
=> SELECT v_idol.idol_check_acl(acl, security_section, security_type) from cfs_table;
    idol_check_acl
  ----------------
     f
     t
   (2 rows)
```

**Query the IDOL Data**

A user querying IDOL must do the following:

1. **Retrieve the Security Information String (SIS) from your organization’s application.** This is accomplished outside of Vertica.

2. **Set the retrieved SIS for your current user session:**

   ```sql
   => ALTER SESSION set UDTPARAMETER FOR v_idol.IdolLib IdolSecurityInfo = 'MzA0U08/+T59PHj6Pn64v/m8A';
   ``

This example checks the v_idol.t flex table for the idol access control list, security section, and security type. All these parameters must match the metadata in the flex table.

3. **Run the query:**

   ```sql
   => SELECT * FROM idol_view;
   ```
Federal Information Processing Standard

When running on a certified FIPS-140-2 Red Hat 6.6 system, Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module. This meets the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries.

The standard specifies the security requirements that a cryptographic module needs in a system protecting sensitive information. For details on the standard see the Computer Security Resource Center.

**Note:** Vertica itself is not FIPS compliant but it is compatible with running on a FIPS-enabled system using FIPS resources.

For a list of FIPS prerequisites, see FIPS 140-2 Supported Platforms.

OpenSSL Behavior

Dynamic OpenSSL linking is a requirement for a FIPS implementation linking on the client and server. The Vertica server uses the OpenSSL that resides on the host system (version 1.0.1e as indicated in FIPS 140-2 Supported Platforms). OpenSSL dynamically links with LDAP and Kerberos.

For more information see Locate OpenSSL Libraries.

Libraries on CentOS 6.6 FIPS Systems

On a CentOS 6.6 FIPS system, Vertica runs only with the OpenSSL libraries `libcrypto.so.1.0.1e` and `libssl.so.1.0.1e`. Other versions of these libraries do not run on a FIPS system. This incompatibility occurs because the FIPS security policy checksums the library to which an application is linked and verifies that the library the application executes with the same checksum.
Library Versioning on Non-FIPS Systems

Be aware that on some non-FIPS systems, versioning anomalies can occur when you install a new version of OpenSSL. Sometimes, the default OpenSSL build procedure produces libraries with versions named 1.0.0. For Vertica to recognize that a library has a higher version number, you must provide the library name with a higher version number. For example, when installing OpenSSL version 1.0.1t, name the libraries libcrypto.so.1.0.1t or libssl.1.0.1t (symbolic links with these names are sufficient).

Install FIPS-enabled Vertica

The Vertica Analytic Database installation process determines if your system environment is FIPS compliant by checking the file /proc/sys/crypto/fips_enabled as follows:

```
$ sysctl crypto.fips_enabled
crypto.fips_enabled = 1
```

- If fips_enabled contains a 1, the host is FIPS enabled.
- If fips_enabled contains a 0, the host is not FIPS enabled.

If the host is FIPS enabled, the installation does the following:

- Verifies that OpenSSL resides in the appropriate area. If application does not exist before installation, the installer uses the OpenSSL provided by Vertica as the default. (OpenSSL is stored in /opt/vertica/lib).
- Runs a test to verify that Vertica was successfully configured for FIPS. If this test fails on any node, the installer fails.

For more information see Installing Vertica.

FIPS-Enabled Databases

Manually creating a new database on a FIPS-enabled Vertica Analytic Database requires a different approach than for a non-FIPS machine. Be aware of the following limitations:
You cannot create a FIPS-enabled database on a non-FIPS machine.

You cannot create a non-FIPS database on a FIPS-enabled machine.

Copying data generated with the MD5 hashing algorithm from a non-FIPS machine to a FIPS-enabled machine results in data corruption.

Implementing FIPS 140-2

Implementing FIPS 140-2 on your Vertica Analytic Database requires configuration on the server and client. The Vertica server uses FIPS-approved algorithms; however Vertica clients may be running on non-FIPS-approved systems. Therefore, you must implement FIPS 140-2 compliance from end to end.

For more information on implementing FIPS, see:

- Implement FIPS on the Server
- Implement FIPS on the Client

Implement FIPS on the Server

To implement FIPS on the Vertica server, you must:

- Generate a secure SSL certificate to establish a secure connection to the client.
- If necessary, set the LD_LIBRARY_PATH environment variable to locate the OpenSSL libraries.

RequireFIPS Parameter

Upon startup Vertica sets the RequireFIPS parameter on the server to reflect the FIPS state of the system, as follows:
Specify that FIPS is disabled:

```
RequireFIPS = 0
```

Specify that FIPS is enabled:

```
RequireFIPS = 1
```

The value of RequireFIPS matches the value of crypto.fips_enabled file. See Install FIPS-enabled Vertica.

Verify the value of the RequireFIPS parameter as follows:

```
=> SELECT get_config_parameter('RequireFIPS');
get_config_parameter
----------------------
0
(1 row)
```

Depending on the FIPS state, the following behaviors can occur:

- If the file `/proc/sys/crypto/fips_enabled` exists and contains a 1 (FIPS-enabled), Vertica sets RequireFIPS to 1. Modifying RequireFIPS with `ALTER DATABASE (RequireFIPS = 0)` generates an error.

- If the file `/proc/sys/crypto/fips_enabled` does not exist, or exists and contains a 0 (non-FIPS), Vertica automatically sets RequireFIPS to 0. Modifying RequireFIPS with `ALTER DATABASE (RequireFIPS = 1)` generates an error.

- If the FIPS state of a node, as determined from the existence of `/proc/sys/crypto/fips_enabled`, differs from the state received from the cluster initiator, the node fails. This behavior prevents the creation of clusters of mixed FIPS and non-FIPS systems.

**Important:** If you attempt to restore a FIPS-enabled node to a non-FIPS cluster, the restore process fails.

**Locate OpenSSL Libraries**

Vertica must find and load the correct OpenSSL libraries, `libcrypto.so.1.0.1.e` and `libssl.so.1.0.1.e`. To do so, it searches the system directory where the libraries reside. If the SSL libraries are not found, Vertica uses its own openssl libraries that reside under `/opt/vertica/lib`. 
Note: If you do not use admintools to start Vertica, or have conflicting libraries in your system, you must manually set LD_LIBRARY_PATH with `/opt/vertica/lib` appearing first in the list. When admintools starts or reboots Vertica, the path is set automatically.

Secure Client-Server Connection

Vertica uses TLS 1.2 to support the server-client connection for a FIPS-enabled system. This specification includes using a server certificate issued by a Certificate Authority.

Note: Using TLS 1.2 prevents you from using the MD5 algorithm for hashing passwords. Vertica accepts only AuthenticatedClearTextPasswords hashed by SHA-512. Users with MD5 passwords must migrate to SHA-512 passwords. For more information, see Upgrade Considerations for Hash Authentication.

For instructions on generating a self-signed certificate see Generating SSL Certificates and Keys. After generating a certificate, you need to distribute it to all hosts on the cluster. See Distributing Certificates and Keys. This distribution stores the certificate in the SSLCertificate parameter and the private key in the SSLPrivateKey parameter. For more information see Security Parameters.

Implement FIPS on the Client

Vertica provides a FIPS-compliant client driver, which you can install on a FIPS-enabled system. The 64-bit client includes vsq1 and ODBC drivers.

For information on the FIPS client, and installation, refer to the following

- Installing the FIPS Client Driver for ODBC and vsq1.
- Installing the FIPS Client Driver for JDBC

FIPS 140-2 Compliance Statement

Contents

1. Summary
2. Overview
1. Summary

Vertica complies with Federal Information Processing Standard 140-2 (FIPS 140-2), which defines the technical requirements to be used by Federal Agencies when these organizations specify cryptographic-based security systems for protection of sensitive or valuable data. The compliance of Vertica with FIPS 140-2 is ensured by: 1) Integrating validated and NIST-certified third party cryptographic module(s), and using the module(s) as the only provider(s) of cryptographic services; 2) Using FIPS-approved cryptographic functions; 3) Using FIPS-approved and NIST-validated technologies applicable for Vertica design, implementation and operation.

2. Overview

a. About Vertica

- Vertica is a high performance relational database management system used for advanced analytics applications. Its performance and scale is achieved through a columnar storage and execution architecture that offers a massively parallel processing solution. Aggressive encoding and compression allows Vertica analytics to perform by reducing CPU, memory and disk I/O Processing times.

- For more details about Vertica and its usage, see Vertica Concepts.

b. About FIPS 140-2

FIPS (Federal Information Processing Standard) 140-2, *Security requirements for cryptographic modules*, is the Federal standard for proper cryptography for computer systems purchased by the government.

The benefits of using FIPS 140-2 validated crypto module is that the crypto algorithms are deemed appropriate and that they perform the encrypt/decrypt/hash functions correctly. The standard specifies the security requirements for cryptographic modules utilized within a
security system that protects sensitive or valuable data. The requirements can be found in the following documents:

- SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES
- Annex A: Approved Security Functions for FIPS PUB 140-2, Security Requirements for Cryptographic Modules

3. Vertica and FIPS 140-2

FIPS 140-2 validated third party module

Vertica conforms with FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by the Operating System, which in our initial release is RedHat Enterprise Linux 6.6 OpenSSL Module.

Vertica can be configured to operate in FIPS-compliant mode ensuring its functions and procedures like SSL/TLS connections, which require cryptography (secure hash, encryption, digital signatures, etc.) makes use of the crypto services provided by RedHat Enterprise 6.6 OpenSSL module Version 3.0 which is validated for FIPS 140-2. If you are not running on RedHat 6.6 you will not be able to run Vertica on FIPS mode. The assurance that Vertica is using the right FIPS 140-2 encryption modules is managed at the operating system level by RedHat’s implementation.

Vertica checks the OS level flag setting /proc/sys/crypto/fips_enabled to kick off Vertica’s FIPS mode installation. Further details about how to install and configure Vertica and its components to conform to FIPS 140-2 standard appear in the installation and security guides:

- Installing Vertica with the Installation Script
- Federal Information Processing Standard

Modes of Operation

Vertica Server operates in one of two modes determined by the OS configuration.

- FIPS-compliant mode – supports FIPS 140-2 compliant cryptographic functions. In this mode, all cryptographic functions, default algorithms and key lengths are bound to those allowed by FIPS 140-2.
- Standard mode – non-FIPS 140-2 compliant mode which utilizes all existing Vertica cryptography functions.
**TLS/SSL3.x**

All the Vertica client/server communications can be secured with FIPS-compliant Transport Layer Security TLS1.2/SSL3.1 or higher. It is relying on FIPS 140-2 approved hash algorithms and ciphers.

- TLS handshake, key negotiation and authentication provides data integrity and uses secure hash and FIPS 140-2 approved cryptography and digital signature.
- TLS encryption of data in transit provides confidentiality and making use of FIPS 140-2 approved cryptography.

**Secure Hash**

Per FIPS 140-2 standards, Vertica, in the FIPS 140-2 compliant mode, can be configured to use only the SHA-512 algorithm.

**FIPS 140-2 Architecture**

Vertica is a relational database system that is comprised of a client component and a server component. On the Client Side, we offer a suite of drivers for host clients to access the Vertica Server Side component. Both client and server Vertica components conform to FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by RedHat Enterprise Linux 6.6 OpenSSL Module.

---

**Supported platforms**

Supported operating systems (both client and server):

- RedHat Enterprise Linux 6.6 64 bit

Supported client drivers:

- ODBC only
**Design Assurance**

Vertica uses the security provider Red Hat Enterprise Linux 6.6 OpenSSL Module v3.0. This is the only supported security provider for FIPS 140-2.

Once you have configured Vertica to be compliant with FIPS 140-2, you cannot revert back to the standard configuration unless you disable FIPS 140-2 at the operating system level. Please reference the following documentation section for considerations:

- Implement FIPS on the Server
- Implement FIPS on the Client
System Table Restriction and Access

Two functions let you restrict and open access to system tables for a given session:

- **RESTRICT_SYSTEM_TABLES_ACCESS** restricts access to non-superuser-only tables that are not accessible during lockdown.

- **RELEASE_SYSTEM_TABLES_ACCESS** allows access to non-superuser-only tables that are not accessible during lockdown.
Extending Vertica

You can extend Vertica to perform new operations or handle new types of data. There are several types of extensions:

- External procedures let you execute external scripts or programs that are installed on a host in your database cluster.

- User-Defined SQL Functions let you store frequently-used SQL expressions. They can help you simplify and standardize your SQL scripts.

- User-Defined Extensions (UDxs) let you develop your own analytic or data-loading tools using the C++, Python, Java, and R programming languages. They are useful when the type of data processing you want to perform is difficult or slow using SQL.

The following sections explain how to use extensions that have already been written:

- Using External Procedures
- Using User-Defined SQL Functions
- Using User-Defined Extensions

Developing User-Defined Extensions (UDxs) explains how to write new UDxs, including the following types:
- **Aggregate Functions (UDAFs)**
- **Analytic Functions (UDAnFs)**
- **Scalar Functions (UDSFs)**
- **Transform Functions (UDTFs)**
- **Load (UDLs)**
Using External Procedures

The external procedure feature lets you call a script or executable program on a host in your database cluster from within Vertica. You can pass literal values to this external procedure as arguments. The external procedure cannot communicate back to Vertica.

This chapter explains how to create, install, and use external procedures.
Implementing External Procedures

To implement an external procedure:

   
   See Requirements for External Procedures.

2. Enable the set-user-ID (SUID), user execute, and group execute attributes for the file. The file must either be readable by the dbadmin or the file owner's password must be given with the Administration Tools install_procedure command.

3. Install the external procedure executable file.

4. Create the external procedure in Vertica.

Once a procedure is created in Vertica, you can execute or drop it, but you cannot alter it.

Requirements for External Procedures

External procedures have requirements regarding their attributes, where you store them, and how you handle their output. You should also be cognizant of their resource usage.

Procedure File Attributes

The procedure file cannot be owned by root. It must have the set-user-ID (SUID), user execute, and group execute attributes set. If it is not readable by the Linux database administrator user, then the owner's password will have to be specified when installing the procedure.

Handling Procedure Output

Vertica does not provide a facility for handling procedure output. Therefore, you must make your own arrangements for handling procedure output, which should include writing error, logging, and program information directly to files that you manage.
Handling Resource Usage

The Vertica resource manager is unaware of resources used by external procedures. Additionally, Vertica is intended to be the only major process running on your system. If your external procedure is resource intensive, it could affect the performance and stability of Vertica. Consider the types of external procedures you create and when you run them. For example, you might run a resource-intensive procedure during off hours.

Sample Procedure File

```bash
#!/bin/bash
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

Installing External Procedure Executable Files

To install an external procedure, use the Administration Tools through either menu or the command line.

Using the Admin Tools Menus

a. Run the Administration Tools.

```
$ /opt/vertica/bin/adminTools
```

b. On the AdminTools Main Menu, click Configuration Menu, and then click OK.

c. On the Configuration Menu, click Install External Procedure and then click OK.

d. Select the database on which you want to install the external procedure.

e. Either select the file to install or manually type the complete file path, and then click OK.

f. If you are not the superuser, you are prompted to enter your password and click OK.

The Administration Tools automatically create the `<database_catalog_path>/procedures` directory on each node in the database and installs the external
procedure in these directories for you.

g. Click OK in the dialog that indicates that the installation was successful.

Command Line

If you use the command line, be sure to specify the full path to the procedure file and the password of the Linux user who owns the procedure file;

For example:

```bash
$ admintools -t install_procedure -d vmartdb -f /scratch/helloworld.sh -p ownerpassword
Installating external procedure...
External procedure installed
```

Once you have installed an external procedure, you need to make Vertica aware of it. To do so, use the `CREATE PROCEDURE` statement, but review Creating External Procedures first.

Creating External Procedures

Once you have installed an external procedure, you need to make Vertica aware of it. To do so, use the `CREATE PROCEDURE` statement.

Only a superuser can create an external procedure. Initially, only superusers can execute an external procedure. However, a superuser can grant the right to execute a stored procedure to a user on the operating system. (See `GRANT (Procedure)`.)

Once created, a procedure is listed in the `V_CATALOG.USER_PROCEDURES` system table. Users can see only those procedures that they have been granted the privilege to execute.

Example

This example creates a procedure named `helloplanet` for the `helloplanet.sh` external procedure file. This file accepts one `VARCHAR` argument. The sample code is provided in Requirements for External Procedures.

```sql
=> CREATE PROCEDURE helloplanet(arg1 VARCHAR) AS 'helloplanet.sh' LANGUAGE 'external'
   USER 'dbadmin';
```

This example creates a procedure named `proctest` for the `copy_vertica_database.sh` script. This script copies a database from one cluster to another, and it is included in the server RPM located in the `/opt/vertica/scripts` directory.
CREATE PROCEDURE proctest(shosts VARCHAR, thosts VARCHAR, dbdir VARCHAR)
AS 'copy_vertica_database.sh' LANGUAGE 'external' USER 'dbadmin';

Overloading External Procedures
You can create multiple external procedures with the same name as long as they have a different signature (accept a different set of arguments). For example, you can overload the helloplanet external procedure to also accept an integer value:

CREATE PROCEDURE helloplanet(arg1 INT) AS 'helloplanet.sh' LANGUAGE 'external'
USER 'dbadmin';

After executing the above statement, your database catalog will have two external procedures named helloplanet—one that accepts a VARCHAR argument and one that accepts an integer. When you call the external procedure, Vertica determines which procedure to call based on the arguments you passed in the procedure call.

See Also
- CREATE PROCEDURE
- GRANT (Procedure)

Executing External Procedures
Once you define a procedure through the CREATE PROCEDURE statement, you can use it as a meta command through a simple SELECT statement. Vertica does not support using procedures in more complex statements or in expressions.

The following example runs a procedure named helloplanet:

SELECT helloplanet('earthlings');
helloplanet
---------
0
(1 row)

The following example runs a procedure named proctest. This procedure references the copy_vertica_database.sh script that copies a database from one cluster to another. It is installed by the server RPM in the /opt/vertica/scripts directory.
=> SELECT proctest(
   '-s qa01',
   '-t rbench1',
   '-D /scratch_b/qa/PROC_TEST');

Note: External procedures have no direct access to database data. If available, use ODBC or JDBC for this purpose.

Procedures are executed on the initiating node. Vertica runs the procedure by forking and executing the program. Each procedure argument is passed to the executable file as a string. The parent fork process waits until the child process ends.

To stop execution, cancel the process by sending a cancel command (for example, CTRL+C) through the client. If the procedure program exits with an error, an error message with the exit status is returned.

Permissions

To execute an external procedure, the user needs:

- EXECUTE privilege on procedure
- USAGE privilege on schema that contains the procedure

See Also

- CREATE PROCEDURE
- External Procedure Privileges

Dropping External Procedures

Only a superuser can drop an external procedure. To drop the definition for an external procedure from Vertica, use the DROP PROCEDURE statement. Only the reference to the procedure is removed. The external file remains in the <database>/procedures directory on each node in the database.

Note: The definition Vertica uses for a procedure cannot be altered; it can only be dropped.
Example

=> DROP PROCEDURE helloplanet(arg1 varchar);

- DROP PROCEDURE
Using User-Defined SQL Functions

User-Defined SQL Functions let you define and store commonly-used SQL expressions as a function. User-Defined SQL Functions are useful for executing complex queries and combining Vertica built-in functions. You simply call the function name you assigned in your query.

A User-Defined SQL Function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

For syntax and parameters for the commands and system table discussed in this section, see the following topics in the SQL Reference Manual:

- CREATE FUNCTION
- ALTER FUNCTION (UDF)
- DROP FUNCTION
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
- V_CATALOG.USER_FUNCTIONS

Creating User-Defined SQL Functions

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

To create a SQL function, the user must have CREATE privileges on the schema. To use a SQL function, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function.

This following statement creates a SQL function called myzeroifnull that accepts an INTEGER argument and returns an INTEGER result.

```sql
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
       RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
   END;
```
You can use the new SQL function (myzeroifnull) anywhere you use an ordinary SQL expression. For example, create a simple table:

```sql
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
```

```sql
<table>
<thead>
<tr>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
(3 rows)
```

Use the myzeroifnull function in a SELECT statement, where the function calls col1 from table tabwnulls:

```sql
=> SELECT myzeroifnull(col1) FROM tabwnulls;
```

```sql
myzeroifnull
-----------
  1
  0
  0
(3 rows)
```

Use the myzeroifnull function in the GROUP BY clause:

```sql
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
```

```sql
count
-----
  2
  1
(2 rows)
```

If you want to change a user-defined SQL function's body, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```sql
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
     RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
   END;
```

To see how this information is stored in the Vertica catalog, see Viewing Information About SQL Functions in this guide.

See Also

- CREATE FUNCTION (SQL Functions)
- USER_FUNCTIONS
## Altering and Dropping User-Defined SQL Functions

Vertica allows multiple functions to share the same name with different argument types. Therefore, if you try to alter or drop a SQL function without specifying the argument data type, the system returns an error message to prevent you from dropping the wrong function:

```sql
=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull
```

Note: Only a superuser or owner can alter or drop a SQL Function.

### Altering a User-Defined SQL Function

The `ALTER FUNCTION (UDF)` command lets you assign a new name to a user-defined function, as well as move it to a different schema.

In the previous topic, you created a SQL function called `myzeroifnull`. The following command renames the `myzeroifnull` function to `zerowhennull`:

```sql
=> ALTER FUNCTION myzeroifnull(x INT) RENAME TO zerowhennull;
ALTER FUNCTION
```

This next command moves the renamed function into a new schema called `macros`:

```sql
=> ALTER FUNCTION zerowhennull(x INT) SET SCHEMA macros;
ALTER FUNCTION
```

### Dropping a SQL Function

The `DROP FUNCTION` command drops a SQL function from the Vertica catalog.

Like with `ALTER FUNCTION`, you must specify the argument data type or the system returns the following error message:

```sql
=> DROP FUNCTION zerowhennull();
ROLLBACK: Function with specified name and parameters does not exist: zerowhennull
```

Specify the argument type:
DROP FUNCTION macros.zerowhennull(x INT);

Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL Functions), Vertica returns an error when those objects are used, not when the function is dropped.

Tip: To view a list of all user-defined SQL functions on which you have EXECUTE privileges, (which also returns their argument types), query the V_CATALOG.USER_FUNCTIONS system table.

See Also

- ALTER FUNCTION (UDF)
- DROP FUNCTION

Managing Access to SQL Functions

Before a user can execute a user-defined SQL function, he or she must have USAGE privileges on the schema and EXECUTE privileges on the defined function. Only the superuser or owner can grant/revoke EXECUTE usage on a function.

To grant EXECUTE privileges to user Fred on the myzeroifnull function:

```sql
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Fred;
```

To revoke EXECUTE privileges from user Fred on the myzeroifnull function:

```sql
=> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Fred;
```

See Also

- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
Viewing Information About User-Defined SQL Functions

You can access information about any User-Defined SQL Functions on which you have EXECUTE privileges. This information is available in the system table `V_CATALOG.USER_FUNCTIONS` and from the vsql meta-command `\df`.

To view all of the User-Defined SQL Functions on which you have EXECUTE privileges, query the `USER_FUNCTIONS` table:

```sql
=> SELECT * FROM USER_FUNCTIONS;
```

<table>
<thead>
<tr>
<th>schema_name</th>
<th>public</th>
</tr>
</thead>
<tbody>
<tr>
<td>function_name</td>
<td>myzeroifnull</td>
</tr>
<tr>
<td>function_return_type</td>
<td>Integer</td>
</tr>
<tr>
<td>function_argument_type</td>
<td>x Integer</td>
</tr>
<tr>
<td>function_definition</td>
<td>RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END</td>
</tr>
<tr>
<td>volatility</td>
<td>immutable</td>
</tr>
<tr>
<td>is_strict</td>
<td>f</td>
</tr>
</tbody>
</table>

If you want to change a User-Defined SQL Function's body, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```sql
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
  AS BEGIN
    RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
  END;
```

Now when you query the `USER_FUNCTIONS` table, you can see the changes in the `function_definition` column:

```sql
=> SELECT * FROM USER_FUNCTIONS;
```

<table>
<thead>
<tr>
<th>schema_name</th>
<th>public</th>
</tr>
</thead>
<tbody>
<tr>
<td>function_name</td>
<td>myzeroifnull</td>
</tr>
<tr>
<td>function_return_type</td>
<td>Integer</td>
</tr>
<tr>
<td>function_argument_type</td>
<td>x Integer</td>
</tr>
<tr>
<td>function_definition</td>
<td>RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END</td>
</tr>
<tr>
<td>volatility</td>
<td>immutable</td>
</tr>
<tr>
<td>is_strict</td>
<td>f</td>
</tr>
</tbody>
</table>

If you use CREATE OR REPLACE syntax to change only the argument name or argument type (or both), the system maintains both versions of the function. For example, the following command tells the function to accept and return a numeric data type instead of an integer for the `myzeroifnull` function:
CREATE OR REPLACE FUNCTION myzeroifnull(z NUMERIC) RETURN NUMERIC
AS BEGIN
    RETURN (CASE WHEN (z IS NULL) THEN 0 ELSE z END);
END;

Now query the USER_FUNCTIONS table, and you can see the second instance of myzeroifnull in Record 2, as well as the changes in the function_return_type, function_argument_type, and function_definition columns.

Note: Record 1 still holds the original definition for the myzeroifnull function:

Because Vertica allows functions to share the same name with different argument types, you must specify the argument type when you alter or drop a function. If you do not, the system returns an error message:

=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull

See Also

- USER_FUNCTIONS

Migrating Built-In SQL Functions

If you have built-in SQL functions from another RDBMS that do not map to a Vertica-supported function, you can migrate them into your Vertica database by using a user-defined SQL function.
The example scripts below show how to create user-defined functions for the following DB2 built-in functions:

- **UCASE()**
- **LCASE()**
- **LOCATE()**
- **POSSTR()**

**UCASE()**

This script creates a user-defined SQL function for the `UCASE()` function:

```sql
=> CREATE OR REPLACE FUNCTION UCASE (x VARCHAR)
   RETURN VARCHAR
   AS BEGIN
   RETURN UPPER(x);
   END;
```

**LCASE()**

This script creates a user-defined SQL function for the `LCASE()` function:

```sql
=> CREATE OR REPLACE FUNCTION LCASE (x VARCHAR)
   RETURN VARCHAR
   AS BEGIN
   RETURN LOWER(x);
   END;
```

**LOCATE()**

This script creates a user-defined SQL function for the `LOCATE()` function:

```sql
=> CREATE OR REPLACE FUNCTION LOCATE(a VARCHAR, b VARCHAR)
   RETURN INT
   AS BEGIN
   RETURN POSITION(a IN b);
   END;
```
POSSTR()

This script creates a user-defined SQL function for the POSSTR() function:

=> CREATE OR REPLACE FUNCTION POSSTR(a VARCHAR, b VARCHAR)
   RETURN INT
   AS BEGIN
   RETURN POSITION(b IN a);
   END;
Using User-Defined Extensions

A User-Defined Extension (abbreviated as UDx) is a component that adds new abilities to the Vertica Analytics Platform. UDxs provide features such as new types of data analysis and the ability to parse and load new types of data.

This section provides an overview of how to install and use a UDx. If you are using a UDx developed by a third party, you should consult any documentation that accompanies it for detailed installation and usage instructions.

Loading UDxs

User-Defined Extensions (UDxs) are contained in libraries. A library can contain multiple UDxs. To add UDxs to Vertica you must:

1. Load the library (once per library).
2. Declare each UDx (once per UDx).

If you are using UDxs written in Java, you must also set up a Java runtime environment. See Installing Java on Vertica Hosts.

Loading Libraries

To deploy a library to your Vertica database:

1. Copy the UDx shared library file (.so), Python file, or JAR that contains your function to a node on your Vertica cluster. You do not need to copy it to every node.
2. Connect to the node where you copied the library (for example, using vsql).
3. Add your library to the database catalog using the CREATE LIBRARY statement.

```
=> CREATE LIBRARY libname AS '/path_to_lib/filename'
     LANGUAGE 'language';
```

libname is the name you want to use to reference the library. path_to_lib/filename is the fully-qualified path to the library or JAR file you copied to the host. language is the implementation language.
For example, if you created a JAR file named TokenizeStringLib.jar and copied it to the dbadmin account's home directory, you would use this command to load the library:

```sql
=> CREATE LIBRARY tokenizelib AS '/home/dbadmin/TokenizeStringLib.jar'
    LANGUAGE 'Java';
```

You can load any number of libraries into Vertica.

## Declaring Individual UDx

Once the library is loaded, define individual UDx using SQL statements such as `CREATE FUNCTION` and `CREATE SOURCE`. These statements assign SQL function names to the extension classes in the library. They add the UDx to the database catalog and remain available after a database restart.

The statement you use depends on the type of UDx you are declaring, as shown in the following table.

<table>
<thead>
<tr>
<th>UDx Type</th>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregate Function (UDAF)</td>
<td><code>CREATE AGGREGATE FUNCTION</code></td>
</tr>
<tr>
<td>Analytic Function (UDAnF)</td>
<td><code>CREATE ANALYTIC FUNCTION</code></td>
</tr>
<tr>
<td>Scalar Function (UDSF)</td>
<td><code>CREATE FUNCTION (UDF)</code></td>
</tr>
<tr>
<td>Transform Function (UDTF)</td>
<td><code>CREATE TRANSFORM FUNCTION</code></td>
</tr>
<tr>
<td>Load (UDL): Source</td>
<td><code>CREATE SOURCE</code></td>
</tr>
<tr>
<td>Load (UDL): Filter</td>
<td><code>CREATE FILTER</code></td>
</tr>
<tr>
<td>Load (UDL): Parser</td>
<td><code>CREATE PARSER</code></td>
</tr>
</tbody>
</table>

After you add the UDx to the database, you can use your extension within SQL statements. The database superuser can grant access privileges to the UDx for users. See `GRANT (User Defined Extension)` in the SQL Reference Manual for details.

When you call a UDx, Vertica creates an instance of the UDx class on each node in the cluster and provides it with the data it needs to process.
Installing Java on Vertica Hosts

If you are using UDxs written in Java, follow the instructions in this section.

You must install a Java Virtual Machine (JVM) on every host in your cluster in order for Vertica to be able to execute your Java UDxs.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.

2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.

Installing a Java Runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or OpenJDK. You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the Java Standard Edition (SE) Download Page. You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the java command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

Note: Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible
version of Java before installing the Java 6 or Java 7 runtime.

Setting the JavaBinaryForUDx Configuration Parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example /usr/bin/java). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

$ which java
/usr/bin/java

If the java command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in /usr/java/default (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is /usr/java/default/bin/java.

You set the configuration parameter by executing the following statement as a database superuser:

```sql
=> ALTER DATABASE mydb SET JavaBinaryForUDx = '/usr/bin/java';
```

See `ALTER DATABASE` for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the `CONFIGURATION_PARAMETERS` system table:

```sql
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[ RECORD 1 ]-+----------------------------------+
<table>
<thead>
<tr>
<th>node_name</th>
<th>parameter_name</th>
<th>current_value</th>
<th>default_value</th>
<th>change_under_support_guidance</th>
<th>change_requires_restart</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>JavaBinaryForUDx</td>
<td>/usr/bin/java</td>
<td></td>
<td>f</td>
<td>f</td>
<td>Path to the java binary for executing UDx written in Java</td>
</tr>
</tbody>
</table>
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

Note: Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same...
path on all of the hosts in the cluster.

Notes on Individual UDx Types

Some UDx types have special considerations or restrictions.

Analytic Functions

UDAnFs do not support framing windows using ROWS.

As with Vertica's built-in analytic functions, UDAnFs cannot be used with Pattern Matching Functions.

Scalar Functions

If the result of applying a UDSF is an invalid record, COPY aborts the load even if CopyFaultTolerantExpressions is set to true.

Transform Functions

A query that includes a UDTF cannot contain:

- Any statements other than the SELECT statement containing the call to the UDTF and a PARTITION BY expression
- Any other analytic function
- A call to another UDTF
- A TIMESERIES clause
- A pattern matching clause
- A gap filling and interpolation clause
Load

Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD Source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDxs to untrusted users.

You cannot ALTER UDL functions.

Fenced Mode

User-Defined Extensions (UDxs) written in the C++ programming language have the option of running in unfenced mode, which means running directly within the Vertica process. Since they run within Vertica, unfenced UDxs have little overhead, and can perform almost as fast as Vertica's own built-in functions. However, since they run within Vertica directly, any bugs in their code (memory leaks, for example) can destabilize the main Vertica process that can bring one or more database nodes down.

You can instead opt to run most C++ UDxs in fenced mode, which runs the UDxs code outside of the main Vertica process in a separate zygote process. UDx code that crashes while running in fenced mode does not impact the core Vertica process. There is a small performance impact when running UDx code in fenced mode. On average, using fenced mode adds about 10% more time to execution compared to unfenced mode.

Fenced mode is currently available for all C++ UDxs with the exception of User-Defined Aggregates. All UDxs developed in the Python, R, and Java programming languages must run in fenced mode, since the Python, R, and Java runtimes cannot be directly run within the Vertica process.

Using fenced mode does not affect the development of your UDx. Fenced mode is enabled by default for UDx's that support fenced mode. The CREATE FUNCTION command can optionally be issued with the NOT FENCED modifier to disable fenced mode for the function. Also, you can enable or disable fenced mode on any fenced mode-supported C++ UDx by using the ALTER FUNCTION command.

About the Zygote Process

The Vertica zygote process starts when Vertica starts. Each node has a single zygote process. Side processes are created "on demand". The zygote listens for requests and spawns a UDx
side session that runs the UDx in fenced mode when a UDx is called by the user.

About Fenced Mode Logging:

UDx code that runs in fenced mode is logged in the UDxZygote.log and is stored in the UDxLogs directory in the catalog directory of Vertica. Log entries for the side process are denoted by the UDx language (for example, C++), node, and zygote process ID, and the UDxSideProcess ID.

