Java Virtual Machines (JVMs) allocate a set amount of memory when they start. This set memory allocation complicates memory management for Java UDxs, because memory cannot
be dynamically allocated and freed by the UDx as it is processing data. This is differs from C++ UDxs which can dynamically allocate resources.

To control the amount of memory consumed by Java UDxs, Vertica has a memory pool named jvm that it uses to allocate memory for JVMs. If this memory pool is exhausted, queries that call Java UDxs block until enough memory in the pool becomes free to start a new JVM.

By default, the jvm pool has:

- no memory of its own assigned to it, so it borrows memory from the GENERAL pool.
- its MAXMEMORYSIZE set to either 10% of system memory or 2GB, whichever is smaller.
- its PLANNEDCONCURRENCY set to AUTO, so that it inherits the GENERAL pool's PLANNEDCONCURRENCY setting.

You can view the current settings for the jvm pool by querying the RESOURCE_POOLS table:

```
=> SELECT MAXMEMORYSIZE, PLANNEDCONCURRENCY FROM V_CATALOG.RESOURCE_POOLS WHERE NAME = 'jvm';
```

```
MAXMEMORYSIZE | PLANNEDCONCURRENCY
---------------+------------------
10%             | AUTO
```

When a SQL statement calls a Java UDx, Vertica checks if the jvm memory pool has enough memory to start a new JVM instance to execute the function call. Vertica starts each new JVM with its heap memory size set to approximately the jvm pool's MAXMEMORYSIZE parameter divided by its PLANNEDCONCURRENCY parameter. If the memory pool does not contain enough memory, the query blocks until another JVM exits and return their memory to the pool.

If your Java UDx attempts to consume more memory than has been allocated to the JVM's heap size, it exits with a memory error. You can attempt to resolve this issue by:

- increasing the jvm pool's MAXMEMORYSIZE parameter.
- decreasing the jvm pool's PLANNEDCONCURRENCY parameter.
- changing your Java UDx's code to consume less memory.

**Adjusting the jvm Pool**

When adjusting the jvm pool to your needs, you must consider two factors:

- the amount of RAM your Java UDx requires to run
- how many concurrent Java UDx functions you expect your database to run
You can learn the amount of memory your Java UDx needs using several methods. For example, your code can use Java's Runtime class to get an estimate of the total memory it has allocated and then log the value using ServerInterface.log(). (An instance of this class is passed to your UDx.) If you have multiple Java UDxs in your database, set the jvm pool memory size based on the UDx that uses the most memory.

The number of concurrent sessions that need to run Java UDxs may not be the same as the global PLANNEDCONCURRENCY setting. For example, you may have just a single user who runs a Java UDx, which means you can lower the jvm pool's PLANNEDCONCURRENCY setting to 1.

When you have an estimate for the amount of RAM and the number of concurrent user sessions that need to run Java UDxs, you can adjust the jvm pool to an appropriate size. Set the pool's MAXMEMORYSIZE to the maximum amount of RAM needed by the most demanding Java UDx multiplied by the number of concurrent user sessions that need to run Java UDxs. Set the pool's PLANNEDCONCURRENCY to the number of simultaneous user sessions that need to run Java UDxs.

For example, suppose your Java UDx requires up to 4GB of memory to run and you expect up to two user sessions use Java UDx/s. You would use the following command to adjust the jvm pool:

```sql
=> ALTER RESOURCE POOL jvm MAXMEMORYSIZE '8G' PLANNEDCONCURRENCY 2;
```

The MEMORYSIZE is set to 8GB, which is the 4GB maximum memory use by the Java UDx multiplied by the 2 concurrent user sessions.

**Note:** The PLANNEDCONCURRENCY value is not the number of calls to Java UDx that you expect to happen simultaneously. Instead, it is the number of concurrently open user sessions that call Java UDxs at any time during the session. See below for more information.

See Managing Workloads in the Administrator's Guide for more information on tuning the jvm and other resource pools.

**Freeing JVM Memory**

The first time users call a Java UDx during their session, Vertica allocates memory from the jvm pool and starts a new JVM. This JVM remains running for as long as the user's session is open so it can process other Java UDx calls. Keeping the JVM running lowers the overhead of executing multiple Java UDxs by the same session. If the JVM did not remain open, each call to a Java UDx would require additional time for Vertica to allocate resources and start a new JVM. However, having the JVM remain open means that the JVM’s memory remains allocated for the life of the session whether or not it will be used again.
If the JVM memory pool is depleted, queries containing Java UDxs either block until memory becomes available or eventually fail due a lack of resources. If you find queries blocking or failing for this reason, you can allocate more memory to the JVM pool and increase its PLANNEDCONCURRENCY. Another option is to ask users to call the RELEASE_JVM_MEMORY function when they no longer need to run Java UDxs. This function closes any JVM belonging to the user's session and returns its allocated memory to the JVM memory pool.

The following example demonstrates querying V_MONITOR.SESSIONS to find the memory allocated to JVMs by all sessions. It also demonstrates how the memory is allocated by a call to a Java UDx, and then freed by calling RELEASE_JVM_MEMORY.

```
 => SELECT USER_NAME, EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 user_name | external_memory_kb
-----------|------------------------
 dbadmin   | 0                      
 (1 row)

 => -- Call a Java UDx
 => SELECT add2ints(123,456);
 add2ints
 579
 (1 row)

 => -- JVM is now running and memory is allocated to it.
 => SELECT USER_NAME, EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 user_name | external_memory_kb
-----------|------------------------
 dbadmin   | 79785                  
 (1 row)

 => -- Shut down the JVM and deallocate memory
 => SELECT RELEASE_JVM_MEMORY();
 RELEASE_JVM_MEMORY

 Java process killed and memory released
 (1 row)

 => SELECT USER_NAME, EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 user_name | external_memory_kb
-----------|------------------------
 dbadmin   | 0                      
 (1 row)
```

In rare cases, you may need to close all JVMs. For example, you may need to free memory for an important query, or several instances of a Java UDx may be taking too long to complete. You can use the RELEASE_ALL_JVM_MEMORY to close all of the JVMs in all user sessions:

```
 => SELECT USER_NAME, EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 user_name | external_memory_kb
-----------|------------------------
 ExampleUser | 79705                  
 dbadmin     | 79705                  
 (2 rows)
```
Caution: This function terminates all JVMs, including ones that are currently executing Java UDXs. This will cause any query that is currently executing a Java UDX to return an error.

Notes

- The jvm resource pool is used only to allocate memory for the Java UDX function calls in a statement. The rest of the resources required by the SQL statement come from other memory pools.

- The first time a Java UDX is called, Vertica starts a JVM to execute some Java methods to get metadata about the UDX during the query planning phase. The memory for this JVM is also taken from the jvm memory pool.

Developing with the Python SDK

The Vertica SDK supports writing UDXs of some types in Python 3.

The Python SDK does not require any additional system configuration or header files. This low overhead allows you to develop and deploy new capabilities to your Vertica cluster in a short amount of time.

The following workflow is typical for the Python SDK:

```
=> SELECT RELEASE_ALL_JVM_MEMORY();
RELEASE_ALL_JVM_MEMORY
---------------------------------------------
Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITORSESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
-----------|-----------------------
dbadmin | 0
(1 row)
```
Because Python is an interpreted language, you do not have to compile your program before loading the UDx in Vertica. However, you should expect to do some debugging of your code after you create your function and begin testing it in Vertica.

This section covers Python-specific topics that apply to all UDx types. For information that applies to all languages, see Handling Different Numbers and Types of Arguments, UDx Parameters, Handling Cancel Requests and the sections for specific Types of UDxs. For full API documentation, see the Python SDK Documentation.

Python Libraries

Before you can use your Python UDx, you need to verify that it meets the following library requirements:

- Your UDx must import the `vertica_sdk` package in your code. You do not need to download this package. It is included as a part of the Vertica server.

```python
import vertica_sdk
```

- The Vertica Python SDK includes the Python Standard Library. Be aware that importing a package other than the Python Standard Library results in failure.

Python and Vertica Data Types

The Vertica Python SDK converts native Vertica data types into the appropriate Python data types, as follows:

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Python Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>int</td>
</tr>
<tr>
<td>FLOAT</td>
<td>float</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>decimal.Decimal</td>
</tr>
<tr>
<td>DATE</td>
<td>datetime.date</td>
</tr>
<tr>
<td>CHAR, VARCHAR, LONG VARCHAR</td>
<td>string (UTF-8 encoded)</td>
</tr>
<tr>
<td>BINARY, VARBINARY, LONG VARBINARY</td>
<td>binary</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>datetime.datetime</td>
</tr>
</tbody>
</table>
### Vertica Data Type

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Python Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME</td>
<td>datetime.time</td>
</tr>
</tbody>
</table>

**Note:** Some Vertica Analytic Database data types are not supported in Python.

### Handling Errors

If your UDx encounters an unrecoverable error, it should throw a `UdfException`. The exception triggers a rollback of the function call. In Python, this function rollback occurs when the UDx raises an exception.

The following code shows how you can add error checking to your UDx. In this example, if one of the arguments is less than 100, then the Python UDx throws an error.

```python
while(True):
    # Example of error checking best practices.
    product_id = block_reader.getInt(2)
    if product_id < 100:
        raise ValueError("Invalid Product ID")
```

When an exception is raised in your Python UDx, the UDx throws a `UdfException` and generates an error message.

```sql
=> SELECT add2ints(prod_cost, sale_price, product_id) FROM bunch_of_numbers;
ERROR 3399: Failure in UDx RPC call InvokeProcessBlock(): Error calling processBlock() in User Defined Object [add2ints]
 at [/scratch_a/release/svrtar11244/vbuild/vertica/OSS/UDxFence/PythonInterface.cpp:168], error code: 0,
 message: Error [/scratch_a/release/svrtar11244/vbuild/vertica/OSS/UDxFence/PythonInterface.cpp:385]

- [Writing Messages to Log Files](#)
Writing Messages to Log Files

Writing messages to a log can help you when you debug your Python UDxs and want to output additional information about an error condition.

To write a message to the vertica log file, use the server_interface.log() function:

```python
def processBlock(self, server_interface, arg_reader, res_writer):
    server_interface.log("Python UDx - Adding 2 ints!")
    while(True):
        first_int = block_reader.getInt(0)
        second_int = block_reader.getInt(1)
        block_writer.setInt(first_int + second_int)
        server_interface.log("Values: first_int is {} second_int is {}".format(first_int, second_int))
        block_writer.next()
    if not block_reader.next():
        break
```

Vertica writes the messages to a log file stored in the catalog directory's UDxLog subdirectory, which is named UDxFencedProcesses.log:

```bash
$ tail /home/dbadmin/py_db/v_py_db_node0001_catalog/UDxLogs/UDxFencedProcesses.log
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 PythonExecContext::processBlock
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Python UDx - Adding 2 ints!
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Values: first_int is 100 second_int is 100
```

Vertica adds the SQL name of the UDx to the log message. It also adds the string [UserMessage] to mark the entry as a message added by a call to the server_interface.log() function. These additions allow you to filter the log to find the messages generated by your UDx.

Handling Errors

Developing with the R SDK

The Vertica R SDK extends the capabilities of the Vertica Analytic Database so you can leverage additional R libraries. Before you can begin developing User Defined Extensions (UDxs) in R, you must install the R Language Pack for Vertica on each of the nodes in your cluster. The R
SDK supports scalar and transform functions in fenced mode. Other UDx types are not supported.

The following workflow is typical for the R SDK:

You can find detailed documentation of all of the classes in the Vertica R SDK API Documentation.

Installing/Upgrading the R Language Pack for Vertica

To create R UDxs in Vertica, install the R Language Pack package that matches your server version. The R Language Pack includes the R runtime and associated libraries for interfacing with Vertica.

You must install the R Language Pack on each node in the cluster. The Vertica R Language Pack must be the only R Language Pack installed on the node.

Vertica R Language Pack Prerequisites

The R Language Pack package requires a number of packages for installation and execution. The names of these dependencies vary among Linux distributions. For Vertica supported Linux platforms the packages are:

- RHEL/CentOS: libfortran, xz-libs, libgomp
- SUSE Linux Enterprise Server: libfortran3, liblzma5, libgomp1
- Debian/Ubuntu: libfortran3, liblzma5, libgomp1
- Amazon Linux 2.0: compat-gcc-48-libgfortran, xz-libs, libgomp

Installing the Vertica R Language Pack

If you use your operating systems package manager, rather than the rpm or dpkg command, for installation, you do not need to manually install the R Language Pack. The native package
managers for each supported Linux version are:

- RHEL/CentOS: yum
- SUSE Linux Enterprise Server: zypper
- Debian/Ubuntu: apt-get
- Amazon Linux 2.0: yum

1. Download the R language package by going to the myVertica portal, clicking the downloads tab, and selecting the `vertica-R-lang_<version>.rpm` (or `vertica-R-lang_<version>.deb`) file for your server version. The R language package version must match your server version to three decimal points.

2. Install the package as root or using `sudo`:

   - **RHEL/CentOS**
     ```
     $ yum install vertica-R-lang_<version>.rpm
     ```

   - **SUSE Linux Enterprise Server**
     ```
     $ zypper install vertica-R-lang_<version>.rpm
     ```

   - **Debian**
     ```
     $ apt-get install ./vertica-R-lang_<version>.deb
     ```

   - **Amazon Linux 2.0**
     ```
     $ yum install vertica-R-lang_<version>.AMZN.rpm
     ```

   The installer puts the R binary in `/opt/vertica/R`.

### Upgrading the Vertica R Language Pack

When upgrading, some R packages you have manually installed may not work and may have to be reinstalled. If you do not update your package(s), then R returns an error if the package cannot be used. Instructions for upgrading these packages are below.

**Note:** The R packages provided in the R Language Pack are automatically upgraded and do not need to be reinstalled.
1. You must uninstall the R Language package before upgrading Vertica. Any additional R packages you manually installed remain in /opt/vertica/R and are not removed when you uninstall the package.

2. Upgrade your server package as detailed in Upgrading Vertica to a New Version.

3. After the server package has been updated, install the new R Language package on each host.

If you have installed additional R packages, on each node:

1. As root run /opt/vertica/R/bin/R and issue the command:

   ```
   > update.packages(checkBuilt=TRUE)
   ```

2. Select a CRAN mirror from the list displayed.

3. You are prompted to update each package that has an update available for it. You must update any packages that you manually installed and are not compatible with the current version of R in the R Language Pack.

   Do NOT update:
   - Rcpp
   - RInside

   The packages you selected to be updated are installed. Quit R with the command:
   ```
   > quit()
   ```

   Vertica UDx functions written in R do not need to be compiled and you do not need to reload your Vertica-R libraries and functions after an upgrade.

### R Packages

The Vertica R Language Pack includes the following R packages in addition to the default packages bundled with R:

- Rcpp
- RInside
You can install additional R packages not included in the Vertica R Language Pack by using one of two methods. You must install the same packages on all nodes.

### Installing R Packages

You can install additional R packages by using one of the two following methods.

**Using the `install.packages()` R command:**

```bash
$ sudo /opt/vertica/R/bin/R
> install.packages("Zelig");
```

**Using CMD INSTALL:**

```
/opt/vertica/R/bin/R CMD INSTALL <path-to-package-tgz>
```

The installed packages are located in: `/opt/vertica/R/library`

### R and Vertica Data Types

The following data types are supported when passing data to/from an R UDx:

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>R Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>logical</td>
</tr>
<tr>
<td>DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP, TIMESTAMPZ, TIMETZ</td>
<td>numeric</td>
</tr>
<tr>
<td>DOUBLE PRECISION, FLOAT, REAL</td>
<td>numeric</td>
</tr>
<tr>
<td>BIGINT, DECIMAL, INT, NUMERIC, NUMBER, MONEY</td>
<td>numeric</td>
</tr>
<tr>
<td>BINARY, VARBINARY</td>
<td>character</td>
</tr>
<tr>
<td>CHAR, VARCHAR</td>
<td>character</td>
</tr>
</tbody>
</table>

NULL values in Vertica are translated to R NA values when sent to the R function. R NA values are translated into Vertica null values when returned from the R function to Vertica.
Important: When specifying LONG VARCHAR or LONG VARBINARY data types, include the space between the two words. For example, datatype = c("long varchar").

Handling Errors

If your UDx encounters an unrecoverable error, it should throw a UdfException. The error triggers a rollback of the function call. In R, this function rollback occurs when the UDx executes an error action.

The following code shows how you can add error checking to your UDx. In this example, if the third column of the data frame does not match the specified Product ID, then the R UDx throws an error.

```r
Calculate_Cost_w_Tax <- function(input.data.frame) {
  # Must match the Product ID 11444
  if ( !is.numeric(input.data.frame[, 3]) == 11444 ) {
    stop("Invalid Product ID!")
  } else {
    cost_w_tax <- data.frame(input.data.frame[, 1] * input.data.frame[, 2])
  }
  return(cost_w_tax)
}
```

When an exception is raised in your R UDx, the UDx throws a UdfException and generates an error message.

```
=> SELECT Calculate_Cost_w_Tax(item_price, tax_rate, prod_id) FROM Inventory_Sales_Data;
```

```
```

Adding Metadata to R Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the `USER_LIBRARIES` system table after your library has been loaded into the Vertica Analytic Database catalog.
You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```c
RegisterLibrary(author, library_build_tag, library_version, library_sdk_version, source_url, description, licenses_required, signature);
```

- **author** contains whatever name you want associated with the creation of the library (your own name or your company's name for example).

- **library_build_tag** is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.

- **library_version** is the version of your library. You can use whatever numbering or naming scheme you want.

- **library_sdk_version** is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

  **Note:** This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- **source_url** is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.

- **description** is a concise description of your library.

- **licenses_required** is a placeholder for licensing information. You must pass an empty string for this value.

- **signature** is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.
The following example shows how to add metadata to an R UDx.

```r
```

Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to `RegisterLibrary`:

```sql
CREATE LIBRARY rLib AS '/home/dbadmin/sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'rLib';
- [ RECORD 1 ]-+-----------------------------------------------------------------+
schema_name | public
lib_name     | rLib
lib_oid      | 45035996273708350

sal_storage_id | 02552872a35d9352b4907d3fcd03cf9700a000000000d3e
```

Setting Null Input and Volatility Behavior for R Functions

Vertica supports defining volatility and null-input settings for UDxs written in R. Both settings aid in the performance of your R function.

Volatility Settings

Volatility settings describe the behavior of the function to the Vertica optimizer. For example, if you have identical rows of input data and you know the UDx is immutable, then you can define the UDx as IMMUTABLE. This tells the Vertica optimizer that it can return a cached value for subsequent identical rows on which the function is called rather than having the function run on each identical row.
To indicate your UDx's volatility, set the volatility parameter of your R factory function to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLATILE</td>
<td>Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.</td>
</tr>
<tr>
<td>IMMUTABLE</td>
<td>Calls to the function with the same arguments always results in the same return value.</td>
</tr>
<tr>
<td>STABLE</td>
<td>Repeated calls to the function with the same arguments within the same statement returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.</td>
</tr>
<tr>
<td>DEFAULT_VOLATILITY</td>
<td>The default volatility. This is the same as VOLATILE.</td>
</tr>
</tbody>
</table>

If you do not define a volatility, then the function is considered to be VOLATILE.

The following example sets the volatility to STABLE in the multiplyTwoIntsFactory function:

```r
multiplyTwoIntsFactory <- function() {
  list(name = multiplyTwoInts,
       udxtype = c("scalar"),
       intype = c("float","float"),
       outtype = c("float"),
       volatility = c("stable"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```

**Null Input Behavior**

Null input setting determine how to respond to rows that have null input. For example, you can choose to return null if any inputs are null rather than calling the function and having the function deal with a NULL input.

To indicate how your UDx reacts to NULL input, set the strictness parameter of your R factory function to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLED_ON_NULL_INPUT</td>
<td>The function must be called, even if one or more arguments are NULL.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RETURN_NULL_ON_NULL_INPUT</td>
<td>The function always returns a NULL value if any of its arguments are NULL.</td>
</tr>
<tr>
<td>STRICT</td>
<td>A synonym for RETURN_NULL_ON_NULL_INPUT</td>
</tr>
<tr>
<td>DEFAULT_STRINGNESS</td>
<td>The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.</td>
</tr>
</tbody>
</table>

If you do not define a null input behavior, then the function is called on every row of data regardless of the presence of NULL values.

The following example sets the NULL input behavior to STRICT in the multiplyTwoIntsFactory function:

```r
multiplyTwoIntsFactory <- function() {
  list(name = multiplyTwoInts,
       udxtype = c("scalar"),
       intype = c("float","float"),
       outtype = c("float"),
       strictness = c("strict"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```
Aggregate Functions (UDAFs)

Aggregate functions perform an operation on a set of values and return one value. Vertica provides standard built-in aggregate functions such as AVG, MAX, and MIN. User-Defined Aggregate Functions work similarly to the built-in aggregate functions.

User-Defined Aggregate Functions:

- Support a single input column (or set) of values and provide a single output column.
- Support RLE decompression; RLE input is decompressed before it is sent to a UDAF.
- Can be used with the GROUP BY and HAVING clauses. Only columns appearing in the GROUP BY clause can be selected.
- Cannot be used with correlated subquery.

UDAFs are available for C++ only.

UDAF Class Overview

You create your UDAF by subclassing two classes defined by the Vertica SDK: AggregateFunction and AggregateFunctionFactory.

AggregateFunction

The AggregateFunction class performs the aggregation. It computes values on each database node where relevant data is stored and then combines the results from the nodes. You must implement the following methods:

- initAggregate() - Initializes the class, defines variables, and sets the starting value for the variables. This function must be idempotent.
- aggregate() - The main aggregation operation, executed on each node.
- combine() - If multiple invocations of aggregate() are needed, Vertica calls combine() to combine all the sub-aggregations into a final aggregation. Although this method might
not be called, you must define it.

- `terminate()` - Terminates the function and returns the result as a column.

**Important:** The `aggregate()` function might not operate on the complete input set all at once. For this reason, `initAggregate()` must be idempotent.

The `AggregateFunction` class also provides optional methods that you can implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDAF API (see [Allocating Resources for UDxs](https://www.vertica.com/docs/9.1.x/VerticaAnalyticDatabase/VerticaAnalyticDatabase_9.1.x.pdf) for details).

### AggregateFunctionFactory

The `AggregateFunctionFactory` class specifies metadata information such as the argument and return types of your aggregate function. It also instantiates your `AggregateFunction` subclass. Your subclass must implement the following methods:

- `getPrototype()` - Defines the number of parameters and data types accepted by the function. There is a single parameter for aggregate functions.

- `getIntermediateTypes()` - Defines the intermediate variable(s) used by the function. These variables are used when combining the results of `aggregate()` calls.

- `getParameterType()` - Defines the names and types of parameters that this function uses (optional).

- `getReturnType()` - Defines the type of the output column.

Vertica uses this data when you call the `CREATE AGGREGATE FUNCTION` SQL statement to add the function to the database catalog.

### UDAF Performance in Statements Containing a GROUP BY Clause

You may see slower-than-expected performance from your UDAF if the SQL statement calling it also contains a **GROUP BY Clause**. For example:

```
=> SELECT a, MYUDAF(b) FROM sampletable GROUP BY a;
```
In statements like this one, Vertica does not consolidate row data together before calling your UDAF's `aggregate()` method. Instead, it calls `aggregate()` once for each row of data. Usually, the overhead of having Vertica consolidate the row data is greater than the overhead of calling `aggregate()` for each row of data. However, if your UDAF's `aggregate()` method has significant overhead, then you might notice an impact on your UDAF's performance.

For example, suppose `aggregate()` allocates memory. When called in a statement with a GROUP BY clause, it performs this memory allocation for each row of data. Because memory allocation is a relatively expensive process, this allocation can impact the overall performance of your UDAF and the query.

There are two ways you can address UDAF performance in a statement containing a GROUP BY clause:

- Reduce the overhead of each call to `aggregate()`. If possible, move any allocation or other setup operations to the UDAF's `setup()` function.
- Declare a special parameter that tells Vertica to group row data together when calling a UDAF. This technique is explained below.

### Using the _minimizeCallCount Parameter

Your UDAF can tell Vertica to always batch row data together to reduce the number of calls to its `aggregate()` method. To trigger this behavior, your UDAF must declare an integer parameter named `_minimizeCallCount`. You do not need to set a value for this parameter in your SQL statement. The fact that your UDAF declares this parameter triggers Vertica to group row data together when calling `aggregate()`.

You declare the `_minimizeCallCount` parameter the same way you declare other UDx parameters. See UDx Parameters for more information.

**Important:** Always test the performance of your UDAF before and after implementing the `_minimizeCallCount` parameter to ensure that it improves performance. You might find that the overhead of having Vertica group row data for your UDAF is greater than the cost of the repeated calls to `aggregate()`.

### C++ API

This section provides APIs and examples for the C++ API for UDAFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.
AggregateFunction and AggregateFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDAF Class Overview for general information about implementing the AggregateFunction and AggregateFunctionFactory classes.

AggregateFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
                   const SizedColumnTypes &argTypes);
virtual void initAggregate(ServerInterface &srvInterface, IntermediateAggs &aggs)=0;
void aggregate(ServerInterface &srvInterface, BlockReader &arg_reader,
                IntermediateAggs &aggs);
virtual void combine(ServerInterface &srvInterface, IntermediateAggs &aggs_output,
                     MultipleIntermediateAggs &aggs_other)=0;
virtual void terminate(ServerInterface &srvInterface, BlockWriter &res_writer,
                       IntermediateAggs &aggs);
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AggregateFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual AggregateFunction *
    createAggregateFunction ServerInterface &srvInterface)=0;
virtual void getPrototype(ServerInterface &srvInterface,
                           ColumnTypes &argTypes, ColumnTypes &returnType)=0;
virtual void getIntermediateTypes(ServerInterface &srvInterface,
                                   const SizedColumnTypes &inputTypes, SizedColumnTypes &intermediateTypeMetaData)=0;
virtual void getReturnType(ServerInterface &srvInterface,
                           const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;
virtual void getParameterType(ServerInterface &srvInterface,
                             SizedColumnTypes &parameterTypes);
```
C++ Example: Average

The `Average` aggregate function created in this example computes the average of values in a column.

You can find the source code used in this example on the Vertica GitHub page.

Loading the Example

Use `CREATE LIBRARY` and `CREATE AGGREGATE FUNCTION` to declare the function:

```sql
=> CREATE LIBRARY AggregateFunctions AS
'/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE aggregate function ag_avg AS LANGUAGE 'C++'
name 'AverageFactory' library AggregateFunctions;
CREATE AGGREGATE FUNCTION
```

Using the Example

Use the function as part of a SELECT statement:

```sql
=> SELECT * FROM average;
   id | count
   ---+-------
    A |  8
    B |  3
    C |  6
    D |  2
    E |  9
    F |  7
    G |  5
    H |  4
    I |  1
(9 rows)
=> SELECT ag_avg(count) FROM average;
ag_avg
-------
   5
(1 row)
```

AggregateFunction Implementation

This example adds the input argument values in the `aggregate()` method and keeps a counter of the number of values added. The server runs `aggregate()` on every node and different data chunks, and combines all the individually added values and counters in the
combine() method. Finally, the average value is computed in the terminate() method by dividing the total sum by the total number of values processed.

For this discussion, assume the following environment:

- A three-node Vertica cluster
- A table column that contains nine values that are evenly distributed across the nodes. Schematically, the nodes look like the following figure:
<table>
<thead>
<tr>
<th>Node</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node 1</td>
<td>1, 2, 3</td>
</tr>
<tr>
<td>Node 2</td>
<td>4, 5, 6</td>
</tr>
<tr>
<td>Node 3</td>
<td>7, 8, 9</td>
</tr>
</tbody>
</table>
The function uses sum and count variables. *Sum* contains the sum of the values, and *count* contains the count of values.

First, `initAggregate()` initializes the variables and sets their values to zero.

```c++
virtual void initAggregate(ServerInterface &srvInterface,
                          IntermediateAggs &aggs)
{
  try {
    VNumeric &sum = aggs.getNumericRef(0);
    sum.setZero();

    vint &count = aggs.getIntRef(1);
    count = 0;
  }
  catch (std::exception &e) {
    vt_report_error(0, "Exception while initializing intermediate aggregates: [% s]", e.what());
  }
}
```

The `aggregate()` function reads the block of data on each node and calculates partial aggregates.

```c++
void aggregate(ServerInterface &srvInterface,
               BlockReader &argReader,
               IntermediateAggs &aggs)
{
  try {
    VNumeric &sum = aggs.getNumericRef(0);
    vint &count = aggs.getIntRef(1);

    do {
      const VNumeric &input = argReader.getNumericRef(0);
      if (!input.isNull()) {
        sum.accumulate(&input);
        count++;
      }
    } while (argReader.next());
  } catch (std::exception &e) {
    vt_report_error(0, " Exception while processing aggregate: [% s]", e.what());
  }
}
```

Each completed instance of the `aggregate()` function returns multiple partial aggregates for sum and count. The following figure illustrates this process using the `aggregate()` function:
Node 1
Values 1,2,3

aggregate()
sum = 6; count = 3

initAggregate()
sum = 0; count = 0

Node 2
Values 4,5,6

aggregate()
sum = 15; count = 3

Node 3
Values 7,8,9

aggregate()
sum = 24; count = 3
The `combine()` function puts together the partial aggregates calculated by each instance of the average function.

```cpp
virtual void combine(ServerInterface &srvInterface,
                      IntermediateAggs &aggs,
                      MultipleIntermediateAggs &aggsOther)
{
    try {
        VNumeric &mySum = aggs.getNumericRef(0);
        vint &myCount = aggs.getIntRef(1);
        do {
            const VNumeric &otherSum = aggsOther.getNumericRef(0);
            const vint &otherCount = aggsOther.getIntRef(1);
            mySum.accumulate(&otherSum);
            myCount += otherCount;
        } while (aggsOther.next());
    } catch (std::exception &e) {
        vt_report_error(0, "Exception while combining intermediate aggregates: [\%s]", e.what());
    }
}
```

The following figure shows how each partial aggregate is combined:
After all input has been evaluated by the `aggregate()` function Vertica calls the `terminate()` function. It returns the average to the caller.
virtual void terminate(ServerInterface &srvInterface,
    BlockWriter &resWriter,
    IntermediateAggs &aggs)
{
    try {
        const int32 MAX_INT_PRECISION = 20;
        const int32 prec = Basics::getNumericWordCount(MAX_INT_PRECISION);
        uint64 words[prec];
        VNumeric count(words, prec, 0 /*scale*/);
        count.copy(aggs.getIntRef(1));
        VNumeric &out = resWriter.getNumericRef();
        if (count.isZero()) {
            out.setNull();
        } else {
            VNumeric &sum = aggs.getNumericRef(0);
            out.div(&sum, &count);
        }
    } catch (const Exception &e) {
        vertica::Log::error("terminate() threw an exception:
        ", e.toString());
    }
}

The following figure shows the implementation of the terminate() function:
AggregateFunctionFactory Implementation

The `getPrototype()` function allows you to define the variables that are sent to your aggregate function and returned to Vertica after your aggregate function runs. The following example accepts and returns a numeric value:

```cpp
virtual void getPrototype(ServerInterface &srvfloaterface,
ColumnTypes &argTypes,
ColumnTypes &returnType)
{
    argTypes.addNumeric();
    returnType.addNumeric();
}
```

The `getIntermediateTypes()` function defines any intermediate variables that you use in your aggregate function. **Intermediate variables** are values used to pass data among multiple invocations of an aggregate function. They are used to combine results until a final result can be computed. In this example, there are two results - total (numeric) and count (int).

```cpp
virtual void getIntermediateTypes(ServerInterface &srvInterface,
const SizedColumnTypes &inputTypes,
SizedColumnTypes &intermediateTypeMetaData)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    intermediateTypeMetaData.addNumeric(inType.getPrecision(),
                                          inType.getScale());
    intermediateTypeMetaData.addInt();
}
```

The `getReturnType()` function defines the output data type:

```cpp
virtual void getReturnType(ServerInterface &srvfloaterface,
const SizedColumnTypes &inputTypes,
SizedColumnTypes &outputTypes)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    outputTypes.addNumeric(inType.getPrecision(),
                            inType.getScale());
}
```

### Analytic Functions (UDAnFs)

User-Defined Analytic Functions (UDAnFs) are used for analytics. See [SQL Analytics](https://vertica.com/manuals/Vertica-9.1.0/verticaenda.html#VERTICA-9.1.0-verticaenda.html) for an overview of Vertica's built-in analytics. Like User-Defined Scalar Functions (UDSFs), UDAnFs
must output a single value for each row of data read and can have no more than 1600 arguments.

Unlike UDSFs, the UDAnF’s input reader and output reader can be advanced independently. This feature lets you create UDAnF’s where the output value is calculated over multiple rows of data. By advancing the reader and writer independently, you can create functions similar to the built-in analytic functions such as LAG, which uses data from prior rows to output a value for the current row.

**UDAnF Class Overview**

You create your UDAnF by subclassing two classes defined by the Vertica SDK: AnalyticFunction and AnalyticFunctionFactory.

**AnalyticFunction**

The AnalyticFunction subclass performs the analytic processing. Your subclass must define the `processPartition()` method to perform the operation. It may define methods to set up and tear down the function.

**Performing the Operation**

The `processPartition()` method reads a partition of data, performs some sort of processing, and outputs a single value for each input row.

Vertica calls `processPartition()` once for each partition of data. It supplies the partition using an AnalyticPartitionReader object from which you read its input data. In addition, there is a unique method on this object named `isNewOrderByKey()`, which returns a Boolean value indicating whether your function has seen a row with the same ORDER BY key (or keys). This method is very useful for analytic functions (such as the example RANK function) which need to handle rows with identical ORDER BY keys differently than rows with different ORDER BY keys.

Note: You can specify multiple ORDER BY columns in the SQL query you use to call your UDAnF. The `isNewOrderByKey` method returns true if any of the ORDER BY keys are different than the previous row.

Once your method has finished processing the row of data, you advance it to the next row of input by calling `next()` on AnalyticPartitionReader.
Your method writes its output value using an `AnalyticPartitionWriter` object that Vertica supplies as a parameter to `processPartition()`. This object has data-type-specific methods to write the output value (such as `setInt()`). After setting the output value, call `next()` on `AnalyticPartitionWriter` to advance to the next row in the output.

**Note:** You must be sure that your function produces a row of output for each row of input in the partition. You must also not output more rows than are in the partition, otherwise the zygote size process (if running in Fenced Mode) or Vertica itself could generate an out of bounds error.

### Setting Up and Tearing Down

The `AnalyticFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

### AnalyticFunctionFactory

The `AnalyticFunctionFactory` class tells Vertica metadata about your UDAnF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `AnalyticFunction`.

Your `AnalyticFunctionFactory` subclass must implement the following methods:

- `getPrototype()` describes the input parameters and output value of your function. You set these values by calling functions on two `ColumnType` objects that are passed to your method.

- `createAnalyticFunction()` supplies an instance of your `AnalyticFunction` that Vertica can call to process a UDAnF function call.

- `getReturnType()` provides details about your function's output. This method is where you set the width of the output value if your function returns a variable-width value (such as `VARCHAR`) or the precision of the output value if it has a settable precision (such as `TIMESTAMP`).

### C++ API

This section provides APIs and examples for the C++ API for UDAnFs.
For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

AnalyticFunction and AnalyticFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDAnF Class Overview for general information about implementing the AnalyticFunction and AnalyticFunctionFactory classes.

AnalyticFunction API

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
                    const SizedColumnTypes &argTypes);
virtual void processPartition (ServerInterface &srvInterface,
                               AnalyticPartitionReader &input_reader,
                               AnalyticPartitionWriter &output_writer)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

```cpp
virtual AnalyticFunction * createAnalyticFunction (ServerInterface &srvInterface)=0;
virtual void getPrototype(ServerInterface &srvInterface,
                           ColumnTypes &argTypes, ColumnTypes &returnType)=0;
virtual void getReturnType(ServerInterface &srvInterface,
                           const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;
virtual void getParameterType(ServerInterface &srvInterface,
                               SizedColumnTypes &parameterTypes);
```

C++ Example: Rank

The Rank analytic function ranks rows based on how they are ordered.
Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.so library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```sql
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
    NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named an_rank, is:

```sql
=> SELECT * FROM hits;
  site | date   | num_hits
-------+--------+--------
 www.example.com | 2012-01-02 | 97
 www.vertica.com | 2012-01-01 | 343435
 www.example.com | 2012-01-01 | 123
 www.example.com | 2012-01-04 | 112
 www.vertica.com | 2012-01-02 | 503695
 www.vertica.com | 2012-01-03 | 490387
 www.example.com | 2012-01-03 | 123
(7 rows)
=> SELECT site,date,num_hits,an_rank()
    OVER (PARTITION BY site ORDER BY num_hits DESC)
    AS an_rank FROM hits;
  site | date   | num_hits | an_rank
-------+--------+--------+--------
 www.example.com | 2012-01-03 | 123 | 1
 www.example.com | 2012-01-01 | 123 | 1
 www.example.com | 2012-01-04 | 112 | 3
 www.example.com | 2012-01-02 | 97  | 4
 www.vertica.com | 2012-01-02 | 503695 | 1
 www.vertica.com | 2012-01-03 | 490387 | 2
 www.vertica.com | 2012-01-01 | 343435 | 3
(7 rows)
```

As with the built-in RANK analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

AnalyticFunction Implementation

The following code defines an AnalyticFunction subclass named Rank. It is based on example code distributed in the examples directory of the SDK.
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 *
 */
class Rank : public AnalyticFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
                                   AnalyticPartitionReader &inputReader,
                                   AnalyticPartitionWriter &outputWriter)
    {
        // Always use a top-level try-catch block to prevent exceptions from
        // leaking back to Vertica or the fenced-mode side process.
        try {
            rank = 1; // The rank to assign a row
            rowCount = 0; // Number of rows processed so far
            do {
                rowCount++;
                // Do we have a new order by row?
                if (inputReader.isNewOrderByKey()) {
                    // Yes, so set rank to the total number of rows that have been
                    // processed. Otherwise, the rank remains the same value as
                    // the previous iteration.
                    rank = rowCount;
                }
                // Write the rank
                outputWriter.setInt(0, rank);
                // Move to the next row of the output
                outputWriter.next();
            } while (inputReader.next()); // Loop until no more input
        } catch(exception & e) {
            // Standard exception. Quit.
            vt_report_error(0, "Exception while processing partition: %s", e.what());
        }
    }
private:
    vint rank, rowCount;
};

In this example, the processPartition() method does not actually read any of the data
from the input row; it just advances through the rows. It does not need to read data; it just
counts the rows that have been read and determine whether those rows have the same
ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is
set to the total number of rows that have been processed. If the current row has the same
ORDER BY value as the previous row, then the rank remains the same.

Note that the function has a top-level try-catch block. All of your U Dx functions should always
have one to prevent stray exceptions from being passed back to Vertica (if you run the function
unfenced) or the side process.

AnalyticFunctionFactory Implementation

The following code defines the AnalyticFunctionFactory that corresponds with the Rank
analytic function.
class RankFactory : public AnalyticFunctionFactory
{
    virtual void getPrototype(ServerInterface &srvInterface,
                                ColumnTypes &argTypes,
                                ColumnTypes &returnType)
    {
        returnType.addInt();
    }
    virtual void getReturnType(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes,
                                SizedColumnTypes &outputTypes)
    {
        outputTypes.addInt();
    }
    virtual AnalyticFunction *createAnalyticFunction(ServerInterface
                                                      &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Rank); }
};

The first method defined by the RankFactory subclass, getPrototype(), sets the data type of the return value. Because the Rank UDAnF does not read input, it does not define any arguments by calling methods on the ColumnTypes object passed in the argTypes parameter.

The next method is getReturnType(). If your function returns a data type that needs to define a width or precision, your implementation of the getReturnType() method calls a method on the SizedColumnType object passed in as a parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls addInt() to report its output data type.

Finally, RankFactory defines the createAnalyticFunction() method that returns an instance of the AnalyticFunction class that Vertica can call. This code is mostly boilerplate. All you need to do is add the name of your analytic function class in the call to vt_createFuncObj(), which takes care of allocating the object for you.

Java API

This section provides APIs and examples for the Java API for UDAnFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

AnalyticFunction and AnalyticFunctionFactory Java Interface

This section describes information that is specific to the Java API. See UDAnF Class Overview for general information about implementing the AnalyticFunction and AnalyticFunctionFactory classes.
AnalyticFunction API

The API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

public abstract void processPartition (ServerInterface srvInterface,
                                          AnalyticPartitionReader input_reader, AnalyticPartitionWriter output_writer)
                                           throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

```java
public abstract AnalyticFunction createAnalyticFunction (ServerInterface srvInterface);

public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);

public abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
                                      SizedColumnTypes returnType) throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

Java Example: Rank

The Rank analytic function ranks rows based on how they are ordered.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.jar library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```sql
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.jar';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'Java'
    NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named an_rank, is:
As with the built-in `RANK` analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

**AnalyticFunction Implementation**

The following code defines an `AnalyticFunction` subclass named `Rank`. The code can be found in the SDK examples directory.

```java
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 */
public class Rank extends AnalyticFunction {
    private int rank, numRowsWithSameOrder;

    @Override
    public void processPartition(ServerInterface srvInterface,
                                  AnalyticPartitionReader inputReader,
                                  AnalyticPartitionWriter outputWriter)
        throws UdfException, DestroyInvocation {
        rank = 0;
        numRowsWithSameOrder = 1;
        do{
            if(!inputReader.isNewOrderByKey()){
                ++numRowsWithSameOrder;
            }else {
```
In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It just needs to count the number of rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

AnalyticFunctionFactory Implementation

The following code defines the `AnalyticFunctionFactory` that corresponds with the Rank analytic function.

```java
public class RankFactory extends AnalyticFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType) {
        returnType.addInt();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException {
        returnType.addInt();
    }

    @Override
    public AnalyticFunction createAnalyticFunction(ServerInterface srvInterface) {
        return new Rank();
    }
}
```

The first method defined by the `RankFactory` subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAnF does not read input, it does not define any arguments by calling methods on the `ColumnTypes` object passed in the `argTypes` parameter.

The next method is `getReturnType()`. If your analytic function returns a data type that needs to define a width or precision, your implementation of the `getReturnType` function calls a method on the `SizedColumnType` parameter to tell Vertica the width or precision.
Rank returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls addInt() to report its output data type.

Finally, RankFactory defines the createAnalyticFunction() method that returns an instance of the AnalyticFunction class that Vertica can call.
Scalar Functions (UDSFs)

A User-Defined Scalar Function (UDSF) returns a single value for each row of data it reads. You can use a UDSF anywhere you can use a built-in Vertica function. You usually develop a UDSF to perform data manipulations that are too complex or too slow to perform using SQL statements and functions. UDSFs also let you use analytic functions provided by third-party libraries within Vertica while still maintaining high performance.

Your UDSF must return a value for every input row (unless it generates an error; see Handling Errors for details). Failing to return a value for a row will result in incorrect results and potentially destabilize the Vertica server if not run in Fenced Mode.

A UDSF cannot have more than 1600 arguments.

UDSF Class Overview

You create your UDSF by subclassing two classes defined by the Vertica SDK: ScalarFunction and ScalarFunctionFactory.

ScalarFunction

The ScalarFunction class is the heart of a UDSF. Your subclass must define the processBlock() method to perform the scalar operation. It may define methods to set up and tear down the function.

Performing the Operation

The processBlock() method carries out all of the processing that you want your UDSF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to processBlock().

The input and output of the processBlock() method are supplied by objects of the BlockReader and BlockWriter classes. They define methods that you use to read the input data and write the output data for your UDSF.

The majority of the work in developing a UDSF is writing processBlock(). This is where all of the processing in your function occurs. Your UDSF should follow this basic pattern:
Read in a set of parameters from the BlockReader object using data-type-specific methods.

Process the data in some manner.

Output the resulting value using one of the BlockWriter class's data-type-specific methods.

Advance to the next row of output and input by calling BlockWriter.next() and BlockReader.next().

This process continues until there are no more rows of data to be read (BlockReader.next() returns false).

You must make sure that processBlock() reads all of the rows in its input and outputs a single value for each row. Failure to do so can corrupt the data structures that Vertica reads to get the output of your UDSF. The only exception to this rule is if your processBlock() function reports an error back to Vertica (see HandlingErrors). In that case, Vertica does not attempt to read the incomplete result set generated by the UDSF.

Setting Up and Tearing Down

The ScalarFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy(). You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

Notes

While the name you choose for your ScalarFunction subclass does not have to match the name of the SQL function you will later assign to it, Vertica considers making the names the same a best practice.

Do not assume that your function will be called from the same thread that instantiated it.

The same instance of your ScalarFunction subclass can be called on to process multiple blocks of data.

The rows of input sent to processBlock() are not guaranteed to be any particular order.

Writing too many output rows can cause Vertica to emit an out-of-bounds error.
ScalarFunctionFactory

The ScalarFunctionFactory class tells Vertica metadata about your UDSF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of ScalarFunction.

Methods

You must implement the following methods in your ScalarFunctionFactory subclass:

- `createScalarFunction()` instantiates a ScalarFunction subclass. If writing in C++, you can call the `vt_createFuncObj` macro with the name of the ScalarFunction subclass. This macro takes care of allocating and instantiating the class for you.

- `getPrototype()` tells Vertica about the parameters and return type for your UDSF. In addition to a `ServerInterface` object, this method gets two `ColumnType` objects. All you need to do in this function is to call class functions on these two objects to build the list of parameters and the single return value type.

After defining your factory class, you need to call the RegisterFactory macro. This macro instantiates a member of your factory class, so Vertica can interact with it and extract the metadata it contains about your UDSF.

Declaring Return Values

If your function returns a sized column (a return data type whose length can vary, such as a VARCHAR) or a value that requires precision, you must implement `getReturnType()`. This method is called by Vertica to find the length or precision of the data being returned in each row of the results. The return value of this method depends on the data type your `processBlock()` method returns:

- CHAR or VARCHAR return the maximum length of the string.
- NUMERIC types specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone) specify precision.
- INTERVAL YEAR TO MONTH specifies range.
- INTERVAL DAY TO SECOND specifies precision and range.
If your UDSF does not return one of these data types, it does not need a `getReturnType()` method.

The input to the `getReturnType()` method is a `SizedColumnTypes` object that contains the input argument types along with their lengths. This object will be passed to an instance of your `processBlock()` function. Your implementation of `getReturnType()` must extract the data types and lengths from this input and determine the length or precision of the output rows. It then saves this information in another instance of the `SizedColumnTypes` class.

### Setting Null Input and Volatility Behavior

Normally, Vertica calls your UDSF for every row of data in the query. There are some cases where Vertica can avoid executing your UDSF. You can tell Vertica when it can skip calling your function and just supply a return value itself by changing your function's volatility and strictness settings.

- Your function's volatility indicates whether it always returns the same output value when passed the same arguments. Depending on its behavior, Vertica can cache the arguments and the return value. If the user calls the UDSF with the same set of arguments, Vertica returns the cached value instead of calling your UDSF.

- Your function's strictness indicates how it reacts to NULL arguments. If it always returns NULL when any argument is NULL, Vertica can just return NULL without having to call the function. This optimization also saves you work, because you do not need to test for and handle null arguments in your UDSF code.

You indicate the volatility and null handling of your function by setting the `vol` and `strict` fields in your `ScalarFunctionFactory` class's constructor.

### Volatility Settings

To indicate your function's volatility, set the `vol` field to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLATILE</td>
<td>Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.</td>
</tr>
<tr>
<td>IMMUTABLE</td>
<td>Calls to the function with the same arguments always results in the same return value.</td>
</tr>
<tr>
<td>STABLE</td>
<td>Repeated calls to the function with the same arguments <em>within the same</em> invocation.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>statement</td>
<td>returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.</td>
</tr>
<tr>
<td>DEFAULT_</td>
<td>VOLATILITY</td>
</tr>
<tr>
<td></td>
<td>The default volatility. This is the same as VOLATILE.</td>
</tr>
</tbody>
</table>

**C++ Example**

The following example shows a version of the Add2ints example factory class that makes the function immutable.

```cpp
class Add2intsImmutableFactory : public Vertica::ScalarFunctionFactory
{
  virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
  { return vt_createFuncObj(srvInterface.allocator, Add2Ints); }
  virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
  {
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }

  public:
  Add2intsImmutableFactory() { vol = IMMUTABLE; }
};
RegisterFactory(Add2intsImmutableFactory);
```

**Java Example**

The following example demonstrates setting the Add2IntsFactory's vol field to IMMUTABLE to tell Vertica it can cache the arguments and return value.

```java
public class Add2IntsFactory extends ScalarFunctionFactory {
  @Override
  public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType){
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }

  @Override
  public ScalarFunction createScalarFunction(ServerInterface srvInterface){
    return new Add2Ints();
  }
```

Null Input Behavior

To indicate how your function reacts to NULL input, set the strictness field to one of the following values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLED_ON_NULL_INPUT</td>
<td>The function must be called, even if one or more arguments are NULL.</td>
</tr>
<tr>
<td>RETURN_NULL_ON_NULL_INPUT</td>
<td>The function always returns a NULL value if any of its arguments are NULL.</td>
</tr>
<tr>
<td>STRICT</td>
<td>A synonym for RETURN_NULL_ON_NULL_INPUT</td>
</tr>
<tr>
<td>DEFAULT STRICTNESS</td>
<td>The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.</td>
</tr>
</tbody>
</table>

C++ Example

The following example demonstrates setting the null behavior of Add2ints so Vertica does not call the function with NULL values.

```cpp
class Add2intsNullOnNullInputFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    {
        return vt_createFuncObj(srvInterfaceallocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
} public:
Add2intsNullOnNullInputFactory() {strict = RETURN_NULL_ON_NULL_INPUT;}
```
Java Example

The following example demonstrates setting the strictness setting of the Add2Ints example to STRICT. This means that if either of the two values to be added is NULL, Vertica can set the return value to NULL without having to call the Add2Ints function.

```java
public class Add2IntsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType){
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new Add2Ints();
    }
    public Add2IntsFactory()
    {
        // Tell Vertica that any NULL arguments results in a NULL return value
        strict = strictness.RETURN_NULL_ON_NULL_INPUT;
    }
}
```

C++ API

This section provides APIs and examples for the C++ API for UDSFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

ScalarFunction and ScalarFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDSF Class Overview for general information about implementing the ScalarFunction and ScalarFunctionFactory classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:
virtual void setup(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes);

virtual void processBlock(ServerInterface &srvInterface,
    BlockReader &arg_reader, BlockWriter &res_writer)=0;

double processBlock(ServerInterface &srvInterface,
    BlockReader &arg_reader, BlockWriter &res_writer)=0;

cancel(ServerInterface &srvInterface);

destroy(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes);

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

virtual ScalarFunction * createScalarFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes, ColumnTypes &returnType)=0;

double getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes, ColumnTypes &returnType)=0;

class Add2Ints : public ScalarFunction
{

C++ Example: Add2Ints

The following example shows a very basic subclass of ScalarFunction called Add2Ints. As
the name implies it adds two integers together, returning a single integer result. It also
demonstrates including the main Vertica SDK header file (Vertica.h) and using the Vertica
namespace. While not required, using the namespace saves you from having to prefix every
Vertica SDK class reference with Vertica::

ScalarFunction Implementation

    // Include the top-level Vertica SDK file
    #include "Vertica.h"
    // Using the Vertica namespace means we don’t have to prefix all
    // class references with Vertica::
    using namespace Vertica;
    /*
    * ScalarFunction implementation for a UDSF that adds
    * two numbers together.
    */
    class Add2Ints : public ScalarFunction
    {
public:
/*
* This function does all of the actual processing for the UDF.
* In this case, it simply reads two integer values and returns
* their sum.
* The inputs are retrieved via arg_reader
* The outputs are returned via arg_writer
*/
virtual void processBlock(ServerInterface &srvInterface,
    BlockReader &arg_reader,
    BlockWriter &res_writer)
{
    // While we have input to process
    do {
        // Read the two integer input parameters by calling the
        // BlockReader.getIntRef class function
        const vint a = arg_reader.getIntRef(0);
        const vint b = arg_reader.getIntRef(1);
        // Call BlockWriter.setInt to store the output value, which is the
        // two input values added together
        res_writer.setInt(a+b);
        // Finish writing the row, and advance to the next output row
        res_writer.next();
        // Continue looping until there are no more input rows
    } while (arg_reader.next());
}
};

ScalarFunctionFactory Implementation

/*
* This class provides metadata about the ScalarFunction class, and
* also instantiates a member of that class when needed.
*/
class Add2IntsFactory : public ScalarFunctionFactory
{
    // return an instance of Add2Ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2Ints class instance.
        return vt_createFuncObj(interface.allocator, Add2Ints);
    }
    // This function returns the description of the input and outputs of the
    // Add2Ints class's processBlock function. It stores this information in
    // two ColumnTypes objects, one for the input parameters, and one for
    // the return value.
    virtual void getPrototype(ServerInterface &interface,
        ColumnTypes &argTypes,
        ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object
        argTypes.addInt();
        argTypes.addInt();
        // returns a single int, so add a single int to the returnType object.
        // Note that ScalarFunctions *always* return a single value.
The RegisterFactory Macro

Use the RegisterFactory macro to register a ScalarFunctionFactory subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```c++
RegisterFactory(Add2IntsFactory);
```

C++ Example: Calling a UDSF from a Check Constraint

This example shows you the C++ code needed to create a UDSF that can be called by a check constraint. The name of the sample function is `LargestSquareBelow`. The sample function determines the largest number whose square is less than the number in the subject column. For example, if the number in the column is 1000, the largest number whose square is less than 1000 is 31 (961).

Important: A UDSF used within a check constraint must be immutable, and the constraint must handle null values properly. Otherwise, the check constraint might not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated, so consider performance in writing your function.

For information on check constraints, see Check Constraints the Administrator's Guide.

For information about implementing the ScalarFunction and ScalarFunctionFactory classes, see UDSF Class Overview.

Loading and Using the Example

The following example shows how you can create and load a library named `MySqLib`, using CREATE LIBRARY. Adjust the library path in this example to the absolute path and file name for the location where you saved the shared object `LargestSquareBelow`.