For example, for the following processes...

```sql
-> SELECT * FROM UDx_FENCED_PROCESSES;
node_name | process_type | session_id | pid | port | status
----------|--------------|------------|-----|------|--------
v_vmart_node0001 | UDxZygoteProcess | | 27468 | 51900 | UP
v_vmart_node0001 | UDxSideProcess | localhost.localdoma-27465:0x800b | 5677 | 44123 | UP
```

... the corresponding log file displays:

```
2016-05-16 11:24:43.990 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7f00 UDx side process started
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7f00 Finished setting up signal handlers.
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7f00 My port: 44123
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7f00 My address: 0.0.0.0
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7f00 Vertica port: 51900
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7f00 Vertica address: 127.0.0.1
11:25:19.749 [C++-localhost.localdoma-27465:0x800b-5677] 0x41037940 Setting memory resource limit to -1
11:30:11.523 [C++-localhost.localdoma-27465:0x800b-5677] 0x41037940 Exiting UDx side process
```

The last line indicates that the side process was killed. In this case it was killed when the user session (vsql) closed.

About Fenced Mode Configuration Parameters

Fenced mode supports three configuration parameters:

- **FencedUDxMemoryLimitMB** - The maximum memory size, in MB, to use for Fenced Mode processes. The default is -1 (no limit). The side process is killed if this limit is exceeded.

- **ForceUDxFencedMode** - When set to 1, force all UDx's that support fenced mode to run in fenced mode even if their definition specified NOT FENCED. The default is 0 (disabled).

- **UDxFencedBlockTimeOut** - The maximum time, in seconds, that the Vertica server waits for a UDx to return before aborting with ERROR 3399. The default is 60.

Updating UDx Libraries

There are two cases where you need to update libraries that you have already deployed:

- When you have upgraded Vertica to a new version that contains changes to the SDK API. For your libraries to work with the new server version, you need to recompile them with new version of the SDK. See UDx Library Compatibility with New Server Versions for more information.

- When you have made changes to your UDxs and you want to deploy these changes. Before updating your UDx library, you need to determine if you have changed the signature of any of the functions contained in the library. If you have, you need to drop the functions from the Vertica catalog before you update the library.

UDx Library Compatibility with New Server Versions

The Vertica SDK defines an application programming interface (API) that UDxs use to interact with the database. When a developer compiles his or her UDx code, it is linked to the SDK code to form a library. This library is only compatible with Vertica servers that support the version of the SDK API used to compile the code. The library and servers that share the same API version are compatible on a binary level (referred to as "binary compatible").

The Vertica server returns an error message if you attempt to load a library that is not binary compatible with it. Similarly, if you upgrade your Vertica server to a version that supports a new SDK API, any existing UDx that relies on newly-incompatible libraries returns an error messages when you call it:

```
ERROR 2858: Could not find function definition
HINT: This usually happens due to missing or corrupt libraries, libraries built with the wrong SDK version, or due to a concurrent session dropping the library or function. Try recreating the library and function
```

To resolve this issue, you must install UDx libraries that have been recompiled with correct version of the SDK.

New versions of the Vertica server do not always change the SDK API version. The SDK API version changes whenever OpenText changes the components that make up the SDK. If the SDK API does not change in a new version of the server, then the old libraries remain compatible with the new server.
The SDK API almost always changes between major releases of Vertica (for example between versions 6.0 and 6.1), as OpenText expands the SDK’s features in each major release. In addition, OpenText reserves the right to change the SDK API in the first service pack release (for example between (from version 9.0.0 to 9.0.1) to address any issues found in the initial release of a major version. After the first service pack, the SDK API is frozen and will not change for rest of the service packs for that major release (for example, 9.0.2, 9.0.3, and so forth).

These policies mean that:

- You need to update UDx libraries when you upgrade between major versions. For example, if you upgrade from version 7.0.1 to 7.1.0 you need to update your UDx libraries.

- You may need to update the UDx libraries if you upgrade from the first version of a major release to a later service pack release. For example, if you upgrade the server from version 7.1.0 to 7.1.2, you may need to update your UDx libraries. Version 7.1.1 (the first service pack release) may have SDK changes that make your libraries compiled with the 7.1.0 SDK incompatible with the Vertica 7.1.2 server.

- You do not need to update your UDx libraries when upgrading from one service pack to another. For example, if you upgrade from version 7.1.1 to 7.1.2, you do not need to update your UDx libraries. The SDK API version is the same between there versions and any later 7.1.x service pack releases.

Note: Since the R language is interpreted, a UDx written in R is not linked to the Vertica SDK. There is no binary compatibility that has to be maintenanted from one version to another. Therefore, changes to the Vertica SDK between Vertica versions do not make your R-based UDx libraries incompatible with a new server version. An R-based UDx only becomes incompatible if the APIs uses in the SDK actually change. For example, if the number of arguments to an API call changes, the UDx written in R has to be changed to use the new number of arguments.

Pre-Upgrade Steps

Before upgrading your Vertica server, consider whether you have any UDx libraries that may be incompatible with the new version. Consult the release notes of the new server version to determine whether the SDK API has changed between the version of Vertica server you currently have installed and the new version. As mentioned previously, only upgrades from a previous major version or from the initial release of a major version to a service pack release can cause your currently-loaded UDx libraries to become incompatible with the server.

Any UDx libraries that are incompatible with the new version of the Vertica server must be recompiled. If you got the UDx library from a third party (such as through the Vertica
Marketplace), you need to see if a new version has been released. If so, then download the UDx library and deploy it after you have upgraded the server (see Deploying A New Version of Your UDx Library).

If you developed the UDx yourself (or if whoever developed it supplied the UDx's source code) you must:

1. Recompile your UDx library using the new version of the Vertica SDK. See Compiling Your C++ Library or Compiling and Packaging a Java Library for more information.

2. Deploy the new version of your library. See Deploying A New Version of Your UDx Library.

Determining If a UDx Signature Has Changed

You need to be careful when making changes to UDx libraries that contain functions you have already deployed in your Vertica database. When you deploy a new version of your UDx library, Vertica does not ensure that the signatures of the functions that are defined in the library match the signature of the function that is already defined in the Vertica catalog. If you have changed the signature of a UDx in the library then update the library in the Vertica database, calls to the altered UDx will produce errors.

Making any of the following changes to a UDx alters its signature:

- Changing the number of arguments accepted or the data type of any argument accepted by your function (not including polymorphic functions).

- Changing the number or data types of any return values or output columns.

- Changing the name of the factory class that Vertica uses to create an instance of your function code.

- Changing the null handling or volatility behavior of your function.

- Removed the function's factory class from the library completely.

The following changes do not alter the signature of your function, and do not require you to drop the function before updating the library:

- Changing the number or type of arguments handled by a polymorphic function. Vertica does not process the arguments the user passes to a polymorphic function.

- Changing the name, data type, or number of parameters accepted by your function. The parameters your function accepts are not determined by the function signature. Instead,
Vertica passes all of the parameters the user included in the function call, and your function processes them at runtime. See UDx Parameters for more information about parameters.

- Changing any of the internal processing performed by your function.
- Adding new UDxs to the library.

After you drop any functions whose signatures have changed, you load the new library file, then re-create your altered functions. If you have not made any changes to the signature of your UDxs, you can just update the library file in your Vertica database without having to drop or alter your function definitions. As long as the UDx definitions in the Vertica catalog match the signatures of the functions in your library, function calls will work transparently after you have updated the library. See Deploying A New Version of Your UDx Library.

Deploying A New Version of Your UDx Library

You need to deploy a new version of your UDx library if:

- You have made changes to the library that you now want to roll out to your Vertica database.
- You have upgraded your Vertica to a new version whose SDK is incompatible with the previous version.

The process of deploying a new version of your library is similar to deploying it initially.

1. If you are deploying a UDx library developed in C++ or Java, you must compile it with the current version of the Vertica SDK.

2. Copy your UDx's library file (a .so file for libraries developed in C++, a .py file for libraries developed in Python, or a .jar file for libraries developed in Java) or R source file to a host in your Vertica database.

3. Connect to the host using vsql.

4. If you have changed the signature of any of the UDxs in the shared library, you must drop them using DROP statements such as DROP FUNCTION or DROP SOURCE. If you are unsure whether any of the signatures of your functions have changed, see Determining If a UDx Signature Has Changed.
Note: If all of the UDx signatures in your library have changed, you may find it more convenient to drop the library using the DROP LIBRARY statement with the CASCADE option to drop the library and all of the functions and loaders that reference it. Dropping the library can save you the time it would take to drop each UDx individually. You can then reload the library and recreate all of the extensions using the same process you used to deploy the library in the first place. See CREATE LIBRARY in the SQL Reference Manual.

5. Use the ALTER LIBRARY statement to update the UDx library definition with the file you copied in step 1. For example, if you want to update the library named ScalarFunctions with a file named ScalarFunctions-2.0.so in the dbadmin user’s home directory, you could use the command:

```sql
=> ALTER LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions-2.0.so';
```

Once you have updated the UDx library definition to use the new version of your shared library, the UDxs that are defined using classes in your UDx library begin using the new shared library file without any further changes.

6. If you had to drop any functions in step 4, recreate them using the new signature defined by the factory classes in your library. See CREATE FUNCTION Statements in the SQL Reference Manual.
Listing the UDxs Contained in a Library

Once a library has been loaded using the **CREATE LIBRARY** statement, you can find the UDxs and UDLs it contains by querying the **USER_LIBRARY_MANIFEST** system table:

```sql
=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions.so';
CREATE LIBRARY => \\x
Expanded display is on.
=> SELECT * FROM USER_LIBRARY_MANIFEST WHERE lib_name = 'ScalarFunctions';
- [ RECORD 1 ]----------------------
schema_name | public
lib_name     | ScalarFunctions
lib_oid      | 45035996273792402
obj_name     | RemoveSpaceFactory
obj_type     | Scalar Function
arg_types    | Varchar
return_type  | Varchar
- [ RECORD 2 ]----------------------
schema_name | public
lib_name     | ScalarFunctions
lib_oid      | 45035996273792402
obj_name     | Div2intsInfo
obj_type     | Scalar Function
arg_types    | Integer, Integer
return_type  | Integer
- [ RECORD 3 ]----------------------
schema_name | public
lib_name     | ScalarFunctions
lib_oid      | 45035996273792402
obj_name     | Add2intsInfo
obj_type     | Scalar Function
arg_types    | Integer, Integer
return_type  | Integer
```

The `obj_name` column lists the factory classes contained in the library. These are the names you use to define UDxs and UDLs in the database catalog using statements such as **CREATE FUNCTION** and **CREATE SOURCE**.

Using Wildcards In Your UDx

Vertica supports wildcard * characters in the place of column names in user-defined functions. You can use wildcards when:
- Your query contains a table in the FROM clause
- You are using a Vertica-supported development language
- Your UDx is running in fenced or unfenced mode

**Supported SQL Statements**

The following SQL statements can accept wildcards:

- DELETE
- INSERT
- SELECT
- UPDATE

**Unsupported Configurations**

The following situations do not support wildcards:

- You cannot pass a wildcard in the OVER clause of a query
- You cannot us a wildcard with a DROP statement
- You cannot use wildcards with any other arguments

**Examples**

These examples show wildcards and user-defined functions in a range of data manipulation operations.

**DELETE statements:**

```sql
=> DELETE FROM tablename WHERE udf(tablename.*) = 5;
```

**INSERT statements:**
### INSERT INTO table1 SELECT udf(*) FROM table2;

### SELECT statements:

- `=> SELECT udf(*) FROM tablename;`  
- `=> SELECT udf(tablename.*) FROM tablename;`  
- `=> SELECT udf(f.*) FROM table f;`  
- `=> SELECT udf(*) FROM table1,table2;`  
- `=> SELECT udf1( udf2(*) ) FROM table1,table2;`  
- `=> SELECT udf( db.schema.table.*) FROM tablename;`  
- `=> SELECT udf(sub.*) FROM (select col1, col2 FROM table) sub;`  
- `=> SELECT x FROM tablename WHERE udf(*) = y;`  
- `=> WITH sub as (SELECT * FROM tablename) select x, udf(*) FROM sub;`  
- `=> SELECT udf( * using parameters x=1) FROM tablename;`  
- `=> SELECT udf(table1.*, table2.col2) FROM table1,table2;`  

### UPDATE statements:

- `=> UPDATE tablename set col1 = 4 FROM tablename WHERE udf(*) = 3;`
Developing User-Defined Extensions (UDxs)

User-Defined Extensions (UDxs) are functions contained in external shared libraries that are developed in C++, Python, Java, or R using the Vertica SDK. The external libraries are defined in the Vertica catalog using the CREATE LIBRARY statement. They are best suited for analytic operations that are difficult to perform in SQL, or need to be performed frequently enough that their speed is a major concern.

The primary strengths of UDxs are:

- They can be used anywhere an internal function can be used.
- They take full advantage of Vertica's distributed computing features. The extensions usually execute in parallel on each node in the cluster.
- Vertica handles the distribution of the UDx library to the individual nodes. You only need to copy the library to the initiator node.
- All of the complicated aspects of developing a distributed piece of analytic code are handled for you by Vertica. Your main programming task is to read in data, process it, and then write it out using the Vertica SDK APIs.

There are a few things to keep in mind about developing UDxs:

- UDxs can be developed in the programming languages C++, Python, Java, and R. (Not all UDx types support all languages.)
- UDxs written in Java always run in Fenced Mode, because the Java Virtual Machine that executes Java programs cannot run directly within the Vertica process.
- UDxs written in Python and R always run in Fenced Mode
- UDxs developed in C++ have the option of running in unfenced mode, which means they load and run directly in the Vertica database process. This option provides the lowest overhead and highest speed. However, any bugs in the UDx's code can cause database instability. You must thoroughly test any UDxs you intend to run in unfenced mode before deploying them in a live environment. Consider whether the performance boost of running a C++ UDx unfenced is worth the potential database instability that a buggy UDx can cause.
• Because a UDx runs on the Vertica cluster, it can take processor time and memory away from the database processes. A UDx that consumes large amounts of computing resources can negatively impact database performance.

**Structure**

Each UDx type consists of two classes. The main class does the primary work (a transformation, an aggregation, and so on). The class usually has at least three methods: one to set up, one to tear down (release reserved resources), and one to do the actual work. Sometimes additional methods are defined.

The main processing method receives an instance of the ServerInterface class as an argument. This object is used by the underlying Vertica SDK code to make calls back into the Vertica process, for example to allocate memory. You can use this class to write to the server log during UDx execution.

The second class is a singleton factory. It defines one method that produces instances of the first class, and might define other methods to manage parameters.

When implementing a UDx you must subclass both classes.

**Conventions**

The C++, Python, and Java APIs are nearly identical. Where possible, this documentation describes these interfaces without respect to language. Documentation specific to C++, Python, or Java is covered in language-specific sections.

Because some documentation is language-independent, it is not always possible to use ideal, language-based terminology. This documentation uses the term "method" to refer to a Java method or a C++ member function.

Loading UDxs
Setting Up a Development Environment

Before you start developing your UDx, you need to configure your development environment. You can choose to develop your UDx on a node in a development Vertica database (not in a production environment) or on another machine.

To test, you need access to a (non-production) Vertica database. You can install a single-node Vertica database on your development machine for easier development.

You should develop your UDx code on the same Linux platform that you use on your Vertica database cluster. This will ensure that your UDx library is compatible with the Vertica version deployed on your cluster.

The following sections describe language-specific requirements.

C++ Requirements

At a minimum, you need to install the following on your development machine:

- `g++` and its associated tool chain such as ld. (Note: some Linux distributions package g++ separately from gcc.)

- A copy of the Vertica SDK. See Setting Up the C++ SDK for details.

*Note: The Vertica binaries are compiled using the default version of g++ installed on the supported Linux platforms. Vertica requires a minimum of gcc version 4.8.4. The default version of gcc on Ubuntu 16.04 is not compatible; see Requirements for Ubuntu 16.04.*

While not required, the following additional software packages can ease development:

- make, or some other build-management tool.

- gdb, or some other debugger.

- Valgrind, or similar tools that detect memory leaks.

- Although not currently required, future versions of Vertica may require that you compile with the flag `-std=c++11`.

If you want to use any third-party libraries (for example, statistical analysis libraries), you need to install them on your development machine. If you do not statically link these libraries into
your UDx library, you also have to install them on every node in the cluster. See Compiling Your C++ Library for details.

Requirements for Ubuntu 16.04

Ubuntu 16.04 ships with a compiler that is incompatible with the Vertica C++ SDK. To compile UDxs on this platform, you must install packages for 4.8 compatibility:

```bash
$ sudo apt-get remove g++
$ sudo apt-get remove gcc
$ sudo apt-get install gcc-4.8
$ sudo apt-get install g++-4.8
$ cd /usr/bin
$ sudo ln -s ./gcc-4.8 gcc
$ sudo ln -s ./g++-4.8 g++
```

To test your environment, install the packages used by the SDK examples (if you haven’t already) and then compile the examples:

```bash
$ sudo apt-get install libbz2-dev
$ sudo apt-get install libghc-zlib-dev
$ sudo apt-get install libboost-dev
$ sudo apt-get install libghc-curl-dev
$ cd /opt/vertica/sdk/examples
$ sudo make
```

Java Requirements

At a minimum, you need to install the following on your development machine:

- The Java Development Kit (JDK) version that matches the Java version you have installed on your database hosts (see Installing Java on Vertica Hosts).

- A copy of the Vertica SDK. See Setting Up the Java SDK for details.

While not required, make or some other build-management tool can ease development.

Python Requirements

Vertica does not require any additional files or packages. You can develop your Python UDx on any system with a text editor.
Important: When you begin UDx development, make sure that your code runs using Python 3.5.1. because you cannot change the version used by the Vertica Python interpreter.

When Vertica calls your UDx, it starts a side process that manages the interaction between the server and the Python interpreter.

R Requirements

Vertica does not require any additional files or packages. You can develop your R UDx on any system with a text editor.

Downloading and Running UDx Example Code

You can download all of the examples shown in this documentation, and many more, from the Vertica GitHub repository. This repository includes examples of all types of UDxs.

You can download the examples in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the repository. Using a terminal window, run the following command:

  `git clone https://github.com/vertica/UDx-Examples.git`

The repository includes a makefile that you can use to compile the C++ and Java examples. It also includes .sql files that load and use the examples. See the README file for instructions on compiling and running the examples.

Running the examples not only helps you understand how a UDx works, but also helps you ensure your development environment is properly set up to compile UDx libraries.

See Also

- Aggregate Functions (UDAFs)
- Analytic Functions (UDAnFs)
- Scalar Functions (UDSFs)
Types of UDxs

Vertica supports five types of user-defined extensions:

- **User-Defined Aggregate Functions (UDAF)** allow you to create custom Aggregate Functions specific to your needs. They read one column of data, and return one output column. UDAFs can be developed in C++. Developing UDAFs is described in Aggregate Functions (UDAFs).

- **User-Defined Analytic Functions (UDAnF)** are similar to UDSFs, in that they read a row of data and return a single row. However, the function can read input rows independently of outputting rows, so that the output values can be calculated over several input rows. UDAnFs can be developed in C++ and Java. Developing UDAnFs is described in Analytic Functions (UDAnFs).

- **User-Defined Scalar Functions (UDSFs)** take in a single row of data and return a single value. These functions can be used anywhere a native function can be used, except CREATE TABLE BY PARTITION and SEGMENTED BY expressions. UDSFs can be developed in C++, Python, Java, and R. Developing UDSFs is described in Scalar Functions (UDSFs).

- **User-Defined Transform Functions (UDTFs)** operate on table segments and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, including having its own ordering and segmentation expressions. They can only be used in the SELECT list of a query. UDTFs can be developed in C++, Java, and R. Developing UDTFs is described in Transform Functions (UDTFs).

  To optimize query performance, you can use live aggregate projections to pre-aggregate the data that a UDTF returns. For more information, see Pre-Aggregating UDTF Results.

- **User-Defined Load (UDLs)** allows you to create custom sources, filters, and parsers to load data. These extensions are used in the COPY statement. UDLs can be developed in C++ and Java. Developing UDLs is described in Load (UDLs).

While each UDx type has a unique base class, developing them is similar in many ways. Different UDx types can also share the same library.
Handling Different Numbers and Types of Arguments

Usually, your UDxs accept a set number of arguments that are a specific data type (called its signature). You can create UDxs that handle multiple signatures, or even accept all arguments supplied to them by the user, using either of these techniques:

- Overloading your UDx by assigning the same SQL function name to multiple factory classes, each of which defines a unique function signature. When a user uses the function name in a query, Vertica tries to match the signature of the function call to the signatures declared by the factory's getPrototype method. This is the best technique to use if your UDx needs to accept a few different signatures (for example, accepting two required and one optional argument).

- Creating a polymorphic UDx by using the special "Any" argument type that tells Vertica to send all arguments that the user supplies to your function. Your UDx decides whether it can handle the arguments or not.

Overloading Your UDx

You may want your UDx to accept several different signatures (sets of arguments). For example, you might want your UDx to accept:

- One or more optional arguments.
- One or more arguments that can be one of several data types.
- Completely distinct signatures (either all INTEGER or all VARCHAR, for example).

You can create a function with this behavior by creating several factory classes, each of which accepts a different signature (the number and data types of arguments). You can then associate a single SQL function name with all of them. You can use the same SQL function name to refer to multiple factory classes as long as the signature defined by each factory is unique. When a user calls your UDx, Vertica matches the number and types of arguments supplied by the user to the arguments accepted by each of your function's factory classes. If one matches, Vertica uses it to instantiate a function class to process the data.
Multiple factory classes can instantiate the same function class, so you can re-use one function class that is able to process multiple sets of arguments and then create factory classes for each of the function signatures. You can also create multiple function classes if you want.

See the C++ Example: Overloading Your UDx and Java Example: Overloading Your UDx examples.

C++ Example: Overloading Your UDx

The following example code demonstrates creating a User-Defined Scalar Function (UDSF) that adds two or three integers together. The Add2or3ints class is prepared to handle two or three arguments. The processBlock() function checks the number of arguments that have been passed to it, and adds all two or three of them together. It also exits with an error message if it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user’s function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else’s) factory class inaccurately reports a set of arguments your function class cannot handle.

```cpp
#include "Vertica.h"
using namespace Vertica;
using namespace std;
// a ScalarFunction that accepts two or three integers and adds them together.
class Add2or3ints : public Vertica::ScalarFunction
{
public:
  virtual void processBlock(Vertica::ServerInterface &srvInterface,
     Vertica::BlockReader &arg_reader,
     Vertica::BlockWriter &res_writer)
  {
    const size_t numCols = arg_reader.getNumCols();

    // Ensure that only two or three parameters are passed in
    if (numCols < 2 || numCols > 3)
      vt_report_error(0, "Function only accept 2 or 3 arguments, "
        "but %zu provided", arg_reader.getNumCols());
    // Add two integers together
    do {
      const vint a = arg_reader.getIntRef(0);
      const vint b = arg_reader.getIntRef(1);
      vint c = 0;
      // Check for third argument, add it in if it exists.
      if (numCols == 3)
        c = arg_reader.getIntRef(2);
      res_writer.setInt(a+b+c);
      res_writer.next();
    } while (arg_reader.next());
  }
  // This factory accepts function calls with two integer arguments.
};
```
class Add2intsFactory : public Vertica::ScalarFunctionFactory
{
  virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
  { return vt_createFuncObj(srvInterfaceallocator, Add2or3ints); }
  virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                           Vertica::ColumnTypes &argTypes,
                           Vertica::ColumnTypes &returnType)
  {
    // Accept 2 integer values
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }
};
RegisterFactory(Add2intsFactory);
// This factory defines a function that accepts 3 ints.
class Add3intsFactory : public Vertica::ScalarFunctionFactory
{
  virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
  { return vt_createFuncObj(srvInterfaceallocator, Add2or3ints); }
  virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                           Vertica::ColumnTypes &argTypes,
                           Vertica::ColumnTypes &returnType)
  {
    // accept 3 integer values
    argTypes.addInt();
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }
};
RegisterFactory(Add3intsFactory);

The example has two ScalarFunctionFactory classes, one for each signature that the function accepts (two integers and three integers). There is nothing unusual about these factory classes, except that their implementation of 
ScalarFunctionFactory::createScalarFunction() both create Add2or3ints objects.

The final step is to bind the same SQL function name to both factory classes. You can assign multiple factories to the same SQL function, as long as the signatures defined by each factory's 
getPrototype() implementation are different.

```sql
=> CREATE LIBRARY add2or3IntsLib AS '/home/dbadmin/Add2or3Ints.so';
CREATE LIBRARY
=> CREATE FUNCTION add2or3Ints as NAME 'Add2intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> CREATE FUNCTION add2or3Ints as NAME 'Add3intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> SELECT add2or3Ints(1,2);
add2or3Ints
-------------
 3
(1 row)
=> SELECT add2or3Ints(1,2,4);
```
add2or3Ints
-----------
    7
(1 row)
=> SELECT add2or3Ints(1,2,3,4); -- Will generate an error
ERROR 3467: Function add2or3Ints(int, int, int, int) does not exist, or
permission is denied for add2or3Ints(int, int, int, int)
HINT: No function matches the given name and argument types. You may
need to add explicit type casts

The error message in response to the final call to the add2or3Ints function was generated by
Vertica, since it could not find a factory class associated with add2or3Ints that accepted four
integer arguments. To expand add2or3Ints further, you could create another factory class that
accepted this signature, and either change the Add2or3Ints ScalarFunction class or create a
totally different class to handle adding more integers together. However, adding more classes
to accept each variation in the arguments quickly becomes overwhelming. In that case, you
should consider creating a polymorphic UDx.

Java Example: Overloading Your UDx

The following example code demonstrates creating a User-Defined Scalar Function (UDSF) that
adds two or three integers together. The Add2or3Ints class is prepared to handle two or three
arguments. It checks the number of arguments that have been passed to it, and adds all two or
three of them together. The `processBlock()` method checks whether it has been called with
less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only
calls the UDSF if the user's function call matches a signature on one of the factory classes you
create for your function. In practice, it is a good idea to perform this sanity checking, in case
your (or someone else's) factory class reports that your function class accepts a set of
arguments that it actually does not.

```java
// You need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// This ScalarFunction accepts two or three integer arguments. It tests
// the number of input columns to determine whether to read two or three
// arguments as input.
public class Add2or3Ints extends ScalarFunction
{
    @Override
    public void processBlock(ServerInterface srvInterface,
                              BlockReader argReader,
                              BlockWriter resWriter)
            throws UdfException, DestroyInvocation
    {
        // See how many arguments were passed in
        int numCols = argReader.getNumCols();
    }
```
// Return an error if less than two or more than 3 arguments were given. This error only occurs if a factory class that accepts the wrong number of arguments instantiates this class.
if (numCols < 2 || numCols > 3) {
    throw new UdfException(0,
            "Must supply 2 or 3 integer arguments");
}

// Process all of the rows of input.
do {
    // Get the first two integer arguments from the BlockReader
    long a = argReader.getLong(0);
    long b = argReader.getLong(1);

    // Assume no third argument.
    long c = 0;

    // Get third argument value if it exists
    if (numCols == 3) {
        c = argReader.getLong(2);
    }

    // Process the arguments and come up with a result. For this example, just add the three arguments together.
    long result = a+b+c;

    // Write the integer output value.
    resWriter.setLong(result);

    // Advance the output BlockWriter to the next row.
    resWriter.next();

    // Continue processing input rows until there are no more.
} while (argReader.next());

The main difference between the Add2ints class and the Add2or3ints class is the inclusion of a section that gets the number of arguments by calling BlockReader.getNumCols(). This class also tests the number of columns it received from Vertica to ensure it is in the range it is prepared to handle. This test will only fail if you create a ScalarFunctionFactory whose getPrototype() method defines a signature that accepts less than two or more than three arguments. This is not really necessary in this simple example, but for a more complicated class it is a good idea to test the number of columns and data types that Vertica passed your function class.

Within the do loop, Add2or3ints uses a default value of zero if Vertica sent it two input columns. Otherwise, it retrieves the third value and adds that to the other two. Your own class needs to use default values for missing input columns or alter its processing in some other way to handle the variable columns.
You must define your function class in its own source file, rather than as an inner class of one of your factory classes since Java does not allow the instantiation of an inner class from outside its containing class. You factory class has to be available for instantiation by multiple factory classes.

Once you have created a function class or classes, you create a factory class for each signature you want your function class to handle. These factory classes can call individual function classes, or they can all call the same class that is prepared to accept multiple sets of arguments.

The following example's createScalarFunction() method instantiates a member of the Add2or3ints class.

```java
package com.mycompany.multiparamexample;

import com.vertica.sdk.*;

public class Add2or3intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                               ColumnTypes argTypes,
                               ColumnTypes returnType)
    {
        // Accept two integers as input
        argTypes.addInt();
        argTypes.addInt();
        // writes one integer as output
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiate the class that can handle either 2 or 3 integers.
        return new Add2or3ints();
    }
}
```

The following ScalarFunctionFactory subclass accepts three integers as input. It, too, instantiates a member of the Add2or3ints class to process the function call:

```java
package com.mycompany.multiparamexample;

import com.vertica.sdk.*;

public class Add3intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                               ColumnTypes argTypes,
                               ColumnTypes returnType)
    {
        // Accepts three integers as input
        argTypes.addInt();
    }
}
```
argTypes.addInt();
argTypes.addInt();
// Returns a single integer
returnType.addInt();
}

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface)
{
// Instantiates the Add2or3ints ScalarFunction class, which is able to
// handle either 2 or 3 integers as arguments.
    return new Add2or3ints();
}

The factory classes and the function class or classes they call must be packaged into the same JAR file (see Compiling and Packaging a Java Library for details). If a host in the database cluster has the JDK installed on it, you could use the following commands to compile and package the example:

$ cd pathToJavaProject$
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
> com/mycompany/multiparamexample/*.java
$ jar -cvf Add2or3intslib.jar com/vertica/sdk/BuildInfo.class \
> com/mycompany/multiparamexample/*.class

Once you have packaged your overloaded UDX, you deploy it the same way as you do a regular UDX, except you use multiple CREATE FUNCTION statements to define the function, once for each factory class.

=> CREATE LIBRARY add2or3intslib as '*/home/dbadmin/Add2or3intslib.jar'
=> language 'Java';
CREATE LIBRARY
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
'com.mycompany.multiparamexample/Add2intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
'com.mycompany.multiparamexample/Add3intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION

You call the overloaded function the same way you call any other function.

=> SELECT add2or3ints(2,3);
    add2or3ints
    -----------
    5
(1 row)
=> SELECT add2or3ints(2,3,4);
    add2or3ints
    -----------
    9
The last error was generated by Vertica, not the UDx code. It returns an error if it cannot find a factory class whose signature matches the function call's signature.

Creating an overloaded UDx is useful if you want your function to accept a limited set of potential arguments. If you want to create a more flexible function, you can create a polymorphic function.

Creating a Polymorphic UDx

Polymorphic UDxs accept any number and type of argument that the user supplies. Vertica does not check the number or types of argument that the user passes to the UDx—it just passes the UDx all of the arguments supplied by the user. It is up to your polymorphic UDx's main processing function (for example, processBlock() in User-Defined Scalar Functions) to examine the number and types of arguments it received and determine if it can handle them.

Note: UDxs have a maximum 1600 arguments.

Polymorphic UDxs are more flexible than using multiple factory classes for your function (see Overloading Your UDx), because your function can determine at run time if it can process the arguments rather than accepting specific sets of arguments. However, your polymorphic function needs to perform more work to determine whether it can process the arguments that it has been given.

Your polymorphic UDx declares that it accepts any number of arguments in its factory's getPrototype() function by calling the addAny() function on the ColumnTypes object that defines its arguments. This "any parameter" argument type is the only one that your function can declare. You cannot define required arguments and then call addAny() to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

Polymorphic UDxs and Schema Search Paths

If a user does not supply a schema name as part of a UDx call, Vertica searches each schema in the schema search path for a function whose name and signature match the function call. See Setting Search Paths in the Administrator's Guide for more information about schema search paths.
Since polymorphic UDxs do not have a specific signature associated with them, Vertica initially skips them when searching for a function to handle the function call. If none of the schemas in the search path contain a U Dx whose name and signature match the function call, Vertica searches the schema search path again for a polymorphic UDx whose name matches the function name in the function call.

This behavior gives precedence to UDxs whose signature exactly matches the function call. It allows you to create a "catch all" polymorphic UDx that Vertica calls only when none of the non-polymorphic UDxs with the same name have matching signatures.

This behavior may cause confusion if your users expect the first polymorphic function in the schema search path to handle a function call. To avoid confusion, you should:

- Avoid using the same name for different UDxs. You should always uniquely name UDxs unless you intend to create an overloaded UDx with multiple signatures.

- When you cannot avoid having UDxs with the same name in different schemas, always supply the schema name as part of the function call. Using the schema name prevents ambiguity and ensures that Vertica uses the correct UDx to process your function calls.