```sql
=> CREATE OR REPLACE LIBRARY MySqLib AS '/home/dbadmin/LargestSquareBelow.so';
```

1. After you create and load the library, add the function to the catalog using the CREATE FUNCTION (UDF) statement.
CREATE OR REPLACE FUNCTION largestSqBelow AS LANGUAGE 'C++' NAME 'LargestSquareBelowInfo' LIBRARY MySqLib;

2. Next, include the UDSF in a check constraint.

CREATE TABLE squaretest(
  ceiling INTEGER UNIQUE,
  CONSTRAINT chk_sq CHECK (largestSqBelow(ceiling) < ceiling*ceiling)
);

3. Add data to the table, squaretest.

COPY squaretest FROM stdin DELIMITER ',' NULL
-1
null
0
1
1000
1000000
1000001
.

Your output should be similar to the following sample, based upon the data you use:

```
SELECT ceiling, largestSqBelow(ceiling)
FROM squaretest ORDER BY ceiling;
```

```
<table>
<thead>
<tr>
<th>ceiling</th>
<th>largestSqBelow</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>-1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1000</td>
<td>31</td>
</tr>
<tr>
<td>1000000</td>
<td>999</td>
</tr>
<tr>
<td>1000001</td>
<td>1000</td>
</tr>
</tbody>
</table>
(7 rows)
```

ScalarFunction Implementation

This ScalarFunction implementation does the processing work for a UDSF that determines the largest number whose square is less than the number input.

```c++
#include "Vertica.h"

/*
 * ScalarFunction implementation for a UDSF that
determines the largest number whose square is less than
* the number input.
*/
class LargestSquareBelow : public Vertica::ScalarFunction {
```
public:
/*
 * This function does all of the actual processing for the UDSF.
 * The inputs are retrieved via arg_reader
 * The outputs are returned via arg_writer
 */
virtual void processBlock(Vertica::ServerInterface &srvInterface,
Vertica::BlockReader &arg_reader,
Vertica::BlockWriter &res_writer)
{
    if (arg_reader.getNumCols() != 1)
        vt_report_error(0, "Function only accept 1 argument, but %zu provided", arg_reader.getNumCols());
    // While we have input to process
    do {
        // Read the input parameter by calling the
        // BlockReader.getIntRef class function
        const Vertica::vint a = arg_reader.getIntRef(0);
        Vertica::vint res;
        // Determine the largest square below the number
        if ((a != Vertica::vint_null) && (a > 0))
            res = (Vertica::vint)sqrt(a - 1);
        else
            res = Vertica::vint_null;
        // Call BlockWriter.setInt to store the output value,
        // which is the largest square
        res_writer.setInt(res);
        // Write the row and advance to the next output row
        res_writer.next();
        // Continue looping until there are no more input rows
    } while (arg_reader.next());
}

ScalarFunctionFactory Implementation

This ScalarFunctionFactory implementation does the work of handling input and output, and marks the function as immutable (a requirement if you plan to use the UDSF within a check constraint).

class LargestSquareBelowInfo : public Vertica::ScalarFunctionFactory
{
    // return an instance of LargestSquareBelow to perform the computation.
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    {
        return Vertica::vt_createFuncObject<LargestSquareBelow>(srvInterface.allocator);
    }

    /*
    * This function returns the description of the input and outputs of the
    * LargestSquareBelow class’s processBlock function. It stores this information in
    * two ColumnTypes objects, one for the input parameter, and one for
    * the return value.
    */
}
virtual void getPrototype(Vertica::ServerInterface &srvInterface,
   Vertica::ColumnTypes &argTypes,
   Vertica::ColumnTypes &returnType)
{
    // Takes one int as input, so adds int to the argTypes object
    argTypes.addInt();
    // Returns a single int, so add a single int to the returnType object.
    returnType.addInt();
    
    public:
    // the function cannot be called within a check constraint unless the UDx author
    // certifies that the function is immutable:
    LargestSquareBelowInfo() { vol = Vertica::IMMUTABLE; }
};

The RegisterFactory Macro

Use the RegisterFactory macro to register a ScalarFunctionFactory subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

    RegisterFactory(LargestSquareBelowInfo);

Java API

This section provides APIs and examples for the Java API for UDSFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

ScalarFunction and ScalarFunctionFactory Java Interface

This section describes information that is specific to the Java API. See UDSF Class Overview for general information about implementing the ScalarFunction and ScalarFunctionFactory classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

public abstract void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_writer) throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

public abstract ScalarFunction createScalarFunction(ServerInterface srvInterface);

public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);

public void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

Java Example: Add2Ints

The Add2Ints scalar function adds two integers together, returning a single integer result.

Loading and Using the Example

Use CREATE LIBRARY to load the jar file containing the function, and then use CREATE FUNCTION (UDF) to declare the function as in the following example:

```shell
=> CREATE FUNCTION add2ints AS LANGUAGE 'Java' NAME 'com.mycompany.example.Add2intsFactory' LIBRARY add2intslib;
```

The following example shows how to use this function.

```shell
=> SELECT Add2Ints(27,15);
Add2Ints
--------
  42
(1 row)
=> SELECT * FROM MyTable;
a | b
----|---
  7 | 0
```
Implementation

The following code example is the full source of the Java Add2ints example. To simplify handling the source code, the ScalarFunction class is defined as an inner class of the ScalarFunctionFactory class.

```java
// You will need to specify the full package when creating functions based on // the classes in your library. package com.mycompany.example; // Import all of the Vertica SDK import com.vertica.sdk.*; public class Add2intsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface,
        ColumnTypes argTypes,
        ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
}

// This ScalarFunction is defined as an inner class of // its ScalarFunctionFactory class. This gets around having // to have a separate source file for this public class. public class Add2ints extends ScalarFunction {
    @Override
    public void processBlock(ServerInterface srvInterface,
        BlockReader argReader,
        BlockWriter resWriter)
        throws UdfException, DestroyInvocation
    {
        do {
            // The input and output objects have already loaded // the first row, so you can start reading and writing // values immediately.
            // Get the two integer arguments from the BlockReader
        }
    }
}"
long a = argReader.getLong(0);
long b = argReader.getLong(1);

// Process the arguments and come up with a result. For this
// example, just add the two arguments together.
long result = a + b;

// Write the integer output value.
resWriter.setLong(result);

// Advance the output BlockWriter to the next row.
resWriter.next();

// Continue processing input rows until there are no more.
} while (argReader.next());

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface)
{
    return new Add2ints();
}

Python API

This section provides APIs and examples for the Python SDK for UDSFs.
For more information on setting up a Python development environment, see Developing with the Python SDK.

ScalarFunction and ScalarFunctionFactory Python Interface

This section describes information that is specific to the Python API. See UDSF Class Overview for general information about implementing the ScalarFunction and ScalarFunctionFactory classes. See Python SDK Documentation for detailed reference documentation for all API classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:

- `setup(self, server_interface, col_types)`
- `processBlock(self, server_interface, block_reader, block_writer)`
- `destroy(self, server_interface, col_types)`
ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

- `createScalarFunction(self, srv)`
- `getPrototype(self, srv_interface, arg_types, return_type)`
- `getReturnType(self, srv_interface, arg_types, return_type)`

Python Example: add2ints

The `add2ints` scalar function adds two integers together, returning a single integer result.

You can find more UDx examples in the Vertica Github repository, [https://github.com/vertica/UDx-Examples](https://github.com/vertica/UDx-Examples).

UDSF Python Code

```python
import vertica_sdk

class add2ints(vertica_sdk.ScalarFunction):
    """Return the sum of two integer columns""
    def __init__(self):
        pass
    def setup(self, server_interface, col_types):
        pass
    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Python UDx - Adding 2 ints!")
        while(True):
            # Example of error checking best practices.
            if arg_reader.isNull(0) or arg_reader.isNull(1):
                raise ValueError("I found a NULL!")
            else:
                first_int = arg_reader.getInt(0) # Input column
                second_int = arg_reader.getInt(1) # Input column
                res_writer.SetInt(first_int + second_int) # Sum of input columns.
                res_writer.next() # Read the next row.
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break
    def destroy(self, server_interface, col_types):
        pass

class add2ints_factory(vertica_sdk.ScalarFunctionFactory):
```

Vertica Analytic Database (9.1.x)
def createScalarFunction(self, srv):
    return add2ints()

def getPrototype(self, srv_interface, arg_types, return_type):
    arg_types.addInt()
    arg_types.addInt()
    return_type.addInt()

def getReturnType(self, srv_interface, arg_types, return_type):
    return_type.addInt()

Load the Function and Library

Create the library and the function.

```sql
=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/add2ints/add2ints.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION add2ints AS LANGUAGE 'Python' NAME 'add2ints_factory' LIBRARY pylib fenced;
CREATE FUNCTION
```

Querying Data with the Function

The following shows how to run a query with the UDSF.

```sql
=> SELECT add2ints(10, 10);
add2ints
--------
20
(1 row)
```

You can query on a table with two integer columns as follows:

```sql
=> SELECT nums_1, nums_2, add2ints(nums_1, nums_2) AS add2ints_sum
FROM bunch_of_numbers;
nums_1 | nums_2 | add2ints_sum
-------|--------|------------------
  10    |   10   |    20
   1    |    4   |     5
   6    |    6   |    12
  30    | 144    |   174
(4 rows)
```

Python Example: currency_convert

The `currency_convert` scalar function reads two values from a table, a currency and a value. It then converts the item's value to USD, returning a single float result.
You can find more UDx examples in the VerticaGithub repository, https://github.com/vertica/UDx-Examples.

**UDSF Python Code**

```python
import vertica_sdk
import decimal

rates2USD = {
    'USD': 1.000,
    'EUR': 0.89977,
    'GBP': 0.68452,
    'INR': 67.0345,
    'AUD': 1.39187,
    'CAD': 1.30335,
    'ZAR': 15.7181,
    'XXX': -1.0000
}

class currency_convert(vertica_sdk.ScalarFunction):
    """Converts a money column to another currency
    Returns a value in USD.
    """
    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, block_reader, block_writer):
        while(True):
            currency = block_reader.getString(0)
            try:
                rate = decimal.Decimal(rates2USD[currency])
                starting_value = block_reader.getNumeric(1)
                converted_value = decimal.Decimal(starting_value / rate)
                block_writer.setNumeric(converted_value)
                block_writer.next()
            except KeyError:
                server_interface.log("ERROR: {} not in dictionary.".format(currency))
                # Scalar functions always need a value to move forward to the
                # next input row. Therefore, we need to assign it a value to
                # move beyond the error.
                currency = 'XXX'
                rate = decimal.Decimal(rates2USD[currency])
                starting_value = block_reader.getNumeric(1)
                converted_value = decimal.Decimal(starting_value / rate)
                block_writer.setNumeric(converted_value)
                block_writer.next()
                if not block_reader.next():
                    break

    def destroy(self, server_interface, col_types):
        pass

class currency_convert_factory(vertica_sdk.ScalarFunctionFactory):
    def createScalarFunction(self, self, srv):
        return currency_convert()
```
Load the Function and Library

Create the library and the function.

```sql
=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/currency_convert/currency_convert.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION currency_convert AS LANGUAGE 'Python' NAME 'currency_convert_factory' LIBRARY pylib fenced;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```sql
=> SELECT product, currency_convert(currency, value) AS cost_in_usd
    FROM items;
```

<table>
<thead>
<tr>
<th>product</th>
<th>cost_in_usd</th>
</tr>
</thead>

Python Example: validate_url

The `validate_url` scalar function reads a string from a table, a URL. It then validates if the URL is responsive, returning a status code or a string indicating the attempt failed.

You can find more UDX examples in the VerticaGithub repository, https://github.com/vertica/UDx-Examples.
import vertica_sdk
import urllib.request
import time

class validate_url(vertica_sdk.ScalarFunction):
    """Validates HTTP requests."
    """
    def __init__(self):
        pass
    def setup(self, server_interface, col_types):
        pass
    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Validating webpage accessibility - UDx")
        while(True):
            url = arg_reader.getString(0)
            try:
                status = urllib.request.urlopen(url).getcode()
                # Avoid overwhelming web servers -- be nice.
                time.sleep(2)
            except (ValueError, urllib.error.HTTPError, urllib.error.URLError):
                status = 'Failed to load page'
                res_writer.setString(str(status))
                res_writer.next()
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break
    def destroy(self, server_interface, col_types):
        pass

class validate_url_factory(vertica_sdk.ScalarFunctionFactory):
    def createScalarFunction(self, srv):
        return validate_url()
    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addChar()
    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addChar(20)
Load the Function and Library

Create the library and the function.

```sql
=> CREATE OR REPLACE LIBRARY pylib AS 'webpage_tester/validate_url.py' LANGUAGE 'Python';
=> CREATE OR REPLACE FUNCTION validate_url AS LANGUAGE 'Python' NAME 'validate_url_factory' LIBRARY pylib_fenced;
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```sql
=> SELECT url, validate_url(url) AS url_status FROM webpages;
```

<table>
<thead>
<tr>
<th>url</th>
<th>url_status</th>
</tr>
</thead>

R API

This section provides APIs and examples for the R API for UDSFs.

For information on setting up an R development environment and compiling and packaging libraries, see Developing with the R SDK.

Scalar Function and Scalar Function Factory R Interface

This section describes information that is specific to the R API. See R SDK API Documentation for general information about implementing Scalar functions.

Scalar Function API

The API provides the following framework for extension by R function:

```r
FunctionName <- function(input.data.frame, parameters.data.frame) {
# Computations
# The function must return a data frame.
```
Scalar Function Factory API

The API provides the following framework for extension by R function:

```r
FunctionNameFactory <- function() {
  list(name = FunctionName,
       udxtype = c("scalar"),
       intype  = c("int"),
       outtype = c("int"))
}
```

For a complete list of factory options, see the R API documentation for Factory Function.

R Example: SalesTaxCalculator

The SalesTaxCalculator scalar function reads a float and a varchar from a table, an item's price and the state abbreviation. It then uses the state abbreviation to find the sales tax rate from a list and calculates the item's price including the state's sales tax, returning the total cost of the item.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```sql
=> CREATE OR REPLACE LIBRARY rLib AS 'sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION SalesTaxCalculator AS LANGUAGE 'R' NAME 'SalesTaxCalculatorFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```sql
=> SELECT item, state_abbreviation, 
    price, SalesTaxCalculator(price, state_abbreviation) AS Price_With_Sales_Tax 
FROM inventory;
```

<table>
<thead>
<tr>
<th>item</th>
<th>state_abbreviation</th>
<th>price</th>
<th>Price_With_Sales_Tax</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Scarf | AZ | 6.88 | 7.53016

(8 rows)

UDSA R Code

```
SalesTaxCalculator <- function(input.data.frame) {
  state.sales.tax <- list(ma = 0.0625,
                           az = 0.087,
                           la = 0.0891,
                           tn = 0.0945,
                           wi = 0.0543,
                           ms = 0.0707)
  for (state_abbreviation in input.data.frame[, 2]) {
    lower_state <- tolower(state_abbreviation)
    if (!is.null(state.sales.tax[[lower_state]])) {
      stop("State is not in our small sample!")
    } else {
      sales.tax.rate <- state.sales.tax[[lower_state]]
      item.price <- input.data.frame[, 1]
      price.with.sales.tax <- (item.price) + (item.price * sales.tax.rate)
    }
  }
  return(price.with.sales.tax)
}
SalesTaxCalculatorFactory <- function() {
  list(name = "SalesTaxCalculator",
       udxtype = c("scalar"),
       intype = c("float", "varchar"),
       outtype = c("float"))
}
```

R Example: kmeans

The KMeans_User scalar function reads any number of columns from a table, the observations. It then uses the observations and the two parameters when applying the kmeans clustering algorithm to the data, returning an integer value associated with the cluster of the row.

You can find more UDx examples in the VerticaGithub repository, [https://github.com/vertica/UDx-Examples](https://github.com/vertica/UDx-Examples).
Load the Function and Library

Create the library and the function.

```sql
=> CREATE OR REPLACE LIBRARY rLib AS 'kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION KMeans_User AS LANGUAGE 'R' NAME 'KMeans_UserFactory' LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```sql
=> SELECT spec, KMeans_User(sl, sw, pl, pw USING PARAMETERS clusters = 3, nstart = 20)
    FROM iris;
```

<table>
<thead>
<tr>
<th>spec</th>
<th>KMeans_User</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
<tr>
<td>Iris-setosa</td>
<td>2</td>
</tr>
</tbody>
</table>

(150 rows)

UDSF R Code

```r
KMeans_User <- function(input.data.frame, parameters.data.frame) {
    # Take the clusters and nstart parameters passed by the user and assign them
    # to variables in the function.
    if ( is.null(parameters.data.frame[['clusters']]) ) {
        stop("NULL value for clusters! clusters cannot be NULL.")
    } else {
        clusters.value <- parameters.data.frame[['clusters']]
    }
    if ( is.null(parameters.data.frame[['nstart']]) ) {
        stop("NULL value for nstart! nstart cannot be NULL.")
    } else {
        nstart.value <- parameters.data.frame[['nstart']]
    }
    # Apply the algorithm to the data.
```
kmeans.clusters <- kmeans(input.data.frame[, 1:length(input.data.frame)],
                         clusters.value, nstart = nstart.value)
final.output <- data.frame(kmeans.clusters$cluster)
return(final.output)

KMeans_UserFactory <- function()
{
  list(name = KMeans_User,
       udxtype = c("scalar"),
       # Since this is a polymorphic function the intype must be any
       intype = c("any"),
       outtype = c("int"),
       parameterstypecallback=KMeansParameters)
}

KMeansParameters <- function()
{
  parameters <- list(datatype = c("int", "int"),
                     length = c("NA", "NA"),
                     scale = c("NA", "NA"),
                     name = c("clusters", "nstart"))
  return(parameters)
}
Transform Functions (UDTFs)

A User-Defined Transform Function (UDTF) lets you transform a table of data into another table. It reads one or more arguments (treated as a row of data), and returns zero or more rows of data consisting of one or more columns. A UDTF can produce any number of rows as output. However, each row it outputs must be complete. Advancing to the next row without having added a value for each column produces incorrect results.

The schema of the output table does not need to correspond to the schema of the input table—they can be totally different. The UDTF can return any number of output rows for each row of input.

UDTFs can only be used in the SELECT list that contains just the UDTF call and a required OVER clause. A multi-phase UDTF can make use of partition columns (PARTITION BY), but other UDTFs cannot.

UDTFs are run after GROUP BY, but before the final ORDER BY, when used in conjunction with GROUP BY and ORDER BY in a statement. The ORDER BY clause may contain only columns or expressions that are in a window partition clause (see Window Partitioning).

UDTFs can take up to 1600 parameters (input columns). Attempting to pass more parameters to a UDTF results in an error.

UDTF Class Overview

You create your UDTF by subclassing two classes defined by the Vertica SDK: TransformFunction and TransformFunctionFactory.

The TransformFunctionFactory performs two roles:

- It provides the number of parameters and their and data types accepted by the UDTF and the number of output columns and their data types UDTF's output. Vertica uses this data when you call the CREATE TRANSFORM FUNCTION SQL statement to add the function to the database catalog.

- It returns an instance of the UDTF function's TransformFunction subclass that Vertica can call to process data.
TransformFunction

The TransformFunction class is where you perform the data-processing, transforming input rows into output rows. Your subclass must define the processPartition() method. It may define methods to set up and tear down the function.

Performing the Transformation

The processPartition() method carries out all of the processing that you want your UDTF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to processPartition().

The input and output of the processPartition() method are supplied by objects of the PartitionReader and PartitionWriter classes. They define methods that you use to read the input data and write the output data for your UDTF.

A UDTF does not necessarily operate on a single row the way a UDSF does. A UDTF can read any number of rows and write output at any time.

Consider the following guidelines when implementing processPartition():

- Extract the input parameters by calling data-type-specific functions in the PartitionReader object to extract each input parameter. Each of these functions takes a single parameter: the column number in the input row that you want to read. Your function might need to handle NULL values.

- When writing output, your UDTF must supply values for all of the output columns you defined in your factory. Similarly to reading input columns, the PartitionWriter object has functions for writing each type of data to the output row.

- Use PartitionReader.next() to determine if there is more input to process, and exit when the input is exhausted.

- In some cases, you might want to determine the number and types of parameters using PartitionReader's getNumCols() and getTypeMetaData() functions, instead of just hard-coding the data types of the columns in the input row. This is useful if you want your TransformFunction to be able to process input tables with different schemas. You can then use different TransformFunctionFactory classes to define multiple function signatures that call the same TransformFunction class. See Handling Different Numbers and Types of Arguments for more information.
Setting Up and Tearing Down

The TransformFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy(). You should use these methods to allocate and deallocate resources that you do not allocate through the U Dx API (see Allocating Resources for U Dxs for details).

TransformFunctionFactory

The TransformFunctionFactory class tells Vertica metadata about your UDTF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of TransformFunction.

You must implement the following methods in your TransformFunctionFactory:

- getPrototype() returns two ColumnTypes objects that describe the columns your UDTF takes as input and returns as output.
- getReturnType() tells Vertica details about the output values: the width of variable-sized data types (such as VARCHAR) and the precision of data types that have settable precision (such as TIMESTAMP). You can also set the names of the output columns using this function. While this method is optional for U Dxs that return single values, you must implement it for UDTFs.
- createTransformFunction() instantiates your TransformFunction subclass.

Creating Multi-Phase UDTFs

Creating Multi-Phase UDTFs

Multi-phase UDTFs let you break your data processing into multiple steps. Using this feature, your UDTFs can perform processing in a way similar to Hadoop or other MapReduce frameworks. You can use the first phase to break down and gather data, and then use subsequent phases to process the data. For example, the first phase of your UDTF could extract specific types of user interactions from a web server log stored in the column of a table, and subsequent phases could perform analysis on those interactions.
Multi-phase UDTFs also let you decide where processing should occur: locally on each node, or throughout the cluster. If your multi-phase UDTF is like a MapReduce process, you want the first phase of your multi-phase UDTF to process data that is stored locally on the node where the instance of the UDTF is running. This prevents large segments of data from being copied around the Vertica cluster. Depending on the type of processing being performed in later phases, you may choose to have the data segmented and distributed across the Vertica cluster.

Each phase of the UDTF is the same as a traditional (single-phase) UDTF: it receives a table as input, and generates a table as output. The schema for each phase's output does not have to match its input, and each phase can output as many or as few rows as it wants.

You create a subclass of TransformFunction to define the processing performed by each stage. If you already have a TransformFunction from a single-phase UDTF that performs the processing you want a phase of your multi-phase UDTF to perform, you can easily adapt it to work within the multi-phase UDTF.

What makes a multi-phase UDTF different from a traditional UDTF is the factory class you use. You define a multi-phase UDTF using a subclass of MultiPhaseTransformFunctionFactory, rather than the TransformFunctionFactory. This special factory class acts as a container for all of the phases in your multi-step UDTF. It provides Vertica with the input and output requirements of the entire multi-phase UDTF (through the getPrototype() function), and a list of all the phases in the UDTF.

Within your subclass of the MultiPhaseTransformFunctionFactory class, you define one or more subclasses of TransformFunctionPhase. These classes fill the same role as the TransformFunctionFactory class for each phase in your multi-phase UDTF. They define the input and output of each phase and create instances of their associated TransformFunction classes to perform the processing for each phase of the UDTF. In addition to these subclasses, your MultiPhaseTransformFunctionFactory includes fields that provide a handle to an instance of each of the TransformFunctionPhase subclasses.

Partitioning Options for Processing Local Data

UDTFs typically process data that is partitioned in a specific way. For example, a UDTF that processes a web server log file to count the number of hits referred by each partner web site needs to have its input partitioned by a referrer column. Each instance of the UDTF sees the hits referred by a particular partner site so it can count them.

In cases like this, the window partitioning clause should use a PARTITION BY clause. Each node in the cluster partitions the data it stores, sends some of these partitions off to other nodes, and then consolidates the partitions it receives from other nodes and runs an instance of the UDTF to process them.
In other cases, a UDTF might not need to partition input data in a particular way—for example, a UDTF that parses data out of an Apache log file. In this case, you can specify that each UDTF instance process only the data that is stored locally by the node on which it is running. By eliminating the overhead of partitioning data, processing can be much more efficient.

You can tell a UDTF to process only local data with one of the following window partitioning options:

- **PARTITION BEST**: For thread-safe UDTFs only, optimizes performance through multi-threaded queries across multiple nodes.

- **PARTITION NODES**: Optimizes performance of single-threaded queries across multiple nodes.

The query must specify a source table that is replicated across all nodes and contains a single row (similar to the DUAL table). For example, the following statements call a UDTF that parses locally-stored Apache log files:

```sql
=> CREATE TABLE rep (dummy INTEGER) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO rep VALUES (1);
OUTPUT
---------
 1
(1 row)
=> SELECT ParseLogFile('/data/apache/log*') OVER (PARTITION BEST) FROM rep;
```

**C++ API**

This section provides APIs and examples for the C++ API for UDTFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

**TransformFunction and TransformFunctionFactory C++ Interface**

This section describes information that is specific to the C++ API. See UDTF Class Overview for general information about implementing the TransformFunction and TransformFunctionFactory classes.
TransformFunction API

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
        const SizedColumnTypes &argTypes);

virtual void processPartition(ServerInterface &srvInterface,
        PartitionReader &input_reader, PartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface,
        const SizedColumnTypes &argTypes);
```

The PartitionReader and PartitionWriter classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```cpp
virtual TransformFunction *
createTransformFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
        ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
        const SizedColumnTypes &argTypes,
        SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
        SizedColumnTypes &parameterTypes);
```

MultiPhaseTransformFunctionFactory API

The MultiPhaseTransformFunctionFactory class extends TransformFunctionFactory The API provides the following additional methods for extension by subclasses:

```cpp
virtual void getPhases(ServerInterface &srvInterface,
        std::vector< TransformFunctionPhase * > &phases)=0;
```
If using this factory you must also extend TransformFunctionPhase. See the SDK reference documentation.

C++ Example: String Tokenizer

The following example shows a subclass of TransformFunction named StringTokenizer. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the TransformFunctions.so library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```sql
=> CREATE LIBRARY TransformFunctions AS
   '/home/dbadmin/TransformFunctions.so';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize
   AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION

You can then use it from SQL statements, for example:

```sql
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
OUTPUT
--------
  1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
OUTPUT
--------
  1
(1 row)
=> COMMIT;
COMMIT
=> -- Invoke the UDTF
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
  url  | words
-----|-------
www.amazon.com | Online
www.amazon.com | retail
www.amazon.com | merchant
www.amazon.com | and
www.amazon.com | provider
www.amazon.com | of
www.amazon.com | cloud
Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

TransformFunction Implementation

The following code shows the StringTokenizer class.

class StringTokenizer : public TransformFunction
{
  virtual void processPartition(ServerInterface &srvInterface,
                                 PartitionReader &inputReader,
                                 PartitionWriter &outputWriter)
  {
    try {
      if (inputReader.getNumCols() != 1)
        vt_report_error(0, "Function only accepts 1 argument, but %zu provided",
                        inputReader.getNumCols());
      do {
        const VString &sentence = inputReader.getStringRef(0);
        // If input string is NULL, then output is NULL as well
        if (sentence.isNull())
          {
            VString &word = outputWriter.getStringRef(0);
            word.setNull();
            outputWriter.next();
          }
        else
          {
            // Otherwise, let's tokenize the string and output the words
            std::string tmp = sentence.str();
            std::istringstream ss(tmp);
            do
            {
              std::string buffer;
              ss >> buffer;
              // Copy to output
              if (!buffer.empty()) {
                VString &word = outputWriter.getStringRef(0);
                word.copy(buffer);
                outputWriter.next();
              }
            } while (ss);
          }
    } while (inputReader.next() && !isCanceled());
  } catch(std::exception& e) {
    // Handle exception
  }
}
The `processPartition()` function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row and checking for cancellation before advancing. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, `processPartition()` first extracts the VString containing the text from the `PartitionReader` object. The VString class represents a Vertica string value (VARCHAR or CHAR). If there is input, it then tokenizes it and adds it to the output using the `PartitionWriter` object.

Similarly to reading input columns, the `PartitionWriter` class has functions for writing each type of data to the output row. In this case, the example calls the `PartitionWriter` object's `getStringRef()` function to allocate a new VString object to hold the token to output for the first column, and then copies the token's value into the VString.

### TranformFunctionFactory Implementation

The following code shows the factory class.

```cpp
class TokenFactory : public TransformFunctionFactory
{
    // Tell Vertica that we take in a row with 1 string, and return a row with 1 string
    virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
    {
        argTypes.addVarchar();
        returnType.addVarchar();
    }

    // Tell Vertica what our return string length will be, given the input
    // string length
    virtual void getReturnType(ServerInterface &srvInterface,
                                 const SizedColumnTypes &inputTypes,
                                 SizedColumnTypes &outputTypes)
    {
        // Error out if we're called with anything but 1 argument
        if (inputTypes.getColumnCount() != 1)
            vt_report_error(0, "Function only accepts 1 argument, but %zu provided",
                            inputTypes.getColumnCount());

        int input_len = inputTypes.getColumnType(0).getStringLength();

        // Our output size will never be more than the input size
```
outputTypes.addVarchar(input_len, "words");
}

virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface) {
    return vt_createFuncObject<StringTokenizer>(srvInterface.allocator);
};

In this example:

- The UDTF takes a VARCHAR column as input. To define the input column, getPrototype() calls addVarchar() on the ColumnTypes object that represents the input table.
- The UDTF returns a VARCHAR as output. The getPrototype() function calls addVarchar() to define the output table.

This example must return the maximum length of the VARCHAR output column. It sets the length to the length of the input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "words".

Note: You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, getReturnType() sets the column name to ".". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the createTransformFunction() function in the example is boilerplate code. It just calls the vt_returnFuncObj macro with the name of the TransformFunction class associated with this factory class. This macro takes care of instantiating a copy of the TransformFunction class that Vertica can use to process data.

The RegisterFactory Macro

The final step in creating your UDTF is to call the RegisterFactory macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The RegisterFactory macro just takes the name of your factory class:

```
RegisterFactory(TokenFactory);
```
C++ Example: Multi-Phase Transform Function

The following code fragment is from the InvertedIndex UDTF example distributed with the Vertica SDK. It demonstrates subclassing the MultiPhaseTransformFunctionFactory including two TransformFunctionPhase subclasses that define the two phases in this UDTF.

class InvertedIndexFactory : public MultiPhaseTransformFunctionFactory
{
public:
  /**
   * Extracts terms from documents.
   */
  class ForwardIndexPhase : public TransformFunctionPhase
  {
    virtual void getReturnType(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes,
                                SizedColumnTypes &outputTypes)
    {
      // Sanity checks on input we've been given.
      // Expected input: (doc_id INTEGER, text VARCHAR)
      vector<size_t> argCols;
      inputTypes.getArgumentColumns(argCols);
      if (argCols.size() < 2 ||
          !inputTypes.getColumnType(argCols.at(0)).isInt() ||
          !inputTypes.getColumnType(argCols.at(1)).isVarchar())
        vt_report_error(0, "Function only accepts two arguments"
                        "(INTEGER, VARCHAR)");

      // Output of this phase is:
      // (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
      // Number of times term appears within a document.
      outputTypes.addInt("term_freq");
      // Add analytic clause columns: (PARTITION BY term ORDER BY doc_id).
      // The length of any term is at most the size of the entire document.
      outputTypes.addVarcharPartitionColumn(      inputTypes.getColumnType(argCols.at(1)).getStringLength(),
                                              "term");
      // Add order column on the basis of the document id’s data type.
      outputTypes.addOrderColumn(inputTypes.getColumnType(argCols.at(0)),
                                  "doc_id");
    }
    virtual TransformFunction *createTransformFunction(ServerInterface
                                                        &srvInterface)
    {
      return vt_createFuncObj(srvInterface.allocator, ForwardIndexBuilder); }
  }

  /**
   * Constructs terms' posting lists.
   */
  class InvertedIndexPhase : public TransformFunctionPhase
  {
    virtual void getReturnType(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes,
                                SizedColumnTypes &outputTypes)
    {
      // Sanity checks on input we've been given.
      // Expected input:
Most of the code in this example is similar to the code in a TransformFunctionFactory class:
Both TransformFunctionPhase subclasses implement the getReturnType() function, which describes the output of each stage. This is similar to the getReturnType() function from the TransformFunctionFactory class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF.

The first phase calls SizedColumnTypes::addVarcharPartitionColumn() (rather than just addVarcharColumn()) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls SizedColumnTypes::addOrderColumn() to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as addIntOrderColumn()) so it can pass the data type of the original column through to the output column.

Note: Any order by column or partition by column set by the final phase of the UDTF in its getReturnType() function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

The MultiPhaseTransformFunctionFactory class implements the getPrototype() function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the TransformFunctionFactory::getPrototype() function.

The unique function implemented by the MultiPhaseTransformFunctionFactory class is getPhases(). This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.

The MultiPhaseTransformFunctionFactory.getPhases() function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.

Note: Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the TransformFunctionPhase::setPrepass() function of the first phase's TransformFunctionPhase instance from within the getPhase() function.
Notes

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each `TransformFunctionPhase::getReturnType()` implementation performs a sanity check on its input and output schemas. Your `TransformFunction` subclasses can also perform these checks in their `processPartition()` function.

- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode, Vertica may terminate UDTFs that use too much memory. See Resource Use for C++ UDxs.

Java API

This section provides APIs and examples for the Java API for UDTFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

TransformFunction and TransformFunctionFactory

Java Interface

This section describes information that is specific to the Java API. See UDTF Class Overview for general information about implementing the `TransformFunction` and `TransformFunctionFactory` classes.

TransformFunction API

The API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);
public abstract void processPartition(ServerInterface srvInterface,
                                       PartitionReader input_reader, PartitionWriter input_writer)
                                          throws UdfException, DestroyInvocation;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```
The PartitionReader and PartitionWriter classes provide getters and setters for column values, along with next() to iterate through partitions. See the API reference documentation for details.

TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```java
public abstract TransformFunction createTransformFunction(ServerInterface srvInterface);
public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);
public abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException;
public voidgetParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

MultiPhaseTransformFunctionFactory API

The MultiPhaseTransformFunctionFactory class extends TransformFunctionFactory The API provides the following additional methods for extension by subclasses:

```java
public abstract void getPhases(ServerInterface srvInterface, Vector<TransformFunctionPhase> phases);
```

If using this factory you must also extend TransformFunctionPhase. See the SDK reference documentation.

Java Example: String Tokenizer

The following example shows a subclass of TransformFunction named StringTokenizer. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

You can then use it from SQL statements, for example:

```sql
CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE T
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
OUTPUT
--------
```
1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
OUTPUT
-------
 1
(1 row)
=> COMMIT;
COMMIT
=> -- Invoke the UDTF
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
        url   |   words
-----------------------------
www.amazon.com  | Online
www.amazon.com  | retail
www.amazon.com  | merchant
www.amazon.com  | and
www.amazon.com  | provider
www.amazon.com  | of
www.amazon.com  | cloud
www.amazon.com  | services
www.vertica.com | World's
www.vertica.com | fastest
www.vertica.com | analytic
www.vertica.com | database
(12 rows)

TransformFunction Implementation

The following code defines the StringTokenizer class.

To make code management simpler, the TransformFunction class is defined as an inner class of the TransformFactoryClass.

// You will need to specify the full package when creating functions based on // the classes in your library.
package com.mycompany.example;
// Import the entire Vertica SDK
import com.vertica.sdk.*;

public class TokenFactory extends TransformFunctionFactory
{
    // Set the number and data types of the columns in the input and output rows.
    @Override
    public void getPrototype(ServerInterface srvInterface,
                               ColumnTypes argTypes, ColumnTypes returnType)
    {
        // Define two input columns: an INTEGER and a VARCHAR
        argTypes.addInt(); // Row id
        argTypes.addVarchar(); // Line of text

        // Define the output columns
        returnType.addVarchar(); // The token
        returnType.addInt(); // The row in which this token occurred
        returnType.addInt(); // The position in the row of the token
Set the width of any variable-width output columns, and also name
// them.
@Override
public void getReturnType(ServerInterface srvInterface, SizedColumnTypes
        inputTypes, SizedColumnTypes outputTypes)
{
    // Set the maximum width of the token return column to the width
    // of the input text column and name the output column "Token"
    outputTypes.addVarchar(inputTypes.getColumnType(1).getStringLength(), "token");
    // Name the two INTEGER output columns
    outputTypes.addInt("row_id");
    outputTypes.addInt("token_position");
}

// Inner class that actually performs work.
public class TokenizeString extends TransformFunction
{
    @Override
    public void processPartition(ServerInterface srvInterface,
        PartitionReader inputReader,
        PartitionWriter outputWriter)
        throws UdfException, DestroyInvocation
    {
        try {
            // Loop over all rows passed in in this partition.
            do {
                // Test if the row ID is null. If so, then do not
                // process any further. Skip to next row of input.
                if(inputReader.isLongNull(0)) {
                    srvInterface.log("Skipping row with null id.");
                    continue; // Move on to next row of input
                }
                // Get the row ID now that we know it has a value
                long rowId = inputReader.getLong(0);
                // Test if the input string is NULL. If so, return NULL
                // for token and string position.
                if (inputReader.isStringNull(1)) {
                    outputWriter.setStringNull(0);
                    outputWriter.setLong(1, rowId);
                    outputWriter.setLongNull(2);
                    outputWriter.next(); // Move to next line of output
                } else {
                    // Break string into tokens. Output each word as its own
                    // value.
                    String[] tokens = inputReader.getString(1).split("\\s+");
                    // Output each token on a separate row.
                    for (int i = 0; i < tokens.length; i++) {
                        outputWriter.getStringWriter(0).copy(tokens[i]);
                        outputWriter.setLong(1,rowId);
                        outputWriter.setLong(2,i);
                        outputWriter.next(); // Advance to next row of output
                    }
                }
            } // Loop until there are no more input rows in partition.
            } while (inputReader.next());
        } catch (Exception e) {
            throw new UdfException(e);
Java Example: Multi-Phase Transform Function

The following code is excerpted from the InvertedIndexFactory SDK example. You can find the complete code in /opt/vertica/sdk/examples/JavaUDx/TransformFunctions.

```java
public class InvertedIndexFactory extends MultiPhaseTransformFunctionFactory {
    public class ForwardIndexPhase extends TransformFunctionPhase {
        // ...
    }

    public class InvertedIndexPhase extends TransformFunctionPhase {
        @Override
        public TransformFunction createTransformFunction(ServerInterface srvInterface) {
            return new InvertedIndexBuilder();
        }

        @Override
        public void getType(ServerInterface srvInterface,
                            SizedColumnTypes inputTypes,
                            SizedColumnTypes outputTypes) {
            // Sanity checks on input we've been given.
            // Expected input:
            // (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
            ArrayList<Integer> argCols = new ArrayList<Integer>();
            inputTypes.getArgumentColumns(argCols);

            ArrayList<Integer> pByCols = new ArrayList<Integer>();
            inputTypes.getPartitionByColumns(pByCols);

            ArrayList<Integer> oByCols = new ArrayList<Integer>();
            inputTypes.getOrderByColumns(oByCols);

            if (argCols.size() != 1 || pByCols.size() != 1 || oByCols.size() != 1)
```
|| !inputTypes.getColumnType(argCols.get(0)).isInt()
|| !inputTypes.getColumnType(pByCols.get(0)).isVarchar()
|| !inputTypes.getColumnType(oByCols.get(0)).isInt())
    throw new UdfException(0, "Function expects an argument (INTEGER) with "
        + "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
}

// Output of this phase is:
// (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq
// INTEGER).
outputTypes.addVarchar(inputTypes.getColumnType(pByCols.get(0))
    .getLength(), "term");
outputTypes.addInt("doc_id");
// Number of times term appears within the document.
outputTypes.addInt("term_freq");
// Number of documents where the term appears in.
outputTypes.addInt("corp_freq");
}

@Override
public void getPhases(ServerInterface srvInterface,
    Vector<TransformFunctionPhase> phases) {
 ForwardIndexPhase fwardIdxPh;
 InvertedIndexPhase invIdxPh;
 fwardIdxPh = new ForwardIndexPhase();
 invIdxPh = new InvertedIndexPhase();
    fwardIdxPh.setPrepass();
    phases.add(fwardIdxPh);
    invIdxPh = new InvertedIndexPhase();
    invIdxPh.setPrepass();
    phases.add(invIdxPh);
}

@Override
public void getPrototype(ServerInterface srvInterface,
    ColumnTypes argTypes, ColumnTypes returnTypes) {
    // Expected input: (doc_id INTEGER, text VARCHAR).
    argTypes.addInt();
    argTypes.addVarchar();
    // Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER,
    // corp_freq INTEGER)
    returnTypes.addVarchar();
    returnTypes.addInt();
    returnTypes.addInt();
    returnTypes.addInt();
}

Most of the code in this example is similar to the code in a TransformFunctionFactory
class. The getReturnType method is similar, but in a TransformFunctionPhase it can also
partition and order the data. The partitions and order are used by the next phase, but they are ignored after the final phase.

The MultiPhaseTransformFunctionFactory class adds the getPhases method. This method defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute. You should also indicate the first phase by calling setPrepass() on it. Doing so can lead to better performance.

There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. Vertica might terminate UDTFs that use too much memory.

**Python API**

This section provides APIs and examples for the Python SDK for UDTFs.

For more information on setting up a Python development environment, see Developing with the Python SDK.

**UDTF Python Interface**

This section describes information that is specific to the Python API. See UDTF Class Overview for general information about implementing the TransformFunction and TransformFunctionFactory classes. See Python SDK Documentation for detailed reference documentation for all API classes.

**TransformFunction API**

The API provides a single method for extension by subclasses:

```python
setup(self, server_interface, col_types)
processPartition(self, server_interface, partition_reader, partition_writer)
destroy(self, server_interface, col_types)
```

The PartitionReader and PartitionWriter classes provide getters and setters for column values, along with next() to iterate through partitions. See the API reference documentation for details.

**TransformFunctionFactory API**

The API provides the following methods for extension by subclasses:
createTransformFunction(self, srv)
getPrototype(self, srv_interface, arg_types, return_type)
getReturnType(self, srv_interface, arg_types, return_type)
getParameterType(self, server_interface, parameterTypes)

Python Example: String Tokenizer

The following example shows a transform function that breaks an input string into tokens (based on whitespace). It is similar to the tokenizer examples for C++ and Java.

Loading and Using the Example

Create the library and function:

```sql
=> CREATE LIBRARY pyudtf AS '/home/dbadmin/udx/tokenize.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize AS NAME 'StringTokenizerFactory' LIBRARY pyudtf;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```sql
=> CREATE TABLE words (w VARCHAR);
CREATE TABLE
=> COPY words FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> this is a test of the python udtf
>> .

=> SELECT tokenize(w) OVER () FROM words;
token
--------
this
is
a
test
of
the
python
udtf
(8 rows)
```

UDTF Python Code

The following code defines the tokenizer and its factory.
class StringTokenizer(vertica_sdk.TransformFunction):
    """
    Transform function which tokenizes its inputs.
    For each input string, each of the whitespace-separated tokens of that string is produced as output.
    """
    def processPartition(self, server_interface, input, output):
        while True:
            for token in input.getString(0).split():
                output.setString(0, token)
                output.next()
            if not input.next():
                break

class StringTokenizerFactory(vertica_sdk.TransformFunctionFactory):
    def getPrototype(self, server_interface, arg_types, return_type):
        arg_types.addVarChar()
        return_type.addVarChar()
    def getReturnType(self, server_interface, arg_types, return_type):
        return_type.addColumn(arg_types.getColumnType(0), "tokens")
    def createTransformFunction(cls, server_interface):
        return StringTokenizer()

R API

This section provides APIs and examples for the R API for UDFs.
For information on setting up an R development environment and compiling and packaging libraries, see Developing with the R SDK.

Transform Function and Transform Function Factory R Interface

This section describes information that is specific to the R API. See R SDK API Documentation for general information about implementing transform functions.

Transform Function API

The API provides the following framework for extension by R function:

```r
FunctionName <- function(input.data.frame, parameters.data.frame) {
    # Computations
    # The function must return a data frame.
    return(output.data.frame)
}
```
Transform Function Factory API

The API provides the following framework for extension by R function:

```r
FunctionNameFactory <- function() {
  list(name = FunctionName,
       udxtype = c("transform"),
       intype = c("int"),
       outtype = c("int"))
}
```

R Example: Log Tokenizer

The LogTokenizer transform function reads a varchar from a table, a log message. It then tokenizes each of the log messages, returning each of the tokens.

You can find more UDx examples in the VerticaGithub repository, [https://github.com/vertica/UDx-Examples](https://github.com/vertica/UDx-Examples).

Load the Function and Library

Create the library and the function.

```sql
=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDTF.