### C++ Example: Polymorphic UDx

The following example shows an implementation of a ScalarFunction that adds together two or more integers.

```c++
#include "Vertica.h"
using namespace Vertica;
using namespace std;

// Adds two or more integers together.
class AddManyInts : public Vertica::ScalarFunction
{
public:
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                          Vertica::BlockReader &arg_reader,
                          Vertica::BlockWriter &res_writer)
    {
        // Always catch exceptions to prevent causing the side process or
        // Vertica itself from crashing.
        try
        {
            // Find the number of arguments sent.
            size_t numCols = arg_reader.getNumCols();

            // Make sure at least 2 arguments were supplied
            if (numCols < 2)
                vt_report_error(0, "Function expects at least 2 integer parameters");

            // Make sure all types are ints
            const SizedColumnTypes &inTypes = arg_reader.getTypeMetaData();
            for (int param=0; param < (int)numCols; param++)
```
Most of the work in the example is done by the `ScalarFunction.processBlock()` function. It performs two checks on the arguments that have been passed in through the `BlockReader` object:

- **Ensures there are at least two arguments**
- **Checks the data type of all arguments to ensure they are all integers**

Once the checks are performed, the example processes the block of data by looping over the arguments and adding them together.
You assign a SQL name to your polymorphic UDx using the same statement you use to assign one to a non-polymorphic UDx. The following demonstration shows how you load and call the polymorphic function from the example.

```sql
CREATE LIBRARY addManyIntsLib AS '/home/dbadmin/AddManyInts.so';
CREATE FUNCTION addManyInts AS NAME 'AddManyIntsFactory' LIBRARY addManyIntsLib FENCED;
CREATE FUNCTION
SELECT addManyInts(1,2);
addManyInts 3
(1 row)
SELECT addManyInts(1,2,3,40,60,70,80,900);
addManyInts 1206
(1 row)
SELECT addManyInts(1); -- Too few parameters
ERROR 3412: Failure in UDx RPC call InvokeProcessBlock(): Error calling processBlock() in User-Defined Object [addManyInts] at [AddManyInts.cpp:51], error code: 0, message: Exception while processing partition: [Function expects at least 2 integer parameters]
SELECT addManyInts(1,2.232343); -- Wrong data type
ERROR 3412: Failure in UDx RPC call InvokeProcessBlock(): Error calling processBlock() in User-Defined Object [addManyInts] at [AddManyInts.cpp:51], error code: 0, message: Exception while processing partition: [Function expects all arguments to be INTEGER. Argument 2 was Numeric(7,6)]
```

Notice that the errors returned by last two calls to the function were generated by the `processBlock()` function. It is up to your UDx to ensure that the user supplies the correct number and types of arguments to your function and exit with an error if it cannot process them.

**Java Example: Polymorphic UDx**

The following example shows an implementation of a `ScalarFunctionFactory` class with an inner `ScalarFunction` class that adds together two or more integers.

```java
public class AddManyIntsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface,
                              ColumnTypes argTypes,
                              ColumnTypes returnType)
```

Vertica Analytic Database (9.0.x)  Page 4160 of 6180
{  
    // Accepts any number and type or arguments. The ScalarFunction  
    // class handles parsing the arguments.  
    argTypes.addAny();  
    // writes one integer as output  
    returnType.addInt();  
}  
// This polymorphic ScalarFunction adds all of the integer arguments passed  
// to it. Returns an error if there are less than two arguments, or if one  
// argument is not an integer.  
public class AddManyInts extends ScalarFunction  
{  
    @Override  
    public void processBlock(ServerInterface srvInterface,  
              BlockReader argReader,  
              BlockWriter resWriter)  
        throws UdfException, DestroyInvocation  
    {  
        // See how many arguments were passed in  
        int numCols = argReader.getNumCols();  
        
        // Return an error if less than two arguments were given.  
        if (numCols < 2) {  
            throw new UdfException(0,  
                       "Must supply at least 2 integer arguments");  
        }  
        
        // Make sure all input columns are integer.  
        SizedColumnTypes inTypes = argReader.getTypeMetaData();  
        for (int param = 0; param < numCols; param++) {  
            VerticaType paramType = inTypes.getColumnType(param);  
            if (!paramType.isInt()) {  
                throw new UdfException(0, "Error: Argument "+ (param+1) +  
                                       " was not an integer. All arguments must be integer.");  
            }  
        }  
        
        // Process all of the rows of input.  
        do {  
            long total = 0; // Hold the running total of arguments  
            
            // Get all of the arguments and add them up  
            for (int x = 0; x < numCols; x++) {  
                total += argReader.getLong(x);  
            }  
            
            // Write the integer output value.  
            resWriter.setLong(total);  
            
            // Advance the output BlockWriter to the next row.  
            resWriter.next();  
            
            // Continue processing input rows until there are no more.  
            } while (argReader.next());  
    }  
}  

@Override  
public ScalarFunction createScalarFunction(ServerInterface srvInterface)  
{
// Instantiate the polymorphic UDF class.
return new AddManyInts();
}

The ScalarFunctionFactory.getPrototype() method calls the addAny() method to declare that the UDSF is polymorphic.

Most of the work in the example is done by the ScalarFunction.processBlock() method. It performs two checks on the arguments that have been passed in through the BlockReader object:

- There are at least two arguments.
- The data type of all arguments are integers.

It is up to your polymorphic UDX to determine that all of the input passed to it is valid.

Once the processBlock() method validates its arguments, it loops over them, adding them together.

You assign a SQL name to your polymorphic UDX using the same statement you use to assign one to a non-polymorphic UDX. The following demonstration shows how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY addmanyintslib AS '/home/dbadmin/AddManyIntsLib.jar'
  LANGUAGE 'Java';
CREATE LIBRARY => create function addmanyints AS LANGUAGE 'Java' NAME => 'com.mycompany.multiparamexample.AddManyIntsFactory' LIBRARY addmanyintslib;
CREATE FUNCTION => SELECT addmanyints(1,2,3,4,5,6,7,8,9,10);
addmanyints
------------------
  55
(1 row)
=> SELECT addmanyints(1); --Too few parameters
ERROR 3399: Failure in UDX RPC call InvokeProcessBlock(): Error in User Defined Object [addmanyints], error code: 0

R Example: Polymorphic UDx

The following example shows an implementation of a Transform Function (UDTF) that performs kmeans clustering on one or more input columns.

```r
kmeansPoly <- function(v.data.frame, v.param.list) {
  # Computes clusters using the kmeans algorithm.
  # # Input: A dataframe and a list of parameters.
  # # Output: A dataframe with one column that tells the cluster to which each data
  # # point belongs.
  # Args:
  # v.data.frame: The data from Vertica cast as an R data frame.
  # v.param.list: List of function parameters.
  # # Returns: # The cluster associated with each data point.
  # Ensure k is not null.
  if(!is.null(v.param.list[['k']])) {
    number_of_clusters <- as.numeric(v.param.list[['k']])
  } else {
    stop("k cannot be NULL! Please use a valid value.")
  }
  # Run the kmeans algorithm.
  kmeans_clusters <- kmeans(v.data.frame, number_of_clusters)
  final.output <- data.frame(kmeans_clusters$cluster)
  return(final.output)
}

kmeansFactoryPoly <- function() {
  # This function tells Vertica the name of the R function,
  # and the polymorphic parameters.
  list(name=kmeansPoly, udxtype=c("transform"), intype=c("any"),
       outtype=c("int"), parametertypecallback=kmeansParameters)
}

kmeansParameters <- function() {
  # Callback function for the parameter types.
  function.parameters <- data.frame(datatype=rep(NA, 1), length=rep(NA, 1),
                                     scale=rep(NA, 1), name=rep(NA, 1))
  function.parameters[1,1] = "int"
  function.parameters[1,4] = "k"
  return(function.parameters)
}
```

The polymorphic R function declares it accepts any number of arguments in its factory function by specifying "any" as the argument to the intype parameter and optionally the outtype parameter. If you define "any" argument for intype or outtype, then it is the only type that your function can declare for the respective parameter. You cannot define required arguments...
and then call "any" to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

The `outtypecallback` method is used to indicate the argument types and sizes it has been called with, and is expected to indicate the types and sizes that the function returns. The `outtypecallback` method can also be used to check for unsupported types and/or number of arguments. For example, the function may require only integers, with no more than 10 of them.

You assign a SQL name to your polymorphic U Dx using the same statement you use to assign one to a non-polymorphic U Dx. The following statements show how you load and call the polymorphic function from the example.

```sql
=> CREATE LIBRARY rlib2 AS '/home/dbadmin/R_UDx/poly_kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION kmeansPoly AS LANGUAGE 'R' name 'kmeansFactoryPoly' LIBRARY rlib2;
CREATE FUNCTION
=> SELECT spec, kmeansPoly(sl,sw,pl,pw USING PARAMETERS k = 3)
       OVER(PARTITION BY spec) AS Clusters
       FROM iris;
spec | Clusters
---+----------------
Iris-setosa | 1
Iris-setosa | 1
Iris-setosa | 1
Iris-setosa | 1
... ...
(150 rows)
```
### UDx Parameters

Parameters let you define arguments for your UDxs that remain constant across all of the rows processed by the SQL statement that calls your UDx. Typically, your UDxs accept arguments that come from columns in a SQL statement. For example, in the following SQL statement, the arguments `a` and `b` to the `add2ints` UDFS change value for each row processed by the SELECT statement:

```sql
=> SELECT a, b, add2ints(a,b) AS 'sum' FROM example;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>11</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>15</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>19</td>
</tr>
</tbody>
</table>

(5 rows)

Parameters remain constant for all the rows your UD processes. You can also make parameters optional so that if the user does not supply it, your UD uses a default value. For example, the following example demonstrates calling a UDFS named `add2intsWithConstant` that has a single parameter value named `constant` whose value is added to each the arguments supplied in each row of input:

```sql
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' FROM example;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a+b+42</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>45</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>49</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>53</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>57</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>61</td>
</tr>
</tbody>
</table>

(5 rows)

**Note:** When calling a UDx with parameters, there is no comma between the last argument and the USING PARAMETERS clause.

The topics in this section explain how to develop UDxs that accept parameters.

### Defining the Parameters Your UDx Accepts

You define the parameters that your UDx accepts in its factory class (`ScalarFunctionFactory`, `AggregateFunctionFactory`, and so on) by implementing
getParameterType(). This method is similar to getReturnType(): you call data-type-specific methods on a SizedColumnTypes object that is passed in as a parameter. Each function call sets the name, data type, and width or precision (if the data type requires it) of the parameter.

### Setting Parameter Properties (C++ Only)

When you add parameters to the getParameterType() function using the C++ API, you can also set properties for each parameter. For example, you can define a parameter as being required by the UDx. Doing so lets the Vertica server know that every UDx invocation must provide the specified parameter, or the query fails.

By passing an object to the SizedColumnTypes:Properties class, you can define the following four parameter properties:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>visible</td>
<td>BOOLEAN</td>
<td>If set to TRUE, the parameter appears in the USER_FUNCTION_PARAMETERS table. You may want to set this to FALSE to declare a parameter for internal use only.</td>
</tr>
<tr>
<td>required</td>
<td>BOOLEAN</td>
<td>If set to TRUE:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The parameter is required when invoking the UDx.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Invoking the UDx without supplying the parameter results in an error, and the UDx does not run.</td>
</tr>
<tr>
<td>canBeNull</td>
<td>BOOLEAN</td>
<td>If set to TRUE, the parameter can have a NULL value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If set to FALSE, make sure that the supplied parameter does not contain a NULL value when invoking the UDx. Otherwise, an error results, and the UDx does not run.</td>
</tr>
<tr>
<td>comment</td>
<td>VARCHAR (128)</td>
<td>A comment to describe the parameter.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If you exceed the 128 character limit, Vertica generates an error when you run the CREATE_FUNCTION command. Additionally, if you replace the existing function definition in the comment parameter, make sure that the new definition does not exceed 128 characters. Otherwise, you delete all existing entries in the USER_FUNCTION_PARAMETERS table related to the UDx.</td>
</tr>
</tbody>
</table>
Setting Parameter Properties (R Only)

When using parameters in your R UDx, you must specify a field in the factory function called `parametertypecallback`. This field points to the callback function that defines the parameters expected by the function. The callback function defines a four-column data frame with the following properties:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datatype</td>
<td>VARCHAR(128)</td>
<td>The data type of the parameter.</td>
</tr>
<tr>
<td>length</td>
<td>INTEGER</td>
<td>The dimension of the parameter.</td>
</tr>
<tr>
<td>scale</td>
<td>INTEGER</td>
<td>The proportional dimensions of the parameter.</td>
</tr>
<tr>
<td>name</td>
<td>VARCHAR(128)</td>
<td>The name of the parameter.</td>
</tr>
</tbody>
</table>

If any of the columns are left blank (or the `parametertypecallback` function is omitted), then Vertica uses default values.

For more information, see `parametertypecallback Function`.

Getting Parameter Values in UDxs

Your UDx uses the parameter values it declared in its factory class (see `Defining the Parameters Your UDx Accepts`) in its function class's processing method (for example, `processBlock()` or `processPartition()`). It gets its parameter values from a `ParamReader` object, which is available from the `ServerInterface` object that is passed to your processing method. Reading parameters from this object is similar to reading argument values from `BlockReader` or `PartitionReader` objects: you call a data-type-specific function with the name of the parameter to retrieve its value. For example, in C++:

```cpp
// Get the parameter reader from the ServerInterface to see if there are supplied parameters.
ParamReader paramReader = srvInterface.getParamReader();
// Get the value of an int parameter named constant.
const vint constant = paramReader.getIntRef("constant");
```

**Note:** String data values do not have any of their escape characters processed before they are passed to your function. Therefore, your function may need to process the escape sequences itself if it needs to operate on unescaped character values.
Using Parameters in the Factory Class

In addition to using parameters in your UDx function class, you can also access the parameters in the factory class. You may want to access the parameters to let the user control the input or output values of your function in some way. For example, your UDx can have a parameter that lets the user choose to have your UDx return a single- or double-precision value. The process of accessing parameters in the factory class is the same as accessing it in the function class: get a ParamReader object from the ServerInterface's getParamReader() method, then read the parameter values.

Testing Whether the User Supplied Parameter Values

Unlike its handling of arguments, Vertica does not immediately return an error if a user's function call does not include a value for a parameter defined by your UDx's factory class. This means that your function can attempt to read a parameter value that the user did not supply. If it does so, by default Vertica returns a non-existent parameter warning to the user, and the query containing the function call continues.

If you want your parameter to be optional, you can test whether the user supplied a value for the parameter before attempting to access its value. Your function determines if a value exists for a particular parameter by calling the ParamReader's containsParameter() method with the parameter's name. If this call returns true, your function can safely retrieve the value. If this call returns false, your UDx can use a default value or change its processing in some other way to compensate for not having the parameter value. As long as your UDx does not try to access the non-existent parameter value, Vertica does not generate an error or warning about missing parameters.

Note: If the user passes your UDx a parameter that it has not defined, by default Vertica issues a warning that the parameter is not used. It still executes the SQL statement, ignoring the parameter. You can change this behavior by altering the StrictUDxParameterChecking configuration parameter.

See C++ Example: Defining Parameters for an example.
Calling UDxs with Parameters

You pass parameters to a UDx by adding a USING PARAMETERS clause in the function call after the last argument.

- Do not insert a comma between the last argument and the USING PARAMETERS clause.
- After the USING PARAMETERS clause, add one or more parameter definitions, in the following form:

  `<parameter name> = <parameter value>`

  - Separate parameter definitions by commas.

Parameter values can be a constant expression (for example `1234 + SQRT(5678)`). You cannot use volatile functions (such as `RANDOM`) in the expression, because they do not return a constant value. If you do supply a volatile expression as a parameter value, by default, Vertica returns an incorrect parameter type warning. Vertica then tries to run the UDx without the parameter value. If the UDx requires the parameter, it returns its own error, which cancels the query.

Calling a UDx with a Single Parameter

The following example demonstrates how you can call the Add2intsWithConstant UDSF example shown in C++ Example: Defining Parameters:

```sql
=> SELECT a, b, Add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' from example;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a+b+42</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>45</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>49</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>53</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>57</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>61</td>
</tr>
</tbody>
</table>

(5 rows)

To remove the first instance of the number 3, you can call the RemoveSymbol UDSF example:

```sql
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3');
```

<table>
<thead>
<tr>
<th>original_string</th>
<th>RemoveSymbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>3re3mo3ve3sy3mb3ol</td>
<td>re3mo3ve3sy3mb3ol</td>
</tr>
</tbody>
</table>

(1 row)
Calling a UDx with Multiple Parameters

The following example shows how you can call a version of the tokenize UDTF. This UDTF includes parameters to limit the shortest allowed word and force the words to be output in uppercase. Separate multiple parameters with commas.

```sql
=> SELECT url, tokenize(description USING PARAMETERS minLength=4, uppercase=true) OVER (partition by url) FROM T;
```

<table>
<thead>
<tr>
<th>url</th>
<th>words</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>ONLINE</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>RETAIL</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>MERCHAND</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>PROVIDER</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>CLOUD</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>SERVICES</td>
</tr>
<tr>
<td><a href="http://www.hpe.com">www.hpe.com</a></td>
<td>LEADING</td>
</tr>
<tr>
<td><a href="http://www.hpe.com">www.hpe.com</a></td>
<td>PROVIDER</td>
</tr>
<tr>
<td><a href="http://www.hpe.com">www.hpe.com</a></td>
<td>COMPUTER</td>
</tr>
<tr>
<td><a href="http://www.hpe.com">www.hpe.com</a></td>
<td>HARDWARE</td>
</tr>
<tr>
<td><a href="http://www.hpe.com">www.hpe.com</a></td>
<td>IMAGING</td>
</tr>
<tr>
<td><a href="http://www.hpe.com">www.hpe.com</a></td>
<td>SOLUTIONS</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>WORLD'S</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>FASTEST</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>ANALYTIC</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>DATABASE</td>
</tr>
</tbody>
</table>

(16 rows)

The following example calls the RemoveSymbol UDSF. By changing the value of the optional parameter, n, you can remove all instances of the number 3:

```sql
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', n=6);
```

<table>
<thead>
<tr>
<th>original_string</th>
<th>RemoveSymbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>3re3mo3ve3sy3mb3ol</td>
<td>removesymbol</td>
</tr>
</tbody>
</table>

(1 row)

Calling a UDx with Optional or Incorrect Parameters

You can optionally add the Add2intsWithConstant UDSF's constant parameter. Calling this constraint without the parameter does not return an error or warning:

```sql
=> SELECT a,b,Add2intsWithConstant(a, b) AS 'sum' FROM example;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>11</td>
</tr>
</tbody>
</table>

(16 rows)
Although calling a UDx with incorrect parameters generates a warning, by default, the query still runs. For further information on setting the behavior of your UDx when you supply incorrect parameters, see Specifying the Behavior of Passing Unregistered Parameters.

```sql
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS wrongparam=42) AS 'result' from example;

WARNING 4332: Parameter wrongparam was not registered by the function and cannot be coerced to a definite data type

    a | b | result
----------
    1 | 2 | 3
    3 | 4 | 7
    5 | 6 | 11
    7 | 8 | 15
    9 | 10| 19

(5 rows)
```

Specifying the Behavior of Passing Unregistered Parameters

By default, Vertica issues a warning message when you pass a UDx an unregistered parameter. An unregistered parameter is one that you did not declare in the `getParameterType()` method.

You can control the behavior of your UDx when you pass it an unregistered parameter by altering the `StrictUDxParameterChecking` configuration parameter.

Unregistered Parameter Behavior Settings

You can specify the behavior of your UDx in response to one or more unregistered parameters. To do so, set the `StrictUDxParameterChecking` configuration parameter to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Allows unregistered parameters to be accessible to the UDx. The <code>ParamReader</code> class's <code>getType()</code> method determines the data type of the unregistered parameter. Vertica does not display any warning or error message.</td>
</tr>
</tbody>
</table>
### Examples

The following examples demonstrate the behavior you can specify using different values with the StrictUDxParameterChecking parameter.

**View the Current Value of StrictUDxParameterChecking**

To view the current value of the StrictUDxParameterChecking configuration parameter, run the following query:

```sql
=> \x
Expanded display is on.
=> SELECT * FROM configuration_parameters WHERE parameter_name = 'StrictUDxParameterChecking';
- [ RECORD 1 ]-----------------------------------------------
    node_name | ALL
    parameter_name | StrictUDxParameterChecking
    current_value | 1
    restart_value | 1
    database_value | 1
    default_value | 1
    current_level | DATABASE
    restart_level | DATABASE
    is_mismatch | f
    groups | |
    allowed_levels | DATABASE
    superuser_only | f
    change_under_support_guidance | f
    change_requires_restart | f
    description | Sets the behavior to deal with undeclared UDx function parameters
```

**Change the Value of StrictUDxParameterChecking**

You can change the value of the StrictUDxParameterChecking configuration parameter at the database, node, or session level. For example, you can change the value to '0' to specify that unregistered parameters can pass to the UDx without displaying a warning or error message:

```sql
=> ALTER DATABASE mydb SET StrictUDxParameterChecking = 0;
```
Invalid Parameter Behavior with RemoveSymbol

The following example demonstrates how to call the RemoveSymbol UDSF example. The RemoveSymbol UDSF has a required parameter, symbol, and an optional parameter, n. In this case, you do not use the optional parameter.

If you pass both symbol and an additional parameter called wrongParam, which is not declared in the UDx, the behavior of the UDx changes corresponding to the value of StrictUDxParameterChecking.

When you set StrictUDxParameterChecking to '0', the UDx runs normally without a warning. Additionally, wrongParam becomes accessible to the UDx through the ParamReader object of the ServerInterface object:

```sql
=> ALTER DATABASE mydb SET StrictUDxParameterChecking = 0;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
  original_string  | RemoveSymbol
-------------------+------------------
  3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set StrictUDxParameterChecking to '1', the UDx ignores wrongParam and runs normally. However, it also issues a warning message:

```sql
=> ALTER DATABASE mydb SET StrictUDxParameterChecking = 1;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
WARNING 4320: Parameter wrongParam was not registered by the function and cannot be coerced to a definite data type
  original_string  | RemoveSymbol
-------------------+------------------
  3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set StrictUDxParameterChecking to '2', the UDx encounters an error when it tries to call wrongParam and does not run. Instead, it generates an error message:

```sql
=> ALTER DATABASE mydb SET StrictUDxParameterChecking = 2;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
ERROR 0: Parameter wrongParam was not registered by the function
```

- Setting Configuration Parameter Values

User-Defined Session Parameters

User-defined session parameters allow you to write more generalized parameters than what Vertica provides. You can configure user-defined session parameters in these ways:

- From the client—for example, with `ALTER SESSION`
- Through the UDx itself

A user-defined session parameter can be passed into any type of UDx supported by Vertica. You can also set parameters for your UDx at the session level. By specifying a user-defined session parameter, you can have the state of a parameter saved continuously. Vertica saves the state of the parameter even when the UDx is invoked multiple times during a single session.

The RowCount example uses a user-defined session parameter. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions. See C++ Example: Using Session Parameters and Java Example: Using Session Parameters for implementations.

Viewing the User-Defined Session Parameter

Enter the following command to see the value of the session parameter:

```sql
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
--------+--------+----+------
(0 rows)
```

Now, execute the UDx:

```sql
=> SELECT RowCount(5,5);
RowCount
--------
10
(1 row)
```

Again, enter the command to see the value of the session parameter:
Because the UDx has processed one row, the value of RowCount is now 1. Running the UDx two more times should increase the value of RowCount by 2:

```
=> SELECT RowCount(10,10);
RowCount
--------
20
(1 row)
=> SELECT RowCount(15,15);
RowCount
--------
30
(1 row)
```

You have now executed the UDx three times, obtaining the sum of 5 + 5, 10 + 10, and 15 + 15. Now, check the value of RowCount.

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key   | value
--------+---------+-------+-------
public | UDSession| rowcount | 3
(1 row)
```

### Altering the User-Defined Session Parameter

You can also manually alter the value of RowCount. To do so, enter the following command:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession RowCount = 25;
ALTER SESSION
```

Check the value of RowCount:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key   | value
--------+---------+-------+-------
public | UDSession| rowcount | 25
(1 row)
```

### Clearing the User-Defined Session Parameter

**From the client:**

To clear the current value of RowCount, enter the following command:
ALTER SESSION CLEAR UPARAMETER FOR UDSession RowCount;
ALTER SESSION

Verify that RowCount has been cleared:

SHOW SESSION UPARAMETER all;
schema | library | key | value
----------+---------+-----+-------
(0 rows)

Through the UDx in C++:

You can set the session parameter to clear through the UDx itself. For example, to clear RowCount when its value reaches 10 or greater do the following:

1. Remove the following line from the destroy() method in RowCount:

   udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);

2. Replace the removed line from the destroy() method with the following code:

   if (rowCount < 10)
   {
     udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
   }
   else
   {
     udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
   }

3. To see the UDx clear the session parameter, set RowCount to a value of 9:

   ALTER SESSION SET UPARAMETER FOR UDSession RowCount = 9;
   ALTER SESSION

4. Check the value of RowCount:

   SELECT RowCount(15,15);
   RowCount
   -------
   30
6. Check the value of RowCount. Because the value has reached 10, the threshold specified in the UDx, expect that RowCount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
```

<table>
<thead>
<tr>
<th>schema</th>
<th>library</th>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>---------</td>
<td>---------</td>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>(0 rows)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

As expected, RowCount is cleared.

**Through the UDx in Java:**

1. Remove the following lines from the `destroy()` method in `RowCount`:

   ```java
   udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
   srvInterface.log("RowNumber processed %d records", count);
   ```

2. Replace the removed lines from the `destroy()` method with the following code:

   ```java
   if (rowCount < 10) {
   udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
   srvInterface.log("RowNumber processed %d records", count);
   } else {
   udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
   }
   ```

3. To see the UDx clear the session parameter, set RowCount to a value of 9:

   ```
   => ALTER SESSION SET UDPARAMETER FOR UDSession RowCount = 9;
   ALTER SESSION
   ```

4. Check the value of RowCount:

   ```
   => SHOW SESSION UDPARAMETER all;
   ```

<table>
<thead>
<tr>
<th>schema</th>
<th>library</th>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>UDSession</td>
<td>rowcount</td>
<td>9</td>
</tr>
<tr>
<td>(1 row)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. Invoke RowCount so that its value becomes 10:
SELECT RowCount(15,15);
RowCount
----------
   30
(1 row)

6. Check the value of RowCount. Since the value has reached 10, the threshold specified in the UDx, expect that RowCount is cleared:

SHOW SESSION UDPARAMETER all;
schema | library | key    | value
----------+---------+--------+--------
          |         |        |        
(0 rows)

As expected, RowCount is cleared.

Read-Only and Hidden Session Parameters

If you don't want a parameter to be set anywhere except in the UDx, you can make it read-only. If, additionally, you don't want a parameter to be visible in the client, you can make it hidden.

To make a parameter read-only, meaning that it cannot be set in the client, but can be viewed, add a single underscore before the parameter's name. For example, to make rowCount read-only, change all instances in the UDx of "rowCount" to "_rowCount".

To make a parameter hidden, meaning that it cannot be viewed in the client nor set, add two underscores before the parameter's name. For example, to make rowCount hidden, change all instances in the UDx of "rowCount" to "__rowCount".

User-Defined Session Parameters

C++ Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the C++ add2ints UDSF example. The getParameterType() function defines a single integer parameter that is named constant.

class Add2intsWithConstantFactory : public ScalarFunctionFactory
{

```cpp
```
// Return an instance of Add2ints to perform the actual addition.
virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
{
    // Calls the vt_createFuncObj to create the new Add2ints class instance.
    return vt_createFuncObj(interface.allocator, Add2intsWithConstant);
}

// Report the argument and return types to Vertica.
virtual void getPrototype(ServerInterface &interface,
    ColumnTypes &argTypes,
    ColumnTypes &returnType)
{
    // Takes two ints as inputs, so add ints to the argTypes object.
    argTypes.addInt();
    argTypes.addInt();
    // Returns a single int.
    returnType.addInt();
}

// Defines the parameters for this UDSF. Works similarly to defining arguments and return types.
virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes)
{
    // One int parameter named constant.
    parameterTypes.addInt("constant");
}

};
RegisterFactory(Add2intsWithConstantFactory);

See the Vertica SDK entry for SizedColumnType for a full list of the data-type-specific functions you can call to define parameters.

The following code fragment demonstrates using the parameter value. The Add2intsWithConstant class defines a function that adds two integer values. If the user supplies it, the function also adds the value of the optional integer parameter named constant.

/***
 * A UDSF that adds two numbers together with a constant value.
 *
 */
class Add2intsWithConstant : public ScalarFunction
{
public:
    // Processes a block of data sent by Vertica.
    virtual void processBlock(ServerInterface &srvInterface,
        BlockReader &arg_reader,
        BlockWriter &res_writer)
    {
        try
        {
            // The default value for the constant parameter is 0.
            vint constant = 0;
            // Get the parameter reader from the ServerInterface to see if there are supplied parameters.
            ParamReader paramReader = srvInterface.getParamReader();
            // See if the user supplied the constant parameter.
            if (paramReader.containsParameter("constant"))
                // There is a parameter, so get its value.

C++ Example: Using Session Parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDX each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```cpp
#include <string>
#include <sstream>
#include <iostream>
#include "Vertica.h"
#include "VerticaUDx.h"

using namespace Vertica;

class RowCount : public Vertica::ScalarFunction
{
private:
    int rowCount;
    int count;

public:
    virtual void setup(Vertica::ServerInterface &srvInterface, const Vertica::SizedColumnType &argTypes) {
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        std::string rCount = pSessionParams.getStringRef("rowCount").str;
        rowCount = atoi(rCount.c_str());
    }
};
```
virtual void processBlock(Vertica::ServerInterface &srvInterface, Vertica::BlockReader &arg_reader, Vertica::BlockWriter &res_writer) {
    count = 0;
    if(arg_reader.getNumCols() != 2)
        vt_report_error(0, "Function only accepts two arguments, but %zu provided", arg_reader.getNumCols());
    do {
        const Vertica::vint a = arg_reader.getIntRef(0);
        const Vertica::vint b = arg_reader.getIntRef(1);
        res_writer.setInt(a+b);
        count++;
        res_writer.next();
    } while (arg_reader.next());
    srvInterface.log("count %d", count);
}

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes, SessionParamWriterMap &udParams) {
    rowCount = rowCount + count;
    std::ostringstream s;
    s << rowCount;
    const std::string i_as_string(s.str());
    udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
}

class RowCountsInfo : public Vertica::ScalarFunctionFactory {
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface) {
        return Vertica::vt_createFuncObject<RowCount>(srvInterface.allocator);
    }

    virtual void getPrototype(Vertica::ServerInterface &srvInterface, Vertica::ColumnTypes &argTypes, Vertica::ColumnTypes &returnType) {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
};

RegisterFactory(RowCountsInfo);

Java Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the Java add2ints UDSF example. The getParameterType() method defines a single integer parameter that is
named constant.

```java
package com.mycompany.example;
import com.vertica.sdk.*;
public class Add2IntsWithConstantFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface,
                               ColumnTypes argTypes,
                               ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
    @Override
    public void getReturnType(ServerInterface srvInterface,
                               SizedColumnTypes argTypes,
                               SizedColumnTypes returnType)
    {
        returnType.addInt("sum");
    }
    // Defines the parameters for this UDSF. Works similarly to defining
    // arguments and return types.
    public void getParameterType(ServerInterface srvInterface,
                                  SizedColumnTypes parameterTypes)
    {
        // One INTEGER parameter named constant
        parameterTypes.addInt("constant");
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        return new Add2IntsWithConstant();
    }
}
```

See the Vertica Java SDK entry for `SizedColumnTypes` for a full list of the data-type-specific methods you can call to define parameters.

**Java Example: Using Session Parameters**

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```java
package com.mycompany.example;
import com.vertica.sdk.*;
public class RowCountFactory extends ScalarFunctionFactory {
    //...
}
```
@Override
class RowCount extends ScalarFunction {
    private Integer count;
    private Integer rowCount;
    // In the setup method, you look for the rowCount parameter. If it doesn't exist, it is created.
    // Look in the default namespace which is "library," but it could be anything else, most likely
    "public" if not "library".
    @Override
    public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes) {
        count = new Integer(0);
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        String rCount = pSessionParams.containsKey("rowCount")?
                pSessionParams.getString("rowCount"):
                "0";
        rowCount = Integer.parseInt(rCount);
    }
    @Override
    public void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_writer)
            throws UdfException, DestroyInvocation {
        do {
            ++count;
            long a = arg_reader.getLong(0);
            long b = arg_reader.getLong(1);
            res_writer.setLong(a+b);
            res_writer.next();
        } while (arg_reader.next());
    }
    @Override
    public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes, SessionParamWriterMap udParams){
        rowCount = rowCount+count;
        udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
        srvInterface.log("RowNumber processed %d records", count);
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new RowCount();
    }
}
Debugging Tips

You must thoroughly debug your UDx before deploying it to a production environment. The following tips can help you get your UDx ready for deployment.

Use a Single Node For Initial Debugging

You can attach to the Vertica process using a debugger such as gdb to debug your UDx code. Doing this in a multi-node environment, however, is very difficult. Therefore, consider setting up a single-node Vertica test environment to initially debug your UDx.

Write Messages to the Vertica Log

You can write to log files using the ServerInterface.log function. Every function in your UDx receives an instance of the ServerInterface object, so you can call the log function from anywhere in your UDx. The function acts similarly to printf, taking a formatted string, and an optional set of values and writing the string to a log file. Where the message is written depends on whether your function runs in fenced mode or unfenced mode:

- Functions running in unfenced mode write their messages into the vertica.log file in the catalog directory.
- Functions running in fenced mode write their messages into a log file named UDxLogs/UDxFencedProcesses.log in the catalog directory.

To help identify your function's output, Vertica adds the SQL function name bound to your UDx function to the log message.

The following code fragment shows how you can add a call to srvInterface.log in the Add2ints example code's processBlock() function to log its input values:

```c
const vint a = arg_reader.getIntRef(0);
const vint b = arg_reader.getIntRef(1);
srvInterface.log("got a: %d and b: %d", (int) a, (int) b);
```

This code generates an entries in the log file for each row the UDx processes. For example:

```
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 1 and b: 2
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 2 and b: 2
```
See Monitoring the Log Files in the Administrator's Guide for details on viewing the Vertica log files.

Developing with the C++ SDK

The Vertica SDK supports writing both fenced and unfenced UDxs of all types in C++ 11. You can download, compile, and run the examples; see Downloading and Running UDx Example Code. Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

Extending Vertica provides a high-level description of the key APIs in the SDK. For more details, see the C++ SDK Documentation.

Setting Up the C++ SDK

The Vertica C++ Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and header files you need to create your UDx library. For examples that you can compile and run, see Downloading and Running UDx Example Code. For requirements for your development environment, see Setting Up a Development Environment.

The SDK files are located in the sdk subdirectory under the root Vertica server directory (usually, /opt/vertica/sdk). This directory contains a subdirectory, include, which contains the headers and source files needed to compile UDx libraries.

There are two files in the include directory you need when compiling your UDx:
Vertica.h is the main header file for the SDK. Your UDx code needs to include this file in order to find the SDK's definitions.

Vertica.cpp contains support code that needs to be compiled into the UDx library.

Much of the Vertica SDK API is defined in the VerticaUDx.h header file (which is included by the Vertica.h file). If you're curious, you might want to review the contents of this file in addition to reading the API documentation.

Finding the Current SDK Version

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:

```sql
=> SELECT sdk_version();
```

Running the Examples

You can download the examples from the GitHub repository (see Downloading and Running UDx Example Code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

To compile all of the examples, including the Java examples, issue the following command in the Java-and-C++ directory under the examples directory:

```
$ make
```

Note: To compile the examples, you must have a g++ development environment installed. To install a g++ development environment on Red Hat systems, run `yum install gcc gcc-c++ make`.

Compiling Your C++ Library

GNU g++ is the only supported compiler for compiling UDx libraries. Always compile your UDx code on the same version of Linux that you use on your Vertica cluster.

When compiling your library, you must always:
Pass the -shared and -fPIC flags to the linker. The simplest method is to just pass these flags to g++ when you compile and link your library.

Use the -Wno-unused-value flag to suppress warnings when macro arguments are not used. If you do not use this flag, you may get "left-hand operand of comma has no effect" warnings.

Compile sdk/include/Vertica.cpp and link it into your library. This file contains support routines that help your UDx communicate with Vertica. The easiest way to do this is to include it in the g++ command to compile your library. Vertica supplies this file as C++ source rather than a library to limit library compatibility issues.

Add the Vertica SDK include directory in the include search path using the g++ -I flag.

The SDK examples include a working makefile. See Downloading and Running UDx Example Code.

Example of Compiling a UDx

The following command compiles a UDx contained in a single source file named MyUDx.cpp into a shared library named MyUDx.so:

```
g++ -I/opt/vertica/sdk/include -Wall -shared -Wno-unused-value -fPIC -o MyUDx.so MyUDx.cpp /opt/vertica/sdk/include/Vertica.cpp
```

**Important:** Vertica only supports UDx development on 64-bit architectures.

After you debug your UDx, you are ready to deploy it. Recompile your UDx using the -O3 flag to enable compiler optimization.

You can add additional source files to your library by adding them to the command line. You can also compile them separately and then link them together.

**Tip:** The examples subdirectory in the Vertica SDK directory contains a make file that you can use as starting point for your own UDx project.

Handling External Libraries

You must link your UDx library to any supporting libraries that your UDx code relies on. These libraries might be either ones you developed or others provided by third parties. You have two options for linking:
• Statically link the support libraries into your UDx. The benefit of this method is that your UDx library does not rely on external files. Having a single UDx library file simplifies deployment because you just transfer a single file to your Vertica cluster. This method’s main drawback is that it increases the size of your UDx library file.

• Dynamically link the library to your UDx. You must sometimes use dynamic linking if a third-party library does not allow static linking. In this case, you must copy the libraries to your Vertica cluster in addition to your UDx library file.

Adding Metadata to C++ Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library’s metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library’s metadata.

The `RegisterLibrary()` function takes eight string parameters:

```c
RegisterLibrary(author,
    library_build_tag,
    library_version,
    library_sdk_version,
    source_url,
    description,
    licenses_required,
    signature);
```

• `author` contains whatever name you want associated with the creation of the library (your own name or your company's name for example).

• `library_build_tag` is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.

• `library_version` is the version of your library. You can use whatever numbering or naming scheme you want.
- **library_sdk_version** is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

  Note: This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- **source_url** is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.

- **description** is a concise description of your library.

- **licenses_required** is a placeholder for licensing information. You must pass an empty string for this value.

- **signature** is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates adding metadata to the Add2Ints example (see **C++ Example: Add2Ints**).

```cpp
// Include the top-level Vertica SDK file
#include "Vertica.h"
// Using the Vertica namespace means we don't have to prefix all
// class references with Vertica::
using namespace Vertica;
/*
 * ScalarFunction implementation for a UDF that adds
 * two numbers together.
 */
class Add2Ints : public ScalarFunction
{
    public:
    /*
     * This function does all of the actual processing for the UDF.
     * In this case, it simply reads two integer values and returns
     * their sum.
     *
     * The inputs are retrieved via arg_reader
     * The outputs are returned via arg_writer
     */
    virtual void processBlock(ServerInterface &srvInterface,
        BlockReader &arg_reader,
        BlockWriter &res_writer)
    {
```
// While we have input to process
  do
  {
    // Read the two integer input parameters by calling the
    // BlockReader.getIntRef class function
    const vint a = arg_reader.getIntRef(0);
    const vint b = arg_reader.getIntRef(1);
    // Call BlockWriter.setInt to store the output value, which is the
    // two input values added together
    res_writer.setInt(a+b);
    // Finish writing the row, and advance to the next output row
    res_writer.next();
    // Continue looping until there are no more input rows
  }
  while (arg_reader.next());
}

/*
* This class provides metadata about the ScalarFunction class, and
* also instantiates a member of that class when needed.
*/
class Add2IntsFactory : public ScalarFunctionFactory
{
  // return an instance of Add2Ints to perform the actual addition.
  virtual ScalarFunction *createScalarFunction(ServerInterface &interface) {
    // Calls the vt_createFuncObj to create the new Add2Ints class instance.
    return vt_createFuncObj(interface allocator, Add2Ints);}

  // This function returns the description of the input and outputs of the
  // Add2Ints class's processBlock function. It stores this information in
  // two ColumnTypes objects, one for the input parameters, and one for
  // the return value.
  virtual void getPrototype(ServerInterface &interface,
                             ColumnTypes &argTypes,
                             ColumnTypes &returnType) {
    // Takes two ints as inputs, so add ints to the argTypes object
    argTypes.addInt();
    argTypes.addInt();
    // returns a single int, so add a single int to the returnType object.
    // Note that ScalarFunctions *always* return a single value.
    returnType.addInt();
  }
};

// Register the factory with Vertica
RegisterFactory(Add2IntsFactory);

// Register the library’s metadata.
RegisterLibrary("Whizzo Analytics Ltd.",
               "1234",
               "2.0",
               "7.0.0",
               "http://www.example.com/add2ints",
               "Add 2 Integer Library",
               ",",
               ",");
Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to RegisterLibrary():

```sql
=> CREATE LIBRARY add2intslib AS '/home/dbadmin/add2ints.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'add2intslib';

**C++ SDK Data Types**

The Vertica SDK has typedefs and classes for representing Vertica data types within your UDx code. Using these typedefs ensures data type compatibility between the data your UDx processes and generates and the Vertica database. The following table describes some of the typedefs available. Consult the Vertica C++ SDK Documentation for a complete list, as well as lists of helper functions to convert and manipulate these data types.

<table>
<thead>
<tr>
<th>Type Definition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval</td>
<td>A Vertica interval</td>
</tr>
<tr>
<td>IntervalYM</td>
<td>A Vertica year-to-month interval.</td>
</tr>
<tr>
<td>Timestamp</td>
<td>A Vertica timestamp</td>
</tr>
<tr>
<td>vint</td>
<td>A standard Vertica 64-bit integer</td>
</tr>
<tr>
<td>vint_null</td>
<td>A null value for integer values</td>
</tr>
<tr>
<td>vbool</td>
<td>A Boolean value in Vertica</td>
</tr>
<tr>
<td>Type Definition</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>vbool_null</td>
<td>A null value for a Boolean data types</td>
</tr>
<tr>
<td>vfloat</td>
<td>A Vertica floating point value</td>
</tr>
</tbody>
</table>
| VString         | String data types (such as varchar and char)  
|                 | **Note:** Do not use a VString object to hold an intermediate result. Use a std::string or char[] instead. |
| VNumeric        | Fixed-point data types from Vertica |

**Notes**

- When making some Vertica SDK API calls (such as VerticaType::getNumericLength()) on objects, make sure they have the correct data type. To minimize overhead and improve performance, most of the APIs do not check the data types of the objects on which they are called. Calling a function on an incorrect data type can result in an error.

- A NULL Vertica value string data type is converted into an empty C++ string.

- You cannot create instances of VString or VNumeric yourself. You can manipulate the values of existing objects of these classes that Vertica passes to your UDx, and extract values from them. However, only Vertica can instantiate these classes.

**Handling Errors**

If your UDx encounters some sort of error, it can report it back to Vertica using the vt_report_error macro. When called, this macro halts the execution of the UDx and causes the statement that called the function to fail. The macro takes two parameters: an error number and an error message string. Both the error number and message appear in the error that Vertica reports to the user. The error number is not defined by Vertica. You can use whatever value that you wish.

For example, the following ScalarFunction class divides two integers. To prevent division by zero, it tests the second parameter. If it is zero, the function reports the error back to Vertica.

```c++
/*  
 * Demonstrate reporting an error  
 */
```
class Div2ints : public ScalarFunction
{
public:
  virtual void processBlock(ServerInterface &srvInterface,
                             BlockReader &arg_reader,
                             BlockWriter &res_writer)
  {
    // While we have inputs to process
    do
    {
      const vint a = arg_reader.getIntRef(0);
      const vint b = arg_reader.getIntRef(1);
      if (b == 0)
      {
        vt_report_error(1, "Attempted divide by zero");
      }
      res_writer.setInt(a/b);
      res_writer.next();
    } while (arg_reader.next());
  }
};

Loading and invoking the function demonstrates how the error appears to the user.

=> CREATE LIBRARY Div2IntsLib AS '/home/dbadmin/Div2ints.so';
CREATE LIBRARY
=> CREATE FUNCTION div2ints AS LANGUAGE 'C++' NAME 'Div2intsInfo' LIBRARY Div2IntsLib;
CREATE FUNCTION
=> SELECT div2ints(25, 5);
 div2ints
   --------

12 | 2
18 | 9
 (4 rows)
=> SELECT * FROM MyTable WHERE div2ints(a, b) > 2;
ERROR: Error in calling processBlock() for User Defined Scalar Function div2ints at Div2ints.cpp:21, error code: 1, message: Attempted divide by zero

Your function must not allow an exception to be passed back to Vertica. You should use a top-level try-catch block to catch any stray exceptions that might be thrown by your code or any functions or libraries your code calls. This is especially important when running a UDx in unfenced mode. Any errors in an unfenced UDx can result in database instability or even data loss.
Handling Cancel Requests

You can cancel a query that calls your UDx (usually, by by pressing CTRL+C in vsqI). How Vertica handles the cancelation of the query and your UDx depends on whether your UDx is running in fenced or unfenced mode:

- If your UDx is running in unfenced mode, Vertica either stops the function when it requests a new block of input or output, or waits until your function completes running and discards the results.

- If your UDx is running in Fenced Mode, Vertica kills the zygote process that is running your function if it continues processing past a timeout.

See Fenced Mode for more information about running functions in fenced mode.

To give you more control over what happens to your function when the user cancels its query, the Vertica SDK includes an API for some UDxs to handle cancelation. Any function class that inherits from the Vertica::UDXObjectCancelable class can test whether the query calling it has been canceled using a function named isCanceled(). Your function can also implement a callback function named cancel() that Vertica calls when the function's query is canceled. Currently, the two classes that inherit from UDXObjectCancelable are TransformFunction and AnalyticFunction.

Exiting When the Calling Query Has Been Canceled

The processPartition() function in your User-Defined Transform Function (UDTF) or Analytic Function (UDAnF) can call Vertica::UDXObjectCancelable.isCanceled() to determine if the user has canceled the query that called it. If isCanceled() returns true, the query has been canceled and your processPartition() function should exit immediately to prevent it from wasting CPU time. If your UDx is not running in Fenced Mode, Vertica cannot halt your function, and has to wait for it to finish. If it is running in fenced mode, Vertica can eventually kill the side process running it, but not until it has wasted some processing time.

How often your processPartition() function calls isCanceled() depends on how much processing it performs on each row of data. Calling isCanceled() does add some overhead to your function, so you shouldn't call it too often. For transforms that do not perform lengthy processing, you could check for cancellation every 100 or 1000 rows or so. If your processPartition() function performs extensive processing for each row, you may want to check isCanceled() every 10 or so rows.
The following code fragment shows how you could have the StringTokenizer UDTF example check whether its query has been canceled:

```java
// The primary class for the StringTokenizer UDTF.
class StringTokenizer : public TransformFunction {
    // Called for each partition in the table. Recieves the data from
    // The source table and
    virtual void processPartition(ServerInterface &srvInterface,
                                   PartitionReader &inputReader,
                                   PartitionWriter &outputWriter) {
        try {
            // Loop through the input rows
            int rowCount = 0; // Count the number of rows processed.
            do {
                rowCount++; // Processing a new row of data
                // Check for cancelation every 100 rows.
                if (rowCount % 100 == 0) {
                    if (isCanceled()) // See if query has been canceled
                    {
                        // Log cancelation
                        srvInterface.log("Got canceled!");
                        return; // Exit out of UDTF immediately.
                    }
                }
            } // Rest of the function here
            . . .
        }
    }
}
```

This example checks for cancellation after processing 100 rows in the partition of data. If the query has been canceled, the example logs a message, then returns to the caller to exit the function.

**Note:** You need to strike a balance between adding overhead to your functions by calling `isCanceled()` and having your functions waste CPU time by running after their query has been canceled (usually, a rare event). For functions such as `StringTokenizer` which have a low overall processing cost, it usually does not make sense to test for cancellation. The cost of adding overhead to all function calls outweighs the amount of resources wasted by having the function run to completion or having its zygote process killed by Vertica on the rare occasions that its query is canceled.

### Implementing the Cancel Callback Function

Your User-Defined Transform Function (UDTF) or Analytic Function (UDAnF) can implement a `cancel()` callback function that Vertica calls if the query that called the function has been canceled. You usually implement this function to perform an orderly shutdown of any additional processing that your UDx spawned. For example, you can have your `cancel()` function shut down threads that your UDx has spawned or signal a third-party library that it needs to stop processing and exit. Your `cancel()` function should leave your UDx's function
class ready to be destroyed, since Vertica calls the UDx's destroy function after the cancel function has exited.

Notes

- If your UDTF or UDAnF does not implement cancel(), Vertica assumes your UDx does not need to perform any special cancel processing, and calls the function class's destroy() function to have it free any resources (see Resource Use for C++ UDxs).

- Your cancel() function is called from a different thread than the thread running your UDx's processPartition() function.

- The call to the cancel() function is not synchronized in any way with your UDx's processPartition() function. If you need your processPartition() function to exit before your cancel() function performs some action (killing threads, for example) you need to have the two function synchronize their actions.

- If your cancel() function runs for too long, Vertica kills the side process running your function, if it is running in Fenced Mode.
Resource Use for C++ UDxs

Your UDxs consume at least a small amount of memory by instantiating classes and creating local variables. This basic memory usage by UDxs is small enough that you do not need to be concerned about it.

If your UDx needs to allocate more than one or two megabytes of memory for data structures, or requires access to additional resources such as files, you must inform Vertica about its resource use. Vertica can then ensure that the resources your UDx requires are available before running a query that uses it. Even moderate memory use (10MB per invocation of a UDx, for example) can become an issue if there are many simultaneous queries that call it.

Note: If your UDx allocates its own memory, you must make absolutely sure it properly frees it. Failing to free even a single byte of allocated memory can have huge consequences if your UDx is called to operate on a multi-million-row table. Instead of having your code allocate its own memory, you should use the C++ vt_alloc macro, which uses Vertica's own memory manager to allocate and track memory. This memory is guaranteed to be properly disposed of when your UDx completes execution. See Allocating Resources for UDxs for more information.

Allocating Resources for UDxs

You have two options for allocating memory and file handles for your User-Defined Extensions (UDxs):

- Use Vertica SDK macros to allocate resources. This is the best method, since it uses Vertica's own resource manager, and guarantees that resources used by your UDx are reclaimed. See Allocating Resources with the SDK Macros.

- Allocate resources in your UDxs yourself using standard C++ methods (instantiating objects using new, allocating memory blocks using malloc(), etc.). You must manually free these resources before your UDx exits.

Note: You must be extremely careful if you choose to allocate your own resources in your UDx. Failing to free resources properly will have significant negative impact, especially if your UDx is running in unfenced mode.

Whichever method you choose, you usually allocate resources in a function named setup() in your UDx class. This function is called after your UDx function object is instantiated, but before Vertica calls it to process data.
If you allocate memory on your own in the `setup()` function, you must free it in a corresponding function named `destroy()`. This function is called after your U Dx has performed all of its processing. This function is also called if your U Dx returns an error (see Handling Errors).

**Note:** Always use the `setup()` and `destroy()` functions to allocate and free resources instead of your own constructors and destructors. The memory for your U Dx object is allocated from one of Vertica's own memory pools. Vertica always calls your U Dx's `destroy()` function before it deallocates the object's memory. There is no guarantee that your U Dx's destructor is will be called before the object is deallocated. Using the `destroy()` function ensures that your U Dx has a chance to free its allocated resources before it is destroyed.

The following code fragment demonstrates allocating and freeing memory using a `setup()` and `destroy()` function.

```cpp
class MemoryAllocationExample : public ScalarFunction
{
public:
    uint64* myarray;
    // Called before running the UDF to allocate memory used throughout
    // the entire UDF processing.
    virtual void setup(ServerInterface &srvInterface, const SizedColumnTypes &argTypes)
    {
        try
        {
            // Allocate an array. This memory is directly allocated, rather than
            // letting Vertica do it. Remember to properly calculate the amount
            // of memory you need based on the data type you are allocating.
            // This example divides 500MB by 8, since that's the number of
            // bytes in a 64-bit unsigned integer.
            myarray = new uint64[1024 * 1024 * 500 / 8];
        }
        catch (std::bad_alloc &ba)
        {
            // Always check for exceptions caused by failed memory
            // allocations.
            vt_report_error(1, "Couldn't allocate memory :[%s]", ba.what());
        }
    }

    // Called after the UDF has processed all of its information. Use to free
    // any allocated resources.
    virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes)
    {
        try
        {
            // Properly dispose of the allocated memory.
            delete[] myarray;
        }
    }
};
```
catch (std::bad_alloc &ba)
{
    // Always check for exceptions caused by failed memory
    // allocations.
    vt_report_error(1, "Couldn't free memory :[%s]", ba.what());
}

Allocating Resources with the SDK Macros

The Vertica SDK provides three macros to allocate memory:

- **vt_alloc** allocates a block of memory to fit a specific data type (vint, struct, etc.).
- **vt.alloc** allocates a block of memory to hold an array of a specific data type.
- **vt.alloc** allocates an arbitrarily-sized block of memory.

All of these macros allocate their memory from memory pools managed by Vertica. The main benefit of allowing Vertica to manage your UDx's memory is that the memory is automatically reclaimed after your UDx has finished. This ensures there is no memory leaks in your UDx.

Because Vertica frees this memory automatically, do not attempt to free any of the memory you allocate through any of these macros. Attempting to free this memory results in run-time errors.

Informing Vertica of Resource Requirements

When you run your UDx in fenced mode, Vertica monitors its use of memory and file handles. If your UDx uses more than a few megabytes of memory or any file handles, it should tell Vertica about its resource requirements. Knowing the resource requirements of your UDx allows Vertica to determine whether it can run the UDx immediately or needs to queue the request until enough resources become available to run it.

Determining how much memory your UDx requires can be difficult in some cases. For example, if your UDx extracts unique data elements from a data set, there is potentially no bound on the number of data items. In this case, a useful technique is to run your UDx in a test environment and monitor its memory use on a node as it handles several differently-sized queries, then extrapolate its memory use based on the worst-case scenario it may face in your production environment. In all cases, it's usually a good idea to add a safety margin to the amount of memory you tell Vertica your UDx uses.
Note: The information on your UDx's resource needs that you pass to Vertica is used when planning the query execution. There is no way to change the amount of resources your UDx requests from Vertica while the UDx is actually running.

Your UDx informs Vertica of its resource needs by implementing the getPerInstanceResources() function in its factory class (see Vertica::UDXFactory::getPerInstanceResources() in the SDK documentation). If your UDx's factory class implements this function, Vertica calls it to determine the resources your UDx requires.

The getPerInstanceResources() function receives an instance of the Vertica::VResources struct. This struct contains fields that set the amount of memory and the number of file handles your UDx needs. By default, the Vertica server allocates zero bytes of memory and 100 file handles for each instance of your UDx.

Your implementation of the getPerInstanceResources() function sets the fields in the VResources struct based on the maximum resources your UDx may consume for each instance of the UDx function. So, if your UDx's processBlock() function creates a data structure that uses at most 100MB of memory, your UDx must set the VResources.scratchMemory field to at least 104857600 (the number of bytes in 100MB). Leave yourself a safety margin by increasing the number beyond what your UDx should normally consume. In this example, allocating 115000000 bytes (just under 110MB) is a good idea.

The following ScalarFunctionFactory class demonstrates calling getPerInstanceResources() to inform Vertica about the memory requirements of the MemoryAllocationExample class shown in Allocating Resources for UDxs. It tells Vertica that the UDSF requires 510MB of memory (which is a bit more than the UDSF actually allocates, to be on the safe size).

class MemoryAllocationExampleFactory : public ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    {
        return vt_createFuncObj(srvInterface.allocator, MemoryAllocationExample);
    }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                                Vertica::ColumnTypes &argTypes,
                                Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    // Tells Vertica the amount of resources that this UDF uses.
    virtual void getPerInstanceResources(ServerInterface &srvInterface,
                                           VResources &res)
    {

res.scratchMemory += 1024LL * 1024 * 510; // request 510MB of memory
}

Setting Memory Limits for Fenced-Mode UDxs

Vertica calls a fenced-mode UDx's implementation of Vertica::UDXFactory::getPerInstanceResources() to determine if there are enough free resources to run the query containing the UDx (see Informing Vertica of Resource Requirements). Since these reports are not generated by actual memory use, they can be inaccurate. Once started by Vertica, a UDx could allocate far more memory or file handles than it reported it needs.

The FencedUDxMemoryLimitMB configuration parameter lets you create an absolute memory limit for UDxs. Any attempt by a UDx to allocate more memory than this limit results in a bad_alloc exception. For more information on configuration parameters, see Configuration Parameters in the Administrator's Guide. For an example of setting FencedUDxMemoryLimitMB, see How Resource Limits Are Enforced.

How Resource Limits Are Enforced

Before running a query, Vertica determines how much memory it requires to run. If the query contains a fenced-mode UDx which implements the getPerInstanceResources() function in its factory class, Vertica calls it to determine the amount of memory the UDx needs and adds this to the total required for the query. Based on these requirements, Vertica decides how to handle the query:

- If the total amount of memory required (including the amount that the UDxs report that they need) is larger than the session's MEMORYCAP or resource pool's MAXMEMORYSIZE setting, Vertica rejects the query. For more information about resource pools, see Resource Pool Architecture in the Administrator's Guide.

- If the amount of memory is below the limit set by the session and resource pool limits, but there is currently not enough free memory to run the query, Vertica queues it until enough resources become available.

- If there are enough free resources to run the query, Vertica executes it.

Note: Vertica has no other way to determine the amount of resources a UDx requires other than the values it reports using the getPerInstanceResources() function. A
UDX could use more resources than it claims, which could cause performance issues for other queries that are denied resources. You can set an absolute limit on the amount of memory UDXs can allocate. See Setting Memory Limits for Fenced-Mode UDXs for more information.

If the process executing your UDX attempts to allocate more memory than the limit set by the FencedUDxMemoryLimitMB configuration parameter, it receives a bad_alloc exception. For more information about FencedUDxMemoryLimitMB, see Setting Memory Limits for Fenced-Mode UDXs.

Below is the output of loading a UDSF that consumes 500MB of memory, then changing the memory settings to cause out-of-memory errors. The MemoryAllocationExample UDSF in the following example is just the Add2Ints UDSF example altered as shown in Allocating Resources for UDXs and Informing Vertica of Resource Requirements to allocate 500MB of RAM.

```sql
=> CREATE LIBRARY mylib AS '/home/dbadmin/MemoryAllocationExample.so';
CREATE LIBRARY
=> CREATE FUNCTION usemem AS NAME 'MemoryAllocationExampleFactory' LIBRARY mylib
  -> FENCED;
CREATE FUNCTION
=> SELECT usemem(1,2);
usemem
--------
3
(1 row)
```

The following statements demonstrate setting the session's MEMORYCAP to lower than the amount of memory that the UDSF reports it uses. This causes Vertica to return an error before it executes the UDSF.

```sql
=> SET SESSION MEMORYCAP '100M';
SET
=> SELECT usemem(1,2);
ERROR 3596: Insufficient resources to execute plan on pool sysquery
[Request exceeds session memory cap: 520328KB > 102400KB]
=> SET SESSION MEMORYCAP = default;
SET
```

The resource pool can also prevent a UDX from running if it requires more memory than is available in the pool. The following statements demonstrate the effect of creating and using a resource pool that has too little memory for the UDSF to run. Similar to the session's MAXMEMORYCAP limit, the pool's MAXMEMORYSIZE setting prevents Vertica from executing the query containing the UDSF.

```sql
=> CREATE RESOURCE POOL small MEMORYSIZE '100M' MAXMEMORYSIZE '100M';
CREATE RESOURCE POOL
=> SET SESSION RESOURCE POOL small;
SET
=> CREATE TABLE ExampleTable(a int, b int);
```
CREATE TABLE
=> INSERT /*+direct*/ INTO ExampleTable VALUES (1,2);
OUTPUT
--------
1
(1 row)
=> SELECT usemem(a, b) FROM ExampleTable;
ERROR 3596: Insufficient resources to execute plan on pool small 
[Request Too Large:Memory(KB) Exceeded: Requested = 523136, Free = 102400 (Limit = 102400, Used = 0)]
=> DROP RESOURCE POOL small; --Dropping the pool resets the session's pool
DROP RESOURCE POOL

Finally, setting the FencedUDxMemoryLimitMB configuration parameter to lower than the UDx actually allocates results in the UDx throwing an exception. This is a different case than either of the previous two examples, since the query actually executes. The UDx's code needs to catch and handle the exception. In this example, it uses the vt_report_error macro to report the error back to Vertica and exit.

=> ALTER DATABASE mydb SET FencedUDxMemoryLimitMB = 300;
=> SELECT usemem(1,2);
    ERROR 3412: Failure in UDx RPC call InvokeSetup(): Error calling setup() in User Defined Object [usemem] at [MemoryAllocationExample.cpp:32], error code: 1, message: Couldn't allocate memory :[std::bad_alloc]
=> ALTER DATABASE mydb SET FencedUDxMemoryLimitMB = -1;
=> SELECT usemem(1,2);
    usemem
--------
    3
(1 row)

Developing with the Java SDK

The Vertica SDK supports writing Java UDxs of all types except aggregate functions. All Java UDxs are fenced.

You can download, compile, and run the examples; see Downloading and Running UDx Example Code. Running the examples is a good way to verify that your development environment has all needed libraries.
If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

Extending Vertica provides a high-level description of the key APIs in the SDK. For more details, see the Java SDK Documentation.

**Setting Up the Java SDK**

The Vertica Java Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and JAR files you need to create your UDx library. For examples that you can compile and run, see Downloading and Running UDx Example Code. For requirements for your development environment, see Setting Up a Development Environment.

To use the SDK you need two files from the Java support package:

- `/opt/vertica/bin/VerticaSDK.jar` contains the Vertica Java SDK and other supporting files.
- `/opt/vertica/sdk/BuildInfo.java` contains version information about the SDK. You must compile this file and include it within your Java UDx JAR files.

If you are not doing your development on a database node, you can copy these two files from one of the database nodes to your development system.

The `BuildInfo.java` and `VerticaSDK.jar` files that you use to compile your UDx must be from the same SDK version. Both files must also match the version of the SDK files on your Vertica hosts. Versioning is only an issue if you are not compiling your UDxs on a Vertica host. If you are compiling on a separate development system, always refresh your copies of these two files and recompile your UDxs just before deploying them.

**Finding the Current SDK Version**

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:
SELECT sdk_version();

Compiling BuildInfo.java

You need to compile the `BuildInfo.java` file into a class file, so you can include it in your Java UDx JAR library. If you are using a Vertica node as a development system, you can either:

- Copy the `BuildInfo.java` file to another location on your host.
- If you have root privileges, compile the `BuildInfo.java` file in place. (Only the root user has privileges to write files to the `/opt/vertica/sdk` directory.)

Compile the file using the following command. Replace `path` with the path to the file and `output-directory` with the directory where you will compile your UDxs.

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar /path/BuildInfo.java -d output-directory
```

If you use an IDE such as Eclipse, you can include the `BuildInfo.java` file in your project instead of compiling it separately. You must also add the `VerticaSDK.jar` file to the project's build path. See your IDE's documentation for details on how to include files and libraries in your projects.

Running the Examples

You can download the examples from the GitHub repository (see Downloading and Running UDx Example Code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

If you have not already done so, set the JAVA_HOME environment variable to your JDK (not JRE) directory.

To compile all of the examples, including the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make
```

To compile only the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make JavaFunctions
```
To compile the examples, you must have make installed. To install make on Red Hat systems, run yum install make.

Compiling and Packaging a Java Library

Before you can use your Java UDx, you need to compile it and package it into a JAR file. The SDK examples include a working makefile. See Downloading and Running UDx Example Code.

Compile Your Java UDx

You must include the SDK JAR file in the classpath when you compile your Java UDx source files so the Java compiler can resolve the Vertica API calls. If you are using the command-line Java compiler on a host in your database cluster, enter this command:

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar factorySource.java 
[functionSource.java...] -d output-directory
```

If all of your source files are in the same directory, you can use *.java on the command line instead of listing the files individually.

If you are using an IDE, verify that a copy of the VerticaSDK.jar file is in the build path.

UDx Class File Organization

After you compile your UDx, you must package its class files and the BuildInfo.class file into a JAR file.

Note: You can package as many UDxs as you want into the same JAR file. Bundling your UDxs together saves you from having to load multiple libraries.

To use the jar command packaged as part of the JDK, you must organize your UDx class files into a directory structure matching your class package structure. For example, suppose your UDx's factory class has a fully-qualified name of com.mycompany.udfs.Add2ints. In this case, your class files must be in the directory hierarchy com/mycompany/udfs relative to your project's base directory. In addition, you must have a copy of the BuildInfo.class file in the path com/vertica/sdk so that it can be included in the JAR file. This class must appear in your JAR file to indicate the SDK version that was used to compile your Java UDx.
The JAR file for the Add2ints UDSF example explained in Java Example: Add2Ints has the following directory structure after compilation:

- com/vertica/sdk/BuildInfo.class
- com/mycompany/example/Add2intsFactory.class
- com/mycompany/example/Add2intsFactory$Add2 ints.class

Package Your UDx Into a JAR File

To create a JAR file from the command line:

1. Change to the root directory of your project.
2. Use the jar command to package the BuildInfo.class file and all of the classes in your UDx:

```
# jar -cvf libname.jar com/vertica/sdk/BuildInfo.class \
    packagePath/*.class
```

When you type this command, `libname` is the filename you have chosen for your JAR file (choose whatever name you like), and `packagePath` is the path to the directory containing your UDx's class files.

- For example, to package the files from the Add2ints example, you use the command:

```
# jar -cvf Add2intsLib.jar com/vertica/sdk/BuildInfo.class \
    com/mycompany/example/*.class
```

- More simply, if you compiled `BuildInfo.class` and your class files into the same root directory, you can use the following command:

```
# jar -cvf Add2intsLib.jar .
```

You must include all of the class files that make up your UDx in your JAR file. Your UDx always consists of at least two classes (the factory class and the function class). Even if you defined your function class as an inner class of your factory class, Java generates a separate class file for the inner class.

After you package your UDx into a JAR file, you are ready to deploy it to your Vertica database.
Handling Java UDx Dependencies

If your Java UDx relies on one or more external libraries, you can handle the dependencies in one of three ways:

- Bundle the JAR files into your UDx JAR file using a tool such as One-JAR or Eclipse Runnable JAR Export Wizard.

- Unpack the JAR file and then repack its contents in your UDx's JAR file.

- Copy the libraries to your Vertica cluster in addition to your UDx library. Then, use the DEPENDS keyword of the CREATE LIBRARY statement to tell Vertica that the UDx library depends on the external libraries. This keyword acts as a library-specific CLASSPATH setting. Vertica distributes the support libraries to all of the nodes in the cluster and sets the class path for the UDx so it can find them.

If your UDx depends on native libraries (SO files), use the DEPENDS keyword to specify their path. When you call System.loadLibrary in your UDx (which you must do before using a native library), this function uses the DEPENDS path to find them. You do not need to also set the LD_LIBRARY_PATH environment variable.

Important: In previous versions of Vertica, the JavaClassPathForUDx configuration parameter set the locations of external libraries for all Java UDxs. In Vertica Version 7.1, this configuration parameter is deprecated. It will be removed in a future version. If you upgrade from a previous version of Vertica, switch any existing Java UDxs that rely on support libraries to use the new DEPENDS keyword. To make this switch, use the ALTER LIBRARY statement to recreate the UDx library. In this statement, supply the DEPENDS keyword to specify the directory containing the support libraries.

External Library Example

The following example demonstrates using an external library with a Java UDx.

The following sample code defines a simple class, named VowelRemover. It contains a single method, named removevowels, that removes all of the vowels (the letters a, e, i, o u, and y) from a string.

```java
package com.mycompany.libs;

public class VowelRemover {
```
public String removevowels(String input) {
    return input.replaceAll("(?i)[aeiouy]", ");
}

You can compile this class and package it into a JAR file with the following commands:

$ javac -g com/mycompany/libs/VowelRemover.java
$ jar cf mycompanylibs.jar com/mycompany/libs/VowelRemover.class

The following code defines a Java UDSF, named DeleteVowels, that uses the library defined in the preceding example code. DeleteVowels accepts a single VARCHAR as input, and returns a VARCHAR.