```sql
=> SELECT machine,
        LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)
FROM error_logs;
```

<table>
<thead>
<tr>
<th>machine</th>
<th>Token</th>
</tr>
</thead>
<tbody>
<tr>
<td>node001</td>
<td>ERROR</td>
</tr>
<tr>
<td>node001</td>
<td>345</td>
</tr>
<tr>
<td>node001</td>
<td>-</td>
</tr>
<tr>
<td>node001</td>
<td>Broken</td>
</tr>
<tr>
<td>node001</td>
<td>pipe</td>
</tr>
<tr>
<td>node001</td>
<td>WARN</td>
</tr>
<tr>
<td>node001</td>
<td>-</td>
</tr>
<tr>
<td>node001</td>
<td>Nearly</td>
</tr>
<tr>
<td>node001</td>
<td>filled</td>
</tr>
</tbody>
</table>
UDTF R Code

LogTokenizer <- function(input.data.frame, parameters.data.frame) {
  # Take the spliton parameter passed by the user and assign it to a variable
  # in the function so we can use that as our tokenizer.
  if (is.null(parameters.data.frame[['spliton']])) {
    stop("NULL value for spliton! Token cannot be NULL.")
  } else {
    split.on <- as.character(parameters.data.frame[['spliton']])
  }
  # Tokenize the string.
  tokens <- vector(length=0)
  for (string in input.data.frame[, 1]) {
    tokenized.string <- strsplit(string, split.on)
    for (token in tokenized.string) {
      tokens <- append(tokens, token)
    }
  }
  final.output <- data.frame(tokens)
  return(final.output)
}

LogTokenizerFactory <- function() {
  list(name = LogTokenizer,
       udxtype = c("transform"),
       intype = c("varchar"),
       outtype = c("varchar"),
       outtypecallback=LogTokenizerReturn,
       parametertypecallback=LogTokenizerParameters)
}

LogTokenizerParameters <- function() {
  parameters <- list(datatype = c("varchar"),
                     length = c("NA"),
                     scale = c("NA"),
                     name = c("spliton"))
  return(parameters)
}

LogTokenizerReturn <- function(arg.data.frame, parm.data.frame) {
  output.return.type <- data.frame(datatype = rep(NA,1),
"node001" | disk
"node002" | ERROR
"node002" | 111
"node002" | -
"node002" | Flooded
"node002" | roads
"node003" | ERROR
"node003" | 222
"node003" | -
"node003" | Plain
"node003" | old
"node003" | broken
(21 rows)
```r
length = rep(NA,1),
scale = rep(NA,1),
name = rep(NA,1))
output.return.type$datatype <- c("varchar")
output.return.type$name <- c("Token")
return(output.return.type)
}
```
Load (UDLs)

The **COPY statement** offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The User-Defined Load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process. The SDK provides APIs for C++ and Java.

You use three types of UDL functions during development, one for each stage of the data-load process:

- **User-Defined Source** (UDSource): Controls how the COPY statement obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.

- **User-Defined Filter** (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple User-Defined Filters together, for example unzipping and then converting.

- **User-Defined Parser** (UDP parse r): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a User-Defined Chunker (UDChunker, C++ only), to have the parser perform parallel parsing.

After the final step, COPY inserts the data into a table, or rejects it, if it is not in the correct format.

User-Defined Source

A User-Defined Source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a User-Defined Source to access the data from an HTTP source using cURL. While you can use only a single User-Defined Source in a COPY statement, that source function can pull data from multiple sources.

The UDSource class is responsible for acquiring data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a UDSource, you must also implement a corresponding SourceFactory.

See UDSource Class and SourceFactory Class for API details.
UDSource Class

You can subclass the UDSOURCE class when you need to load data from a source type that COPY does not already support.

Each instance of your UDSOURCE subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

UDSource Methods

The UDSOURCE class defines the following methods. Your subclass must override process(). You can optionally override the others.

For the signatures of these methods and language-specific information, see Source Classes (C++) and Source Classes (Java).

Setting Up

COPY calls setup() before the first time it calls process(). Use setup() to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the UDSOURCE can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Processing a Source

COPY calls process() repeatedly during query execution to read data and write it to the DataBuffer passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value StreamState.OUTPUT_NEEDED. When Vertica gets this return value, it will call the method again. This second call occurs after the output buffer has been processed by the next stage in the data-load process. Returning StreamState.DONE indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.
**Tearing Down**

COPY calls destroy() after the last time that process() is called. This method frees any resources reserved by the setup() or process() methods, such as file handles or network connections that the setup() method allocated.

**Accessors**

A source can define two accessors, getSize() and getUri().

COPY might call getSize() to estimate the number of bytes of data to be read before calling process(). This value is an estimate only and is used to indicate the file size in the LOAD_STREAMS table. Because Vertica can call this method before calling setup(), getSize() must not rely on any resources allocated by setup().

This method should not leave any resources open. For example, do not save any file handles opened by getSize() for use by the process() method. Doing so can exhaust the available resources, because Vertica calls getSize() on all instances of your UDSource subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system's supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls getUri() during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this UDSource.

**SourceFactory Class**

If you write a source, you must also write a source factory. Your subclass of the SourceFactory class is responsible for:

- Performing the initial validation of the parameters passed to your UDSource.
- Setting up any data structures your UDSource instances need to perform their work. This information can include recording which nodes will read which data source.
- Creating one instance of your UDSource subclass for each data source (or portion thereof) that your function reads on each host.
The simplest source factory creates one UDSource instance per data source per executor node. You can also use multiple concurrent UDSource instances on each node. This behavior is called concurrent load. To support both options, SourceFactory has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

SourceFactory Methods

The SourceFactory class defines several methods. Your class must override prepareUDSources(); it may override the other methods.

**Setting Up**

Vertica calls plan() once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the COPY statement and provide error messages if there are any issues. You can read the parameters by getting a ParamReader object from the instance of ServerInterface passed into the plan() method.

- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's filesystem, can be read only by a single specified host.

You store the list of hosts to read the data source by calling the setTargetNodes() method on the NodeSpecifyingPlanContext object. This object is passed into your plan() method.

- Store any information that the individual hosts need to process the data sources in the NodeSpecifyingPlanContext instance passed to the plan() method. For example, you could store assignments that tell each host which data sources to process. The plan() method runs only on the initiator node, and the prepareUDSources() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the NodeSpecifyingPlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString().
Creating Sources

Vertica calls prepareUDSources() on all hosts that the plan() method selected to load data. This call instantiates and returns a list of UDSource subclass instances. If you are not using concurrent load, return one UDSource for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an ExecutorPlanContext as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

For concurrent load, you can find out how many threads are available on the node to run UDSource instances by calling getLoadConcurrency() on the ExecutorPlanContext that is passed in.

Defining Parameters

Implement getParameterTypes() to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Requesting Threads for Concurrent Load

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement getDesiredThreads(). Vertica calls this method before it calls prepareUDSources(), so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into
account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The `FilePortionSourceFactory` example implements this method; see Source Example: Concurrent Load.

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing `isSourceApportionable()`. Returning `true` from this method does not guarantee that the source will apportion the load. However, returning `false` indicates that it will not try to do so. See Apportioned Load for more information.

Often, a `SourceFactory` that implements `getDesiredThreads()` also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without ssapportioning.

### User-Defined Filter

User-Defined Filter functions allow you to manipulate data obtained from a source in various ways.

For example, a filter could:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.

You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a `UDFilter`, you must also implement a corresponding `FilterFactory`. See `UDFilter Class` and `FilterFactory Class` for API details.

### UDFilter Class

The `UDFilter` class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A `UDFilter` is instantiated by a corresponding `FilterFactory` on each host in the Vertica cluster that is performing filtering for the data source.
UDFilter Methods

The `UDFilter` class defines the following methods. Your subclass must override `process()`. You can optionally override the other methods.

For the signatures of these methods and language-specific information, see Filter Classes (C++) and Filter Classes (Java).

Setting Up

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Filtering Data

COPY calls `process()` repeatedly during query execution to filter data. The method receives two instances of the `DataBuffer` class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The `process()` method should process data until it either runs out of data to read or runs out of space in the output buffer. When one of these conditions occurs, your method should return one of the following values defined by StreamState:

- OUTPUT_NEEDED if the filter needs more room in its output buffer.
- INPUT_NEEDED if the filter has run out of input data (but the data source has not yet been fully processed).
- DONE if the filter has processed all of the data in the data source.
- KEEP_GOING if the filter cannot proceed for an extended period of time. The method will be called again, so do not block indefinitely. If you do, then you prevent your user from canceling the query.

Before returning, your `process()` method must set the `offset` property in each `DataBuffer`. In the input buffer, set it to the number of bytes that the method successfully
read. In the output buffer, set it to the number of bytes the method wrote. Setting these properties allows the next call to process() to resume reading and writing data at the correct points in the buffers.

Your process() method also needs to check the InputState object passed to it to determine if there is more data in the data source. When this object is equal to END_OF_FILE, then the data remaining in the input data is the last data in the data source. Once it has processed all of the remaining data, process() must return DONE.

## Tearing Down

COPY calls destroy() after the last time it calls process(). This method frees any resources reserved by the setup() or process() methods. Vertica calls this method after the process() method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call setup() on the object again. On subsequent calls Vertica directs the method to filter the data in a new data stream. Therefore, your destroy() method should leave an object of your UDFilter subclass in a state where the setup() method can prepare it to be reused.

## FilterFactory Class

If you write a filter, you must also write a filter factory to produce filter instances. To do so, subclass the FilterFactory class.

Your subclass performs the initial validation and planning of the function execution and instantiates UDFilter objects on each host that will be filtering data.

Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

## FilterFactory Methods

The FilterFactory class defines the following methods. Your subclass must override the prepare() method. It may override the other methods.

## Setting Up

Vertica calls plan() once on the initiator node, to perform the following tasks:
Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a ParamReader object from the instance of ServerInterface passed into your plan() method.

Store any information that the individual hosts need in order to filter data in the PlanContext instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The plan() method runs only on the initiator node, and the prepare() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString.

Note: ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating Filters

Vertica calls prepare() to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to complete the work based on available resources. You cannot specify the nodes on which the work is done.

Defining Parameters

Implement getParameterTypes() to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.
User-Defined Parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use User-Defined Parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you could load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

COPY supports a single User-Defined Parser that you can use with a UDSource and zero or more instances of UDFilter.

Sometimes you can improve the performance of your parser by adding a chunker. A chunker divides up the input and uses multiple threads to parse it. See Cooperative Parse. Chunkers are available only in the C++ API.

Under special circumstances you can further improve performance by using apportioned load, an approach where multiple Vertica nodes parse the input. See Apportioned Load.

If you implement a UDParser, you must also implement a corresponding ParserFactory. See UDParser Class, ParserFactory Class, and UDChunker Class for API details.

UDParser Class

You can subclass the UDParser class when you need to parse data that is in a format that the COPY statement's native parser cannot handle.

During parser execution, Vertica always calls three methods: setup(), process(), and destroy(). It might also call getRejectedRecord().

UDParser Methods

The UDParser class defines the following methods. Your subclass must override the process() and getRejectedRecord() methods. You can optionally override the other methods.

For the signatures of these methods and language-specific information, see Parser Classes (C++) and Parser Classes (Java).
Note: The UDParse class performs important initialization required by all subclasses, including initializing the StreamWriter object used by the parser. Therefore, your constructor must call super().

Setting Up

COPY calls setup() before the first time it calls process(). Use setup() to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the process() method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Parsing

COPY calls process() repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by InputState:

- **OK**: currently at the start of or in the middle of a stream
- **END_OF_FILE**: no further data is available.
- **END_OF_CHUNK**: the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.
- **START_OF_PORTION**: the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load. You can use the getPortion() method to access the offset and size of the portion.
- **END_OF_PORTION**: the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.
The process() method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is not automatically null-terminated.

A parser has an associated StreamWriter object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on StreamWriter to write that value to the output stream. See Writing Data for more information about these methods.

A single call to process() might write several rows of data. When your parser finishes processing a row of data, it must call next() on its StreamWriter to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your process() method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by StreamState:

- **INPUT_NEEDED**: the parser has reached the end of the buffer and needs more data to parse.
- **DONE**: the parser has reached the end of the input data stream.
- **REJECT**: the parser has rejected the last row of data it read (see Rejecting Rows).

### Tearing Down

COPY calls destroy() after the last time that process() is called. It frees any resources reserved by the setup() or process() method.

Vertica calls this method after the process() method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might remain. In such cases, Vertica might later call setup() on the object again and have it parse the data in a new data stream. Therefore, write your destroy() method so that it leaves an instance of your UDParse subclass in a state where setup() can be safely called again.

### Reporting Rejections

If process() rejects a row, Vertica calls getRejectedRecord() to report it. Usually, this method returns an instance of the RejectedRecord class with details of the rejected row.
Writing Data

A parser has an associated StreamWriter object, which you access by calling getStreamWriter(). In your process() implementation, use the setType() methods on the StreamWriter object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type long to the fourth column (index 3) in the current row:

```java
StreamWriter writer = getStreamWriter();
...
writer.setLongValue(3, 98.6);
```

StreamWriter provides methods for all the basic types, such as setBooleanValue(), setStringValue(), and so on. See the API documentation for a complete list of StreamWriter methods, including options that take primitive types or explicitly set entries to null.

The Java API supports additional options for writing data. See Parser Classes.

Rejecting Rows

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a RejectedRecord object, or in fields on your UDParse subclass, until they are needed.

2. Updating the row's position in the input buffer by updating input.offset so it can resume parsing with the next row.

3. Signaling that it has rejected a row by returning with the value StreamState.REJECT.

4. Returning an instance of the RejectedRecord class with the details about the rejected row.

Breaking Up Large Loads

Vertica provides two ways to break up large loads. Apportioned Load allows you to distribute a load among several database nodes. Cooperative Parse (C++ only) allows you to distribute a load among several threads on one node.
UDChunker Class

You can subclass the UDChunker class to allow your parser to support Cooperative Parse. This class is available only in the C++ API.

Fundamentally, a UDChunker is a very simplistic parser. Like UDParse, it has the following three methods: setup(), process(), and destroy(). You must override process(); you may override the others. This class has one additional method, alignPortion(), which you must implement if you want to enable Apportioned Load for your UDChunker.

For the signatures of these methods, see Parser Classes.

Setting Up and Tearing Down

As with UDParse, you can define initialization and cleanup code for your chunker. Vertica calls setup() before the first call to process() and destroy() after the last call to process(). Your object might be reused among multiple load sources, so make sure that setup() completely initializes all fields.

Chunking

Vertica calls process() to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:

- **OK**: the input buffer begins at the start of or in the middle of a stream.
- **END_OF_FILE**: no further data is available.
- **END_OF_PORTION**: the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is END_OF_FILE, the chunker should set the input.offset marker to input.size and return DONE. Returning INPUT_NEEDED is an error.

If the input state is OK, the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the input.offset marker with the byte after the end of the last record in the buffer and return CHUNK_ALIGNED. For example, if the input is "abc~def" and "~" is a record terminator, this method should set input.offset to 4, the position of "d". If process() reaches the end of the input without finding a record boundary, it should return INPUT_NEEDED.

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of
the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is END_OF_PORTION, the chunker should behave as it does for an input state of OK, except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The process() method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return KEEP_GOING. Failing to return KEEP_GOING has several consequences, such as preventing your user from being able to cancel the query.

See Chunker Example: Delimited Parser and Chunker for an example of the process() method using chunking.

Aligning Portions

If your chunker supports apportioned load, implement the alignPortion() method. Vertica calls this method one or more times, before calling process(), to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

- START_OF_PORTION: the beginning of the buffer corresponds to the start of the portion. You can use the getPortion() method to access the offset and size of the portion.
- OK: the input buffer is in the middle of a portion.
- END_OF_PORTION: the end of the buffer corresponds to the end of the portion or beyond the end of a portion.
- END_OF_FILE: no further data is available.

The method should scan from the beginning of the buffer to the start of the first complete record. It should set input.offset to this position and return one of the following values:

- DONE, if it found input.offset to this position and return one of the following values:
- INPUT_NEEDED, if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of END_OF_FILE.
- REJECT, if the portion (not buffer) does not contain the start of any chunk.
ParserFactory Class

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the ParserFactory class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The ParserFactory class defines the following methods. Your subclass must override the prepare() method. It may override the other methods.

Setting Up

Vertica calls plan() once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a ParamReader object from the instance of ServerInterface passed into your plan() method.

- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the PlanContext instance passed in through the planCtxt parameter. The plan() method runs only on the initiator node, and the prepareUDSources() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString.

Note: ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating Parsers

Vertica calls prepare() on each node to create and initialize your parser, using data stored by the plan() method.
Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Defining Parser Outputs

Implement `getParserReturnType()` to define the data types of the table columns that the parser outputs. If applicable, `getParserReturnType()` also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the `argType` and `perColumnParamReader` arguments and verifies that it can output the appropriate data types. If `getParserReturnType()` is prepared to output the data types, it calls methods on the `SizedColumnTypes` object passed in the `returnType` argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as CHAR, VARCHAR, and LONG VARBINARY), specify its maximum length.
- For NUMERIC types, specify its precision and scale.
- For Time/Timestamp types (with or without time zone), specify its precision (-1 means unspecified).
- For all other types, no length or precision specification is required.

Supporting Cooperative Parse

To support Cooperative Parse, implement `prepareChunker()` and return an instance of your UDChunker subclass. If `isChunkerApportionable()` returns true, then it is an error for this method to return null.

Cooperative parse is currently supported only in the C++ API.

Supporting Apportioned Load

To support Apportioned Load, your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement `isParserApportionable()` and
return true. To indicate that the chunker can apportion a load, implement isChunkerApportionable() and return true.

The isChunkerApportionable() method takes a ServerInterface as an argument, so you have access to the parameters supplied in the COPY statement. You might need this information if the user can specify a record delimiter, for example. Return true from this method if and only if the factory can create a chunker for this input.

Load Parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- Distributed load: Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.

- Cooperative parse: A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See Cooperative Parse.

- Apportioned load: Vertica; divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load divides the load at planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See Apportioned Load.

You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See Combining Cooperative Parse and Apportioned Load.

Cooperative Parse

By default, Vertica parses a data source in a single thread on one database node. You can optionally use cooperative parse to parse a source using multiple threads on a node. More specifically, data from a source passes through a chunker that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDxs. (See Fenced Mode.)

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.
Chunkers are created by parser factories. At load time, Vertica first calls the UDChunker to divide the input into chunks and then calls the UDParser to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See Combining Cooperative Parse and Apportioned Load.

How Vertica Divides a Load

When Vertica receives data from a source, it calls the chunker's process() method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the process() method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the process() method on the parser.

Implementing Cooperative Parse

To implement cooperative parse, perform the following actions:

- Subclass UDChunker and implement process().
- In your ParserFactory, implement prepareChunker() to return a UDChunker.

See Chunker Example: Delimited Parser and Chunker for a UDChunker that also supports apportioned load.

Apportioned Load

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as apportioned load. Some of the parsers built into Vertica support apportioned load.

Apportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

It is possible for a parser to not support apportioned load directly but to have a chunker that supports apportioning.

You can use apportioned load and cooperative parse independently or together. See Combining Cooperative Parse and Apportioned Load.
How Vertica Apportions a Load

If both the parser and its source support apportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The SourceFactory breaks the input into portions and assigns them to execution nodes. Each Portion consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a UDSource for the given portion.

The UDParse first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
- If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.

The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that begin in the assigned portion, regardless of where they end. Most of this work occurs within the process() method of the parser.

Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses Cooperative Parse, then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

Implementing Apportioned Load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

In your SourceFactory subclass:

- Implement isSourceApportionable() and return true.
- Implement plan() to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter writer on the plan context (PlanContext::getWriter()).
Implement `prepareUDSources()`. Vertica calls this method on each execution node with the plan context created by the factory. This method returns the `UDSource` instances to be used for this node's assigned portions.

If sources can take advantage of parallelism, you can implement `getDesiredThreads()` to request a number of threads for each source. See `SourceFactory Class` for more information about this method.

In your `UDSource` subclass, implement `process()` as you would for any other source, using the assigned portion. You can retrieve this portion with `getPortion()`.

In your `ParserFactory` subclass:

- Implement `isParserApportionable()` and return true.

- If your parser uses a `UDChunker` that supports apportioned load, implement `isChunkerApportionable()`.

In your `UDParser` subclass:

- Write your `UDParser` subclass to operate on portions rather than whole sources. You can do so by handling the stream states `PORTION_START` and `PORTION_END`, or by using the `ContinuousUDParser API`. Your parser must scan for the beginning of the portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.

- Handle the special case of a portion containing no record start by returning without writing any output.

In your `UDChunker` subclass, implement `alignPortion()`. See `Aligning Portions`.

Example

The SDK provides a C++ example of apportioned load in the `ApportionLoadFunctions` directory:

- `FilePortionSource` is a subclass of `UDSource`.

- `DelimFilePortionParser` is a subclass of `ContinuousUDParser`.

Use these classes together. You could also use `FilePortionSource` with the built-in delimited parser.
The following example shows how you can load the libraries and create the functions in the database:

```sql
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';
=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';
=> CREATE SOURCE FilePortionSource AS
    LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;
=> CREATE PARSER DelimFilePortionParser AS
    LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```sql
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSER DelimFilePortionParser(delimiter = '|', record_terminator = '~');
```

## Combining Cooperative Parse and Apportioned Load

You can enable both [Cooperative Parse](#) and [Apportioned Load](#) in the same parser, allowing Vertica to decide how to load data.

### Deciding How to Divide a Load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires SourceFactory support. Given a suitable UDSource, at planning time Vertica calls the `isParserApportionable()` method on the ParserFactory. If this method returns `true`, Vertica apportions the load.

If `isParserApportionable()` returns `false` but `isChunkerApportionable()` returns `true`, then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apportions the load.

If neither of these methods returns `true`, then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.
If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but `prepareChunker()` does not return a UDChunker instance, Vertica reports an error.

**Executing Apportioned, Cooperative Loads**

If a load uses both apportioned load and cooperative parse, Vertica uses the `SourceFactory` to break the input into portions. It then assigns the portions to execution nodes. See [How Vertica Apportions a Load](#).

On the execution node, Vertica calls the chunker's `alignPortion()` method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's `process()` method repeatedly. See [How Vertica Divides a Load](#).

The chunks found by the chunker are then sent to the parser's `process()` method for processing in the usual way.

**Continuous Load**

The `ContinuousUDSource`, `ContinuousUDFilter`, and `ContinuousUDPParser` classes allow you to write and process data as needed instead of having to iterate through the data.

Each class includes the following functions:

- `initialize()` - Invoked before `run()`. You can optionally override this function to perform setup and initialization.

- `run()` - Processes the data.

- `deinitialize()` - Invoked after `run()` has returned. You can optionally override this function to perform tear-down and destruction.

Do not override the `setup()`, `process()`, and `destroy()` functions that are inherited from parent classes.

You can use the `yield()` function to yield control back to the server during idle or busy loops so the server can check for status changes or query cancellations.
These three classes use associated ContinuousReader and ContinuousWriter classes to read input data and write output data.

C++ API

This section provides APIs and examples for the C++ API for UDLs. For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

Requirements for C++ UDLs

C++ UDLs:

- Can run in Fenced Mode. Vertica enables fenced mode by default when you create a source, filter, or parser function, in Vertica unless you explicitly state otherwise.

- Must not permit an exception to be passed back to Vertica. Doing so could lead to issues such as memory leaks caused by the memory allocated by the exception never being freed. Your UDL should always contain a top-level try-catch block to catch any stray exceptions caused by your code or libraries that your code calls.

- Must properly free any resources that the UDL function allocates. Even a single byte of allocated memory that is not freed can become an issue in a UDL that is called over millions of rows. Instead of allocating memory directly, your function should use the memory allocation macros in the Vertica SDK. See Allocating Resources for UDxs for details.

The header files that define the majority of classes and methods are VerticaUDx.h and VerticaUDl.h. These header files, along with the main Vertica.h header file, are available in /opt/vertica/sdk/include.

Source Classes

See User-Defined Source for general information about implementing the UDSource and SourceFactory classes. This section describes information that is specific to the C++ API.

In addition to the examples in this section, see C++ Example: Cancelable UDSource.

UDSource API

The API provides the following methods for extension by subclasses:
virtual void setup(ServerInterface &srvInterface);
virtual StreamState process(ServerInterface &srvInterface,
DataBuffer &output)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface);
virtual vint getSize();
virtual std::string getUri();

ContinuousUDSource API

The ContinuousUDSource class extends UDSource and adds the following methods for extension by subclasses:

virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);

SourceFactory API

The API provides the following methods for extension by subclasses:

virtual void plan(ServerInterface &srvInterface,
NodeSpecifyingPlanContext &planCtxt);
// must implement exactly one of prepareUDSources() or prepareUDSourcesExecutor()
virtual std::vector< UDSource * > prepareUDSources(ServerInterface &srvInterface,
    NodeSpecifyingPlanContext &planCtxt);

virtual std::vector< UDSource * > prepareUDSourcesExecutor(ServerInterface &srvInterface,
    ExecutorPlanContext &planCtxt);

virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes);

virtual bool isSourceApportionable();

ssize_t getDesiredThreads(ServerInterface &srvInterface,
    ExecutorPlanContext &planContext);

After creating your SourceFactory, you must register it with the RegisterFactory macro.
Filter Classes

This section describes information that is specific to the C++ API. See User-Defined Filter for general information about implementing the UDFilter and FilterFactory classes.

UDFilter API

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface);
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
                             InputState input_state, DataBuffer &output)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface);
```

ContinuousUDFilter API

The ContinuousUDFilter class extends UDFilter and adds the following methods for extension by subclasses:

```cpp
virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);
```

FilterFactory API

The API provides the following methods for extension by subclasses:

```cpp
virtual void plan(ServerInterface &srvInterface, PlanContext &planCtxt);
virtual UDFilter * prepare(ServerInterface &srvInterface, PlanContext &planCtxt)=0;
virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
```

After creating your FilterFactory, you must register it with the RegisterFactory macro.
Parser Classes

This section describes information that is specific to the C++ API. See User-Defined Parser for general information about implementing the UDParse and ParserFactory classes.