```java
package com.mycompany.udx;
// Import the support class created earlier
import com.mycompany.libs.VowelRemover;
// Import the Vertica SDK
import com.vertica.sdk.*;

public class DeleteVowelsFactory extends ScalarFunctionFactory {
    @Override
    public ScalarFunction createScalarFunction(ServerInterface arg0) {
        return new DeleteVowels();
    }

    @Override
    public void getPrototype(ServerInterface arg0, ColumnTypes argTypes,
        ColumnTypes returnTypes) {
        // Accept a single string and return a single string.
        argTypes.addVarchar();
        returnTypes.addVarchar();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface,
        SizedColumnTypes argTypes,
        SizedColumnTypes returnType){
        returnType.addVarchar(
            // Output will be no larger than the input.
            argTypes.getColumnType(0).getStringLength(), "RemovedVowels");
    }

    public class DeleteVowels extends ScalarFunction {
        @Override
        public void processBlock(ServerInterface arg0, BlockReader argReader,
            BlockWriter resWriter) throws UdfException, DestroyInvocation {
            // Create an instance of the VowelRemover object defined in
            // the library.
            VowelRemover remover = new VowelRemover();
            do {
                String instr = argReader.getString(0);
                instr = remover.removevowels(instr);
                resWriter.getString(0, instr);
            } while (!argReader.isEndBlock());
        }
    }
}
```
// Call the removevowels method defined in the library.
resWriter.setString(remover.removevowels(instr));
resWriter.next();
} while (argReader.next());
}
}

Use the following commands to build the example UDSF and package it into a JAR:

- The first javac command compiles the SDK's BuildInfo class. Vertica requires all UDx libraries to contain this class. The javac command's -d option outputs the class file in the directory structure of your UDSF's source.
- The second javac command compiles the UDSF class. It adds the previously-created mycompanylibs.jar file to the class path so compiler can find the VowelRemover class.
- The jar command packages the BuildInfo and the classes for the UDx library together.

```
$ javac -g -cp /opt/vertica/bin/VerticaSDK.jar
   /opt/vertica/sdk/com/vertica/sdk/BuildInfo.java -d .
$ javac -g -cp mycompanylibs.jar:/opt/vertica/bin/VerticaSDK.jar
   com/mycompany/udx/DeleteVowelsFactory.java
$ jar cf DeleteVowelsLib.jar com/mycompany/udx/*.class
   com/vertica/sdk/*.class
```

To install the UDx library, you must copy both of the JAR files to a node in the Vertica cluster. Then, connect to the node to execute the CREATE LIBRARY statement.

The following example demonstrates how to load the UDx library after you copy the JAR files to the home directory of the dbadmin user. The DEPENDS keyword tells Vertica that the UDx library depends on the mycompanylibs.jar file.

```
=> CREATE LIBRARY DeleteVowelsLib AS
   '/home/dbadmin/DeleteVowelsLib.jar' DEPENDS '/home/dbadmin/mycompanylibs.jar'
   LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION deleteVowels AS language 'java' NAME
   'com.mycompany.udx.DeleteVowelsFactory' LIBRARY DeleteVowelsLib;
CREATE FUNCTION
=> SELECT deleteVowels('I hate vowels!');
  deleteVowels
--------------
  ht vwls!
(1 row)
```
Java and Vertica Data Types

The Vertica Java SDK converts Vertica's native data types into the appropriate Java data type. The following table lists the Vertica data types and their corresponding Java data types.

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Java Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>long</td>
</tr>
<tr>
<td>FLOAT</td>
<td>double</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>com.vertica.sdk.VNumeric</td>
</tr>
<tr>
<td>DATE</td>
<td>java.sql.Date</td>
</tr>
<tr>
<td>CHAR, VARCHAR, LONG VARCHAR</td>
<td>com.vertica.sdk.VString</td>
</tr>
<tr>
<td>BINARY, VARBINARY, LONG VARBINARY</td>
<td>com.vertica.sdk.VString</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>java.sql.Timestamp</td>
</tr>
</tbody>
</table>

Note: Some Vertica data types are not supported.

Setting BINARY, VARBINARY, and LONG VARBINARY Values

The Vertica BINARY, VARBINARY, and LONG VARBINARY data types are converted as the Java UDx SDK's VString class. You can also set the value of a column with one of these data types with a ByteBuffer object (or a byte array wrapped in a ByteBuffer) using the PartitionWriter.setStringBytes() method. See the Java API UDx entry for PartitionWriter.setStringBytes() for more information.

Timestamps and Time Zones

When the SDK converts a Vertica timestamp into a Java timestamp, it uses the time zone of the JVM. If the JVM is running in a different time zone than the one used by Vertica, the results can be confusing.

Vertica stores timestamps in the database in UTC. (If a database time zone is set, the conversion is done at query time.) To prevent errors from the JVM time zone, add the following code to the processing method of your UDx:
Strings

The Java SDK contains a class named `StringUtils` that assists you when manipulating string data. One of its more useful features is its `getStringBytes()` method. This method extracts bytes from a `String` in a way that prevents the creation of invalid strings. If you attempt to extract a substring that would split part of a multi-byte UTF-8 character, `getStringBytes()` truncates it to the nearest whole character.

Handling NULL Values

Your UDxs must be prepared to handle NULL values. These values usually must be handled separately from regular values.

Reading NULL Values

Your UDX reads data from instances of the the `BlockReader` or `PartitionReader` classes. If the value of a column is NULL, the methods you use to get data (such as `getLong`) return a Java `null` reference. If you attempt to use the value without checking for NULL, the Java runtime will throw a null pointer exception.

You can test for null values before reading columns by using the data-type-specific methods (such as `isLongNull`, `isDoubleNull`, and `isBooleanNull`). For example, to test whether the `INTEGER` first column of your UDX's input is a NULL, you would use the statement:

```java
// See if the Long value in column 0 is a NULL
if (inputReader.isLongNull(0)) {
    // value is null
    ...
}
```

Writing NULL Values

You output NULL values using type-specific methods on the `BlockWriter` and `PartitionWriter` classes (such as `setLongNull` and `setStringNull`). These methods take the column number to receive the NULL value. In addition, the `PartitionWriter` class has data-type specific set value methods (such as `setLongValue` and `setStringValue`). If you pass these methods a value, they set the output column to that value. If you pass them a Java `null` reference, they set the output column to NULL.
Handling Errors

If your UDX encounters an unrecoverable error, it should instantiate and throw a UdfException. The exception causes the transaction containing the function call to be rolled back.

The UdfException constructor takes a numeric code (which can be anything you want since it is just reported in the error message) and an error message string. If you want to report additional diagnostic information about the error, you can write messages to a log file before throwing the exception (see Writing Messages to the Log File).

The following code fragment demonstrates adding error checking to the Add2ints UDSF example (shown in Java Example: Add2Ints). If either of the arguments is NULL, the processBlock() method throws an exception.

```java
@Override
public void processBlock(ServerInterface srvInterface,
    BlockReader argReader,
    BlockWriter resWriter)
    throws UdfException, DestroyInvocation
{
    do {
        // Test for NULL value. Throw exception if one occurs.
        if (argReader.isLongNull(0) || argReader.isLongNull(1)) {
            // No nulls allowed. Throw exception
            throw new UdfException(1234, "Cannot add a NULL value");
        }
    }
}
```

Note: This example isn't realistic, since you would likely just replace the NULL value with a zero or return a NULL value. Your UDX should only throw an exception if there is no way to compensate for the error.

When your UDX throws an exception, the side process running your UDX reports the error back to Vertica and exits. Vertica displays the error message contained in the exception and a stack trace to the user:

```sql
=> SELECT add2ints(2, NULL);
ERROR 3399: Failure in UDX RPC call InvokeProcessBlock(): Error in User Defined Object [add2ints], error code: 1234
com.vertica.sdk.UdfException: Cannot add a NULL value
    at com.mycompany.example.Add2intsFactory$Add2ints.processBlock(Add2intsFactory.java:37)
    at com.vertica.udxfence.UDxExecContext.processBlock(UDxExecContext.java:780)
    at com.vertica.udxfence.UDxExecContext.run(UDxExecContext.java:173)
    at java.lang.Thread.run(Thread.java:662)
```
Writing Messages to the Log File

Writing messages to a log is useful when you are debugging your Java UDxs, or you want to output additional information about an error condition. You can write messages to a log file by calling the `ServerInterface.log()` method, passing it a `printf()`-style String value along with any variables referenced in the string. (See the `java.util.Formatter` class documentation for details of formatting this string value.) An instance of the `ServerInterface` class is passed to the main processing method of every SDK class you can override.

The following code fragment demonstrates how you could log the values passed into the `Add2ints` UDFS example.

```java
@override
public void processBlock(ServerInterface srvInterface,
    BlockReader argReader,
    Blockwriter resWriter)
    throws UdfException, DestroyInvocation
{
    do {
        // Get the two integer arguments from the BlockReader
        long a = argReader.getLong(0);
        long b = argReader.getLong(1);
        // Log the input values
        srvInterface.log("Got values a=%d and b=%d", a, b);
    }
```

The messages are written to a log file stored in the catalog directory's `UDxLog` subdirectory named `UDxFencedProcessesJava.log`:

```
$ tail VMart/v_vmart_node0001_catalog/UDxLogs/UDxFencedProcesses.log
2012-12-12 10:23:47.649 [Java-2164] 0x01 UDx side process (Java) started
2012-12-12 10:23:47.871 [Java-2164] 0x0b [UserMessage] add2ints - Got values a=5 and b=6
2012-12-12 10:23:48.598 [Java-2164] 0x0c Exiting UDx side process
```

The SQL name of the UDx is added to the log message, along with the string `[UserMessage]` to mark the entry as a message added by a call to the `log()` method. These additions make it easier for you to filter the log to find the messages generated by your UDx.
Handling Cancel Requests

The query that calls your UDx can be canceled (usually, by the user pressing CTRL+C in vsql). When the calling query is canceled, Vertica begins a process of shutting down your UDx. Since UDTFs can perform lengthy and costly processing, the Vertica Java SDK defines several ways that Vertica attempts to signal UDTFs to terminate before it takes the step of killing the fenced-mode JVM process that is executing the UDTF. These attempts to signal the UDTF can help reduce the amount of CPU and memory that is wasted by having the UDx process continue processing after its results are no longer required.

When the user cancels a UDx, Vertica takes the following steps:

1. It sets the isCanceled property on UDTFs to true. Your processPartition methods can test this property to see if the function call has been canceled.
2. It calls UDTF's TransformFunction.cancel method. You should override this method to perform any shutdown tasks (such as killing threads).
3. It calls all types of UDx's destroy method. You should implement this method to free any resources your UDx has allocated.
4. It kills the JVM process running your UDx.

The topics in this section explain how your UDTF can use the cancel API.

Exiting When the Calling Query Has Been Canceled

Since User-Defined Transform Functions (UDTFs) often perform lengthy and CPU-intensive processing, it makes sense for them to terminate if the query that called them has been canceled. Exiting when the query has been canceled helps prevent wasting CPU cycles and memory on continued processing.

The TransformFunction class has a getter named .isCanceled that returns true if the calling query has been canceled. Your processPartition method can periodically check the value of this getter to determine if the query has been canceled, and exit if it has.

How often your processPartition function calls isCanceled depends on how much processing it performs on each row of data. Calling isCanceled does add overhead to your function, so you shouldn't call it too often. For transforms that do not perform lengthy processing, you could check for cancelation every 100 or 1000 rows. If your processPartition performs extensive processing for each row, you may want to check isCanceled every 10 or so rows.
The following code fragment shows how you could have the StringTokenizer UDTF example check whether its query has been canceled:

```java
public class CancelableTokenizeString extends TransformFunction {
    @Override
    public void processPartition(ServerInterface srvInterface,
                                PartitionReader inputReader,
                                PartitionWriter outputWriter)
        throws UdfException, DestroyInvocation {
        // Loop over all rows passed in this partition.
        int rowcount = 0; // maintain count of rows processed
        do {
            rowcount++; // Processing new row
            // Check for cancelation every 100 rows
            if (rowcount % 100 == 0) {
                // Check to see if Vertica marked this class as canceled
                if (this.isCanceled()) {
                    srvInterface.log("Got canceled! Exiting...");
                    return;
                }
            }
        } // Rest of the function here
        . . .
    }
}
```

This example checks for cancelation after processing 100 rows in the partition of data. If the query has been canceled, the example logs a message, then returns to the caller to exit the function.

**Note:** You need to strike a balance between adding overhead to your functions by calling isCanceled and having your functions waste CPU time by running after their query has been canceled (a rare event). For functions such as StringTokenizer which have a low overall processing cost, it usually does not make sense to test for cancelation. The cost of adding overhead to all function calls outweigh the amount of resources wasted by having the function run to completion or having its JVM process killed by Vertica on the rare occasions that its query is canceled.

### Overriding the Cancel Method

Your User-Defined Transform Function (UDTF) can override the TransformFunction.cancel method that Vertica calls if the query that called the function has been canceled. You should override this method to perform an orderly shutdown of any additional processing that your UDx spawned. For example, you can have your cancel method shut down threads that your UDTF has spawned or signal a third-party library that it needs to stop processing and exit. Your cancel method must leave your UDTF's function class ready to
be destroyed, since Vertica calls the UDx's destroy method after the cancel method has exited.

Notes

- If your UDTF does not override cancel, Vertica assumes your UDTF does not need to perform any special cancel processing and calls the function class's destroy method to have it free any resources.

- Your cancel method is called from a different thread than the thread running your UDx's processPartition function.

- The call to the cancel method is not synchronized in any way with your UDTF's processPartition method. If you need your processPartition function to exit before your cancel method performs some action (killing threads, for example) you need to have the two methods synchronize their actions.

- If your cancel method runs for too long, Vertica kills the JVM side process your UDx.

Adding Metadata to Java UDx Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

To add metadata to your Java UDx library, you create a subclass of the UDXLibrary class that contains your library's metadata. You then include this class within your JAR file. When you load your class into the Vertica Analytic Database catalog using the CREATE LIBRARY statement, looks for a subclass of UDXLibrary for the library's metadata.

In your subclass of UDXLibrary, you need to implement eight getters that return String values containing the library's metadata. The getters in this class are:

- getAuthor() returns the name you want associated with the creation of the library (your own name or your company's name for example).

- getLibraryBuildTag() returns whatever String you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when
the library was compiled). This is useful for tracking instances of your library as you are developing them.

- `getLibraryVersion()` returns the version of your library. You can use whatever numbering or naming scheme you want.

- `getLibrarySDKVersion()` returns the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

Note: This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `getSourceUrl()` returns a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.

- `getDescription()` returns a concise description of your library.

- `getLicensesRequired()` returns a placeholder for licensing information. You must pass an empty string for this value.

- `getSignature()` returns a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates creating a UDXLibrary subclass to be included in the Add2Ints UDSF example JAR file (see Java Example: Add2Ints).

```java
// Import the UDXLibrary class to hold the metadata
import com.vertica.sdk.UDXLibrary;

public class Add2IntsLibrary extends UDXLibrary
{
    // Return values for the metadata about this library.
    @Override public String getAuthor() {return "Whizzo Analytics Ltd.";}
    @Override public String getLibraryBuildTag() {return "1234";}
    @Override public String getLibraryVersion() {return "1.0";}
    @Override public String getLibrarySDKVersion() {return "7.0.0";}
    @Override public String getSourceUrl() {
        return "http://example.com/add2ints";
    }
    @Override public String getDescription() {
        return "My Awesome Add 2 Ints Library";
    }
}
```
@Override
public
String
getLicensesRequired()
{
return "";
}

@Override
public
String
getSignature()
{
return "";
}

When the library containing the Add2IntsLibrary class loaded, the metadata appears in the USER_LIBRARIES system table:

```
=> CREATE LIBRARY JavaAdd2IntsLib AS :libfile LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION JavaAdd2Ints as LANGUAGE 'JAVA' name 'com.mycompany.example.Add2IntsFactory'
library JavaAdd2IntsLib;
CREATE FUNCTION
=> \x
Expanded display is on.

Java UDx Resource Management

Java Virtual Machines (JVMs) allocate a set amount of memory when they start. This set memory allocation complicates memory management for Java UDxs, because memory cannot be dynamically allocated and freed by the UDx as it is processing data. This differs from C++ UDxs which can dynamically allocate resources.

To control the amount of memory consumed by Java UDxs, Vertica has a memory pool named jvm that it uses to allocate memory for JVMs. If this memory pool is exhausted, queries that call Java UDxs block until enough memory in the pool becomes free to start a new JVM.

By default, the jvm pool has:

- no memory of its own assigned to it, so it borrows memory from the GENERAL pool.
- its MAXMEMORYSIZE set to either 10% of system memory or 2GB, whichever is smaller.
• its PLANNEDCONCURRENCY set to AUTO, so that it inherits the GENERAL pool's PLANNEDCONCURRENCY setting.

You can view the current settings for the jvm pool by querying the RESOURCE_POOLS table:

```sql
=> SELECT MAXMEMORYSIZE, PLANNEDCONCURRENCY FROM V_CATALOG.RESOURCE_POOLS WHERE NAME = 'jvm';
MAXMEMORYSIZE | PLANNEDCONCURRENCY
--------------+-------------------
 10%          | AUTO
```

When a SQL statement calls a Java UDx, Vertica checks if the jvm memory pool has enough memory to start a new JVM instance to execute the function call. Vertica starts each new JVM with its heap memory size set to approximately the jvm pool's MAXMEMORYSIZE parameter divided by its PLANNEDCONCURRENCY parameter. If the memory pool does not contain enough memory, the query blocks until another JVM exits and return their memory to the pool.

If your Java UDx attempts to consume more memory than has been allocated to the JVM's heap size, it exits with a memory error. You can attempt to resolve this issue by:

• increasing the jvm pool’s MAXMEMORYSIZE parameter.
• decreasing the jvm pool’s PLANNEDCONCURRENCY parameter.
• changing your Java UDx’s code to consume less memory.

### Adjusting the jvm Pool

When adjusting the jvm pool to your needs, you must consider two factors:

• the amount of RAM your Java UDx requires to run
• how many concurrent Java UDx functions you expect your database to run

You can learn the amount of memory your Java UDx needs using several methods. For example, your code can use Java's `Runtime` class to get an estimate of the total memory it has allocated and then log the value using `ServerInterface.log()`. (An instance of this class is passed to your UDx.) If you have multiple Java UDxs in your database, set the jvm pool memory size based on the UDx that uses the most memory.

The number of concurrent sessions that need to run Java UDxs may not be the same as the global PLANNEDCONCURRENCY setting. For example, you may have just a single user who runs a Java UDx, which means you can lower the jvm pool’s PLANNEDCONCURRENCY setting to 1.
When you have an estimate for the amount of RAM and the number of concurrent user
sessions that need to run Java UDXs, you can adjust the jvm pool to an appropriate size. Set the
pool’s MAXMEMORYSIZE to the maximum amount of RAM needed by the most demanding
Java UDX multiplied by the number of concurrent user sessions that need to run Java UDXs. Set
the pool’s PLANNEDCONCURRENCY to the number of simultaneous user sessions that need to
run Java UDXs.

For example, suppose your Java UDX requires up to 4GB of memory to run and you expect up
to two user sessions use Java UDX's. You would use the following command to adjust the jvm
pool:

```
=> ALTER RESOURCE POOL jvm MAXMEMORYSIZE '8G' PLANNEDCONCURRENCY 2;
```

The MEMORYSIZE is set to 8GB, which is the 4GB maximum memory use by the Java UDX
multiplied by the 2 concurrent user sessions.

**Note:** The PLANNEDCONCURRENCY value is not the number of calls to Java UDX that you
expect to happen simultaneously. Instead, it is the number of concurrently open user
sessions that call Java UDXs at any time during the session. See below for more
information.

See [Managing Workloads](https://vertica.com/docs/Managing-Workloads.html) in the Administrator's Guide for more information on tuning the jvm and other resource pools.

### Freeing JVM Memory

The first time users call a Java UDX during their session, Vertica allocates memory from the jvm
pool and starts a new JVM. This JVM remains running for as long as the user's session is open
so it can process other Java UDX calls. Keeping the JVM running lowers the overhead of
executing multiple Java UDXs by the same session. If the JVM did not remain open, each call to
a Java UDX would require additional time for Vertica to allocate resources and start a new JVM.
However, having the JVM remain open means that the JVM's memory remains allocated for
the life of the session whether or not it will be used again.

If the jvm memory pool is depleted, queries containing Java UDXs either block until memory
becomes available or eventually fail due a lack of resources. If you find queries blocking or
failing for this reason, you can allocate more memory to the jvm pool and increase its
PLANNEDCONCURRENCY. Another option is to ask users to call the `RELEASE_JVM_MEMORY`
function when they no longer need to run Java UDXs. This function closes any JVM belonging to
the user's session and returns its allocated memory to the jvm memory pool.
The following example demonstrates querying V_MONITOR.SESSIONS to find the memory allocated to JVMs by all sessions. It also demonstrates how the memory is allocated by a call to a Java U Dx, and then freed by calling RELEASE_JVM_MEMORY.

```sql
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
user_name | external_memory_kb
----------|---------------------
dbadmin   | 0                   
(1 row)   

=> -- Call a Java U Dx
=> SELECT add2ints(123,456);  
add2ints
579       
(1 row)   

=> -- JVM is now running and memory is allocated to it.
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
----------|---------------------
dbadmin   | 79705               
(1 row)   

=> -- Shut down the JVM and deallocate memory
=> SELECT RELEASE_JVM_MEMORY();  
RELEASE_JVM_MEMORY
----------
Java process killed and memory released
(1 row)   

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
----------|---------------------
dbadmin   | 0                   
(1 row)   
```

In rare cases, you may need to close all JVMs. For example, you may need to free memory for an important query, or several instances of a Java U Dx may be taking too long to complete. You can use the RELEASE_ALL_JVM_MEMORY to close all of the JVMs in all user sessions:

```sql
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
----------|---------------------
ExampleUser| 79705               
  dbadmin  | 79705               
(2 rows)   

=> SELECT RELEASE_ALL_JVM_MEMORY();  
RELEASE_ALL_JVM_MEMORY
----------
Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)   

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
----------|---------------------
dbadmin   | 0                   
(1 row)   
```
Caution: This function terminates all JVMs, including ones that are currently executing Java UDXs. This will cause any query that is currently executing a Java UDX to return an error.

Notes

- The jvm resource pool is used only to allocate memory for the Java UDX function calls in a statement. The rest of the resources required by the SQL statement come from other memory pools.

- The first time a Java UDX is called, Vertica starts a JVM to execute some Java methods to get metadata about the UDX during the query planning phase. The memory for this JVM is also taken from the jvm memory pool.

Developing with the Python SDK

The Vertica Python SDK provides new capabilities to the Vertica Analytic Database. Unlike the other Vertica Software Development Kits (SDKs), the Vertica Python SDK does not require any additional system configuration or header files. This low overhead allows you to develop and deploy new capabilities to your Vertica cluster in a short amount of time.

The following workflow is typical for the Python SDK:

Because Python is an interpreted language, you do not have to compile your program before loading the UDX in Vertica. However, you should expect to do some debugging of your code after you create your function and begin testing it in Vertica.

You can find detailed documentation of all of the classes in the Vertica Python SDK Documentation.
Python Libraries

Before you can use your Python UDx, you need to verify that it meets the following library requirements:

- Your UDx must import the `vertica_sdk` package in your code. You do not need to download this package. It is included as a part of the Vertica server.

```python
import vertica_sdk
```

- The Vertica Python SDK includes the Python Standard Library. Be aware that importing a package other than the Python Standard Library results in failure.

Python and Vertica Data Types

The Vertica Python SDK converts native Vertica data types into the appropriate Python data types, as follows:

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Python Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>int</td>
</tr>
<tr>
<td>FLOAT</td>
<td>float</td>
</tr>
<tr>
<td>NUMERIC</td>
<td><code>decimal.Decimal</code></td>
</tr>
<tr>
<td>DATE</td>
<td><code>datetime.date</code></td>
</tr>
<tr>
<td>CHAR, VARCHAR, LONG VARCHAR</td>
<td>string (UTF-8 encoded)</td>
</tr>
<tr>
<td>BINARY, VARBINARY, LONG VARBINARY</td>
<td><code>binary</code></td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td><code>datetime.datetime</code></td>
</tr>
<tr>
<td>TIME</td>
<td><code>datetime.time</code></td>
</tr>
</tbody>
</table>

*Note: Some Vertica Analytic Database data types are not supported in Python.*
Handling Errors

If your UDx encounters an unrecoverable error, it should throw a UdfException. The exception triggers a rollback of the function call. In Python, this function rollback occurs when the UDx raises an exception.

The following code shows how you can add error checking to your UDx. In this example, if one of the arguments is less than 100, then the Python UDx throws an error.

```python
while(True):
    # Example of error checking best practices.
    product_id = block_reader.getInt(2)
    if product_id < 100:
        raise ValueError("Invalid Product ID")
```

When an exception is raised in your Python UDx, the UDx throws a UdfException and generates an error message.

```sql
=> SELECT add2ints(prod_cost, sale_price, product_id) FROM bunch_of_numbers;
ERROR 3399: Failure in U Dx RPC call InvokeProcessBlock() : Error calling processBlock() in User Defined Object [add2ints]
at [/scratch_a/release/svrtar11244/vbuild/vertica/OSS/UDxFence/PythonInterface.cpp:168], error code: 0,
message: Error [/scratch_a/release/svrtar11244/vbuild/vertica/OSS/UDxFence/PythonInterface.cpp:385] function ['call_method']

Writing Messages to Log Files

Writing Messages to Log Files

Writing messages to a log can help you when you debug your Python UDxs and want to output additional information about an error condition.

To write a message to the vertica log file, use the `server_interface.log()` function:
def processBlock(self, server_interface, arg_reader, res_writer):
    server_interface.log("Python UDx - Adding 2 ints!")
    while(True):
        first_int = block_reader.getInt(0)
        second_int = block_reader.getInt(1)
        block_writer.setInt(first_int + second_int)
        server_interface.log("Values: first_int is {} second_int is ".format(first_int, second_int))
    block_writer.next()
    if not block_reader.next():
        break

Vertica writes the messages to a log file stored in the catalog directory's UDxLog subdirectory, which is named UDxFencedProcesses.log:

$ tail /home/dbadmin/py_db/v_py_db_node0001_catalog/UDxLogs/UDxFencedProcesses.log
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780
PythonExecContext::processBlock
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Python UDx - Adding 2 ints!
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Values: first_int is 100 second_int is 100

Vertica adds the SQL name of the UDx to the log message. It also adds the string [UserMessage] to mark the entry as a message added by a call to the server_interface.log() function. These additions allow you to filter the log to find the messages generated by your UDx.

Handling Errors

Developing with the R SDK

The Vertica R SDK extends the capabilities of the Vertica Analytic Database so you can leverage additional R libraries. Before you can begin developing User Defined Extensions (UDxs) in R, you must install the R Language Pack for Vertica on each of the nodes in your cluster. The R SDK supports scalar and transform functions in fenced mode. Other UDx types are not supported.

The following workflow is typical for the R SDK:
You can find detailed documentation of all of the classes in the Vertica R SDK API Documentation.

Installing/Upgrading the R Language Pack for Vertica

To create R UDxs in Vertica, install the R Language Pack package that matches your server version. The R Language Pack includes the R runtime and associated libraries for interfacing with Vertica.

You must install the R Language Pack on each node in the cluster. The Vertica R Language Pack must be the only R Language Pack installed on the node.

Vertica R Language Pack Prerequisites

The R Language Pack package requires a number of packages for installation and execution. The names of these dependencies vary among Linux distributions. For Vertica supported Linux platforms the packages are:

- RHEL/CentOS - libfortran, xz-libs, libgomp
- SUSE Linux Enterprise Server - libfortran3, liblzma5, libgomp1
- Debian/Ubuntu - libfortran3, liblzma5, libgomp1

Installing the Vertica R Language Pack

If you use your operating systems package manager, rather than the rpm or dpkg command, for installation, you do not need to manually install the R Language Pack. The native package managers for each supported Linux version are:

- RHEL/CentOS - yum
- SUSE Linux Enterprise Server - zypper
- Debian/Ubuntu - apt-get
1. Download the R language package by going to the myVertica portal, clicking the downloads tab, and selecting the vertica-R-lang-_version_.rpm (or vertica-R-lang_<version>.deb) file for your server version. The R language package version must match your server version to three decimal points.

2. Install the package as root or using sudo:

   - **RHEL/CentOS**
     
     ```
     $ yum install vertica-R-lang_<version>.rpm
     ```

   - **SUSE Linux Enterprise Server**
     
     ```
     $ zypper install vertica-R-lang_<version>.rpm
     ```

   - **Debian**
     
     ```
     $ apt-get install ./vertica-R-lang_<version>.deb
     ```

   The installer puts the R binary in /opt/vertica/R.

### Upgrading the Vertica R Language Pack

When upgrading, some R packages you have manually installed may not work and may have to be reinstalled. If you do not update your package(s), then R returns an error if the package cannot be used. Instructions for upgrading these packages are below.

**Note:** The R packages provided in the R Language Pack are automatically upgraded and do not need to be reinstalled.

1. You must uninstall the R Language package before upgrading Vertica. Any additional R packages you manually installed remain in /opt/vertica/R and are not removed when you uninstall the package.

2. Upgrade your server package as detailed in Upgrading Vertica to a New Version.

3. After the server package has been updated, install the new R Language package on each host.

If you have installed additional R packages, on each node:
1. As root run `/opt/vertica/R/bin/R` and issue the command:

   ```
   > update.packages(checkBuilt=TRUE)
   ```

2. Select a CRAN mirror from the list displayed.

3. You are prompted to update each package that has an update available for it. You must update any packages that you manually installed and are not compatible with the current version of R in the R Language Pack. Do NOT update:

   - Rcpp
   - RInside

   The packages you selected to be updated are installed. Quit R with the command:

   ```
   > quit()
   ```

Vertica UDX functions written in R do not need to be compiled and you do not need to reload your Vertica-R libraries and functions after an upgrade.

**R Packages**

The Vertica R Language Pack includes the following R packages in addition to the default packages bundled with R:

- Rcpp
- RInside
- IpSolve
- IpSolveAPI

You can install additional R packages not included in the Vertica R Language Pack by using one of two methods. You must install the same packages on all nodes.

**Installing R Packages**

You can install additional R packages by using one of the two following methods.

Using the `install.packages()` R command:
$ sudo /opt/vertica/R/bin/R
> install.packages("Zelig");

Using CMD INSTALL:

```
/opt/vertica/R/bin/R CMD INSTALL <path-to-package-tgz>
```

The installed packages are located in: /opt/vertica/R/library.

**R and Vertica Data Types**

The following data types are supported when passing data to/from an R UDx:

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>R Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>logical</td>
</tr>
<tr>
<td>DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP, TIMESTAMPZ, TIMETZ</td>
<td>numeric</td>
</tr>
<tr>
<td>DOUBLE PRECISION, FLOAT, REAL</td>
<td>numeric</td>
</tr>
<tr>
<td>BIGINT, DECIMAL, INT, NUMERIC, NUMBER, MONEY</td>
<td>numeric</td>
</tr>
<tr>
<td>BINARY, VARBINARY</td>
<td>character</td>
</tr>
<tr>
<td>CHAR, VARCHAR</td>
<td>character</td>
</tr>
</tbody>
</table>

NULL values in Vertica are translated to R NA values when sent to the R function. R NA values are translated into Vertica null values when returned from the R function to Vertica.

**Important:** When specifying LONG VARCHAR or LONG VARBINARY data types, include the space between the two words. For example, `datatype = c("long varchar")`.

**Handling Errors**

If your UDx encounters an unrecoverable error, it should throw a UdfException. The error triggers a rollback of the function call. In R, this function rollback occurs when the UDx executes an error action.

The following code shows how you can add error checking to your UDx. In this example, if the third column of the data frame does not match the specified Product ID, then the R UDx throws an error.
When an exception is raised in your R UDx, the UDx throws a UdfException and generates an error message.

```sql
=> SELECT Calculate_Cost_w_Tax(item_price, tax_rate, prod_id) FROM Inventory_Sales_Data;
```

Error calling processBlock() in User Defined Object [mul] at
`[/scratch_a/release/svrta30318/vbuild/vertica/OSS/UDxFence/RInterface.cpp:1308]`,
error code: 0, message: Exception in processBlockForR :Invalid Product ID!

### Adding Metadata to R Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the `USER_LIBRARIES` system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```r
RegisterLibrary(author,
    library_build_tag,
    library_version,
    library_sdk_version,
    source_url,
    description,
    licenses_required,
    signature);
```
- **author** contains whatever name you want associated with the creation of the library (your own name or your company's name for example).

- **library_build_tag** is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.

- **library_version** is the version of your library. You can use whatever numbering or naming scheme you want.

- **library_sdk_version** is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

  Note: This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- **source_url** is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.

- **description** is a concise description of your library.

- **licenses_required** is a placeholder for licensing information. You must pass an empty string for this value.

- **signature** is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

The following example shows how to add metadata to an R UDx.

```python
RegisterLibrary("Speedy Analytics Ltd.",
 "1234",
 "1.0",
 "8.1.0",
 "Sales Tax R Library",
 "",
 "")
```

Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to RegisterLibrary:
Setting Null Input and Volatility Behavior for R Functions

Vertica supports defining volatility and null-input settings for UDxs written in R. Both settings aid in the performance of your R function.

Volatility Settings

Volatility settings describe the behavior of the function to the Vertica optimizer. For example, if you have identical rows of input data and you know the UDx is immutable, then you can define the UDx as IMMUTABLE. This tells the Vertica optimizer that it can return a cached value for subsequent identical rows on which the function is called rather than having the function run on each identical row.

To indicate your UDx's volatility, set the volatility parameter of your R factory function to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLATILE</td>
<td>Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.</td>
</tr>
<tr>
<td>IMMUTABLE</td>
<td>Calls to the function with the same arguments always results in the same return value.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>STABLE</td>
<td>Repeated calls to the function with the same arguments <em>within the same statement</em> returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.</td>
</tr>
<tr>
<td>DEFAULT_VOLATILITY</td>
<td>The default volatility. This is the same as VOLATILE.</td>
</tr>
</tbody>
</table>

If you do not define a volatility, then the function is considered to be VOLATILE.