UDParser API

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface, SizedColumnTypes &returnType);
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface, SizedColumnTypes &returnType);
virtual RejectedRecord getRejectedRecord();
```

Rejecting Records

The `process()` method might need to reject input. To reject data, you must do two things:

- Create a `getRejectedRecord()` method on your UDParse subclass that returns an object of type `Vertica::RejectedRecord`. This record contains the data that you want to reject, a string describing the reason for rejection, the size of the data, and the terminator string. See `RejectedRecord` in VerticaUDI.h or the SDK documentation for details.

- Reject a row by returning `REJECT` from `process()`. Vertica then calls `getRejectedRecord()` to process the rejected record before the next call to `process()`.

You can fulfill these requirements by including code in your parser class such as:

```cpp
Vertica::RejectedRecord myRejRec;
Vertica::RejectedRecord getRejectedRecord() {
    return myRejRec;
}
```

In your `process()` method, add code such as:
if (some rejection condition) {
    RejectedRecord rr("Bad Record!", "foo data", 8, "\n");
    myRejRec = rr;
    return Vertica::REJECT;
}

ContinuousUDParser API

The ContinuousUDParser class extends UDFParser and adds the following methods for extension by subclasses:

virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);

UDChunker API

The UDChunker API provides the following methods for extension by subclasses:

virtual void setup(ServerInterface &srvInterface, SizedColumnTypes &returnType);
virtual StreamState alignPortion(ServerInterface &srvInterface, DataBuffer &input, InputState state);
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface, SizedColumnTypes &returnType);

ParserFactory API

The API provides the following methods for extension by subclasses:

virtual void plan(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtxt);
virtual UDFParser * prepare(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtxt, const SizedColumnTypes &returnType)=0;
virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
virtual void getParserReturnType(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtxt, const SizedColumnTypes &argTypes,
If you are using **Apportioned Load** to divide a single input into multiple load streams, implement `isParserApportionable()` and/or `isChunkerApportionable()` and return true. Returning true from these methods does not guarantee that Vertica will apportion the load. However, returning false from both indicates that it will not try to do so.

If you are using **Cooperative Parse**, implement `prepareChunker()` and return an instance of your UDChunker subclass. Cooperative parse is supported only for the C++ API.

Vertica calls the `prepareChunker()` method only for unfenced functions. This method is not available when you use the function in fenced mode.

If you want your chunker to be available for apportioned load, implement `isChunkerApportionable()` and return true.

After creating your `ParserFactory`, you must register it with the `RegisterFactory` macro.

**Source Example: CurlSource**

The `CurlSource` example allows you to use cURL to open and read in a file over HTTP. The example provided is part of:

/`opt/vertica/sdk/examples/SourceFunctions/cURL.cpp`

**Source Implementation**

This example uses the helper library available in

/`opt/vertica/sdk/examples/HelperLibraries/`

`CurlSource` loads the data in chunks. If the parser encounters an EndOfFile marker, then the `process()` method returns DONE. Otherwise, the method returns OUTPUT_NEEDED and processes another chunk of data. The functions included in the helper library (such as `url_fread()` and `url_fopen()`) are based on examples that come with the libcurl library. For an example, see [http://curl.haxx.se/libcurl/c/fopen.html](http://curl.haxx.se/libcurl/c/fopen.html).

The `setup()` function opens a file handle and the `destroy()` function closes it. Both use functions from the helper library.
class CurlSource : public UDSource {
    private:
    URL_FILE *handle;
    std::string url;
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
        output.offset = ur1_fread(output.buf, 1, output.size, handle);
        return ur1_feof(handle) ? DONE : OUTPUT_NEEDED;
    }
    public:
    CurlSource(std::string url) : url(url) {} 
    void setup(ServerInterface &srvInterface) {
        handle = url=fopen(url.c_str(), "r");
    }
    void destroy(ServerInterface &srvInterface) {
        url_fclose(handle);
    }
};

Factory Implementation

CurlSourceFactory produces CurlSource instances.

class CurlSourceFactory : public SourceFactory {
    public:
    virtual void plan(ServerInterface &srvInterface, NodeSpecifyingPlanContext &planCtxt) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (args.size() != 1 || find(args.begin(), args.end(), "url") == args.end()) {
            vt_report_error(0, "You must provide a single URL.");
        }
        /* Populate planData */
        planCtxt.getWriter().getStringRef("url").copy(
            srvInterface.getParamReader().getStringRef("url"));
        /* Assign Nodes */
        std::vector<std::string> executionNodes = planCtxt.getClusterNodes();
        while (executionNodes.size() > 1) executionNodes.pop_back();
        // Only run on the first node in the list.
        planCtxt.setTargetNodes(executionNodes);
    }
    virtual std::vector<UDSource*> prepareUDSources(ServerInterface &srvInterface, NodeSpecifyingPlanContext &planCtxt) {
        std::vector<UDSource*> retVal;
        retVal.push_back(vt_createFuncObj(srvInterface.alloctor, CurlSource, 
            planCtxt.getReader().getStringRef("url"),str()));
        return retVal;
    }
    virtual void getParameterType(ServerInterface &srvInterface, 
        SizedColumnTypes &parameterTypes) {
        parameterTypes.addVarchar(65000, "url");
    }
};
RegisterFactory(CurlSourceFactory);
Source Example: Concurrent Load

The FilePortionSource example demonstrates the use of concurrent load. This example is a refinement of the FileSource example. Each input file is divided into portions and distributed to FilePortionSource instances. The source accepts a list of offsets at which to break the input into portions; if offsets are not provided, the source divides the input dynamically.

Concurrent load is handled in the factory, so this discussion focuses on FilePortionSourceFactory. The full code for the example is located in /opt/vertica/sdk/examples/ApportionLoadFunctions. The distribution also includes a Java version of this example.

Loading and Using the Example

Load and use the FilePortionSource example as follows.

```
=> CREATE LIBRARY FilePortionLib AS '/home/dbadmin/FP.so';

=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++'
=> NAME 'FilePortionSourceFactory' LIBRARY FilePortionLib;

=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat', nodes='initiator,e0,e1', offsets = '0,380000,820000');

=> COPY t WITH SOURCE FilePortionSource(file='g2/*.dat', nodes='e0,e1,e2', local_min_portion_size = 2097152);
```

Implementation

Concurrent load affects the source factory in two places, getDesiredThreads() and prepareUDSourcesExecutor().

**getDesiredThreads()**

The getDesiredThreads() member function determines the number of threads to request. Vertica calls this member function on each executor node before calling prepareUDSourcesExecutor().
The function begins by breaking an input file path, which might be a glob, into individual paths. This discussion omits those details. If apportioned load is not being used, then the function allocates one source per file.

```cpp
template<typename Iter> Iter allocateSources(Iter begin, Iter end) {
    if (begin == end)
        return begin;
    else
        return allocateSources(begin + 1, end);
}
```

If the source can be apportioned, then `getDesiredThreads()` uses the offsets that were passed as arguments to the factory to divide the file into portions. It then allocates portions to available nodes. This function does not actually assign sources directly; this work is done to determine how many threads to request.

```cpp
virtual ssize_t getDesiredThreads(ServerInterface &srvInterface,
                                    ExecutorPlanContext &planCtxt) {
    const std::string filename = srvInterface.getParamReader().getStringRef("file").str();
    std::vector<std::string> paths;
    // expand the glob - at least one thread per source.
    ...
    // figure out how to assign files to sources
    const std::string nodeName = srvInterface.getCurrentNodeName();
    const size_t nodeId = planCtxt.getWriter().getIntRef(nodeName);
    const size_t numNodes = planCtxt.getTargetNodes().size();
    if (!planCtxt.canApportionSource()) {
        /* no apportioning, so the number of files is the final number of sources */
        std::vector<std::string> *expanded =
            vt_createFuncObject<std::vector<std::string>> (srvInterface.allocator, paths);
        /* save expanded paths so we don't have to compute expansion again */
        planCtxt.getWriter().setPointer("expanded", expanded);
        return expanded->size();
    }
    // ...
}
```

```cpp
else if (srvInterface.getParamReader().containsParameter("offsets")) {
    // if the offsets are specified, then we will have a fixed number of portions per file.
    // Round-robin assign offsets to nodes.
    // ...
    /* Construct the portions that this node will actually handle.
    * This isn't changing (since the offset assignments are fixed),
    * so we'll build the Portion objects now and make them available
    * to prepareUDSourcesExecutor() by putting them in the ExecutorContext.
    * We don't know the size of the last portion, since it depends on the file
    * size. Rather than figure it out here we will indicate it with -1 and
    * defer that to prepareUDSourcesExecutor().
    */
    std::vector<Portion> *portions =
        vt_createFuncObject<std::vector<Portion>> (srvInterface.allocator);
    for (std::vector<size_t>::const_iterator offset = offsets.begin();
        offset != offsets.end(); ++offset) {
        Portion p(*offset);
        p.is_first_portion = (offset == offsets.begin());
        p.size = (offset + 1 == offsets.end() ? -1 : (*offset + 1) - *offset));
    }
}````
if ((offset - offsets.begin()) % numNodes == nodeId) {
    portions->push_back(p);
    srvInterface.log("FilePortionSource: assigning portion %ld: [offset = %lld, size = %lld]",
                    offset - offsets.begin(), p.offset, p.size);
}
}

The function now has all the portions and thus the number of portions:

planCtxt.getWriter().setPointer("portions", portions);

/* total number of threads we want is the number of portions per file, which is fixed */
return portions->size() * expanded->size();
} // end of "offsets" parameter

If offsets were not provided, the function divides the file into portions dynamically, one portion per thread. This discussion omits the details of this computation. There is no point in requesting more threads than are available, so the function calls getMaxAllowedThreads() on the PlanContext (an argument to the function) to set an upper bound:

if (portions->size() >= planCtxt.getMaxAllowedThreads()) {
    return paths.size();
}

See the full example for the details of how this function divides the file into portions.

This function uses the vt_createFuncObject template to create objects. Vertica calls the destructors of returned objects created using this macro, but it does not call destructors for other objects like vectors. You must call these destructors yourself to avoid memory leaks. In this example, these calls are made in prepareUDSourcesExecutor().

**prepareUDSourcesExecutor()**

The prepareUDSourcesExecutor() member function, like getDesiredThreads(), has separate blocks of code depending on whether offsets are provided. In both cases, the function breaks input into portions and creates UDSource instances for them.

If the function is called with offsets, prepareUDSourcesExecutor() calls prepareCustomizedPortions(). This function follows.

/* prepare portions as determined via the "offsets" parameter */
void prepareCustomizedPortions(ServerInterface &srvInterface,
                                ExecutorPlanContext &planCtxt,
If `prepareUDSourcesExecutor()` is called without offsets, then it must decide how many portions to create.

The base case is to use one portion per source. However, if extra threads are available, the function divides the input into more portions so that a source can process them concurrently. Then `prepareUDSourcesExecutor()` calls `prepareGeneratedPortions()` to create the portions. This function begins by calling `getLoadConcurrency()` on the plan context to find out how many threads are available.

```cpp
void prepareGeneratedPortions(ServerInterface &srvInterface,
                               ExecutorPlanContext &planCtxt,
                               std::vector<UDSource *> &sources,
                               std::map<std::string, Portion> initialPortions) {

    if ((ssize_t) initialPortions.size() >= planCtxt.getLoadConcurrency()) {
        /* all threads will be used, don't bother splitting into portions */

        for (std::map<std::string, Portion>::const_iterator file = initialPortions.begin();
            file != initialPortions.end(); ++file) {
            sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                                                                       *file->first, *file->second));
        }
        return;
    }

    // Now we can split files to take advantage of potentially-unused threads.
    // First sort by size (descending), then we will split the largest first.

    // details elided...
```
For More Information
See the source code for the full implementation of this example.

Filter Example: Converting Encoding

The following example shows how you can convert encoding for a file from one type to
another by converting UTF-16 encoded data to UTF-8. You can find this example in the SDK at
/opt/vertica/sdk/examples/FilterFunctions/IConverter.cpp.

Filter Implementation

class IConverter : public UDFilter{
private:
  std::string fromEncoding, toEncoding;
  iconv_t cd; // the conversion descriptor opened
  uint converted; // how many characters have been converted
protected:
  virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
                               InputState input_state, DataBuffer &output)
  {
    char *input_buf = (char *)input.buf + input.offset;
    char *output_buf = (char *)output.buf + output.offset;
    size_t inBytesLeft = input.size - input.offset, outBytesLeft = output.size - output.offset;
    // end of input
    if (input_state == END_OF_FILE && inBytesLeft == 0)
    {
      // Gnu libc iconv doc says, it is good practice to finalize the
      // outbuffer for stateful encodings (by calling with null inbuffer).
      //
      iconv(cd, NULL, NULL, &output_buf, &outBytesLeft);
      // output buffer can be updated by this operation
      output.offset = output.size - outBytesLeft;
      return DONE;
    }
    size_t ret = iconv(cd, &input_buf, &inBytesLeft, &output_buf, &outBytesLeft);
    // if conversion is successful, we ask for more input, as input has not reached EOF.
    StreamState retStatus = INPUT_NEEDED;
    if (ret == (size_t)(-1))
    {
      // seen an error
      switch (errno)
      {
        case E2BIG:
          // input size too big, not a problem, ask for more output.
          retStatus = OUTPUT_NEEDED;
          break;
        // other cases...
      }
      return retStatus;
    }
    // successful conversion: remember how many characters were converted.
    converted += res;
    return input_state == END_OF_FILE || inBytesLeft == 0
  }
};
break;
if (EINVAL == input_state)
    input_state = END_OF_FILE ? DONE : INPUT_NEEDED;
break;

// input stops in the middle of a byte sequence, not a problem, ask for more input
if (EINVAL == input_state)
    input_state = END_OF_FILE ? DONE : INPUT_NEEDED;
break;

// invalid sequence seen, throw
// TODO: reporting the wrong byte position
vt_report_error(1, "Invalid byte sequence when doing %u-th conversion", converted);

// something wrong with descriptor, throw
vt_report_error(0, "Invalid descriptor");

default:
    vt_report_error(0, "Uncommon Error");
    break;
}
else
    converted += ret;
// move position pointer
input.offset = input.size - inBytesLeft;
output.offset = output.size - outBytesLeft;
return retStatus;
}

public:
Iconverter(const std::string &from, const std::string &to)
    : fromEncoding(from), toEncoding(to), converted(0)
{
    // note "to encoding" is first argument to iconv...
    cd = iconv_open(to.c_str(), from.c_str());
    if (cd == (iconv_t)(-1))
    {
        // error when creating converters.
        vt_report_error(0, "Error initializing iconv: %m");
    }
}

-Iconverter()
{
    // free iconv resources;
    iconv_close(cd);
}

};

Factory Implementation

class IconverterFactory : public FilterFactory
public:
    virtual void plan(ServerInterface &srvInterface, PlanContext &planCtx) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (!args.size() == 0 ||
            (args.size() == 1 && find(args.begin(), args.end(), "from_encoding")
                != args.end()) || (args.size() == 2
                && find(args.begin(), args.end(), "from_encoding") != args.end()
                && find(args.begin(), args.end(), "to_encoding") != args.end()))
        {
            vt_report_error(0, "Invalid arguments. Must specify either no arguments, or ")
"from_encoding' alone, or 'from_encoding' and 'to_encoding'.");

/* Populate planData */
// By default, we do UTF16->UTF8, and x->UTF8
VString from_encoding = planCtxt.getWriter().getStringRef("from_encoding");
VString to_encoding = planCtxt.getWriter().getStringRef("to_encoding");
from_encoding.copy("UTF-16");
to_encoding.copy("UTF-8");
if (args.size() == 2)
{
    from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
    to_encoding.copy(srvInterface.getParamReader().getStringRef("to_encoding"));
}
else if (args.size() == 1)
{
    from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
}
else if (!from_encoding.length()) {
    vt_report_error(0, "The empty string is not a valid from_encoding value");
}
else if (!to_encoding.length()) {
    vt_report_error(0, "The empty string is not a valid to_encoding value");
}
virtual UDFilter* prepare(ServerInterface &srvInterface,
    PlanContext &planCtxt) {
    return vt_createFuncObj(srvInterface.allocator, Iconverter,
        planCtxt.getReader().getStringRef("from_encoding").str(),
        planCtxt.getReader().getStringRef("to_encoding").str());
}
virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes) {
    parameterTypes.addVarchar(32, "from_encoding");
    parameterTypes.addVarchar(32, "to_encoding");
}
};
RegisterFactory(IconverterFactory);

Parser Example: BasicIntegerParser

The BasicIntegerParser example parses a string of integers separated by non-numeric characters. For a version of this parser that uses continuous load, see Parser Example: ContinuousIntegerParser.

Loading and Using the Example

Load and use the BasicIntegerParser example as follows.

```sql
=> CREATE LIBRARY BasicIntegerParserLib AS '/home/dbadmin/BIP.so';
=> CREATE PARSER BasicIntegerParser AS LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;
```
CREATE TABLE t (i integer);
COPY t FROM stdin WITH PARSER BasicIntegerParser();
0 1 2 3 4 5.

Implementation

The BasicIntegerParser class implements only the process() method from the API. (It also implements a helper method for type conversion.) This method processes each line of input, looking for numbers on each line. When it advances to a new line it moves the input.offset marker and checks the input state. It then writes the output.

```cpp
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
    InputState input_state) {
    // WARNING: This implementation is not trying for efficiency.
    // It is trying for simplicity, for demonstration purposes.

    size_t start = input.offset;
    const size_t end = input.size;

    do {
        bool found_newline = false;
        size_t numEnd = start;
        for (; numEnd < end; numEnd++) {
            if (input.buf[numEnd] < '0' || input.buf[numEnd] > '9') {
                found_newline = true;
                break;
            }
        }

        if (!found_newline) {
            input.offset = start;
            if (input_state == END_OF_FILE) {
                // If we're at end-of-file,
                // emit the last integer (if any) and return DONE.
                if (start != end) {
                    writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
                    writer->next();
                }
                return DONE;
            } else {
                // Otherwise, we need more data.
                return INPUT_NEEDED;
            }
        }

        writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
        writer->next();
    }
```

Vertica Documentation Extending Vertica
In the factory, the `plan()` method is a no-op; there are no parameters to check. The `prepare()` method instantiates the parser using the macro provided by the SDK:

```c++
virtual UDPParser* prepare(ServerInterface &srvInterface,
                            PerColumnParamReader &perColumnParamReader,
                            PlanContext &planCtx,
                            const SizedColumnTypes &returnType) {
    return vt_createFuncObject<BasicIntegerParser>(srvInterface.allocator);
}
```

The `getParserReturnType()` method declares the single output:

```c++
virtual void getParserReturnType(ServerInterface &srvInterface,
                                  PerColumnParamReader &perColumnParamReader,
                                  PlanContext &planCtx,
                                  const SizedColumnTypes &argTypes,
                                  SizedColumnTypes &returnType) {
    // We only and always have a single integer column
    returnType.addInt(argTypes.getColumnName(0));
}
```

As for all UDxs written in C++, the example ends by registering its factory:

```c++
RegisterFactory(BasicIntegerParserFactory);
```

### Parser Example: ContinuousIntegerParser

The `ContinuousIntegerParser` example is a variation of `BasicIntegerParser`. Both examples parse integers from input strings. `ContinuousIntegerParser` uses `Continuous Load` to read data.

### Loading and Using the Example

Load the `ContinuousIntegerParser` example as follows.

```sql
=> CREATE LIBRARY ContinuousIntegerParserLib AS '/home/dbadmin/CIP.so';
=> CREATE PARSER ContinuousIntegerParser AS LANGUAGE 'C++' NAME 'ContinuousIntegerParserFactory'
    LIBRARY ContinuousIntegerParserLib;
```
Use it in the same way that you use BasicIntegerParser. See Parser Example: BasicIntegerParser.

Implementation

ContinuousIntegerParser is a subclass of ContinuousUDParser. Subclasses of ContinuousUDParser place the processing logic in the run() method.

```cpp
virtual void run() {
    // This parser assumes a single-column input, and
    // a stream of ASCII integers split by non-numeric characters.
    size_t pos = 0;
    size_t reserved = cr.reserve(pos+1);
    while (!cr.isEof() || reserved == pos + 1) {
        while (reserved == pos + 1 && isdigit(*ptr(pos))) {
            pos++;
            reserved = cr.reserve(pos + 1);
        }
        std::string st(ptr(), pos);
        writer->setInt(0, strToInt(st));
        writer->next();
        while (reserved == pos + 1 && !isdigit(*ptr(pos))) {
            pos++;
            reserved = cr.reserve(pos + 1);
        }
        cr.seek(pos);
        pos = 0;
        reserved = cr.reserve(pos + 1);
    }
}
```

For a more complex example of a ContinuousUDParser, see ExampleDelimitedParser in the examples. (See Downloading and Running UDx Example Code.) ExampleDelimitedParser uses a chunker; see Chunker Example: Delimited Parser and Chunker.

Chunker Example: Delimited Parser and Chunker

The ExampleDelimitedUDChunker class divides an input at delimiter characters. You can use this chunker with any parser that understands delimited input. ExampleDelimitedParser is a ContinuousUDParser subclass that uses this chunker.

Loading and Using the Example

Load and use the example as follows.
Chunker Implementation

This chunker supports apportioned load. The `alignPortion()` method finds the beginning of the first complete record in the current portion and aligns the input buffer with it. The record terminator is passed as an argument and set in the constructor.

```c
StreamState ExampleDelimitedUDChunker::alignPortion(
    ServerInterface &srvInterface,
    DataBuffer &input, InputState state)
{
    /* find the first record terminator. Its record belongs to the previous portion */
    void *buf = reinterpret_cast<void*>(input.buf + input.offset);
    void *term = memchr(buf, recordTerminator, input.size - input.offset);
    if (term) {
        /* record boundary found. Align to the start of the next record */
        const size_t chunkSize = reinterpret_cast<size_t>(term) - reinterpret_cast<size_t>(buf);
        input.offset += chunkSize
                        + sizeof(char) /* length of record terminator */;
        /* input.offset points at the start of the first complete record in the portion */
        return DONE;
    } else if (state == END_OF_FILE || state == END_OF_PORTION) {
        return REJECT;
    } else {
        VIAssert(state == START_OF_PORTION || state == OK);
        return INPUT_NEEDED;
    }
}
```

The `process()` method has to account for chunks that span portion boundaries. If the previous call was at the end of a portion, the method set a flag. The code begins by checking for and handling that condition. The logic is similar to that of `alignPortion()`, so the example calls it to do part of the division.

```sql
=> CREATE LIBRARY ExampleDelimitedParserLib AS '/home/dbadmin/EDP.so';

=> CREATE PARSER ExampleDelimitedParser AS
    LANGUAGE 'C++' NAME 'DelimitedParserFrameworkExampleFactory'
    LIBRARY ExampleDelimitedParserLib;

=> COPY t FROM stdin WITH PARSER ExampleDelimitedParser();

Vertica Documentation
Extending Vertica

Vertica Analytic Database (9.1.x)  Page 4431 of 6174
StreamState ExampleDelimitedUDChunker::process(
    ServerInterface &srvInterface,
    DataBuffer &input,
    InputState input_state)
{
    const size_t termLen = 1;
    const char *terminator = &recordTerminator;

    if (pastPortion) {
        /*
        * Previous state was END_OF_PORTION, and the last chunk we will produce
        * extends beyond the portion we started with, into the next portion.
        * To be consistent with alignPortion(), that means finding the first
        * record boundary, and setting the chunk to be at that boundary.
        * Fortunately, this logic is identical to aligning the portion (with
        * some slight accounting for END_OF_FILE)!
        */
        const StreamState findLastTerminator = alignPortion(srvInterface, input);

        switch (findLastTerminator) {
            case DONE:
                return DONE;
            case INPUT_NEEDED:
                if (input_state == END_OF_FILE) {
                    /* there is no more input where we might find a record terminator */
                    input.offset = input.size;
                    return DONE;
                }
                return INPUT_NEEDED;
            default:
                VIAssert("Invalid return state from alignPortion()");
                return findLastTerminator;
        }
    }

    size_t ret = input.offset, term_index = 0;
    for (size_t index = input.offset; index < input.size; ++index) {
        const char c = input.buf[index];
        if (c == terminator[term_index]) {
            ++term_index;
            if (term_index == termLen) {
                ret = index + 1;
                term_index = 0;
            } else if (term_index > 0) {
                index -= term_index;
            }
            term_index = 0;
        }
    }

    if (input_state == END_OF_PORTION) {
        /*
        * Regardless of whether or not a record was found, the next chunk will extend
        */
    }
}

Now the method looks for the delimiter. If the input began at the end of a portion, it sets the flag.
Finally, process() moves the input offset and returns.

```cpp
// if we were able to find some rows, move the offset to point at the start of the next
// (potential) row, or end of block
if (ret > input.offset) {
    input.offset = ret;
    return CHUNK_ALIGNED;
}
if (input_state == END_OF_FILE) {
    input.offset = input.size;
    return DONE;
}
return INPUT_NEEDED;
```

**Factory Implementation**

The file ExampleDelimitedParser.cpp defines a factory that uses this UDChunker. The chunker supports apportioned load, so the factory implements isChunkerApportionable():

```cpp
virtual bool isChunkerApportionable(ServerInterface &srvInterface) {
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("d\n    isable_chunker")) {
        return false;
    } else {
        return true;
    }
}
```

**The prepareChunker() method creates the chunker:**

```cpp
virtual UDChunker* prepareChunker(ServerInterface &srvInterface,
                                    PerColumnParamReader &perColumnParamReade\r,
                                    PlanContext &planCtx,
                                    const SizedColumnTypes &returnType)
{
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("d\n    isable_chunker")) {
        return NULL;
    }
```
std::string recordTerminator("\n");

ParamReader args(srvInterface.getParamReader());
if (args.containsParameter("record_terminator")) {
    recordTerminator = args.getStringRef("record_terminator").str();
}

return vt_createFuncObject<ExampleDelimitedUDChunker>(srvInterface.allo\
cator, recordTerminator[0]);

Java API

The Vertica Java SDK supports developing UDLs. The Java SDK enables you to create sources, filters, and parsers, but not chunkers.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

Source Classes

This section describes information that is specific to the Java API. See User-Defined Source for general information about implementing the UDSource and SourceFactory classes.

UDSource API

The API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface) throws UdfException;
public abstract StreamState process(ServerInterface srvInterface, DataBuffer output) throws UdfException;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface) throws UdfException;
public Integer getSize();
public String getUri();
```

SourceFactory API

The API provides the following methods for extension by subclasses:
public void plan(ServerInterface srvInterface, NodeSpecifyingPlanContext planCtxt) throws UdfException;

// must implement one overload of prepareUDSources()
public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface, NodeSpecifyingPlanContext planCtxt) throws UdfException;

public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface, ExecutorPlanContext planCtxt) throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

public boolean isSourceApportionable();

public int getDesiredThreads(ServerInterface srvInterface, ExecutorPlanContext planCtxt) throws UdfException;

### Filter Classes

This section describes information that is specific to the Java API. See User-Defined Filter for general information about implementing the UDFilter and FilterFactory classes.

#### UDFilter API

The API provides the following methods for extension by subclasses:

- public void setup(ServerInterface srvInterface) throws UdfException;
- public abstract StreamState process(ServerInterface srvInterface, DataBuffer input, InputState input_state, DataBuffer output) throws UdfException;
- protected void cancel(ServerInterface srvInterface);
- public void destroy(ServerInterface srvInterface) throws UdfException;

#### FilterFactory API

The API provides the following methods for extension by subclasses:

- public void plan(ServerInterface srvInterface, PlanContext planCtxt) throws UdfException;
- public abstract UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt) throws UdfException;
- public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
Parser Classes

This section describes information that is specific to the Java API. See User-Defined Parser for general information about implementing the UDParse and ParserFactory classes.