The following example sets the volatility to STABLE in the `multiplyTwoIntsFactory` function:

```r
multiplyTwoIntsFactory <- function() {
  list(name = multiplyTwoInts,
       udxtype = c("scalar"),
       intype = c("float","float"),
       outtype = c("float"),
       volatility = c("stable"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```

**Null Input Behavior**

Null input setting determine how to respond to rows that have null input. For example, you can choose to return null if any inputs are null rather than calling the function and having the function deal with a NULL input.

To indicate how your UDx reacts to NULL input, set the strictness parameter of your R factory function to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLED_ON_NULL_INPUT</td>
<td>The function must be called, even if one or more arguments are NULL.</td>
</tr>
<tr>
<td>RETURN_NULL_ON_NULL_INPUT</td>
<td>The function always returns a NULL value if any of its arguments are NULL.</td>
</tr>
<tr>
<td>STRICT</td>
<td>A synonym for RETURN_NULL_ON_NULL_INPUT</td>
</tr>
<tr>
<td>DEFAULT STRICTNESS</td>
<td>The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.</td>
</tr>
</tbody>
</table>
If you do not define a null input behavior, then the function is called on every row of data regardless of the presence of NULL values.

The following example sets the NULL input behavior to STRICT in the multiplyTwoIntsFactory function:

```r
multiplyTwoIntsFactory <- function() {
  list(name = multiplyTwoInts,
       udxtype = c("scalar"),
       intype = c("float","float"),
       outtype = c("float"),
       strictness = c("strict"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```
Aggregate Functions (UDAFs)

Aggregate functions perform an operation on a set of values and return one value. Vertica provides standard built-in aggregate functions such as **AVG**, **MAX**, and **MIN**. User-Defined Aggregate Functions work similarly to the built-in aggregate functions.

User-Defined Aggregate Functions:

- Support a single input column (or set) of values and provide a single output column.
- Support RLE decompression; RLE input is decompressed before it is sent to a UDAF.
- Can be used with the GROUP BY and HAVING clauses. Only columns appearing in the GROUP BY clause can be selected.
- Cannot be used with correlated subquery.

UDAFs are available for C++ only.

UDAF Class Overview

You create your UDAF by subclassing two classes defined by the Vertica SDK: `AggregateFunction` and `AggregateFunctionFactory`.

AggregateFunction

The `AggregateFunction` class performs the aggregation. It computes values on each database node where relevant data is stored and then combines the results from the nodes. You must implement the following methods:

- `initAggregate()` - Initializes the class, defines variables, and sets the starting value for the variables. This function must be idempotent.
- `aggregate()` - The main aggregation operation, executed on each node.
- `combine()` - If multiple invocations of `aggregate()` are needed, Vertica calls `combine()` to combine all the sub-aggregations into a final aggregation. Although this method might
not be called, you must define it.

- **terminate()** - Terminates the function and returns the result as a column.

**Important:** The `aggregate()` function might not operate on the complete input set all at once. For this reason, `initAggregate()` must be idempotent.

The `AggregateFunction` class also provides optional methods that you can implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDAF API (see Allocating Resources for UDxs for details).

### AggregateFunctionFactory

The `AggregateFunctionFactory` class specifies metadata information such as the argument and return types of your aggregate function. It also instantiates your `AggregateFunction` subclass. Your subclass must implement the following methods:

- **getPrototype()** - Defines the number of parameters and data types accepted by the function. There is a single parameter for aggregate functions.

- **getIntermediateTypes()** - Defines the intermediate variable(s) used by the function. These variables are used when combining the results of `aggregate()` calls.

- **getParameterType()** - Defines the names and types of parameters that this function uses (optional).

- **getReturnType()** - Defines the type of the output column.

Vertica uses this data when you call the CREATE AGGREGATE FUNCTION SQL statement to add the function to the database catalog.

### UDAF Performance in Statements Containing a GROUP BY Clause

You may see slower-than-expected performance from your UDAF if the SQL statement calling it also contains a GROUP BY Clause. For example:

```sql
=> SELECT a, MYUDAF(b) FROM sampletable GROUP BY a;
```
In statements like this one, Vertica does not consolidate row data together before calling your UDAF's `aggregate()` method. Instead, it calls `aggregate()` once for each row of data. Usually, the overhead of having Vertica consolidate the row data is greater than the overhead of calling `aggregate()` for each row of data. However, if your UDAF's `aggregate()` method has significant overhead, then you might notice an impact on your UDAF's performance.

For example, suppose `aggregate()` allocates memory. When called in a statement with a GROUP BY clause, it performs this memory allocation for each row of data. Because memory allocation is a relatively expensive process, this allocation can impact the overall performance of your UDAF and the query.

There are two ways you can address UDAF performance in a statement containing a GROUP BY clause:

- Reduce the overhead of each call to `aggregate()`. If possible, move any allocation or other setup operations to the UDAF's `setup()` function.

- Declare a special parameter that tells Vertica to group row data together when calling a UDAF. This technique is explained below.

### Using the `_minimizeCallCount` Parameter

Your UDAF can tell Vertica to always batch row data together to reduce the number of calls to its `aggregate()` method. To trigger this behavior, your UDAF must declare an integer parameter named `_minimizeCallCount`. You do not need to set a value for this parameter in your SQL statement. The fact that your UDAF declares this parameter triggers Vertica to group row data together when calling `aggregate()`.

You declare the `_minimizeCallCount` parameter the same way you declare other UDx parameters. See UDx Parameters for more information.

**Important:** Always test the performance of your UDAF before and after implementing the `_minimizeCallCount` parameter to ensure that it improves performance. You might find that the overhead of having Vertica group row data for your UDAF is greater than the cost of the repeated calls to `aggregate()`.

### C++ API

This section provides APIs and examples for the C++ API for UDAFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.
AggregateFunction and AggregateFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDAF Class Overview for general information about implementing the AggregateFunction and AggregateFunctionFactory classes.

AggregateFunction API

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
                    const SizedColumnTypes &argTypes);

virtual void initAggregate(ServerInterface &srvInterface, IntermediateAggs &aggs)=0;

void aggregate(ServerInterface &srvInterface, BlockReader &arg_reader,
                 IntermediateAggs &aggs);

virtual void combine(ServerInterface &srvInterface, IntermediateAggs &aggs_output,
                      MultipleIntermediateAggs &aggs_other)=0;

virtual void terminate(ServerInterface &srvInterface, BlockWriter &res_writer,
                        IntermediateAggs &aggs);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AggregateFunctionFactory API

The API provides the following methods for extension by subclasses:

```cpp
virtual AggregateFunction *
     createAggregateFunction ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
                            ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getIntermediateTypes(ServerInterface &srvInterface,
                                   const SizedColumnTypes &inputTypes,
                                   SizedColumnTypes &intermediateTypeMetaData)=0;

virtual void getReturnType(ServerInterface &srvInterface,
                            const SizedColumnTypes &argTypes,
                            SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
                               SizedColumnTypes &parameterTypes);
```
C++ Example: Average

The Average aggregate function created in this example computes the average of values in a column.

You can find the source code used in this example on the Vertica GitHub page.

Loading the Example

Use CREATE LIBRARY and CREATE AGGREGATE FUNCTION to declare the function:

```sql
=> CREATE LIBRARY AggregateFunctions AS '/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE aggregate function ag_avg AS LANGUAGE 'C++'
name 'AverageFactory' library AggregateFunctions;
CREATE AGGREGATE FUNCTION
```

Using the Example

Use the function as part of a SELECT statement:

```sql
=> SELECT * FROM average;
  id | count
---+------
 A |  8
 B |  3
 C |  6
 D |  2
 E |  9
 F |  7
 G |  5
 H |  4
 I |  1
(9 rows)
=> SELECT ag_avg(count) FROM average;
 ag_avg
-------
   5
(1 row)
```

AggregateFunction Implementation

This example adds the input argument values in the aggregate() method and keeps a counter of the number of values added. The server runs aggregate() on every node and different data chunks, and combines all the individually added values and counters in the
combine() method. Finally, the average value is computed in the terminate() method by dividing the total sum by the total number of values processed.

For this discussion, assume the following environment:

- A three-node Vertica cluster
- A table column that contains nine values that are evenly distributed across the nodes. Schematically, the nodes look like the following figure:
Node 1
Values 1,2,3

Node 2
Values 4,5,6

Node 3
Values 7,8,9
The function uses sum and count variables. *Sum* contains the sum of the values, and *count* contains the count of values.

First, `initAggregate()` initializes the variables and sets their values to zero.

```cpp
virtual void initAggregate(ServerInterface &srvInterface,
                           IntermediateAggs &aggs)
{
  try {
    VNumeric &sum = aggs.getNumericRef(0);
    sum.setZero();

    vint &count = aggs.getIntRef(1);
    count = 0;
  } catch(std::exception &e) {
    vt_report_error(0, "Exception while initializing intermediate aggregates: [% s]", e.what());
  }
}
```

The aggregate() function reads the block of data on each node and calculates partial aggregates.

```cpp
void aggregate(ServerInterface &srvInterface,
               BlockReader &argReader,
               IntermediateAggs &aggs)
{
  try {
    VNumeric &sum = aggs.getNumericRef(0);
    vint &count = aggs.getIntRef(1);

    do {
      const VNumeric &input = argReader.getNumericRef(0);
      if (!input.isNull()) {
        sum.accumulate(&input);
        count++;
      }
    } while (argReader.next());
  } catch(std::exception &e) {
    vt_report_error(0, " Exception while processing aggregate: [% s]", e.what());
  }
}
```

Each completed instance of the `aggregate()` function returns multiple partial aggregates for *sum* and *count*. The following figure illustrates this process using the `aggregate()` function:
Node 1
Values 1,2,3

aggregate()
sum = 6; count = 3

initAggregate()
sum = 0; count = 0

Node 2
Values 4,5,6

aggregate()
sum = 15; count = 3

Node 3
Values 7,8,9

aggregate()
sum = 24; count = 3
The **combine()** function puts together the partial aggregates calculated by each instance of the average function.

```cpp
virtual void combine(ServerInterface &srvInterface,
                      IntermediateAggs &aggs,
                      MultipleIntermediateAggs &aggsOther)
{
    try {
        VNumeric &mySum = aggs.getNumericRef(0);
        vint &myCount = aggs.getIntRef(1);
        do {
            const VNumeric &otherSum = aggsOther.getNumericRef(0);
            const vint &otherCount = aggsOther.getIntRef(1);
            mySum.accumulate(&otherSum);
            myCount += otherCount;
        } while (aggsOther.next());
    } catch(std::exception &e) {
        vt_report_error(0, "Exception while combining intermediate aggregates: [%s]", e.what());
    }
}
```

The following figure shows how each partial aggregate is combined:
After all input has been evaluated by the `aggregate()` function Vertica calls the `terminate()` function. It returns the average to the caller.
virtual void terminate(ServerInterface &srvInterface,
                      BlockWriter &resWriter,
                      IntermediateAggs &aggs)
{
    try {
        const int32 MAX_INT_PRECISION = 20;
        const int32 prec = Basics::getNumericWordCount(MAX_INT_PRECISION);
        uint64 words[prec];
        VNumeric count(words, prec, 0/*scale*/);
        count.copy(aggs.getIntRef(1));
        VNumeric &out = resWriter.getNumericRef();
        if (count.isZero()) {
            out.setNull();
        } else {
            const VNumeric &sum = aggs.getNumericRef(0);
            out.div(&sum, &count);
        }
    }
}

The following figure shows the implementation of the terminate() function:

Vertica Analytic Database (9.0.x)
AggregateFunctionFactory Implementation

The `getPrototype()` function allows you to define the variables that are sent to your aggregate function and returned to Vertica after your aggregate function runs. The following example accepts and returns a numeric value:

```cpp
virtual void getPrototype(ServerInterface &srvfloaterface, 
ColumnTypes &argTypes, 
ColumnTypes &returnType)
{
    argTypes.addNumeric();
    returnType.addNumeric();
}
```

The `getIntermediateTypes()` function defines any intermediate variables that you use in your aggregate function. *Intermediate variables* are values used to pass data among multiple invocations of an aggregate function. They are used to combine results until a final result can be computed. In this example, there are two results - total (numeric) and count (int).

```cpp
virtual void getIntermediateTypes(ServerInterface &srvInterface, 
const SizedColumnTypes &inputTypes, 
SizedColumnTypes &intermediateTypeMetaData)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    intermediateTypeMetaData.addNumeric(inType.getNumericScale());
    intermediateTypeMetaData.addInt();
}
```

The `getReturnType()` function defines the output data type:

```cpp
virtual void getReturnType(ServerInterface &srvfloaterface, 
const SizedColumnTypes &inputTypes, 
SizedColumnTypes &outputTypes)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    outputTypes.addNumeric(inType.getNumericPrecision(),
    inType.getNumericScale());
}
```

Analytic Functions (UDAnFs)

User-Defined Analytic Functions (UDAnFs) are used for analytics. See SQL Analytics for an overview of Vertica's built-in analytics. Like User-Defined Scalar Functions (UDSFs), UDAnFs
must output a single value for each row of data read and can have no more than 1600 arguments.

Unlike UDSFs, the UDAnF’s input reader and output reader can be advanced independently. This feature lets you create UDAnF’s where the output value is calculated over multiple rows of data. By advancing the reader and writer independently, you can create functions similar to the built-in analytic functions such as LAG, which uses data from prior rows to output a value for the current row.

**UDAnF Class Overview**

You create your UDAnF by subclassing two classes defined by the Vertica SDK: AnalyticFunction and AnalyticFunctionFactory.

**AnalyticFunction**

The AnalyticFunction subclass performs the analytic processing. Your subclass must define the processPartition() method to perform the operation. It may define methods to set up and tear down the function.

**Performing the Operation**

The processPartition() method reads a partition of data, performs some sort of processing, and outputs a single value for each input row.

Vertica calls processPartition() once for each partition of data. It supplies the partition using an AnalyticPartitionReader object from which you read its input data. In addition, there is a unique method on this object named isNewOrderByKey(), which returns a Boolean value indicating whether your function has seen a row with the same ORDER BY key (or keys). This method is very useful for analytic functions (such as the example RANK function) which need to handle rows with identical ORDER BY keys differently than rows with different ORDER BY keys.

**Note:** You can specify multiple ORDER BY columns in the SQL query you use to call your UDAnF. The isNewOrderByKey method returns true if any of the ORDER BY keys are different than the previous row.

Once your method has finished processing the row of data, you advance it to the next row of input by calling next() on AnalyticPartitionReader.

Your method writes its output value using an AnalyticPartitionWriter object that Vertica supplies as a parameter to processPartition(). This object has data-type-specific
methods to write the output value (such as `setInt()`). After setting the output value, call `next()` on `AnalyticPartitionWriter` to advance to the next row in the output.

**Note:** You must be sure that your function produces a row of output for each row of input in the partition. You must also not output more rows than are in the partition, otherwise the zygote size process (if running in Fenced Mode) or Vertica itself could generate an out of bounds error.

**Setting Up and Tearing Down**

The `AnalyticFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

**AnalyticFunctionFactory**

The `AnalyticFunctionFactory` class tells Vertica metadata about your UDAnF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `AnalyticFunction`.

Your `AnalyticFunctionFactory` subclass must implement the following methods:

- `getPrototype()` describes the input parameters and output value of your function. You set these values by calling functions on two `ColumnType` objects that are passed to your method.

- `createAnalyticFunction()` supplies an instance of your `AnalyticFunction` that Vertica can call to process a UDAnF function call.

- `getReturnType()` provides details about your function's output. This method is where you set the width of the output value if your function returns a variable-width value (such as VARCHAR) or the precision of the output value if it has a settable precision (such as TIMESTAMP).

**C++ API**

This section provides APIs and examples for the C++ API for UDAnFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.
AnalyticFunction and AnalyticFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDAf Class Overview for general information about implementing the AnalyticFunction and AnalyticFunctionFactory classes.

AnalyticFunction API

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface, 
                    const SizedColumnTypes &argTypes);

virtual void processPartition (ServerInterface &srvInterface, 
                                AnalyticPartitionReader &input_reader, 
                                AnalyticPartitionWriter &output_writer)=0;

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

```cpp
virtual AnalyticFunction * createAnalyticFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype (ServerInterface &srvInterface, 
                           ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType (ServerInterface &srvInterface, 
                            const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType (ServerInterface &srvInterface, 
                               SizedColumnTypes &parameterTypes);
```

C++ Example: Rank

The Rank analytic function ranks rows based on how they are ordered.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.so library that contains the function has been copied to the dbadmin
user's home directory on the initiator node.

```sql
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
   NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named `an_rank`, is:

```sql
=> SELECT * FROM hits;
site | date | num_hits
----|-----|--------
www.example.com | 2012-01-02 | 97
www.vertica.com | 2012-01-01 | 343435
www.example.com | 2012-01-01 | 123
www.example.com | 2012-01-04 | 112
www.vertica.com | 2012-01-02 | 503695
www.vertica.com | 2012-01-03 | 490387
www.example.com | 2012-01-03 | 123
(7 rows)

=> SELECT site, date, num_hits, an_rank()
   OVER (PARTITION BY site ORDER BY num_hits DESC)
   AS an_rank FROM hits;
   site | date | num_hits | an_rank
----|-----|---------|--------
www.example.com | 2012-01-03 | 123 | 1
www.example.com | 2012-01-01 | 123 | 1
www.example.com | 2012-01-04 | 112 | 3
www.example.com | 2012-01-02 | 97 | 4
www.vertica.com | 2012-01-02 | 503695 | 1
www.vertica.com | 2012-01-03 | 490387 | 2
www.vertica.com | 2012-01-01 | 343435 | 3
(7 rows)
```

As with the built-in `RANK` analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

**AnalyticFunction Implementation**

The following code defines an AnalyticFunction subclass named Rank. It is based on example code distributed in the examples directory of the SDK.

```cpp
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 */
class Rank : public AnalyticFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
                                AnalyticPartitionReader &inputReader,
```
In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It does not need to read data; it just counts the rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

Note that the function has a top-level try-catch block. All of your UDx functions should always have one to prevent stray exceptions from being passed back to Vertica (if you run the function unfenced) or the side process.

**AnalyticFunctionFactory Implementation**

The following code defines the AnalyticFunctionFactory that corresponds with the Rank analytic function.

```cpp
class RankFactory : public AnalyticFunctionFactory
{
    virtual void getPrototype(ServerInterface &srvInterface,
                               ColumnTypes &argTypes, ColumnTypes &returnType)
    {
        returnType.addInt();
    }
};
```
virtual void getReturnType(ServerInterface &srvInterface,
                         const SizedColumnTypes &inputTypes,
                         SizedColumnTypes &outputTypes)
{
    outputTypes.addInt();
}
virtual AnalyticFunction *createAnalyticFunction(ServerInterface &srvInterface)
{
    return vt_createFuncObj(srvInterface.allocator, Rank);
};

The first method defined by the RankFactory subclass, getPrototype(), sets the data type of the return value. Because the Rank UDAnF does not read input, it does not define any arguments by calling methods on the ColumnTypes object passed in the argTypes parameter.

The next method is getReturnType(). If your function returns a data type that needs to define a width or precision, your implementation of the getReturnType() method calls a method on the SizedColumnType object passed in as a parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls addInt() to report its output data type.

Finally, RankFactory defines the createAnalyticFunction() method that returns an instance of the AnalyticFunction class that Vertica can call. This code is mostly boilerplate. All you need to do is add the name of your analytic function class in the call to vt_createFuncObj(), which takes care of allocating the object for you.

Java API

This section provides APIs and examples for the Java API for UDAnFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

AnalyticFunction and AnalyticFunctionFactory Java Interface

This section describes information that is specific to the Java API. See UDAnF Class Overview for general information about implementing the AnalyticFunction and AnalyticFunctionFactory classes.

AnalyticFunction API

The API provides the following methods for extension by subclasses:
void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

abstract void processPartition (ServerInterface srvInterface,
                               AnalyticPartitionReader input_reader, AnalyticPartitionWriter output_writer)
                               throws UdfException, DestroyInvocation;

void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);

AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

abstract AnalyticFunction createAnalyticFunction (ServerInterface srvInterface);

abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);

abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
                             SizedColumnTypes returnType) throws UdfException;

void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

Java Example: Rank

The Rank analytic function ranks rows based on how they are ordered.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.jar library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.jar';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'Java'
     NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION

An example of running this rank function, named an_rank, is:

=> SELECT * FROM hits;
  site     | date      | num_hits
-----------+-----------+--------
www.example.com | 2012-01-02  | 97
www.vertica.com  | 2012-01-01  | 343435
www.example.com  | 2012-01-01  | 123
As with the built-in **RANK** analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

**AnalyticFunction Implementation**

The following code defines an **AnalyticFunction** subclass named **Rank**. The code can be found in the SDK examples directory.

```java
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 * *
 * public class Rank extends AnalyticFunction {
 *     private int rank, numRowsWithSameOrder;
 * 
 *     @Override
 *     public void processPartition(ServerInterface srvInterface,
 *                                  AnalyticPartitionReader inputReader,
 *                                  AnalyticPartitionWriter outputWriter)
 *         throws UdfException, DestroyInvocation {
 *         rank = 0;
 *         numRowsWithSameOrder = 1;
 *         do{
 *             if(!inputReader.isNewOrderByKey()){++numRowsWithSameOrder;
 *         }else {
 *             rank += numRowsWithSameOrder;
 *             numRowsWithSameOrder = 1;
 *         }
 *         outputWriter.setLong(0, rank);
 *         outputWriter.next();
 *     }while(inputReader.next());
 */
```
In this example, the processPartition() method does not actually read any of the data from the input row; it just advances through the rows. It just needs to count the number of rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

AnalyticFunctionFactory Implementation

The following code defines the AnalyticFunctionFactory that corresponds with the Rank analytic function.

```java
public class RankFactory extends AnalyticFunctionFactory {

@Override
public void getPrototype(ServerInterface srvInterface,
   ColumnTypes argTypes,
   ColumnTypes returnType) {
   returnType.addInt();
}

@Override
public void getReturnType(ServerInterface srvInterface,
   SizedColumnTypes argTypes,
   SizedColumnTypes returnType) throws UdfException {
   returnType.addInt();
}

@Override
public AnalyticFunction createAnalyticFunction(ServerInterface srvInterface) {
   return new Rank();
}
}
```

The first method defined by the RankFactory subclass, getPrototype(), sets the data type of the return value. Because the Rank UDAf does not read input, it does not define any arguments by calling methods on the ColumnTypes object passed in the argTypes parameter.

The next method is getReturnType(). If your analytic function returns a data type that needs to define a width or precision, your implementation of the getReturnType function calls a method on the SizedColumnType parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls addInt() to report its output data type.

Finally, RankFactory defines the createAnalyticFunction() method that returns an instance of the AnalyticFunction class that Vertica can call.
Scalar Functions (UDSFs)

A User-Defined Scalar Function (UDSF) returns a single value for each row of data it reads. You can use a UDSF anywhere you can use a built-in Vertica function. You usually develop a UDSF to perform data manipulations that are too complex or too slow to perform using SQL statements and functions. UDSFs also let you use analytic functions provided by third-party libraries within Vertica while still maintaining high performance.

Your UDSF must return a value for every input row (unless it generates an error; see Handling Errors for details). Failing to return a value for a row will result in incorrect results and potentially destabilize the Vertica server if not run in Fenced Mode.

A UDSF cannot have more than 1600 arguments.

UDSF Class Overview

You create your UDSF by subclassing two classes defined by the Vertica SDK: ScalarFunction and ScalarFunctionFactory.

ScalarFunction

The ScalarFunction class is the heart of a UDSF. Your subclass must define the processBlock() method to perform the scalar operation. It may define methods to set up and tear down the function.

Performing the Operation

The processBlock() method carries out all of the processing that you want your UDSF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to processBlock().

The input and output of the processBlock() method are supplied by objects of the BlockReader and BlockWriter classes. They define methods that you use to read the input data and write the output data for your UDSF.

The majority of the work in developing a UDSF is writing processBlock(). This is where all of the processing in your function occurs. Your UDSF should follow this basic pattern:
- Read in a set of parameters from the BlockReader object using data-type-specific methods.
- Process the data in some manner.
- Output the resulting value using one of the BlockWriter class's data-type-specific methods.
- Advance to the next row of output and input by calling BlockWriter.next() and BlockReader.next().

This process continues until there are no more rows of data to be read (BlockReader.next() returns false).

You must make sure that processBlock() reads all of the rows in its input and outputs a single value for each row. Failure to do so can corrupt the data structures that Vertica reads to get the output of your UDSF. The only exception to this rule is if your processBlock() function reports an error back to Vertica (see Handling Errors). In that case, Vertica does not attempt to read the incomplete result set generated by the UDSF.

Setting Up and Tearing Down

The ScalarFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy(). You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

Notes

- While the name you choose for your ScalarFunction subclass does not have to match the name of the SQL function you will later assign to it, Vertica considers making the names the same a best practice.
- Do not assume that your function will be called from the same thread that instantiated it.
- The same instance of your ScalarFunction subclass can be called on to process multiple blocks of data.
- The rows of input sent to processBlock() are not guaranteed to be any particular order.
- Writing too many output rows can cause Vertica to emit an out-of-bounds error.
ScalarFunctionFactory

The ScalarFunctionFactory class tells Vertica metadata about your UDSF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of ScalarFunction.

Methods

You must implement the following methods in your ScalarFunctionFactory subclass:

- `createScalarFunction()` instantiates a ScalarFunction subclass. If writing in C++, you can call the `vt_createFuncObj` macro with the name of the ScalarFunction subclass. This macro takes care of allocating and instantiating the class for you.

- `getPrototype()` tells Vertica about the parameters and return type for your UDSF. In addition to a ServerInterface object, this method gets two `ColumnType` objects. All you need to do in this function is to call class functions on these two objects to build the list of parameters and the single return value type.

After defining your factory class, you need to call the `RegisterFactory` macro. This macro instantiates a member of your factory class, so Vertica can interact with it and extract the metadata it contains about your UDSF.

Declaring Return Values

If your function returns a sized column (a return data type whose length can vary, such as a VARCHAR) or a value that requires precision, you must implement `getReturnType()`. This method is called by Vertica to find the length or precision of the data being returned in each row of the results. The return value of this method depends on the data type your `processBlock()` method returns:

- CHAR or VARCHAR return the maximum length of the string.
- NUMERIC types specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone) specify precision.
- INTERVAL YEAR TO MONTH specifies range.
- INTERVAL DAY TO SECOND specifies precision and range.
If your UDSF does not return one of these data types, it does not need a `getReturnType()` method.

The input to the `getReturnType()` method is a `SizedColumnTypes` object that contains the input argument types along with their lengths. This object will be passed to an instance of your `processBlock()` function. Your implementation of `getReturnType()` must extract the data types and lengths from this input and determine the length or precision of the output rows. It then saves this information in another instance of the `SizedColumnTypes` class.

### Setting Null Input and Volatility Behavior

Normally, Vertica calls your UDSF for every row of data in the query. There are some cases where Vertica can avoid executing your UDSF. You can tell Vertica when it can skip calling your function and just supply a return value itself by changing your function's volatility and strictness settings.

- **Your function's volatility** indicates whether it always returns the same output value when passed the same arguments. Depending on its behavior, Vertica can cache the arguments and the return value. If the user calls the UDSF with the same set of arguments, Vertica returns the cached value instead of calling your UDSF.

- **Your function's strictness** indicates how it reacts to NULL arguments. If it always returns NULL when *any* argument is NULL, Vertica can just return NULL without having to call the function. This optimization also saves you work, because you do not need to test for and handle null arguments in your UDSF code.

You indicate the volatility and null handling of your function by setting the `vol` and `strict` fields in your `ScalarFunctionFactory` class's constructor.

### Volatility Settings

To indicate your function's volatility, set the `vol` field to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLATILE</td>
<td>Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.</td>
</tr>
<tr>
<td>IMMUTABLE</td>
<td>Calls to the function with the same arguments always results in the same return value.</td>
</tr>
<tr>
<td>STABLE</td>
<td>Repeated calls to the function with the same arguments <em>within the same</em></td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>statement</td>
<td>returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.</td>
</tr>
<tr>
<td>DEFAULT_VOLATILITY</td>
<td>The default volatility. This is the same as VOLATILE.</td>
</tr>
</tbody>
</table>

**C++ Example**

The following example shows a version of the Add2ints example factory class that makes the function immutable.

```cpp
class Add2intsImmutableFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    {
        return vt_createFuncObj(srvInterface.allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    public:
        Add2intsImmutableFactory() {vol = IMMUTABLE;}
};
RegisterFactory(Add2intsImmutableFactory);
```

**Java Example**

The following example demonstrates setting the Add2IntsFactory's vol field to IMMUTABLE to tell Vertica it can cache the arguments and return value.

```java
public class Add2IntsFactory extends ScalarFunctionFactory {

    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType){
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new Add2Ints();
    }
```
Null Input Behavior

To indicate how your function reacts to NULL input, set the strictness field to one of the following values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLED_ON_NULL_INPUT</td>
<td>The function must be called, even if one or more arguments are NULL.</td>
</tr>
<tr>
<td>RETURN_NULL_ON_NULL_INPUT</td>
<td>The function always returns a NULL value if any of its arguments are NULL.</td>
</tr>
<tr>
<td>STRICT</td>
<td>A synonym for RETURN_NULL_ON_NULL_INPUT</td>
</tr>
<tr>
<td>DEFAULT_STRICTNESS</td>
<td>The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.</td>
</tr>
</tbody>
</table>

C++ Example

The following example demonstrates setting the null behavior of Add2ints so Vertica does not call the function with NULL values.

class Add2intsNullOnNullInputFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocate, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                               Vertica::ColumnType &argTypes,
                               Vertica::ColumnType &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
}

public:
Add2intsNullOnNullInputFactory() {strict = RETURN_NULL_ON_NULL_INPUT;}
The following example demonstrates setting the strictness setting of the Add2Ints example to STRICT. This means that if either of the two values to be added is NULL, Vertica can set the return value to NULL without having to call the Add2Ints function.

```java
public class Add2IntsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType){
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new Add2Ints();
    }

    public Add2IntsFactory() {
        // Tell Vertica that any NULL arguments results in a NULL return value
        strict = strictness.RETURN_NULL_ON_NULL_INPUT;
    }
}
```

### C++ API

This section provides APIs and examples for the C++ API for UDSFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see [Developing with the C++ SDK](#).

### ScalarFunction and ScalarFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See the [UDSF Class Overview](#) for general information about implementing the ScalarFunction and ScalarFunctionFactory classes.

### ScalarFunction API

The API provides the following methods for extension by subclasses:
virtual void setup(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes);

virtual void processBlock(ServerInterface &srvInterface,
    BlockReader &arg_reader, BlockWriter &res_writer)=0;

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

virtual ScalarFunction * createScalarFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes, SizedColumnTypes &returnType);

virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes);

C++ Example: Add2Ints

The following example shows a very basic subclass of ScalarFunction called Add2Ints. As the name implies it adds two integers together, returning a single integer result. It also demonstrates including the main Vertica SDK header file (Vertica.h) and using the Vertica namespace. While not required, using the namespace saves you from having to prefix every Vertica SDK class reference with Vertica::.

ScalarFunction Implementation

// Include the top-level Vertica SDK file
#include "Vertica.h"
// Using the Vertica namespace means we don’t have to prefix all
// class references with Vertica::
using namespace Vertica;
/*
 * ScalarFunction implementation for a UDSF that adds
 * two numbers together.
 */
class Add2Ints : public ScalarFunction
{
    public:
    /*
* This function does all of the actual processing for the UDF.
* In this case, it simply reads two integer values and returns
* their sum.
* The inputs are retrieved via arg_reader
* The outputs are returned via arg_writer
*/
virtual void processBlock(ServerInterface &srvInterface,
   BlockReader &arg_reader,
   BlockWriter &res_writer)
{
   // While we have input to process
   do {
      // Read the two integer input parameters by calling the
      // BlockReader.getIntRef class function
      const vint a = arg_reader.getIntRef(0);
      const vint b = arg_reader.getIntRef(1);
      // Call BlockWriter.setInt to store the output value, which is the
      // two input values added together
      res_writer.setInt(a+b);
      // Finish writing the row, and advance to the next output row
      res_writer.next();
      // Continue looping until there are no more input rows
   } while (arg_reader.next());
};

ScalarFunctionFactory Implementation

/*
* This class provides metadata about the ScalarFunction class, and
* also instantiates a member of that class when needed.
*/
class Add2IntsFactory : public ScalarFunctionFactory
{
   // return an instance of Add2Ints to perform the actual addition.
   virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
   {
      // Calls the vt_createFuncObj to create the new Add2Ints class instance.
      return vt_createFuncObj(interface.allocator, Add2Ints);
   }
   // This function returns the description of the input and outputs of the
   // Add2Ints class's processBlock function. It stores this information in
   // two ColumnTypes objects, one for the input parameters, and one for
   // the return value.
   virtual void getPrototype(ServerInterface &interface,
      ColumnTypes &argTypes,
      ColumnTypes &returnType)
   {
      // Takes two ints as inputs, so add ints to the argTypes object
      argTypes.addInt();
      argTypes.addInt();
      // returns a single int, so add a single int to the returnType object.
      // Note that ScalarFunctions *always* return a single value.
      returnType.addInt();
   }
};
The RegisterFactory Macro

Use the RegisterFactory macro to register a ScalarFunctionFactory subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```c++
RegisterFactory(Add2IntsFactory);
```

C++ Example: Calling a UDSF from a Check Constraint

This example shows you the C++ code needed to create a UDSF that can be called by a check constraint. The name of the sample function is LargestSquareBelow. The sample function determines the largest number whose square is less than the number in the subject column. For example, if the number in the column is 1000, the largest number whose square is less than 1000 is 31 (961).

Important: A UDSF used within a check constraint must be immutable, and the constraint must handle null values properly. Otherwise, the check constraint might not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated, so consider performance in writing your function.

For information on check constraints, see Check Constraints the Administrator's Guide.
For information about implementing the ScalarFunction and ScalarFunctionFactory classes, see UDSF Class Overview.

Loading and Using the Example

The following example shows how you can create and load a library named MySqLib, using CREATE LIBRARY. Adjust the library path in this example to the absolute path and file name for the location where you saved the shared object LargestSquareBelow.

```sql
=> CREATE OR REPLACE LIBRARY MySqLib AS '/home/dbadmin/LargestSquareBelow.so';
```

1. After you create and load the library, add the function to the catalog using the CREATE FUNCTION (UDF) statement.
CREATE OR REPLACE FUNCTION largestSqBelow AS LANGUAGE 'C++' NAME 'LargestSquareBelowInfo' LIBRARY MySqLib;

2. Next, include the UDSF in a check constraint.

CREATE TABLE squaretest(
    ceiling INTEGER UNIQUE,
    CONSTRAINT chk_sq CHECK (largestSqBelow(ceiling) < ceiling*ceiling)
);

3. Add data to the table, squaretest.

COPY squaretest FROM stdin DELIMITER ',null';
-1
null
0
1
1000
1000000
1000001

Your output should be similar to the following sample, based upon the data you use:

SELECT ceiling, largestSqBelow(ceiling)
FROM squaretest ORDER BY ceiling;

<table>
<thead>
<tr>
<th>ceiling</th>
<th>largestSqBelow</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1000</td>
<td>31</td>
</tr>
<tr>
<td>1000000</td>
<td>999</td>
</tr>
<tr>
<td>1000001</td>
<td>1000</td>
</tr>
</tbody>
</table>
(7 rows)

ScalarFunction Implementation

This ScalarFunction implementation does the processing work for a UDSF that determines the largest number whose square is less than the number input.

#include "Vertica.h"
/*
 * ScalarFunction implementation for a UDSF that
 * determines the largest number whose square is less than
 * the number input.
 */
class LargestSquareBelow : public Vertica::ScalarFunction {

public:
/*
 This function does all of the actual processing for the UDSF.
* The inputs are retrieved via arg_reader
* The outputs are returned via arg_writer
*/
virtual void processBlock(Vertica::ServerInterface &srvInterface,
Vertica::BlockReader &arg_reader,
Vertica::BlockWriter &res_writer)
{
    if (arg_reader.getNumCols() != 1)
        vt_report_error(0, "Function only accept 1 argument, but %zu provided", arg_reader.getNumCols());
    // While we have input to process
    do {
        // Read the input parameter by calling the BlockReader.getIntRef class function
        const Vertica::vint a = arg_reader.getIntRef(0);
        Vertica::vint res;
        // Determine the largest square below the number
        if ((a != Vertica::vint_null) && (a > 0))
            res = (Vertica::vint)sqrt(a - 1);
        else
            res = Vertica::vint_null;
        // Call BlockWriter.setInt to store the output value,
        // which is the largest square
        res_writer.setInt(res);
        // Write the row and advance to the next output row
        res_writer.next();
        // Continue looping until there are no more input rows
    } while (arg_reader.next());
};

ScalarFunctionFactory Implementation
This ScalarFunctionFactory implementation does the work of handling input and output, and marks the function as immutable (a requirement if you plan to use the UDSF within a check constraint).

class LargestSquareBelowInfo : public Vertica::ScalarFunctionFactory
{
    //return an instance of LargestSquareBelow to perform the computation.
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    //Call the vt_createFuncObj to create the new LargestSquareBelow class instance.
    { return Vertica::vt_createFuncObject<LargestSquareBelow>(srvInterface.allocator); }

    /*
    * This function returns the description of the input and outputs of the
    * LargestSquareBelow class’s processBlock function. It stores this information in
    * two ColumnTypes objects, one for the input parameter, and one for
    * the return value.
/*
   virtual void getPrototype(Vertica::ServerInterface &srvInterface,
       Vertica::ColumnTypes &argTypes,
       Vertica::ColumnTypes &returnType)
   {
       // Takes one int as input, so adds int to the argTypes object
       argTypes.addInt();
       // Returns a single int, so add a single int to the returnType object.
       // ScalarFunctions always return a single value.
       returnType.addInt();
   }
public:
   // the function cannot be called within a check constraint unless the UDx author
   // certifies that the function is immutable:
   LargestSquareBelowInfo() { vol = Vertica::IMMUTABLE; }
};

The RegisterFactory Macro

Use the RegisterFactory macro to register a ScalarFunctionFactory subclass. This
macro instantiates the factory class and makes the metadata it contains available for Vertica to
access. To call this macro, pass it the name of your factory class.

RegisterFactory(LargestSquareBelowInfo);

Java API

This section provides APIs and examples for the Java API for UDSFs.
For information on setting up a Java development environment and compiling and packaging
libraries, see Developing with the Java SDK.

ScalarFunction and ScalarFunctionFactory Java Interface

This section describes information that is specific to the Java API. See UDSF Class Overview for
general information about implementing the ScalarFunction and
ScalarFunctionFactory classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:

void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);
abstract void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_writer) throws UdfException, DestroyInvocation;
void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

abstract ScalarFunction createScalarFunction(ServerInterface srvInterface);
abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);
void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException;
void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

Java Example: Add2Ints

The Add2Ints scalar function adds two integers together, returning a single integer result.

Loading and Using the Example

Use CREATE LIBRARY to load the jar file containing the function, and then use CREATE FUNCTION (UDF) to declare the function as in the following example:

=> CREATE FUNCTION add2ints AS LANGUAGE 'Java' NAME 'com.mycompany.example.Add2intsFactory' LIBRARY add2intslib;

The following example shows how to use this function.

=> SELECT Add2Ints(27,15);
Add2int
----------
42
(1 row)
=> SELECT * FROM MyTable;
a | b
----------
7 | 0
12 | 2
12 | 6
18 | 9
1 | 1
Implementation

The following code example is the full source of the Java Add2ints example. To simplify handling the source code, the ScalarFunction class is defined as an inner class of the ScalarFunctionFactory class.

```java
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.example;
// Import all of the Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
        ColumnTypes argTypes,
        ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    // This ScalarFunction is defined as an inner class of
    // its ScalarFunctionFactory class. This gets around having
    // to have a separate source file for this public class.
    public class Add2ints extends ScalarFunction
    {
        @Override
        public void processBlock(ServerInterface srvInterface,
            BlockReader argReader,
            BlockWriter resWriter)
            throws UdfException, DestroyInvocation
        {
            do {
                // The input and output objects have already loaded
                // the first row, so you can start reading and writing
                // values immediately.

                // Get the two integer arguments from the BlockReader
                long a = argReader.getLong(0);
                long b = argReader.getLong(1);

                // Process the arguments and come up with a result. For this
```
// example, just add the two arguments together.
long result = a+b;

// Write the integer output value.
resWriter.setLong(result);

// Advance the output BlockWriter to the next row.
resWriter.next();

// Continue processing input rows until there are no more.
} while (argReader.next());

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface) {
    return new Add2ints();
}
ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

class python_udx_factory(vertica_sdk.ScalarFunctionFactory):
    def createScalarFunction(self, srv):
        pass
    def getPrototype(self, srv_interface, arg_types, return_type):
        pass
    def getReturnType(self, srv_interface, arg_types, return_type):
        pass

Python Example: add2ints

The `add2ints` scalar function adds two integers together, returning a single integer result.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

UDSF Python Code

```python
import vertica_sdk

class add2ints(vertica_sdk.ScalarFunction):
    """Return the sum of two integer columns""
    def __init__(self):
        pass
    def setup(self, server_interface, col_types):
        pass
    def processBlock(self, self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Python UDx - Adding 2 ints!")
        while(True):
            # Example of error checking best practices.
            if arg_reader.isNull(0) or arg_reader.isNull(1):
                raise ValueError("I found a NULL!")
            else:
                first_int = arg_reader.getInt(0) # Input column
                second_int = arg_reader.getInt(1) # Input column
                res_writer.setInt(first_int + second_int) # Sum of input columns.
                res_writer.next() # Read the next row.
                if not arg_reader.next():
                    # Stop processing when there are no more input rows.
                    break
    def destroy(self, self, server_interface, col_types):
```

Vertica Analytic Database (9.0.x)
pass

class add2ints_factory(vertica_sdk.ScalarFunctionFactory):
    
def createScalarFunction(self, srv):
        return add2ints()
    
def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addInt()
        arg_types.addInt()
        return_type.addInt()
    
def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addInt()

Load the Function and Library

Create the library and the function.

=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/add2ints/add2ints.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION add2ints AS LANGUAGE 'Python' NAME 'add2ints_factory' LIBRARY pylib fenced;
CREATE FUNCTION

Querying Data with the Function

The following shows how to run a query with the UDSF.

=> SELECT add2ints(10, 10);
add2ints
----------
  20
(1 row)

You can query on a table with two integer columns as follows:

=> SELECT nums_1, nums_2, add2ints(nums_1, nums_2) AS add2ints_sum
FROM bunch_of_numbers;
nums_1 | nums_2 | add2ints_sum |
----------|---------|---------------
  10 |  10 | 20 |
  1 |  4 |  5 |
  6 |  6 | 12 |
 30 | 144 | 174 |
(4 rows)
Python Example: currency_convert

The currency_convert scalar function reads two values from a table, a currency and a value. It then converts the item’s value to USD, returning a single float result.

You can find more UDX examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

UDSF Python Code

```python
import vertica_sdk
import decimal

rates2USD = {'USD': 1.000,
             'EUR': 0.89977,
             'GBP': 0.68452,
             'INR': 67.0345,
             'AUD': 1.39187,
             'CAD': 1.30335,
             'ZAR': 15.7181,
             'XXX': -1.0000}

class currency_convert(vertica_sdk.ScalarFunction):
    """Converts a money column to another currency

    Returns a value in USD.
    """
    def __init__(self):
        pass

def setup(self, server_interface, col_types):
    pass

def processBlock(self, server_interface, block_reader, block_writer):
    while(True):
        currency = block_reader.getString(0)
        try:
            rate = decimal.Decimal(rates2USD[currency])
        except KeyError:
            server_interface.log("ERROR: {} not in dictionary.".format(currency))
        # Scalar functions always need a value to move forward to the
        # next input row. Therefore, we need to assign it a value to
        # move beyond the error.
        currency = 'XXX'
        rate = decimal.Decimal(rates2USD[currency])

        starting_value = block_reader.getNumeric(1)
        converted_value = decimal.Decimal(starting_value) / rate
        block_writer.setNumeric(converted_value)
        block_writer.next()
        if not block_reader.next():
```
break

def destroy(self, server_interface, col_types):
    pass

class currency_convert_factory(vertica_sdk.ScalarFunctionFactory):
    
def createScalarFunction(self, srv):
        return currency_convert()

    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        arg_types.addNumeric()
        return_type.addNumeric()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addNumeric(9,4)

Load the Function and Library

Create the library and the function.

=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/currency_convert/currency_convert.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION currency_convert AS LANGUAGE 'Python' NAME 'currency_convert_factory' LIBRARY pylib fenced;
CREATE FUNCTION

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

=> SELECT product, currency_convert(currency, value) AS cost_in_usd
    FROM items;

<table>
<thead>
<tr>
<th>product</th>
<th>cost_in_usd</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shoes</td>
<td>133.4008</td>
</tr>
<tr>
<td>Soccer Ball</td>
<td>110.2817</td>
</tr>
<tr>
<td>Coffee</td>
<td>13.5190</td>
</tr>
<tr>
<td>Surfboard</td>
<td>176.2593</td>
</tr>
<tr>
<td>Hockey Stick</td>
<td>76.7177</td>
</tr>
<tr>
<td>Car</td>
<td>17000.0000</td>
</tr>
<tr>
<td>Software</td>
<td>10.4424</td>
</tr>
<tr>
<td>Hamburger</td>
<td>7.5000</td>
</tr>
<tr>
<td>Fish</td>
<td>130.4272</td>
</tr>
<tr>
<td>Cattle</td>
<td>269.2367</td>
</tr>
</tbody>
</table>

(10 rows)
Python Example: validate_url

The `validate_url` scalar function reads a string from a table, a URL. It then validates if the URL is responsive, returning a status code or a string indicating the attempt failed.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

UDSF Python Code

```python
import vertica_sdk
import urllib.request
import time

class validate_url(vertica_sdk.ScalarFunction):
    """Validates HTTP requests.

    Returns the status code of a webpage. Pages that cannot be accessed return "Failed to load page."
    ""

    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Validating webpage accessibility - UDx")
        while(True):
            url = arg_reader.getString(0)
            try:
                status = urllib.request.urlopen(url).getcode()
                # Avoid overwhelming web servers -- be nice.
                time.sleep(2)
            except (ValueError, urllib.error.HTTPError, urllib.error.URLError):
                status = 'Failed to load page'
            res_writer.setString(str(status))
            res_writer.next()  # Stop processing when there are no more input rows.
            break

    def destroy(self, server_interface, col_types):
        pass

class validate_url_factory(vertica_sdk.ScalarFunctionFactory):
    def createScalarFunction(self, srv):
        return validate_url()
```
def getPrototype(self, srv_interface, arg_types, return_type):
    arg_types.addVarchar()
    return_type.addChar()

def getReturnType(self, srv_interface, arg_types, return_type):
    return_type.addChar(20)

Load the Function and Library

Create the library and the function.

=> CREATE OR REPLACE LIBRARY pylib AS 'webpage_tester/validate_url.py' LANGUAGE 'Python';
=> CREATE OR REPLACE FUNCTION validate_url AS LANGUAGE 'Python' NAME 'validate_url_factory' LIBRARY pylib fenced;

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

=> SELECT url, validate_url(url) AS url_status FROM webpages;

<table>
<thead>
<tr>
<th>url</th>
<th>url_status</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.vertica.com/documentation/vertica/">http://www.vertica.com/documentation/vertica/</a></td>
<td>200</td>
</tr>
<tr>
<td><a href="http://www.google.com/">http://www.google.com/</a></td>
<td>200</td>
</tr>
<tr>

R API

This section provides APIs and examples for the R API for UDSFs.

For information on setting up an R development environment and compiling and packaging libraries, see Developing with the R SDK.

Scalar Function and Scalar Function Factory R Interface

This section describes information that is specific to the R API. See R SDK API Documentation for general information about implementing Scalar functions.
Scalar Function API

The API provides the following framework for extension by R function:

```r
FunctionName <- function(input.data.frame, parameters.data.frame) {
    # Computations
    # The function must return a data frame.
    return(output.data.frame)
}
```

Scalar Function Factory API

The API provides the following framework for extension by R function:

```r
FunctionNameFactory <- function() {
    list(name = FunctionName,
         udxtype = c("scalar"),
         intype = c("int"),
         outtype = c("int"))
}
```

For a complete list of factory options, see the R API documentation for Factory Function.

R Example: SalesTaxCalculator

The SalesTaxCalculator scalar function reads a float and a varchar from a table, an item's price and the state abbreviation. It then uses the state abbreviation to find the sales tax rate from a list and calculates the item's price including the state's sales tax, returning the total cost of the item.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```sql
=> CREATE OR REPLACE LIBRARY rLib AS 'sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION SalesTaxCalculator AS LANGUAGE 'R' NAME 'SalesTaxCalculatorFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```
Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT item, state_abbreviation, price, SalesTaxCalculator(price, state_abbreviation) AS Price_With_Sales_Tax
    FROM inventory;
```

<table>
<thead>
<tr>
<th>item</th>
<th>state_abbreviation</th>
<th>price</th>
<th>Price_With_Sales_Tax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scarf</td>
<td>AZ</td>
<td>6.88</td>
<td>7.53016</td>
</tr>
<tr>
<td>Software</td>
<td>MA</td>
<td>88.31</td>
<td>96.655295</td>
</tr>
<tr>
<td>Soccer Ball</td>
<td>MS</td>
<td>12.55</td>
<td>13.735975</td>
</tr>
<tr>
<td>Beads</td>
<td>LA</td>
<td>0.99</td>
<td>1.083555</td>
</tr>
<tr>
<td>Baseball</td>
<td>TN</td>
<td>42.42</td>
<td>46.42869</td>
</tr>
<tr>
<td>Cheese</td>
<td>WI</td>
<td>20.77</td>
<td>22.732765</td>
</tr>
<tr>
<td>Coffee Mug</td>
<td>MA</td>
<td>8.99</td>
<td>9.839555</td>
</tr>
<tr>
<td>Shoes</td>
<td>TN</td>
<td>23.99</td>
<td>26.257055</td>
</tr>
</tbody>
</table>

(8 rows)

UDSF R Code

```R
SalesTaxCalculator <- function(input.data.frame) {
  # Not a complete list of states in the USA, but enough to get the idea.
  state.sales.tax <- list(ma = 0.0625,
                          az = 0.087,
                          la = 0.0891,
                          tn = 0.0945,
                          wi = 0.0543,
                          ms = 0.0707)
  for (state_abbreviation in input.data.frame[, 2]) {
    # Ensure state abbreviations are lowercase.
    lower_state <- tolower(state_abbreviation)
    # Check if the state is in our state.sales.tax list.
    if (is.null(state.sales.tax[[lower_state]])) {
      stop("State is not in our small sample!")
    } else {
      sales.tax.rate <- state.sales.tax[[lower_state]]
      item.price <- input.data.frame[, 1]
      # Calculate the price including sales tax.
      price.with.sales.tax <- (item.price) + (item.price * sales.tax.rate)
    }
  }
  return(price.with.sales.tax)
}

SalesTaxCalculatorFactory <- function() {
  list(name = SalesTaxCalculator,
       udxtype = c("scalar"),
       intype = c("float", "varchar"),
       outtype = c("float"))
}
```
R Example: kmeans

The KMeans_User scalar function reads any number of columns from a table, the observations. It then uses the observations and the two parameters when applying the kmeans clustering algorithm to the data, returning an integer value associated with the cluster of the row.

You can find more UDx examples in the VerticaGithub repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```sql
=> CREATE OR REPLACE LIBRARY rLib AS 'kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION KMeans_User AS LANGUAGE 'R' NAME 'KMeans_UserFactory' LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```sql
=> SELECT spec, KMeans_User(s1, sw, pl, pw USING PARAMETERS clusters = 3, nstart = 20)  
    FROM iris;
```

<table>
<thead>
<tr>
<th>spec</th>
<th>KMeans_User</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
</tbody>
</table>

UDSF R Code

```r
KMeans_User <- function(input.data.frame, parameters.data.frame) {
  # Take the clusters and nstart parameters passed by the user and assign them
  # to variables in the function.
  if (is.null(parameters.data.frame[['clusters']])) {
    stop("NULL value for clusters! clusters cannot be NULL.")
  } else {
    clusters.value <- parameters.data.frame[['clusters']]}
  if (is.null(parameters.data.frame[['nstart']])) {
    stop("NULL value for nstart! nstart cannot be NULL.")
  } else {
    nstart.value <- parameters.data.frame[['nstart']]}
  # Apply the algorithm to the data.
  kmeans.clusters <- kmeans(input.data.frame[, 1:length(input.data.frame)],
    clusters.value, nstart = nstart.value)
  final.output <- data.frame(kmeans.clusters$cluster)
  return(final.output)
}
KMeans_UserFactory <- function() {
  list(name = KMeans_User,
    ud xtype = c("scalar"),
    # Since this is a polymorphic function the intype must be any
    intype = c("any"),
    outtype = c("int"),
    parametertypecallback=KMeansParameters)
}
KMeansParameters <- function() {
  parameters <- list(datatype = c("int", "int"),
    length = c("NA", "NA"),
    scale = c("NA", "NA"),
    name = c("clusters", "nstart"))
  return(parameters)
}
```

Vertica Documentation
Extending Vertica
Transform Functions (UDTFs)

A User-Defined Transform Function (UDTF) lets you transform a table of data into another table. It reads one or more arguments (treated as a row of data), and returns zero or more rows of data consisting of one or more columns. A UDTF can produce any number of rows as output. However, each row it outputs must be complete. Advancing to the next row without having added a value for each column produces incorrect results.

The schema of the output table does not need to correspond to the schema of the input table—they can be totally different. The UDTF can return any number of output rows for each row of input.

UDTFs can only be used in the SELECT list that contains just the UDTF call and a required OVER clause. A multi-phase UDTF can make use of partition columns (PARTITION BY), but other UDTFs cannot.

UDTFs are run after GROUP BY, but before the final ORDER BY, when used in conjunction with GROUP BY and ORDER BY in a statement. The ORDER BY clause may contain only columns or expressions that are in a window partition clause (see Window Partitioning).

UDTFs can take up to 1600 parameters (input columns). Attempting to pass more parameters to a UDTF results in an error.

UDTF Class Overview

You create your UDTF by subclassing two classes defined by the Vertica SDK: TransformFunction and TransformFunctionFactory.

The TransformFunctionFactory performs two roles:

- It provides the number of parameters and their data types accepted by the UDTF and the number of output columns and their data types UDTF's output. Vertica uses this data when you call the CREATE TRANSFORM FUNCTION SQL statement to add the function to the database catalog.

- It returns an instance of the UDTF function's TransformFunction subclass that Vertica can call to process data.
TransformFunction

The TransformFunction class is where you perform the data-processing, transforming input rows into output rows. Your subclass must define the processPartition() method. It may define methods to set up and tear down the function.

Performing the Transformation

The processPartition() method carries out all of the processing that you want your UDTF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to processPartition().

The input and output of the processPartition() method are supplied by objects of the BlockReader and BlockWriter classes. They define methods that you use to read the input data and write the output data for your UDTF.

Your processPartition() method should follow this basic pattern:

- Extract the input parameters by calling a data-type-specific function in the PartitionReader object to extract each input parameter. All of these functions take a single parameter: the column number in the input row that you want to read. Your function might need to handle NULL values.

- Perform the actual transformation.

- Write the output, if any. Unlike a UDSF, outputting data is optional for a UDTF. However, if it does write output, it must supply values for all of the output columns you defined in your factory. Similarly to reading input columns, the PartitionWriter object has functions for writing each type of data to the output row.

- Advance to the next row by calling ProcessReader.next(). This function returns true if there is another row of input data to process and false if all the data in the partition has been read. Once the input rows are exhausted, your UDTF exits so its results are returned back to Vertica.

Note: In some cases, you may want to determine the number and types of parameters using PartitionReader's getNumCols() and getTypeMetaData() functions, instead of just hard-coding the data types of the columns in the input row. This is useful if you want your TransformFunction to be able to process input tables with different schemas. You can then use different TransformFunctionFactory classes to define multiple function signatures that call the same TransformFunction class. See Handling.
**Different Numbers and Types of Arguments** for more information.

Setting Up and Tearing Down

The `TransformFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see *Allocating Resources for UDxs* for details).

**TransformFunctionFactory**

The `TransformFunctionFactory` class tells Vertica metadata about your UDTF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `TransformFunction`.

You must implement the following methods in your `TransformFunctionFactory`:

- `getPrototype()` returns two `ColumnType` objects that describe the columns your UDTF takes as input and returns as output.
- `createTransformFunction()` instantiates your `TransformFunction` subclass.
- `getReturnType()` tells Vertica details about the output values: the width of variable-sized data types (such as `VARCHAR`) and the precision of data types that have settable precision (such as `TIMESTAMP`). You can also set the names of the output columns using this function.

**Note**: The `getReturnType()` function is required for UDTFs. It is optional for UDxs that return single values, such as User-Defined Scalar Functions.

See Also

*Creating Multi-Phase UDTFs*

Creating Multi-Phase UDTFs

Multi-phase UDTFs let you break your data processing into multiple steps. Using this feature, your UDTFs can perform processing in a way similar to Hadoop or other MapReduce frameworks. You can use the first phase to break down and gather data, and then use subsequent phases to process the data. For example, the first phase of your UDTF could extract
specific types of user interactions from a web server log stored in the column of a table, and subsequent phases could perform analysis on those interactions.

Multi-phase UDTFs also let you decide where processing should occur: locally on each node, or throughout the cluster. If your multi-phase UDT is like a MapReduce process, you want the first phase of your multi-phase UDTF to process data that is stored locally on the node where the instance of the UDTF is running. This prevents large segments of data from being copied around the Vertica cluster. Depending on the type of processing being performed in later phases, you may choose to have the data segmented and distributed across the Vertica cluster.

Each phase of the UDTF is the same as a traditional (single-phase) UDTF: it receives a table as input, and generates a table as output. The schema for each phase's output does not have to match its input, and each phase can output as many or as few rows as it wants.

You create a subclass of TransformFunction to define the processing performed by each stage. If you already have a TransformFunction from a single-phase UDTF that performs the processing you want a phase of your multi-phase UDTF to perform, you can easily adapt it to work within the multi-phase UDTF.

What makes a multi-phase UDTF different from a traditional UDTF is the factory class you use. You define a multi-phase UDTF using a subclass of MultiPhaseTransformFunctionFactory, rather than the TransformFunctionFactory. This special factory class acts as a container for all of the phases in your multi-step UDTF. It provides Vertica with the input and output requirements of the entire multi-phase UDTF (through the getPrototype() function), and a list of all the phases in the UDTF.

Within your subclass of the MultiPhaseTransformFunctionFactory class, you define one or more subclasses of TransformFunctionPhase. These classes fill the same role as the TransformFunctionFactory class for each phase in your multi-phase UDTF. They define the input and output of each phase and create instances of their associated TransformFunction classes to perform the processing for each phase of the UDTF. In addition to these subclasses, your MultiPhaseTransformFunctionFactory includes fields that provide a handle to an instance of each of the TransformFunctionPhase subclasses.

**Partitioning Options for Processing Local Data**

UDTFs typically process data that is partitioned in a specific way. For example, a UDTF that processes a web server log file to count the number of hits referred by each partner web site needs to have its input partitioned by a referrer column. Each instance of the UDTF sees the hits referred by a particular partner site so it can count them.

In cases like this, the window partitioning clause should use a PARTITION BY clause. Each node in the cluster partitions the data it stores, sends some of these partitions off to other
nodes, and then consolidates the partitions it receives from other nodes and runs an instance of the UDTF to process them.

In other cases, a UDTF might not need to partition input data in a particular way—for example, a UDTF that parses data out of an Apache log file. In this case, you can specify that each UDTF instance process only the data that is stored locally by the node on which it is running. By eliminating the overhead of partitioning data, processing can be much more efficient.

You can tell a UDTF to process only local data with one of the following window partitioning options:

- **PARTITION BEST**: For thread-safe UDTFs only, optimizes performance through multi-threaded queries across multiple nodes.
- **PARTITION NODES**: Optimizes performance of single-threaded queries across multiple nodes.

The query must specify a source table that is replicated across all nodes and contains a single row (similar to the **DUAL** table). For example, the following statements call a UDTF that parses locally-stored Apache log files:

```plaintext
=> CREATE TABLE rep (dummy INTEGER) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO rep VALUES (1);
OUTPUT
--------
1
(1 row)
=> SELECT ParseLogFile('/data/apache/log*') OVER (PARTITION BEST) FROM rep;
```

### C++ API

This section provides APIs and examples for the C++ API for UDTFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see [Developing with the C++ SDK](#).

### TransformFunction and TransformFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See [UDTF Class Overview](#) for general information about implementing the TransformFunction and TransformFunctionFactory classes.
TransformFunction API

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
const SizedColumnTypes &argTypes);

virtual void processPartition(ServerInterface &srvInterface,
PartitionReader &input_reader, PartitionWriter &output_writer)=0;

virtual void destroy(ServerInterface &srvInterface,
const SizedColumnTypes &argTypes);
```

TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```cpp
virtual TransformFunction *
createTransformFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
const SizedColumnTypes &argTypes,
SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
SizedColumnTypes &parameterTypes);
```

MultiPhaseTransformFunctionFactory API

The MultiPhaseTransformFunctionFactory class extends TransformFunctionFactory The API provides the following additional methods for extension by subclasses:

```cpp
virtual void getPhases(ServerInterface &srvInterface,
std::vector<TransformFunctionPhase * > &phases)=0;
```

If using this factory you must also extend TransformFunctionPhase. See the SDK reference documentation.
C++ Example: String Tokenizer

The following example shows a subclass of TransformFunction named StringTokenizer. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the TransformFunctions.so library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```
=> CREATE LIBRARY TransformFunctions AS
   '/home/dbadmin/TransformFunctions.so';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize
   AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use it from SQL statements, for example:

```
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
OUTPUT
-------
   1
(1 row)
=> INSERT INTO T VALUES ('www.hp.com','Leading provider of computer hardware and imaging solutions');
OUTPUT
-------
   1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
OUTPUT
-------
   1
(1 row)
=> COMMIT;
COMMIT

=> -- Invoke the UDT
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
   url | words
-----------------------
www.amazon.com | Online
www.amazon.com | retail
www.amazon.com | merchant
www.amazon.com | and
www.amazon.com | provider
```
Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

TransformFunction Implementation

The following code defines the StringTokenizer class.

```cpp
#include "Vertica.h"
#include <sstream>
// Use the Vertica namespace to make referring
// to SDK classes easier.
using namespace Vertica;
using namespace std;

// The primary class for the StringTokenizer UDTF. This does the actual work.
class StringTokenizer : public TransformFunction {
    // Called for each partition in the table.
    virtual void processPartition(ServerInterface &srvInterface,
        PartitionReader &inputReader,
        PartitionWriter &outputWriter) {
        // Use a top-level try to prevent exceptions from bubbling up.
        try {
            // Loop through the input rows
            do {
                // First check if the id is NULL. If so, skip the row without
                // writing any output.
                if (inputReader.isNull(0))
                    {  
                        srvInterface.log("Skipping row with NULL ID");
                        continue;
                    }
                // Get an input row containing an int and a varchar
                const int row = inputReader.getIntRef(0);
                const VString &sentence = inputReader.getStringRef(1);
                // If input string is NULL, then output NULL tokens and
                // positions.
                if (sentence.isNull())
```
The `processPartition()` function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, `processPartition()` first extracts the ID number of the row. Then it extracts the `VString` containing the text from the `PartitionReader` object. The `VString` class represents a Vertica string value (VARCHAR or CHAR).

When developing UDTFs, you often need to handle NULL input values in a special way. This example has two different reactions to a NULL value:
If the ID column is NULL, then processPartition() skips the row and moves on to the next row. It writes a message to the Vertica log to indicate that it is skipping the row.

If the VARCHAR column is NULL, processPartition() outputs a single row that contains the row_id value and NULLs for both the token and token_position columns.

After handling any NULL values, the processPartition() function shown in the example moves on to performing the actual processing. It breaks the string into individual tokens and outputs a row for each token.

Similarly to reading input columns, the PartitionWriter object has functions for writing each type of data to the output row. In this case, the example:

- Calls the PartitionWriter object's getStringRef() function to allocate a new VString object to hold the token to output for the first column. It then copies the token's value into the VString object.
- Calls setInt() to output the row ID in the second column.
- Calls setInt() again to output the token's position within the input string.

After setting the three column values, the example calls PartitionWriter.next() to complete the output row.

### TransformFunctionFactory Implementation

The following code shows the factory class.

```cpp
// Provides Vertica with metadata about the StringTokenizer
class TokenFactory : public TransformFunctionFactory {
    // Tell Vertica that StringTokenizer reads 1 int and 1 string,
    // and returns two ints and a string
    virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType) {
        argTypes.addInt(); // Row number
        argTypes.addVarchar(); // Line of text
        returnType.addInt(); // The token
        returnType.addInt(); // The row this token occurred in
        returnType.addInt(); // The position in the row of the token
    }

    // Gives details of the output columns. For integer rows,
    // Tell Vertica the maximum return string length will be, given the input
    // string length. Also names the output columns. This function is only
    // necessary if you have a column that has a variable size (i.e. strings) or
    // have to report their precision.
    virtual void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &input_types,
        ColumnTypes &argTypes, ColumnTypes &returnType, ColumnTypes &inputPrototypes)
```
In this example:

- The UDTF takes an INTEGER and a VARCHAR column as input. To define these input columns, getPrototype() calls addInt() and addVarchar() on the ColumnTypes object that represents the input table.

- The UDTF returns a VARCHAR and two INTEGER columns as output. The getPrototype() function calls addVarchar() once and addInt() twice to define the output table.

This example must return the maximum length of the VARCHAR output column. It sets the length to the length input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "token". You can use getReturnType() to name the output columns, even if they do not require a precision or output length. The example sets the names of the two INTEGER output columns to "row_id" and "token_position".

Note: You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, getReturnType() sets the column name to ". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the createTransformFunction() function in the example is boilerplate code. It just calls the vt_returnFuncObj macro with the name of the TransformFunction class associated with this factory class. This macro takes care of instantiating a copy of the TransformFunction class that Vertica can use to process data.
The RegisterFactory Macro

The final step in creating your UDTF is to call the RegisterFactory macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The RegisterFactory macro just takes the name of your factory class:

```cpp
RegisterFactory(TokenFactory);
```

C++ Example: Multi-Phase Transform Function

The following code fragment is from the InvertedIndex UDTF example distributed with the Vertica SDK. It demonstrates subclassing the MultiPhaseTransformFunctionFactory including two TransformFunctionPhase subclasses that define the two phases in this UDTF.

```cpp
class InvertedIndexFactory : public MultiPhaseTransformFunctionFactory
{
public:
  /**
   * Extracts terms from documents.
   */
  class ForwardIndexPhase : public TransformFunctionPhase
  {
    virtual void getReturnType(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes,
                                SizedColumnTypes &outputTypes)
    {
      // Sanity checks on input we've been given.
      // Expected input: (doc_id INTEGER, text VARCHAR)
      vector<size_t> argCols;
      inputTypes.getArgumentColumns(argCols);
      if (argCols.size() < 2 ||
          !inputTypes.getColumnType(argCols.at(0)).isInt() ||
          !inputTypes.getColumnType(argCols.at(1)).isVarchar())
        vt_report_error(0, "Function only accepts two arguments"
                        "(INTEGER, VARCHAR)");
      // Output of this phase is:
      // (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
      // Number of times term appears within a document.
      outputTypes.addInt("term_freq");
      // Add analytic clause columns: (PARTITION BY term ORDER BY doc_id).
      // The length of any term is at most the size of the entire document.
      outputTypes.addVarcharPartitionColumn(
        inputTypes.getColumnType(argCols.at(1)).getStringLength(),
        "term");
      // Add order column on the basis of the document id's data type.
      outputTypes.addOrderColumn(inputTypes.getColumnType(argCols.at(0)),
                                 "doc_id");
    }
```
virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
{
    return vt_createFuncObj(srvInterface.allocation, ForwardIndexBuilder); }
};

/**
* Constructs terms' posting lists.
*/
class InvertedIndexPhase : public TransformFunctionPhase
{
    virtual void getReturnType(ServerInterface &srvInterface,
        const SizedColumnTypes &inputTypes,
        SizedColumnTypes &outputTypes)
    {
        // Sanity checks on input we've been given.
        // Expected input:
        // (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
        // Output of this phase is:
        // (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
        if (argCols.size() != 1 || pByCols.size() != 1 || oByCols.size() != 1)
        vt_report_error(0, "Function expects an argument (INTEGER) with "
                        "an analytic clause OVER(PBY VARCHAR OBY INTEGER)");
        // Output of this phase is:
        // (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
        outputTypes.addVarchar(inputTypes.getColumnType(pByCols.at(0)).getStringLength(), "term");
        outputTypes.addInt("doc_id");
        // Number of times term appears within the document.
        outputTypes.addInt("term_freq");
        // Number of documents where the term appears in.
        outputTypes.addInt("corp_freq");
    }
    virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
    {
        return vt_createFuncObj(srvInterface.allocation, InvertedIndexBuilder); }
};

ForwardIndexPhase fwardIdxPh;
InvertedIndexPhase invIdxPh;
virtual void getPhases(ServerInterface &srvInterface,
    std::vector<TransformFunctionPhase *> &phases)
{
    fwardIdxPh.setPrepass(); // Process documents wherever they're originally stored.
    phases.push_back(&fwardIdxPh);
    phases.push_back(&invIdxPh);
    }
Most of the code in this example is similar to the code in a TransformFunctionFactory class:

- Both TransformFunctionPhase subclasses implement the getReturnType() function, which describes the output of each stage. This is similar to the getReturnType() function from the TransformFunctionFactory class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF.