UDParser API

The API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes returnType)
    throws UdfException;

public abstract StreamState process(ServerInterface srvInterface,
    DataBuffer input, InputState input_state)
    throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface, SizedColumnTypes returnType)
    throws UdfException;

public RejectedRecord getRejectedRecord() throws UdfException;
```

A UDParse uses a StreamWriter to write its output. StreamWriter provides methods for all the basic types, such as setBooleanValue(), setStringValue(), and so on. In the Java API this class also provides the setValue() method, which automatically sets the data type.

The methods described so far write single column values. StreamWriter also provides a method to write a complete row from a map. The setRowFromMap() method takes a map of column names and values and writes all the values into their corresponding columns. This method does not define new columns but instead writes values only to existing columns. The JsonParser example uses this method to write arbitrary JSON input. (See Parser Example: JSON Parser.)

Note: The setRowFromMap() method does not automatically advance the input to the next line; you must call next(). You can thus read a row and then override selected column values.

setRowsFromMap() also populates any VMap ('__raw__') column of Flex Tables (see Using Flex Tables) with the entire provided map. For most cases, setRowsFromMap() is the appropriate way to populate a Flex Table. However, you can also generate a VMap value into a specified column using setVMap(), similar to other setValue() methods.

The setRowFromMap() method automatically coerces the input values into the types defined for those columns using an associated TypeCoercion. In most cases, using the default implementation (StandardTypeCoercion) is appropriate.
TypeCoercion uses policies to govern its behavior. For example, the FAIL_INVALID_INPUT_VALUE policy means invalid input is treated as an error instead of using a null value. Errors are caught and handled as rejections (see "Rejecting Rows" in User-Defined Parser). Policies also govern whether input that is too long is truncated. Use the setPolicy() method on the parser's TypeCoercion to set policies. See the API documentation for supported values.

You might need to customize type coercion beyond setting these policies. To do so, subclass one of the provided implementations of TypeCoercion and override the asType() methods. Such customization could be necessary if your parser reads objects that come from a third-party library. A parser handling geo-coordinates, for example, might override asLong to translate inputs like "40.4397N" into numbers. See the Vertica API documentation for a list of implementations.

ContinuousUDParser API

The ContinuousUDParser class extends UDPParser and adds the following methods for extension by subclasses:

```java
public void initialize(ServerInterface srvInterface, SizedColumnTypes returnType);
public abstract void run() throws UdfException;
public void deinitialize(ServerInterface srvInterface, SizedColumnTypes returnType);
```

See the API documentation for additional utility methods.

ParserFactory API

The API provides the following methods for extension by subclasses:

```java
public void plan(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext planCtxt) throws UdfException;
public abstract UDPParser prepare(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext planCtxt, SizedColumnTypes returnType) throws UdfException;
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
public void getParserReturnType(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext planCtxt, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException;
```
Source Example: FileSource

The example shown in this section is a simple UDL Source function named FileSource. This function loads data from files stored on the host's file system (similar to the standard COPY statement). To call FileSource, you must supply a parameter named file that contains the absolute path to one or more files on the host file system. You can specify multiple files as a comma-separated list.

The FileSource function also accepts an optional parameter, named nodes, that indicates which nodes should load the files. If you do not supply this parameter, the function defaults to loading data on the initiator node only. Because this example is simple, the nodes load only the files from their own file systems. Any files in the file parameter must exist on all of the hosts in the nodes parameter. The FileSource UDSoure attempts to load all of the files in the file parameter on all of the hosts in the nodes parameter.

Generating Files

You can use the following Python script to generate files and distribute them to hosts in your Vertica cluster. With these files, you can experiment with the example UDSoure function. Running the function requires passwordless-SSH logins to copy the files to the other hosts. Therefore, you must run the script using the database administrator account on one of your database hosts.

```python
#!/usr/bin/python
# Save this file as UDLDataGen.py
import string
import random
import sys
import os

# Read in the dictionary file to provide random words. Assumes the words
# file is located in /usr/share/dict/words
wordFile = open("/usr/share/dict/words")
wordDict = []
for line in wordFile:
    if len(line) > 6:
        wordDict.append(line.strip())

MAXSTR = 4 # Maximum number of words to concatenate
NUMROWS = 1000 # Number of rows of data to generate
FILEPATH = "/tmp/UDLdata.txt" # Final filename to use for UDL source
TMPFILE = "/tmp/UDLtemp.txt" # Temporary filename.

# Generate a random string by concatenating several words together. Max
# number of words set by MAXSTR
def randomWords():
    words = [random.choice(wordDict) for n in xrange(random.randint(1, MAXSTR))]
    sentence = " ".join(words)
```

return sentence

# Create a temporary data file that will be moved to a node. Number of
# rows for the file is set by NUMROWS. Adds the name of the node which will
# get the file, to show which node loaded the data.
def generateFile(node):
    outFile = open(TMPFILE, 'w')
    for line in xrange(NUMROWS):
        outFile.write('{0}|{1}|{2}
'.format(line, randomWords(), node))
    outFile.close()

# Copy the temporary file to a node. Only works if passwordless SSH login
# is enabled, which it is for the database administrator account on
# Vertica hosts.
def copyFile(fileName, node):
    os.system('scp "%s" "%s:%s"' % (TMPFILE, node, fileName))

# Loop through the comma-separated list of nodes given in the first
# parameter, creating and copying data files whose full comma-separated
# paths are passed in the second parameter
for node in [x.strip() for x in sys.argv[1].split(',')]:
    for fileName in [y.strip() for y in sys.argv[2].split(',')]:
        print "generating file", fileName, "for", node
        generateFile(node)
        print "Copying file to", node
        copyFile(fileName, node)

You call this script by giving it a comma-separated list of hosts to receive the files and a
comma-separated list of absolute paths of files to generate. For example:

    python UDLDataGen.py v_vmart_node0001,v_vmart_node0002,v_vmart_node0003
    /tmp/UDLdata01.txt,/tmp/UDLdata02.txt,/tmp/UDLdata03.txt

This script generates files that contain a thousand rows of columns delimited with the pipe
character (|). These columns contain an index value, a set of random words, and the node for
which the file was generated, as shown in the following output sample:

    0|megabits embanks|v_vmart_node0001
    1|unneatly|v_vmart_node0001
    2|self-precipitation|v_vmart_node0001
    3|antihistamine scalados Vatter|v_vmart_node0001

Loading and Using the Example

Load and use the FileSource UDSource as follows:

    => -L<Load library and create the source function
    => CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLlib.jar'
    => LANGUAGE 'JAVA';
    CREATE LIBRARY
    => CREATE SOURCE File as LANGUAGE 'JAVA' NAME
    => 'com.mycompany.UDL.FileSourceFactory' LIBRARY JavaLib;
CREATE SOURCE FUNCTION
 => --Create a table to hold the data loaded from files
 => CREATE TABLE t (i integer, text VARCHAR, node VARCHAR);
CREATE TABLE
 => -- Copy a single file from the currently host using the FileSource
 => COPY t SOURCE File(file='/tmp/UDLdata01.txt');
 Rows Loaded
 --------------------------
   1000
 (1 row)
 => --See some of what got loaded.
 => SELECT * FROM t WHERE i < 5 ORDER BY i;
 i | text | node
-------------------------------
 0 | megabits embanks | v_vmart_node0001
 1 | unneatly | v_vmart_node0001
 2 | self-precipitation | v_vmart_node0001
 3 | antihistamine scalados Vatter | v_vmart_node0001
 4 | fate-menaced toilworn | v_vmart_node0001
(5 rows)

 => TRUNCATE TABLE t;
TRUNCATE TABLE
 => -- Now load a file from three hosts. All of these hosts must have a file
 => -- named /tmp/UDLdata01.txt, each with different data
 => COPY t SOURCE File(file='/tmp/UDLdata01.txt',
   -> nodes='v_vmart_node0001,v_vmart_node0002,v_vmart_node0003');
 Rows Loaded
 --------------------------
   3000
 (1 row)
 => --Now see what has been loaded
 => SELECT * FROM t WHERE i < 5 ORDER BY i,node ;
 i | text | node
-------------------------------
 0 | megabits embanks | v_vmart_node0001
 0 | nimble-eyed undupability frowsier | v_vmart_node0002
 0 | Circean nonrepellence nonnasality | v_vmart_node0003
 1 | unneatly | v_vmart_node0001
 1 | floatmaker trabacolos hit-in | v_vmart_node0002
 1 | revelrous treatableness Halleck | v_vmart_node0003
 2 | self-precipitation | v_vmart_node0001
 2 | whicipords archipelagic protodonatan copycutter | v_vmart_node0002
 2 | Paganalian geochemistry short-shucks | v_vmart_node0003
 3 | antihistamine scalados Vatter | v_vmart_node0001
 3 | swordweed touristical subcommanders desalinized | v_vmart_node0002
 3 | batboys | v_vmart_node0003
 4 | fate-menaced toilworn | v_vmart_node0001
 4 | twice-wanted cirrocumulus | v_vmart_node0002
 4 | doon-head-clock | v_vmart_node0003
(15 rows)

 => TRUNCATE TABLE t;
TRUNCATE TABLE
 => --Now copy from several files on several hosts
 => COPY t SOURCE File(file='/tmp/UDLdata01.txt,/tmp/UDLdata02.txt,/tmp/UDLdata03.txt')
Parser Implementation

The following code shows the source of the FileSource class that reads a file from the host file system. The constructor, which is called by FileSourceFactory.prepareUDSources(), gets the absolute path for the file containing the data to be read. The setup() method opens the file and the destroy() method closes it. The process() method reads from the file into a buffer provided by the instance of the DataBuffer class passed to it as a parameter. If the read operation filled the output buffer, it returns OUTPUT_NEEDED. This value tells Vertica to call the method again after the next stage of the load has processed the output buffer. If the read did not fill the output buffer, then process() returns DONE to indicate it has finished processing the data source.

```java
package com.mycompany.UDL;

import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileReader;
import java.io.IOException;
import java.io.RandomAccessFile;
import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSource extends UDSource {
    private String filename; // The file for this UDSource to read
    private RandomAccessFile reader; // handle to read from file
```
The constructor just stores the absolute filename of the file it will read.

```java
public FileSource(String filename) {
    super();
    this.filename = filename;
}
```

Called before Vertica starts requesting data from the data source. In this case, setup needs to open the file and save to the reader property.

```java
@Override
public void setup(ServerInterface srvInterface) throws UdfException{
    try {
        reader = new RandomAccessFile(new File(filename), "r");
    } catch (FileNotFoundException e) {
        // In case of any error, throw a UdfException. This will terminate the data load.
        String msg = e.getMessage();
        throw new UdfException(0, msg);
    }
}
```

Called after data has been loaded. In this case, close the file handle.

```java
@Override
public void destroy(ServerInterface srvInterface) throws UdfException {
    if (reader != null) {
        try {
            reader.close();
        } catch (IOException e) {
            String msg = e.getMessage();
            throw new UdfException(0, msg);
        }
    }
}
```

Updates the number of bytes processed so far by the data buffer.

```java
@Override
public StreamState process(ServerInterface srvInterface, DataBuffer output) throws UdfException {
    // Read up to the size of the buffer provided in the DataBuffer.buf property. Here we read directly from the file handle into the buffer.
    long offset;
    try {
        offset = reader.read(output.buf,output.offset, output.buf.length-output.offset);
    } catch (IOException e) {
        // Throw an exception in case of any errors.
        String msg = e.getMessage();
        throw new UdfException(0, msg);
    }

    // Update the number of bytes processed so far by the data buffer.
    output.offset +=offset;

    // See end of data source has been reached, or less data was read than can fit in the buffer
    if(offset == -1 || offset < output.buf.length) {
        // No more data to read.
        return StreamState.DONE;
    }
    return StreamState.CONTINUE;
}
```
Factory Implementation

The following code is a modified version of the example Java UDsource function provided in the Java UDx support package. You can find the full example in /opt/vertica/sdk/examples/JavaUDx/UDLFuctions/com/vertica/JavaLibs/FilesourceFactory.java. Its override of the plan() method verifies that the user supplied the required file parameter. If the user also supplied the optional nodes parameter, this method verifies that the nodes exist in the Vertica cluster. If there is a problem with either parameter, the method throws an exception to return an error to the user. If there are no issues with the parameters, the plan() method stores their values in the plan context object.

    package com.mycompany.UDL;
    import java.util.ArrayList;
    import java.util.Vector;
    import com.vertica.sdk.NodeSpecifyingPlanContext;
    import com.vertica.sdk.ParamReader;
    import com.vertica.sdk.ParamWriter;
    import com.vertica.sdk.ServerInterface;
    import com.vertica.sdk.SizedColumnTypes;
    import com.vertica.sdk.SourceFactory;
    import com.vertica.sdk.UDSource;
    import com.vertica.sdk.UdfException;
    public class FileSourceFactory extends SourceFactory {
        // Called once on the initiator host to do initial setup. Checks
        // parameters and chooses which nodes will do the work.
        @Override
        public void plan(ServerInterface srvInterface,
                         NodeSpecifyingPlanContext planCtxt) throws UdfException {
            String nodes; // stores the list of nodes that will load data
            // Get copy of the parameters the user supplied to the UDSource
            // function call.
            ParamReader args = srvInterface.getParamReader();
            // A list of nodes that will perform work. This gets saved as part
            // of the plan context.
            ArrayList<String> executionNodes = new ArrayList<String>();
            // First, ensure the user supplied the file parameter
            if (!args.containsParameter("file")) {
                // Without a file parameter, we cannot continue. Throw an
                // exception that will be caught by the Java UDx framework.
        }
throw new UdfException(0, "You must supply a file parameter");
}

if (args.containsParameter("nodes")) {
    nodes = args.getString("nodes");

    // Get list of nodes in cluster, to ensure that the node the
    // user specified actually exists. The list of nodes is available
    // from the planCtx (plan context) object,
    ArrayList<String> clusterNodes = planCtx.getClusterNodes();

    // Parse the string parameter "nodes" which
    // is a comma-separated list of node names.
    String[] nodeNames = nodes.split(",");
    for (int i = 0; i < nodeNames.length; i++){
        // See if the node the user gave us actually exists
        if(clusterNodes.contains(nodeNames[i]))
            // Node exists. Add it to list of nodes.
            executionNodes.add(nodeNames[i]);
        else {
            // User supplied node that doesn't exist. Throw an
            // exception so the user is notified.
            String msg = String.format("Specified node '%s' but no" +
                " node by that name is available. Available nodes " +
                "are "%s".",
                nodeNames[i], clusterNodes.toString());
            throw new UdfException(0, msg);
        }
    }
} else {
    // User did not supply a list of node names. Assume the initiator
    // is the only host that will read the file. The srvInterface
    // instance passed to this method has a getter for the current
    // node.
    executionNodes.add(srvInterface.getCurrentNodeName());
}

// Set the target node(s) in the plan context
planCtx.setTargetNodes(executionNodes);

// Set parameters for each node reading data that tells it which
// files it will read. In this simple example, just tell it to
// read all of the files the user passed in the file parameter
String files = args.getString("file");

// Get object to write parameters into the plan context object.
ParamWriter nodeParams = planCtx.getWriter();

// Loop through list of execution nodes, and add a parameter to plan
// context named for each node performing the work, which tells it the
// list of files it will process. Each node will look for a
// parameter named something like "filesFor_vmart_node0002" in its
// prepareUDSources() method.
for (int i = 0; i < executionNodes.size(); i++) {
    nodeParams.setString("filesFor" + executionNodes.get(i), files);
}
}  

// Called on each host that is reading data from a source. This method  
// returns an array of UDSource objects that process each source.  
@Override  
public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface,  
NodeSpecifyingPlanContext planCtx) throws UdfException {  
    // An array to hold the UDSource subclasses that we instantiate  
    ArrayList<UDSource> retVal = new ArrayList<UDSource>();  
    // Get the list of files this node is supposed to process. This was  
    // saved by the plan() method in the plancontext  
    String myName = srvInterface.getCurrentNodeName();  
    ParamReader params = planCtx.getReader();  
    String fileNames = params.getString("filesFor" + myName);  
    // Note that you can also be lazy and directly grab the parameters  
    // the user passed to the UDSource functon in the COPY statement directly  
    // by getting parameters from the ServerInterface object. I.e.:  
    //String fileNames = srvInterface.getParamReader().getString("file");  
    // Split comma-separated list into a single list.  
    String[] fileList = fileNames.split("", ");  
    for (int i = 0; i < fileList.length; i++) {  
        // Instantiate a FileSource object (which is a subclass of UDSource)  
        // to read each file. The constructor for FileSource takes the  
        // file name of the  
        //retVal.add(new FileSource(fileList[i]));  
    }  
    // Return the collection of FileSource objects. They will be called,  
    // in turn, to read each of the files.  
    return retVal;  
}  

// Declares which parameters that this factory accepts.  
@Override  
public void getParameterType(ServerInterface srvInterface,  
SizedColumnTypes parameterTypes) {  
    parameterTypes.addVarchar(65000, "file");  
    parameterTypes.addVarchar(65000, "nodes");  
}  

Filter Example: ReplaceCharFilter

The example in this section demonstrates creating a UDFilter that replaces any occurrences of a character in the input stream with another character in the output stream. This example is highly simplified and assumes the input stream is ASCII data.

Always remember that the input and output streams in a UDFilter are actually binary data. If you are performing character transformations using a UDFilter, convert the data stream from a string of bytes into a properly encoded string. For example, your input stream might
consist of UTF-8 encoded text. If so, be sure to transform the raw binary being read from the buffer into a UTF string before manipulating it.

### Loading and Using the Example

The example **UDFilter** has two required parameters. The `from_char` parameter specifies the character to be replaced, and the `to_char` parameter specifies the replacement character. Load and use the `ReplaceCharFilter` UDFilter as follows:

```sql
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLlib.jar'
->LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FILTER ReplaceCharFilter as LANGUAGE 'JAVA'
->name 'com.mycompany.UDL.ReplaceCharFilterFactory' library JavaLib;
CREATE FILTER FUNCTION
=> CREATE TABLE t (text VARCHAR);
CREATE TABLE
=> COPY t FROM STDIN WITH FILTER ReplaceCharFilter(from_char='a', to_char='z');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Mary had a little lamb
>> a man, a plan, a canal, Panama
>> .
=> SELECT * FROM t;
   text
------------------------
 Mzry hzd z little lzmb
 z mzn, z plzn, z cznzl, Pznzmz
(2 rows)
```

Calling the filter with incorrect parameters returns errors

```sql
=> COPY t from stdin with filter ReplaceCharFilter();
ERROR 3399: Failure in U Dx RPC call InvokePlanUDL(): Error in User Defined Object [ReplaceCharFilter], error code: 0
com.vertica.sdk.UdfException: You must supply two parameters to ReplaceChar: 'from_char' and 'to_char'
```

```java
at com.vertica.JavaLibs.ReplaceCharFilterFactory.plan(ReplaceCharFilterFactory.java:22)
at com.vertica.udxfence.UDxExecContext.planUDFilter(UDxExecContext.java:889)

at com.vertica.udxfence.UDxExecContext.run(UDxExecContext.java:242)
at java.lang.Thread.run(Thread.java:662)
```

### Parser Implementation

The `ReplaceCharFilter` class reads the data stream, replacing each occurrence of a user-specified character with another character.

```java
package com.vertica.JavaLibs;
import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
```
import com.vertica.sdk.State.InputState;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDFilter;

public class ReplaceCharFilter extends UDFilter {

    private byte[] fromChar;
    private byte[] toChar;

    public ReplaceCharFilter(String fromChar, String toChar) {
        // Stores the from char and to char as byte arrays. This is
        // not a robust method of doing this, but works for this simple
        // example.
        this.fromChar = fromChar.getBytes();
        this.toChar = toChar.getBytes();
    }

    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input,
                                 InputState inputState, DataBuffer output) {

        // Check if there is no more input and the input buffer has been completely
        // processed. If so, filtering is done.
        if (inputState == InputState.END_OF_FILE && input.buf.length == 0) {
            return StreamState.DONE;
        }

        // Get current position in the input buffer
        int offset = output.offset;

        // Determine how many bytes to process. This is either until input
        // buffer is exhausted or output buffer is filled
        int limit = Math.min((input.buf.length - input.offset),
                              (output.buf.length - output.offset));

        for (int i = input.offset; i < limit; i++) {
            // This example just replaces each instance of from_char
            // with to_char. It does not consider things such as multi-byte
            // UTF-8 characters.
            if (input.buf[i] == fromChar[0]) {
                output.buf[i+offset] = toChar[0];
            } else {
                // Did not find from_char, so copy input to the output
                output.buf[i+offset] = input.buf[i];
            }
        }

        input.offset += limit;
        output.offset += input.offset;

        if (input.buf.length - input.offset < output.buf.length - output.offset) {
            return StreamState.INPUT_NEEDED;
        } else {
            return StreamState.OUTPUT_NEEDED;
        }
    }
}
Factory Implementation

ReplaceCharFilterFactory requires two parameters (from_char and to_char). The plan() method verifies that these parameters exist and are single-character strings. The method then stores them in the plan context. The prepare() method gets the parameter values and passes them to the ReplaceCharFilter objects, which it instantiates, to perform the filtering.

```java
package com.vertica.JavaLibs;
import java.util.ArrayList;
import java.util.Vector;
import com.vertica.sdk.FilterFactory;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDFilter;
import com.vertica.sdk.UdfException;

public class ReplaceCharFilterFactory extends FilterFactory {

    // Run on the initiator node to perform verification and basic setup.
    @Override
    public void plan(ServerInterface srvInterface, PlanContext planCtxt)
    throws UdfException {
        ArrayList<String> args = srvInterface.getParamReader().getParamNames();

        // Ensure user supplied two arguments
        if (!(args.contains("from_char") && args.contains("to_char"))) {
            throw new UdfException(0, "You must supply two parameters " +
                                   " to ReplaceChar: 'from_char' and 'to_char'");
        }

        // Verify that the from_char is a single character.
        String fromChar = srvInterface.getParamReader().getString("from_char");
        if (fromChar.length() != 1) {
            String message = String.format("Replacechar expects a single " +
                                           "character in the 'from_char' parameter. Got length %d",
                                           fromChar.length());
            throw new UdfException(0, message);
        }

        // Save the from character in the plan context, to be read by
        // prepare() method.
        planCtxt.getWriter().setString("fromChar", fromChar);