  The first phase calls SizedColumnTypes::addVarcharPartitionColumn() (rather than just addVarcharColumn()) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls SizedColumnTypes::addOrderColumn() to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as addIntOrderColumn()) so it can pass the data type of the original column through to the output column.

  **Note:** Any order by column or partition by column set by the final phase of the UDTF in its getReturnType() function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

- The MultiPhaseTransformFunctionFactory class implements the getPrototype() function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the TransformFunctionFactory::getPrototype() function.

  The unique function implemented by the MultiPhaseTransformFunctionFactory class is getPhases(). This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.

  The MultiPhaseTransformFunctionFactory::getPhases() function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.
Note: Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the `TransformFunctionPhase::setPrepass()` function of the first phase's `TransformFunctionPhase` instance from within the `getPhase()` function.

Notes

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each `TransformFunctionPhase::getReturnType()` implementation performs a sanity check on its input and output schemas. Your `TransformFunction` subclasses can also perform these checks in their `processPartition()` function.

- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode, Vertica may terminate UDTFs that use too much memory. See Resource Use for C++ UDx.

Java API

This section provides APIs and examples for the Java API for UDTFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

TransformFunction and TransformFunctionFactory

Java Interface

This section describes information that is specific to the Java API. See UDTF Class Overview for general information about implementing the `TransformFunction` and `TransformFunctionFactory` classes.

TransformFunction API

The API provides the following methods for extension by subclasses:

```java
void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);
abstract void processPartition(ServerInterface srvInterface,
```
PartitionReader input_reader, PartitionWriter input_writer) throws UdfException, DestroyInvocation;

void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);

TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

abstract TransformFunction createTransformFunction(ServerInterface srvInterface);

abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);

abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
  SizedColumnTypes returnType) throws UdfException;

void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

MultiPhaseTransformFunctionFactory API

The MultiPhaseTransformFunctionFactory class extends TransformFunctionFactory The API provides the following additional methods for extension by subclasses:

abstract void getPhases(ServerInterface srvInterface, Vector<TransformFunctionPhase> phases);

If using this factory you must also extend TransformFunctionPhase. See the SDK reference documentation.

Java Example: String Tokenizer

The following example shows a subclass of TransformFunction named StringTokenizer. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

You can then use it from SQL statements, for example:

=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
OUTPUT
----------
1
(1 row)
=> INSERT INTO T VALUES ('www.hp.com','Leading provider of computer hardware and imaging solutions');
OUTPUT
----------
1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
OUTPUT
----------
1
(1 row)
=> COMMIT;
COMMIT
=> -- Invoke the UDT
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;

<table>
<thead>
<tr>
<th>url</th>
<th>words</th>
</tr>

TransformFunction Implementation

The following code defines the StringTokenizer class.

To make code management simpler, the TransformFunction class is defined as an inner class of the TransformFactoryClass.

// You will need to specify the full package when creating functions based on // the classes in your library.
package com.mycompany.example;
// Import the entire Vertica SDK
import com.vertica.sdk.*;

public class TokenFactory extends TransformFunctionFactory
{
    // Set the number and data types of the columns in the input and output rows.
    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType)
    {
        // Define two input columns: an INTEGER and a VARCHAR
        argTypes.addInt(); // Row id
        argTypes.addVarchar(); // Line of text

        // Define the output columns
        returnType.addInt(); // The token
        returnType.addInt(); // The row in which this token occurred
        returnType.addInt(); // The position in the row of the token
    }

    // Set the width of any variable-width output columns, and also name
    // them.
    @Override
    public void getReturnType(ServerInterface srvInterface, SizedColumnTypes inputTypes, SizedColumnTypes outputTypes)
    {
        // Set the maximum width of the token return column to the width
        // of the input text column and name the output column “Token”
        outputTypes.addVarchar(inputTypes.getColumnType(1).getStringLength(), "token");

        // Name the two INTEGER output columns
        outputTypes.addInt("row_id");
        outputTypes.addInt("token_position");
    }

    // Inner class that actually performs work.
    public class TokenizeString extends TransformFunction
    {
        @Override
        public void processPartition(ServerInterface srvInterface, PartitionReader inputReader, PartitionWriter outputWriter)
        throws UdfException, DestroyInvocation
        {
            try {
                // Loop over all rows passed in in this partition.
                do {
                    // Test if the row ID is null. If so, then do not
                    // process any further. Skip to next row of input.
                    if(inputReader.isNull(0)) {
                        srvInterface.log("Skipping row with null id.");
                        continue; // Move on to next row of input
                    }

                    // Get the row ID now that we know it has a value
                    long rowId = inputReader.getLong(0);

                    // Test if the input string is NULL. If so, return NULL
                    // for token and string position.
                    if (inputReader.isNull(1)) {
                        outputWriter.setStringNull(0);
                    }
                }
            }
        }
    }
}
outputWriter.setLong(1, rowId);
outputWriter.setLongNull(2);
outputWriter.next(); // Move to next line of output
} else {
    // Break string into tokens. Output each word as its own
    // value.
    String[] tokens = inputReader.getString(1).split("\s+");
    // Output each token on a separate row.
    for (int i = 0; i < tokens.length; i++) {
        outputWriter.getStringWriter(0).copy(tokens[i]);
        outputWriter.setLong(1, rowId);
        outputWriter.setLong(2, i);
        outputWriter.next(); // Advance to next row of output
    }
    // Loop until there are no more input rows in partition.
} while (inputReader.next());
} // Prevent exceptions from bubbling back up to server. Uncaught
// exceptions will cause a transaction rollback.
catch (Exception e) {
    // Use more robust error handling in your own
    // UDTFs. This example just sends a message to the log.
    srvInterface.log("Exception: " + e.getClass().getSimpleName()
        + "Message: " + e.getMessage());
}
}

@Override
public TransformFunction createTransformFunction(ServerInterface srvInterface)
{
    return new TokenizeString();
}

---

Java Example: Multi-Phase Transform Function

The following code is excerpted from the InvertedIndexFactory SDK example. You can find the complete code in
/opt/vertica/sdk/examples/JavaUDx/TransformFunctions.

```java
public class InvertedIndexFactory extends MultiPhaseTransformFunctionFactory {
    public class ForwardIndexPhase extends TransformFunctionPhase {
        // ...
    }

    public class InvertedIndexPhase extends TransformFunctionPhase {

        @Override
        public TransformFunction createTransformFunction(ServerInterface srvInterface) {
            return new InvertedIndexBuilder();
        }
    }
}
```
public void getReturnType(ServerInterface srvInterface,
SizedColumnTypes inputTypes,
SizedColumnTypes outputTypes) {
// Sanity checks on input we've been given.
// Expected input:
// (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
ArrayList<Integer> argCols = new ArrayList<Integer>();
inputTypes.getArgumentColumns(argCols);
ArrayList<Integer> pByCols = new ArrayList<Integer>();
inputTypes.getPartitionByColumns(pByCols);
ArrayList<Integer> oByCols = new ArrayList<Integer>();
inputTypes.getOrderByColumns(oByCols);
if (argCols.size() != 1 || pByCols.size() != 1
|| oByCols.size() != 1 ||
!inputTypes.getColumnType(argCols.get(0)).isInt()
|| !inputTypes.getColumnType(pByCols.get(0)).isVarchar()
|| !inputTypes.getColumnType(oByCols.get(0)).isInt()) {
    throw new UdfException(0,
        "Function expects an argument (INTEGER) with "
        + "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
}

// Output of this phase is:
// (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
outputTypes.addVarchar(inputTypes.getColumnType(pByCols.get(0)).
    getStringLength(), "term");
outputTypes.addInt("doc_id");

// Number of times term appears within the document.
outputTypes.addInt("term_freq");

// Number of documents where the term appears in.
outputTypes.addInt("corp_freq");
}

@Override
public void getPhases(ServerInterface srvInterface,
Vector<TransformFunctionPhase> phases) {
    ForwardIndexPhase fwardIdxPh;
    InvertedIndexPhase invIdxPh;
    fwardIdxPh = new ForwardIndexPhase();
    invIdxPh = new InvertedIndexPhase();
    fwardIdxPh.setPrepass();
    phases.add(fwardIdxPh);;
    phases.add(invIdxPh);
}

@Override
public void getPrototype(ServerInterface srvInterface,
ColumnTypes argTypes, ColumnTypes returnTypes) {

Most of the code in this example is similar to the code in a TransformFunctionFactory class. The getReturnType method is similar, but in a TransformFunctionPhase it can also partition and order the data. The partitions and order are used by the next phase, but they are ignored after the final phase.

The MultiPhaseTransformFunctionFactory class adds the getPhases method. This method defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute. You should also indicate the first phase by calling setPrepass() on it. Doing so can lead to better performance.

There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. Vertica might terminate UDTFs that use too much memory.

R API

This section provides APIs and examples for the R API for UDTFs.

For information on setting up an R development environment and compiling and packaging libraries, see Developing with the R SDK.

Transform Function and Transform Function Factory R Interface

This section describes information that is specific to the R API. See R SDK API Documentation for general information about implementing transform functions.

Transform Function API

The API provides the following framework for extension by R function:
FunctionName <- function(input.data.frame, parameters.data.frame) {
    # Computations
    # The function must return a data frame.
    return(output.data.frame)
}

Transform Function Factory API

The API provides the following framework for extension by R function:

FunctionNameFactory <- function() {
    list(name = FunctionName,
         udxtype = c("transform"),
         intype = c("int"),
         outtype = c("int"))
}

R Example: Log Tokenizer

The LogTokenizer transform function reads a varchar from a table, a log message. It then
tokenizes each of the log messages, returning each of the tokens.

You can find more UDx examples in the VerticaGithub repository,

Load the Function and Library

Create the library and the function.

=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION

Querying Data with the Function

The following query shows how you can run a query with the UDTF.

=> SELECT machine,
    LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)
FROM error_Logs;

machine | Token
---------
node001 | ERROR
```
UDTF R Code

LogTokenizer <- function(input.data.frame, parameters.data.frame) {
  # Take the spliton parameter passed by the user and assign it to a variable
  # in the function so we can use that as our tokenizer.
  if (is.null(parameters.data.frame[['spliton']])) {
    stop("NULL value for spliton! Token cannot be NULL.")
  } else {
    split.on <- as.character(parameters.data.frame[['spliton']])
  }
  # Tokenize the string.
  tokens <- vector(length=0)
  for ( string in input.data.frame[, 1] ) {
    tokenized.string <- strsplit(string, split.on)
    for ( token in tokenized.string ) {
      tokens <- append(tokens, token)
    }
  }
  final.output <- data.frame(tokens)
  return(final.output)
}

LogTokenizerFactory <- function() {
  list(name = LogTokenizer,
       udxtype = c("transform"),
       intype = c("varchar"),
       outtype = c("varchar"),
       outtypecallback=LogTokenizerReturn,
       parametertypecallback=LogTokenizerParameters)
}

LogTokenizerParameters <- function() {
  parameters <- list(datatype = c("varchar"),
```
LogTokenizerReturn <- function(arg.data.frame, parm.data.frame) {
  output.return.type <- data.frame(
    datatype = rep(NA,1),
    length = rep(NA,1),
    scale = rep(NA,1),
    name = rep(NA,1))
  output.return.type$datatype <- c("varchar")
  output.return.type$name <- c("Token")
  return(output.return.type)
}
Load (UDLs)

The COPY statement offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The User-Defined Load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process. The SDK provides APIs for C++ and Java.

You use three types of UDL functions during development, one for each stage of the data-load process:

- **User-Defined Source** (UDSource): Controls how the COPY statement obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.

- **User-Defined Filter** (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple User-Defined Filters together, for example unzipping and then converting.

- **User-Defined Parser** (UDParser): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a User-Defined Chunker (UDChunker, C++ only), to have the parser perform parallel parsing.

After the final step, COPY inserts the data into a table, or rejects it, if it is not in the correct format.

Important: You cannot use fenced-mode UDLs developed in different programming languages together in the same COPY statement. For example, you cannot have a User-Defined Source written in C++ send data to a User-Defined Filter developed in Java. Attempting to do so results in a "Failure in UDx RPC call" error message.

User-Defined Source

A User-Defined Source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a User-Defined Source to access the data from an HTTP source using cURL. While you can use only a single User-Defined Source in a COPY statement, that source function can pull data from multiple sources.
The UDSource class is responsible for acquiring data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a UDSource, you must also implement a corresponding SourceFactory. See UDSource Class and SourceFactory Class for API details.

UDSource Class

You can subclass the UDSource class when you need to load data from a source type that COPY does not already support.

Each instance of your UDSource subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

UDSource Methods

The UDSource class defines the following methods. Your subclass must override process(). You can optionally override the others.

For the signatures of these methods and language-specific information, see Source Classes (C++) and Source Classes (Java).

Setting Up

COPY calls setup() before the first time it calls process(). Use setup() to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the UDSource can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Processing a Source

COPY calls process() repeatedly during query execution to read data and write it to the DataBuffer passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value StreamState.OUTPUT_NEEDED. When Vertica gets this return value, it will call the method again. This second call occurs after the output buffer has been processed by the next stage in
the data-load process. Returning StreamState.DONE indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.

## Tearing Down

COPY calls destroy() after the last time that process() is called. This method frees any resources reserved by the setup() or process() methods, such as file handles or network connections that the setup() method allocated.

## Accessors

A source can define two accessors, getSize() and getUri().

COPY might call getSize() to estimate the number of bytes of data to be read before calling process(). This value is an estimate only and is used to indicate the file size in the LOAD_STREAMS table. Because Vertica can call this method before calling setup(), getSize() must not rely on any resources allocated by setup().

This method should not leave any resources open. For example, do not save any file handles opened by getSize() for use by the process() method. Doing so can exhaust the available resources, because Vertica calls getSize() on all instances of your UDSource subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system’s supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls getUri() during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this UDSource.

## SourceFactory Class

If you write a source, you must also write a source factory. Your subclass of the SourceFactory class is responsible for:

- Performing the initial validation of the parameters passed to your UDSource.

- Setting up any data structures your UDSource instances need to perform their work. This information can include recording which nodes will read which data source.
Creating one instance of your UDSource subclass for each data source (or portion thereof) that your function reads on each host.

The simplest source factory creates one UDSource instance per data source per executor node. You can also use multiple concurrent UDSource instances on each node. This behavior is called concurrent load. To support both options, SourceFactory has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

SourceFactory Methods

The SourceFactory class defines several methods. Your class must override prepareUDSources(); it may override the other methods.

Setting Up

Vertica calls plan() once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the COPY statement and provide error messages if there are any issues. You can read the parameters by getting a ParamReader object from the instance of ServerInterface passed into the plan() method.

- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's filesystem, can be read only by a single specified host.

  You store the list of hosts to read the data source by calling the setTargetNodes() method on the NodeSpecifyingPlanContext object. This object is passed into your plan() method.

- Store any information that the individual hosts need to process the data sources in the NodeSpecifyingPlanContext instance passed to the plan() method. For example, you could store assignments that tell each host which data sources to process. The plan() method runs only on the initiator node, and the prepareUDSources() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.
You store data in the NodeSpecifyingPlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString().

Note: ParamWriter offers the ability to store only simple data types. For complex types, you must serialize the data in some manner and store it as a string or long string.

Creating Sources

Vertica calls prepareUDSources() on all hosts that the plan() method selected to load data. This call instantiates and returns a list of UDSource subclass instances. If you are not using concurrent load, return one UDSource for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an ExecutorPlanContext as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

Note: In the C++ API, the function that supports concurrent load is named prepareUDSourcesExecutor(). In the Java API the class provides two overloads of prepareUDSources().

For concurrent load, you can find out how many threads are available on the node to run UDSource instances by calling getLoadConcurrency() on the ExecutorPlanContext that is passed in.

Defining Parameters

Implement getParameterTypes() to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.
Requesting Threads for Concurrent Load

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement `getDesiredThreads()`. Vertica calls this method before it calls `prepareUDSources()`, so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The `FilePortionSourceFactory` example implements this method; see Source Example: Concurrent Load.

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing `isSourceApportionable()`. Returning `true` from this method does not guarantee that the source will apportion the load. However, returning `false` indicates that it will not try to do so. See Apportioned Load for more information.

Often, a `SourceFactory` that implements `getDesiredThreads()` also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without apportioning.

User-Defined Filter

User-Defined Filter functions allow you to manipulate data obtained from a source in various ways.

For example, a filter could:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.

You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a `UDFilter`, you must also implement a corresponding `FilterFactory`. See `UDFilter Class` and `FilterFactory Class` for API details.
UDFilter Class

The UDFilter class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A UDFilter is instantiated by a corresponding FilterFactory on each host in the Vertica cluster that is performing filtering for the data source.

UDFilter Methods

The UDFilter class defines the following methods. Your subclass must override process(). You can optionally override the other methods.

For the signatures of these methods and language-specific information, see Filter Classes (C++) and Filter Classes (Java).

Setting Up

COPY calls setup() before the first time it calls process(). Use setup() to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Filtering Data

COPY calls process() repeatedly during query execution to filter data. The method receives two instances of the DataBuffer class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The process() method should process data until it either runs out of data to read or runs out of space in the output buffer. When one of these conditions occurs, your method should return one of the following values defined by StreamState:
- **OUTPUT_NEEDED** if the filter needs more room in its output buffer.
- **INPUT_NEEDED** if the filter has run out of input data (but the data source has not yet been fully processed).
- **DONE** if the filter has processed all of the data in the data source.
- **KEEP_GOING** if the filter cannot proceed for an extended period of time. The method will be called again, so do not block indefinitely. If you do, then you prevent your user from canceling the query.

Before returning, your `process()` method must set the `offset` property in each `DataBuffer`. In the input buffer, set it to the number of bytes that the method successfully read. In the output buffer, set it to the number of bytes the method wrote. Setting these properties allows the next call to `process()` to resume reading and writing data at the correct points in the buffers.

Your `process()` method also needs to check the `InputState` object passed to it to determine if there is more data in the data source. When this object is equal to `END_OF_FILE`, then the data remaining in the input data is the last data in the data source. Once it has processed all of the remaining data, `process()` must return **DONE**.

## Tearing Down

COPY calls `destroy()` after the last time it calls `process()`. This method frees any resources reserved by the `setup()` or `process()` methods. Vertica calls this method after the `process()` method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call `setup()` on the object again. On subsequent calls Vertica directs the method to filter the data in a new data stream. Therefore, your `destroy()` method should leave an object of your `UDFilter` subclass in a state where the `setup()` method can prepare it to be reused.

### FilterFactory Class

If you write a filter, you must also write a filter factory to produce filter instances. To do so, subclass the `FilterFactory` class.

Your subclass performs the initial validation and planning of the function execution and instantiates `UDFilter` objects on each host that will be filtering data.
Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

FilterFactory Methods

The FilterFactory class defines the following methods. Your subclass must override the prepare() method. It may override the other methods.

Setting Up

Vertica calls plan() once on the initiator node, to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a ParamReader object from the instance of ServerInterface passed into your plan() method.

- Store any information that the individual hosts need in order to filter data in the PlanContext instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The plan() method runs only on the initiator node, and the prepare() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString.

Note: ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating Filters

Vertica calls prepare() to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to complete the work based on available resources. You cannot specify the nodes on which the work is done.
Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

User-Defined Parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use User-Defined Parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you could load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

COPY supports a single User-Defined Parser that you can use with a UDataSource and zero or more instances of UDFilter.

Sometimes you can improve the performance of your parser by adding a chunker. A chunker divides up the input and uses multiple threads to parse it. See Cooperative Parse. Chunkers are available only in the C++ API.

Under special circumstances you can further improve performance by using apportioned load, an approach where multiple Vertica nodes parse the input. See Apportioned Load.

If you implement a UDParser, you must also implement a corresponding ParserFactory. See UDParser Class and ParserFactory Class for API details.

UDParser Class

You can subclass the UDParser class when you need to parse data that is in a format that the COPY statement's native parser cannot handle.
During parser execution, Vertica always calls three methods: `setup()`, `process()`, and `destroy()`. It might also call `getRejectedRecord()`.

**UDParser Methods**

The `UDParser` class defines the following methods. Your subclass must override the `process()` and `getRejectedRecord()` methods. You can optionally override the other methods.

For the signatures of these methods and language-specific information, see Parser Classes (C++) and Parser Classes (Java).

**Note:** The `UDParser` class performs important initialization required by all subclasses, including initializing the `StreamWriter` object used by the parser. Therefore, your constructor must call `super()`.

**Setting Up**

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the `process()` method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

**Parsing**

COPY calls `process()` repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by `InputState`:

- **OK**: currently at the start of or in the middle of a stream
- **END_OF_FILE**: no further data is available.
- **END_OF Chunk**: the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.
- **START_OF_PORTION**: the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load. You can use the `getPortion()` method to access the offset and size of the portion.

- **END_OF_PORTION**: the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.

The `process()` method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is not automatically null-terminated.

A parser has an associated `StreamWriter` object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on `StreamWriter` to write that value to the output stream. See [Writing Data](#) for more information about these methods.

A single call to `process()` might write several rows of data. When your parser finishes processing a row of data, it must call `next()` on its `StreamWriter` to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your `process()` method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by `StreamState`:

- **INPUT_NEEDED**: the parser has reached the end of the buffer and needs more data to parse.

- **DONE**: the parser has reached the end of the input data stream.

- **REJECT**: the parser has rejected the last row of data it read (see [Rejecting Rows](#)).

## Tearing Down

COPY calls `destroy()` after the last time that `process()` is called. It frees any resources reserved by the `setup()` or `process()` method.
Vertica calls this method after the `process()` method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might remain. In such cases, Vertica might later call `setup()` on the object again and have it parse the data in a new data stream. Therefore, write your `destroy()` method so that it leaves an instance of your `UDParser` subclass in a state where `setup()` can be safely called again.

## Reporting Rejections

If `process()` rejects a row, Vertica calls `getRejectedRecord()` to report it. Usually, this method returns an instance of the `RejectedRecord` class with details of the rejected row.

### Writing Data

A parser has an associated `StreamWriter` object, which you access by calling `getStreamWriter()`. In your `process()` implementation, use the `setType()` methods on the `StreamWriter` object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type `long` to the fourth column (index 3) in the current row:

```java
StreamWriter writer = getStreamWriter();
...
writer.setLongValue(3, 98.6);
```

`StreamWriter` provides methods for all the basic types, such as `setBooleanValue()`, `setStringValue()`, and so on. See the API documentation for a complete list of `StreamWriter` methods, including options that take primitive types or explicitly set entries to null.

The Java API supports additional options for writing data. See Parser Classes.

### Rejecting Rows

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a `RejectedRecord` object, or in fields on your `UDParser` subclass, until they are needed.
2. Updating the row's position in the input buffer by updating `input.offset` so it can resume parsing with the next row.

3. Signaling that it has rejected a row by returning with the value `StreamState.REJECT`.

4. Returning an instance of the `RejectedRecord` class with the details about the rejected row.

Breaking Up Large Loads

Vertica provides two ways to break up large loads. Apportioned Load allows you to distribute a load among several database nodes. Cooperative Parse (C++ only) allows you to distribute a load among several threads on one node.

UDChunker Class

You can subclass the `UDChunker` class to allow your parser to support Cooperative Parse. This class is available only in the C++ API.

Fundamentally, a `UDChunker` is a very simplistic parser. Like `UDParser`, it has the following three methods: `setup()`, `process()`, and `destroy()`. You must override `process()`; you may override the others. This class has one additional method, `alignPortion()`, which you must implement if you want to enable Apportioned Load for your `UDChunker`.

For the signatures of these methods, see Parser Classes.

Setting Up and Tearing Down

As with `UDParser`, you can define initialization and cleanup code for your chunker. Vertica calls `setup()` before the first call to `process()` and `destroy()` after the last call to `process()`. Your object might be reused amongst multiple load sources, so make sure that `setup()` completely initializes all fields.

Chunking

Vertica calls `process()` to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:

- **OK**: the input buffer begins at the start of or in the middle of a stream.
- **END_OF_FILE**: no further data is available.
- **END_OF_PORTION**: the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is **END_OF_FILE**, the chunker should set the `input.offset` marker to `input.size` and return **DONE**. Returning **INPUT_NEEDED** is an error.

If the input state is **OK**, the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the `input.offset` marker with the byte after the end of the last record in the buffer and return **CHUNKAligned**. For example, if the input is "abc~def" and "~" is a record terminator, this method should set `input.offset` to 4, the position of "d". If `process()` reaches the end of the input without finding a record boundary, it should return **INPUT_NEEDED**.

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is **END_OF_PORTION**, the chunker should behave as it does for an input state of **OK**, except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The `process()` method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return **KEEP_GOING**. Failing to return **KEEP_GOING** has several consequences, such as preventing your user from being able to cancel the query.

See **Chunker Example: Delimited Parser and Chunker** for an example of the `process()` method using chunking.

**Aligning Portions**

If your chunker supports apportioned load, implement the `alignPortion()` method. Vertica calls this method one or more times, before calling `process()`, to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

- **START_OF_PORTION**: the beginning of the buffer corresponds to the start of the portion. You can use the `getPortion()` method to access the offset and size of the portion.
- **OK**: the input buffer is in the middle of a portion.
- **END_OF_PORTION**: the end of the buffer corresponds to the end of the portion or beyond the end of a portion.

- **END_OF_FILE**: no further data is available.

The method should scan from the beginning of the buffer to the start of the first complete record. It should set `input.offset` to this position and return one of the following values:

- **DONE**, if it found a chunk. `input.offset` is the first byte of the chunk.

- **INPUT_NEEDED**, if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of **END_OF_FILE**.

- **REJECT**, if the portion (not buffer) does not contain the start of any chunk.

### ParserFactory Class

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the **ParserFactory** class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The **ParserFactory** class defines the following methods. Your subclass must override the **prepare()** method. It may override the other methods.

### Setting Up

Vertica calls **plan()** once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a **ParamReader** object from the instance of **ServerInterface** passed into your **plan()** method.

- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the **PlanContext** instance passed in through the **planCtxt** parameter. The **plan()** method runs only on the initiator node, and the **prepareUDSources()** method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.
You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString.

Note: ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating Parsers

Vertica calls prepare() on each node to create and initialize your parser, using data stored by the plan() method.

Defining Parameters

Implement getParameterTypes() to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Defining Parser Outputs

Implement getParserReturnType() to define the data types of the table columns that the parser outputs. If applicable, getParserReturnType() also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the argType and perColumnParamReader arguments and verifies that it can output the appropriate data types. If getParserReturnType() is prepared to output the data types, it calls methods on the SizedColumnTypes object passed in the returnType argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as CHAR, VARCHAR, and LONG VARBINARY), specify its maximum length.
- For NUMERIC types, specify its precision and scale.
- For Time/Timestamp types (with or without time zone), specify its precision (-1 means
unspecified).

- For all other types, no length or precision specification is required.

Supporting Cooperative Parse

To support Cooperative Parse, implement prepareChunker() and return an instance of your UDCunker subclass. If isChunkerApportionable() returns true, then it is an error for this method to return null.

Cooperative parse is currently supported only in the C++ API.

Supporting Apportioned Load

To support Apportioned Load, your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement isParserApportionable() and return true. To indicate that the chunker can apportion a load, implement isChunkerApportionable() and return true.

The isChunkerApportionable() method takes a ServerInterface as an argument, so you have access to the parameters supplied in the COPY statement. You might need this information if the user can specify a record delimiter, for example. Return true from this method if and only if the factory can create a chunker for this input.

Load Parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- Distributed load: Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.

- Cooperative parse: A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See Cooperative Parse.

- Apportioned load: Vertica; divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load divides the load at
planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See Apportioned Load.

You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See Combining Cooperative Parse and Apportioned Load.

Cooperative Parse

By default, Vertica parses a data source in a single thread on one database node. You can optionally use cooperative parse to parse a source using multiple threads on a node. More specifically, data from a source passes through a chunker that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDx. (See Fenced Mode.)

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.

Chunks are created by parser factories. At load time, Vertica first calls the UDChunker to divide the input into chunks and then calls the UDParser to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See Combining Cooperative Parse and Apportioned Load.

How Vertica Divides a Load

When Vertica receives data from a source, it calls the chunker's process() method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the process() method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the process() method on the parser.

Implementing Cooperative Parse

To implement cooperative parse, perform the following actions:

- Subclass UDChunker and implement process().
- In your ParserFactory, implement prepareChunker() to return a UDChunker.
See Chunker Example: Delimited Parser and Chunker for a UDChunker that also supports apportioned load.

**Apportioned Load**

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as *apportioned load*. Some of the parsers built into Vertica support apportioned load.

Apportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

It is possible for a parser to not support apportioned load directly but to have a chunker that supports apportioning.

You can use apportioned load and cooperative parse independently or together. See Combining Cooperative Parse and Apportioned Load.

**How Vertica Apportions a Load**

If both the parser and its source support apportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The SourceFactory breaks the input into portions and assigns them to execution nodes. Each Portion consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a UDSource for the given portion.

The UDParser first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
- If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.

The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that *begin* in the assigned portion, regardless of where they end. Most of this work occurs within the *process()* method of the parser.
Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses Cooperative Parse, then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

Implementing Apportioned Load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

In your SourceFactory subclass:

- Implement isSourceApportionable() and return true.

- Implement plan() to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter writer on the plan context (PlanContext::getWriter()).

- Implement prepareUDSources(). Vertica calls this method on each execution node with the plan context created by the factory. This method returns the UDSource instances to be used for this node's assigned portions.

- If sources can take advantage of parallelism, you can implement getDesiredThreads() to request a number of threads for each source. See SourceFactory Class for more information about this method.

In your UDSource subclass, implement process() as you would for any other source, using the assigned portion. You can retrieve this portion with getPortion().

In your ParserFactory subclass:

- Implement isParserApportionable() and return true.

- If your parser uses a UDChunker that supports apportioned load, implement isChunkerApportionable().

In your UDParse subclass:

- Write your UDParse subclass to operate on portions rather than whole sources. You can do so by handling the stream states PORTION_START and PORTION_END, or by using the
ContinuousUDParser API. Your parser must scan for the beginning of the portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.

- Handle the special case of a portion containing no record start by returning without writing any output.

In your UDChunker subclass, implement alignPortion(). See Aligning Portions.

Example

The SDK provides a C++ example of apportioned load in the ApportionLoadFunctions directory:

- FilePortionSource is a subclass of UDSource.
- DelimFilePortionParser is a subclass of ContinuousUDParser.

Use these classes together. You could also use FilePortionSource with the built-in delimited parser.

The following example shows how you can load the libraries and create the functions in the database:

```sql
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';
=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';
=> CREATE SOURCE FilePortionSource AS
   LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;
=> CREATE PARSER DelimFilePortionParser AS
   LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```sql
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSER DelimFilePortionParser(delimiter = '|', record_terminator = '~');
```

Combining Cooperative Parse and Apportioned Load

You can enable both Cooperative Parse and Apportioned Load in the same parser, allowing Vertica to decide how to load data.
Deciding How to Divide a Load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires SourceFactory support. Given a suitable UDSource, at planning time Vertica calls the isParserApportionable() method on the ParserFactory. If this method returns true, Vertica apportions the load.

If isParserApportionable() returns false but isChunkerApportionable() returns true, then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apports the load.

If neither of these methods returns true, then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.

If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but prepareChunker() does not return a UDChunker instance, Vertica reports an error.

Executing Apportioned, Cooperative Loads

If a load uses both apportioned load and cooperative parse, Vertica uses the SourceFactory to break the input into portions. It then assigns the portions to execution nodes. See How Vertica Apportions a Load.

On the execution node, Vertica calls the chunker's alignPortion() method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's process() method repeatedly. See How Vertica Divides a Load.
The chunks found by the chunker are then sent to the parser's `process()` method for processing in the usual way.

**Continuous Load**

The `ContinuousUDSource`, `ContinuousUDFilter`, and `ContinuousUDParser` classes allow you to write and process data as needed instead of having to iterate through the data.

Each class includes the following functions:

- `initialize()` - Invoked before `run()`. You can optionally override this function to perform setup and initialization.
- `run()` - Processes the data.
- `deinitialize()` - Invoked after `run()` has returned. You can optionally override this function to perform tear-down and destruction.