        // Ensure to character parameter is a single character
        String toChar = srvInterface.getParamReader().getString("to_char");
        if (toChar.length() != 1) {
            String message = String.format("Replacechar expects a single " +
                                           "character in the 'to_char' parameter. Got length %d",
                                           toChar.length());
            throw new UdfException(0, message);
        }
    }
}
```
Save the to character in the plan data
planCtxt.getWriter().setString("toChar", toChar);
}

// Called on every host that will filter data. Must instantiate the
// UDFilter subclass.
@Override
public UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt)
        throws UdfException {
    // Get data stored in the context by the plan() method.
    String fromChar = planCtxt.getWriter().getString("fromChar");
    String toChar = planCtxt.getWriter().getString("toChar");
    // Instantiate a filter object to perform filtering.
    return new ReplaceCharFilter(fromChar, toChar);
}

// Describe the parameters accepted by this filter.
@Override
public void getParameterType(ServerInterface srvInterface,
        SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "from_char");
    parameterTypes.addVarchar(1, "to_char");
}
}

Parser Example: Numeric Text

This NumericTextParser example parses integer values spelled out in words rather than
digits (for example "one two three" for one-hundred twenty three). The parser:

- Accepts a single parameter to set the character that separates columns in a row of data. The
  separator defaults to the pipe (|) character.

- Ignores extra spaces and the capitalization of the words used to spell out the digits.

- Recognizes the digits using the following words: zero, one, two, three, four, five, six, seven,
  eight, nine.

- Assumes that the words spelling out an integer are separated by at least one space.

- Rejects any row of data that cannot be completely parsed into integers.

- Generates an error, if the output table has a non-integer column.

Loading and Using the Example

Load and use the parser as follows:
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE PARSER NumericTextParser AS LANGUAGE 'java'
  ->  NAME 'com.myCompany.UDParser.NumericTextParserFactory'
  ->  LIBRARY JavaLib;
CREATE PARSER FUNCTION
=> CREATE TABLE t (i INTEGER);
CREATE TABLE
=> COPY t FROM STDIN WITH PARSER NumericTextParser();
End with a backslash and a period on a line by itself.
>> One  
>> Two
>> One Two Three
>> \.
=> SELECT * FROM t ORDER BY i;
  i
-----
  1
  2
  123
(3 rows)

=> DROP TABLE t;
DROP TABLE
=> -- Parse multi-column input
=> CREATE TABLE t (i INTEGER, j INTEGER);
CREATE TABLE
=> COPY t FROM stdin WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> One | Two 
>> Two | Three
>> One Two Three | four Five Six 
>> \.
=> SELECT * FROM t ORDER BY i;
  i | j
--------
  1 | 2

Parser Implementation

The following code implements the parser.

    package com.myCompany.UDParser;

    import java.util.Arrays;
    import java.util.List;
    import java.util.regex.Pattern;
import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.DestroyInvocation;
import com.vertica.sdk.RejectedRecord;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.InputState;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.StreamWriter;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;

public class NumericTextParser extends UDParser {

    private String separator; // Holds column separator character
    private List<String> numbers = Arrays.asList("zero", "one", "two", "three", "four", "five", "six", "seven", "eight", "nine");
    private String rejectedReason;
    private String rejectedRow;

    public NumericTextParser(String sepparam) {
        super();
        this.separator = sepparam;
    }

    // Called to perform the actual work of parsing. Gets a buffer of bytes
    // to turn into tuples.
    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input, InputState input_state) throws UdfException, DestroyInvocation {
        int i=input.offset; // Current position in the input buffer
        boolean lastCharNewline = false;
        String line = new StringBuffer();

        //Continue reading until end of buffer.
        for(; i < input.buf.length; i++){
            char inchar = (char) input.buf[i];
            // Note that this isn't a robust way to find rows. It should
            // accept a user-defined row separator. Also, the following
            // assumes ASCII line break methods, which isn't a good idea
            // in the UTF world. But it is good enough for this simple example.
            if (inchar != '\n' && inchar != '\r') {
                // Keep adding to a line buffer until a full row of data is read
                line.append(inchar);
                lastCharNewline = false; // Last character not a new line
            } else {
                // Found a line break. Process the row.
                lastCharNewline = true; // indicate we got a complete row
                // Update the position in the input buffer. This is updated
                // whether the row is successfully processed or not.
                input.offset = i+1;
            }
        }
    }
}
// Call processRow to extract values and write tuples to the output. Returns false if there was an error.
if (!processRow(line)) {
    // Processing row failed. Save bad row to rejectedRow field
    // and return to caller indicating a rejected row.
    rejectedRow = line.toString();
    // Update position where we processed the data.
    return StreamState.REJECT;
}

line.delete(0, line.length()); // clear row buffer
}

// At this point, process() has finished processing the input buffer.
// There are two possibilities: need to get more data
// from the input stream to finish processing, or there is
// no more data to process. If at the end of the input stream and
// the row was not terminated by a linefeed, it may need
// to process the last row.

if (input_state == InputState.END_OF_FILE & lastCharNewline) {
    // End of input and it ended on a newline. Nothing more to do
    return StreamState.DONE;
} else if (input_state == InputState.END_OF_FILE & !lastCharNewline) {
    // At end of input stream but didn’t get a final newline. Need to
    // process the final row that was read in, then exit for good.
    if (line.length() == 0) {
        // Nothing to process. Done parsing.
        return StreamState.DONE;
    }

    // Need to parse the last row, not terminated by a linefeed. This
    // can occur if the file being read didn’t have a final line break.
    if (processRow(line)) {
        return StreamState.DONE;
    }

    // Processing last row failed. Save bad row to rejectedRow field
    // and return to caller indicating a rejected row.
    rejectedRow = line.toString();
    // Tell Vertica the entire buffer was processed so it won’t
    // call again to have the line processed.
    input.offset = input.buf.length;
    return StreamState.REJECT;
}

else {
    // Stream is not fully read, so tell Vertica to send more. If
    // process() didn’t get a complete row before it hit the end of the
    // input buffer, it will end up re-processing that segment again
    // when more data is added to the buffer.
    return StreamState.INPUT_NEEDED;
}

}

// Breaks a row into columns, then parses the content of the
// columns. Returns false if there was an error parsing the
// row, in which case it sets the rejected row to the input
// line. Returns true if the row was successfully read.
private boolean processRow(StringBuffer line)
    throws UdfException, DestroyInvocation {
    String[] columns = line.toString().split(Pattern.quote(separator));
    // Loop through the columns, decoding their contents
for (int col = 0; col < columns.length; col++) {
    // Call decodeColumn to extract value from this column
    Integer colval = decodeColumn(columns[col]);
    if (colval == null) {
        // Could not parse one of the columns. Indicate row should
        // be rejected.
        return false;
    }
    // Column parsed OK. Write it to the output. writer is a field
    // provided by the parent class. Since this parser only accepts
    // integers, there is no need to verify that data type of the parsed
    // data matches the data type of the column being written. In your
    // UDAParsers, you may want to perform this verification.
    writer.setLong(col, colval);
}
// Done with the row of data. Advance output to next row.

// Note that this example does not verify that all of the output columns
// have values assigned to them. If there are missing values at the
// end of a row, they get automatically get assigned a default value
// (0 for integers). This isn't a robust solution. Your UDAParse
// should perform checks here to handle this situation and set values
// (such as null) when appropriate.
writer.next();
return true; // Successfully processed the row.

// Gets a string with text numerals, i.e. "One Two Five Seven" and turns
// it into an integer value, i.e. 1257. Returns null if the string could not
// be parsed completely into numbers.
private Integer decodeColumn(String text) {
    int value = 0; // Hold the value being parsed.

    // Split string into individual words. Eat extra spaces.
    String[] words = text.toLowerCase().trim().split("\s+");

    // Loop through the words, matching them against the list of
    // digit strings.
    for (int i = 0; i < words.length; i++) {
        if (numbers.contains(words[i])) {
            // Matched a digit. Add the it to the value.
            int digit = numbers.indexOf(words[i]);
            value = (value * 10) + digit;
        } else {
            // The string didn't match one of the accepted string values
            // for digits. Need to reject the row. Set the rejected
            // reason string here so it can be incorporated into the
            // rejected reason object.
            //
            // Note that this example does not handle null column values.
            // In most cases, you want to differentiate between an
            // unparseable column value and a missing piece of input
            // data. This example just rejects the row if there is a missing
            // column value.
            rejectedReason = String.format(
                "Could not parse '%s' into a digit", words[i]);
            return null;
        }
    }
    return value;
Vertica calls this method if the parser rejected a row of data to find out what went wrong and add to the proper logs. Just gathers information stored in fields and returns it in an object.

```java
@Override
public RejectedRecord getRejectedRecord() throws UdfException {
    return new RejectedRecord(rejectedReason, rejectedRow.toCharArray(), rejectedRow.length(), "\n");
}
```

ParserFactory Implementation

The following code implements the parser factory. NumericTextParser accepts a single optional parameter named separator. This parameter is defined in the getParameterType() method, and the plan() method stores its value. NumericTextParser outputs only integer values. Therefore, if the output table contains a column whose data type is not integer, the getParserReturnTypetype() method throws an exception.

```java
package com.myCompany.UDParser;
import java.util.regex.Pattern;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ParserFactory;
import com.vertica.sdk.PerColumnParamReader;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;
import com.vertica.sdk.VerticaType;
public class NumericTextParserFactory extends ParserFactory {
    // Called once on the initiator host to check the parameters and set up the // context data that hosts performing processing will need later.
    @Override
    public void plan(ServerInterface srvInterface,
                     PerColumnParamReader perColumnParamReader,
                     PlanContext planCtx) {
        String separator = "|"; // assume separator is pipe character

        // See if a parameter was given for column separator
        ParamReader args = srvInterface.getParamReader();
        if (args.containsKey("separator")) {
            separator = args.getString("separator");
            if (separator.length() > 1) {
                throw new UdfException(0,
```
"Separator parameter must be a single character";

if (Pattern.quote(separator).matches("[a-zA-Z]")
    throw new UdfException(0,
        "Separator parameter cannot be a letter");
}

// Save separator character in the Plan Data
ParamWriter context = planCtxt.getWriter();
context.setString("separator", separator);

// Define the data types of the output table that the parser will return.
// Mainly, this just ensures that all of the columns in the table which
// is the target of the data load are integer.
@Override
public void getParserReturnType(ServerInterface srvInterface,
    PerColumnParamReader perColumnParamReader,
    PlanContext planCtxt,
    SizedColumnTypes argTypes,
    SizedColumnTypes returnType)
{
    // Get access to the output table's columns
    for (int i = 0; i < argTypes.getColumnCount(); i++) {
        if (argTypes.getColumnType(i).isInt()) {
            // Column is integer... add it to the output
            returnType.addInt(argTypes.getColumnName(i));
        } else {
            // Column isn't an int, so throw an exception.
            // Technically, not necessary since the
            // Udx framework will automatically error out when it sees a
            // Discrepancy between the type in the target table and the
            // types declared by this method. Throwing this exception will
            // provide a clearer error message to the user.
            String message = String.format(
                "Column %d of output table is not an Int", i + 1);
            throw new UdfException(0, message);
        }
    }
}

// Instantiate the UDFParser subclass named NumericTextParser. Passes the
// separator character as a parameter to the constructor.
@Override
public UDFParser prepare(ServerInterface srvInterface,
    PerColumnParamReader perColumnParamReader,
    PlanContext planCtxt,
    SizedColumnTypes returnType) throws UdfException {
    // Get the separator character from the context
    String separator = planCtxt.getReader().getString("separator");
    return new NumericTextParser(separator);
}

// Describe the parameters accepted by this parser.
@Override
public void getParameterType(ServerInterface srvInterface,
    SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "separator");
}
Parser Example: JSON Parser

The JSON Parser consumes a stream of JSON objects. Each object must be well formed and on a single line in the input. Use line breaks to delimit the objects. The parser uses the field names as keys in a map, which become column names in the table. You can find the code for this example in /opt/vertica/packages/flextable/examples. This directory also contains an example data file.

This example uses the setRowFromMap() method to write data.

Loading and Using the Example

1. Load the library and define the JSON parser, using the third-party library (gson-2.2.4.jar). See the comments in JsonParser.java for a download URL.

```java
=> CREATE LIBRARY json
  AS '/opt/vertica/packages/flextable/examples/java/output/json.jar'
  DEPENDS '/opt/vertica/bin/gson-2.2.4.jar' language 'java';
CREATE LIBRARY

=> CREATE PARSER JsonParser AS LANGUAGE 'java'
  NAME 'com.vertica.flex.JsonParserFactory' LIBRARY json;
CREATE PARSER FUNCTION
```

2. Define a table, and then use the JSON parser to load data into that table.

```sql
=> CREATE TABLE mountains(name varchar(64), type varchar(32), height integer);
CREATE TABLE

=> COPY mountains FROM '/opt/vertica/packages/flextable/examples/mountains.json'
  WITH PARSER JsonParser();
  RECORD 1
  Rows Loaded | 2

=> SELECT * from mountains;
  RECORD 1
  name | Everest
  type | mountain
  height | 29029
  RECORD 2
  name | Mt St Helens
  type | volcano
  height |
```

The data file contains a value (hike_safety) that was not loaded because the table definition did not include that column. The data file follows:
Implementation

The following code shows the `process()` method from JsonParser.java. The parser attempts to read the input into a Map. If the read is successful, the JSON Parser calls `setRowFromMap()`:

```java
@Override
public StreamState process(ServerInterface srvInterface, DataBuffer input, InputState inputState) throws UdfException, DestroyInvocation {
    clearReject();
    StreamWriter output = getStreamWriter();

    while (input.offset < input.buf.length) {
        ByteBuffer lineBytes = consumeNextLine(input, inputState);

        if (lineBytes == null) {
            return StreamState.INPUT_NEEDED;
        }

        String lineString = StringUtils.newString(lineBytes);

        try {
            Map<String, Object> map = gson.fromJson(lineString, parseType);

            if (map == null) {
                continue;
            }

            output.setRowFromMap(map);
            // No overrides needed, so just call next() here.
            output.next();
        } catch (Exception ex) {
            setReject(lineString, ex);
        }
        return StreamState.REJECT;
    }
}
```

The factory, JsonParserFactory.java, instantiates and returns a parser in the `prepare()` method. No additional setup is required.
Connecting to Vertica

This book explains several methods of connecting to Vertica, including:

- Directly connecting to Vertica using the vsql client application.
- Installing and configuring the Vertica client libraries to allow client applications to access Vertica.
- Developing your own client applications using the Vertica client libraries.
Using \textit{vsql}

\textit{vsql} is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.

If you are using the \textit{vsql} client installed on the server, then you can connect from the:

- \textit{Administration Tools}
- \textit{Linux command line}

You can also \textbf{install the \textit{vsql} client} for other supported platforms.

A man page is available for \textit{vsql}. If you are running as the \texttt{dbadmin} user, simply type: \texttt{man vsql}. If you are running as a different user, type: \texttt{man -M /opt/vertica/man vsql}.

**General Notes**

- SQL statements can be spread over several lines for clarity.

- \textit{vsql} can handle input and output in UTF-8 encoding. The terminal emulator running \textit{vsql} must be set up to display the UTF-8 characters correctly. Follow the documentation of your terminal emulator. The following example shows the settings in PuTTy from the Change Settings > Window > Translation option:
See also Best Practices for Working with Locales.

- Cancel SQL statements by typing Ctrl+C.
- Traverse command history by typing Ctrl+R.
- When you disconnect a user session, any transactions in progress are automatically rolled back.
- To view wide result sets, use the Linux `less` utility to truncate long lines.
  a. Before connecting to the database, specify that you want to use `less` for query output:

  ```bash
  $ export PAGER=less
  ```

  b. Connect to the database.

  c. Query a wide table:

  ```sql
  => select * from wide_table;
  ```
d. At the less prompt, type:

    -s

- If a shell running vsq1 fails (crashes or freezes), the vsq1 processes continue to run even if you stop the database. In that case, log in as root on the machine on which the shell was running and manually kill the vsq1 process. For example:

```bash
# ps -ef | grep vertica
    fred  2401  1 0 06:02 pts/1 00:00:00 /opt/vertica/bin/vsql -p 5433 -h
              test01_site01 quick_start_single
# kill -9 2401
```
Installing the vsq1 Client

The vsq1 client is installed as part of the Vertica server rpm. It is also available as a download for other Unix-based systems such as HP-UX, AIX, and Mac OSX.

Unix Installation

1. Use a web browser to log in to the myVertica portal.
2. Click Downloads, and choose Client Drivers.
3. Download the appropriate vsq1 client. There are both 32-bit and 64-bit versions for most platforms.

   Important: Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsq1 and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and vsq1.

4. Extract the tarball. The tarball is organized to extract into /opt/vertica if you extract it at the root (/) of the drive.
5. Optionally add the directory where the vsq1 client resides to your path.
6. Verify mode on the vsq1 file is executable. For example: chmod ugo+x vsq1_VERSION
7. Set your shell locale to a locale supported by vsq1. For example, in your .profile, add, export LANG=en_US.UTF-8

Windows Installation

vsq1 on Windows is installed as part of the Windows Client Driver package. For installation details, see The Vertica Client Drivers and Tools for Windows.

See Using vsq1 for Windows Users for details on using vsq1 in a Windows console.
Connecting From the Administration Tools

You can use the Administration Tools to connect to a database using vsq1 on any node in the cluster.

1. Log in as the database administrator user; for example, dbadmin.

   **Note:** Vertica does not allow users with root privileges to connect to a database for security reasons.

2. Run the Administration Tools.

   `/opt/vertica/bin/admintools`

3. On the Main Menu, select Connect to Database.

   ![Main Menu](image)

4. Supply the database password if asked:

   ![Password](image)

   When you create a new user with the `CREATE USER` command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the `ALTER USER` command.

5. The Administration Tools connect to the database and transfer control to vsq1.
Welcome to vsq1, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsq1 commands
\g or terminate with semicolon to execute query
\q to quit

Note: See Meta-Commands for the various commands you can run while connected to the database through the Administration Tools.
Connecting from the Command Line

You can connect to a database using vsq1 from the command line on multiple client platforms. If the connection cannot be made for any reason—for example, you have insufficient privileges, or the server is not running on the targeted host—vsq1 returns an error and terminates.

Syntax

```
/opt/vertica/bin/vsq1 [-h host] [ option...] [ dbname [ username ]]
```

Parameters

<table>
<thead>
<tr>
<th>host</th>
<th>Optional if you connect to a local server. You can provide an IPv4 or IPv6 IP address or a host name. For Vertica servers that have both IPv4 and IPv6 addressed and you have provided a host name instead of an IP address, you can prefer to use an IPv4 address with the -4 option and to use the IPv6 address with the -6 option if the DNS is configured to provide both IPv4 and IPv6 addresses. If you are using IPv6 and provide an IP address, you must append the address with an <code>%interface name</code>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>option</td>
<td>One or more vsq1 Command-Line Options If the database is password protected, you must specify the -w or --password command line option.</td>
</tr>
<tr>
<td>dbname</td>
<td>The name of the target database, by default your Linux user name.</td>
</tr>
<tr>
<td>username</td>
<td>A database username, by default your Linux user name.</td>
</tr>
</tbody>
</table>

Exit Codes

vsq1 returns 0 to the shell when it terminates normally. Otherwise, it returns one of the following:
• 1: A fatal error occurred—for example, out of memory or file not found.

• 2: The connection to the server went bad and the session was not interactive

• 3: An error occurred in a script and the variable ON_ERROR_STOP was set.

• Unrecognized words in the command line might be interpreted as database or user names.

Examples

The following example shows how to capture error messages by redirecting vsq1 output to the output file retail_queries.out:

$ vsq1 --echo-all < retail_queries.sql > retail_queries.out 2>&1

Command-Line Options

This section contains the command-line options for vsq1.

General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--command command</td>
<td>Runs one command and exits. This command is useful in shell scripts.</td>
</tr>
<tr>
<td>-c command</td>
<td></td>
</tr>
<tr>
<td>--dbname dbname</td>
<td>Specifies the name of the database to which you want to connect. Using this command is equivalent to specifying dbname as the first non-option argument on the command line.</td>
</tr>
<tr>
<td>-d dbname</td>
<td></td>
</tr>
<tr>
<td>--file filename</td>
<td>Uses the filename as the source of commands instead of reading commands interactively. After the file is processed, vsq1 terminates.</td>
</tr>
<tr>
<td>-f filename</td>
<td></td>
</tr>
<tr>
<td>--help</td>
<td>Displays help about vsq1 command line arguments and exits.</td>
</tr>
<tr>
<td>--timing</td>
<td>Enables the \timing meta-command.</td>
</tr>
<tr>
<td>-i</td>
<td></td>
</tr>
</tbody>
</table>
### --list

Returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command `\list`.

### --set assignment

### --variable assignment

### -v assignment

Performs a variable assignment, like the `vsql` command `\set`.

### --version

### -V

Prints the `vsql` version and exits.

### --no-vsqlr

### -X

Disables all command line editing and history functionality.

---

### Connection Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>-4</strong></td>
<td>When resolving hostnames in dual stack environments, prefer IPv4 addresses.</td>
</tr>
<tr>
<td><strong>-6</strong></td>
<td>When resolving hostnames in dual stack environments, prefer IPv6 addresses.</td>
</tr>
<tr>
<td><strong>-B server:port[,...]</strong></td>
<td>Sets connection backup server/port. Use comma-separated multiple hosts (default: not set). If using an IPv6 address, enclose the address in brackets ([, ]) and place the port outside of the brackets. For example <code>\B [260::a13:8a4:9d9f:e0e3:1181:7f51]:5433</code></td>
</tr>
<tr>
<td><strong>--enable-connection</strong></td>
<td>Enables connection load balancing (default: not enabled).</td>
</tr>
<tr>
<td><strong>-C</strong></td>
<td></td>
</tr>
<tr>
<td><strong>--host hostname</strong></td>
<td>Specifies the host name of the machine on which the server is running.</td>
</tr>
<tr>
<td><strong>-h hostname</strong></td>
<td></td>
</tr>
<tr>
<td><strong>-k krb-service</strong></td>
<td>Provides the service name portion of the Kerberos principal</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-k krb-host</td>
<td>Provides the instance or host name portion of the Kerberos principal. -k is equivalent to</td>
</tr>
<tr>
<td></td>
<td>the drivers' KerberosHostName connection string.</td>
</tr>
<tr>
<td>--sslmode</td>
<td>Specifies the policy for making SSL connections to the server. Options are require, prefer,</td>
</tr>
<tr>
<td>-m</td>
<td>allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If</td>
</tr>
<tr>
<td></td>
<td>the variable is set, the command-line option overrides it.</td>
</tr>
<tr>
<td>--port port</td>
<td>Specifies the TCP port or the local socket file extension on which the server is listening</td>
</tr>
<tr>
<td>-p port</td>
<td>for connections. Defaults to port 5433.</td>
</tr>
<tr>
<td>--username username</td>
<td>Connects to the database as the user username instead of the default.</td>
</tr>
<tr>
<td>-U username</td>
<td></td>
</tr>
<tr>
<td>-w password</td>
<td>Specifies the password for a database user.</td>
</tr>
<tr>
<td>--password</td>
<td>Forces vsql to prompt for a password before connecting to a database. The password is not</td>
</tr>
<tr>
<td>-W</td>
<td>displayed on the screen. This option remains set for the entire session, even if you change</td>
</tr>
<tr>
<td></td>
<td>the database connection with the meta-command \connect.</td>
</tr>
</tbody>
</table>

**Output Formatting**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--no-align -A</td>
<td>Switches to unaligned output mode. (The default output mode is aligned.)</td>
</tr>
<tr>
<td>-b</td>
<td>Beep on command completion.</td>
</tr>
<tr>
<td>--field-separator</td>
<td>Specifies the field separator for unaligned output (default: Vertica).</td>
</tr>
</tbody>
</table>
### Input and Output Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--echo-all -a</td>
<td>Prints all input lines to standard output as they are read. This approach is more useful for script processing than interactive mode. It is the same as setting the variable ECHO to all.</td>
</tr>
<tr>
<td>--echo-queries -e</td>
<td>Copies all SQL commands sent to the server to standard output. Using this command is equivalent to setting the</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>-E</td>
<td>Displays queries generated by internal commands.</td>
</tr>
<tr>
<td>-n</td>
<td>Disables command line editing.</td>
</tr>
<tr>
<td>--output filename</td>
<td>Writes all query output to <code>filename</code>. Using this command is equivalent to using the <code>vsql</code> meta-command <code>\o</code>.</td>
</tr>
<tr>
<td>-o filename</td>
<td></td>
</tr>
<tr>
<td>--quiet</td>
<td>Specifies that <code>vsql</code> do its work quietly (without informational output, such as welcome messages). This command is useful with the -c option. Within <code>vsql</code> you can also set the QUIET variable to achieve the same effect.</td>
</tr>
<tr>
<td>-q</td>
<td></td>
</tr>
<tr>
<td>--single-step</td>
<td>Runs in single-step mode for debugging scripts. Forces <code>vsql</code> to prompt before each statement is sent to the database and allows you to cancel execution.</td>
</tr>
<tr>
<td>-s</td>
<td></td>
</tr>
<tr>
<td>--single-line</td>
<td>Runs in single-line mode where a newline terminates a SQL command, as if you are using a semicolon.</td>
</tr>
<tr>
<td>-S</td>
<td></td>
</tr>
</tbody>
</table>

Note: This mode is provided only by customer request. Vertica recommends that you not use single-line mode in cases where you mix SQL and meta-commands on a line. In single-line mode, the order of execution might be unclear to the inexperienced user.

-A --no-align

-A or --no-align switches to unaligned output mode. The default output mode is aligned.

-a --echo-all

-a or --echo-all prints all input lines to standard output as they are read. This is more useful for script processing than interactive mode. It is equivalent to setting the variable `ECHO` to all.
-c --command

- c command or --command command runs one command and exits. This is useful in shell scripts.

Use either:

- A command string that can be completely parsed by the server that does not contain features specific to vsql
- A single meta-command

You cannot mix SQL and vsql meta-commands. You can, however, pipe the string into vsql as shown:

```plaintext
echo "\\timing\\select * from t" | ../Linux64/bin/vsql
Timing is on.
 i | c | v
-----+-----
(0 rows)
```

Note: If you use double quotes (") with echo, you must double the backslashes (\).

-d --dbname

- d db-name or --dbname db-name specifies the name of the database to connect to. This is equivalent to specifying db-name as the first non-option argument on the command line.

-E

- E displays queries generated by internal commands.

-e --echo-queries

- e --echo-queries copies all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable ECHO to queries.
-F --field-separator

-F separator or --field-separator separator specifies the field separator for unaligned output (default: "); (-P fieldsep=). (See -A --no-align.) This is equivalent to \pset fieldsep or \.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as \t for tab), or a backslash (\) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (\t), vertical tab (\v) and the octal value of vertical tab (\013).

```shell
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F $'\t' -At -c "SELECT * FROM testtable;"
A 1 2 3
B 4 5 6

$ vsql -F $'\v' -At -c "SELECT * FROM testtable;"
A 1
  2
  3
B 4
  5
  6

$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
A 1
  2
  3
B 4
  5
  6
```

-f --file

-f filename or --file filename uses filename as the source of commands instead of reading commands interactively. After the file is processed, vsql terminates.

If filename is a hyphen (-), standard input is read.
Using this option is different from writing `vsql < filename`. Using `-f` enables some additional features such as error messages with line numbers. Conversely, the variant using the shell's input redirection should always yield exactly the same output that you would have gotten had you entered everything manually.

? --help

-? --help displays help about vsql command line arguments and exits.

-H --html

-H --html turns on HTML tabular output. This is equivalent to `\pset format html` or the `\H` command.

-h --host

-h hostname or --host hostname specifies the host name of the machine on which the server is running.

The following requirements and restrictions apply:

- If you use client authentication with a Kerberos connection method of either `gss` or `krb5`, you must specify -h hostname.

- If you use client authentication with a "local" connection type specified, and you want to match the client authentication entry, do not use -h hostname.

-i -- timing

Enables the `\timing` meta-command. You can only use this command with the `-c` `--command` and `-f` `--file` commands:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

You can only use -i with the -c (command) and -f (filename) commands. For more information see Command-Line Options.

From the command line enter the -i option before running a session to turn timing on. For example:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```
-l --list

-1 or --list returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command \list.

-m --ssmode

-m or --ssmode specifies the policy for making SSL connections to the server. Options are verify_full, verify_ca require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.

For information on these modes see Configuring SSL for ODBC Clients.

-n

-n disables command line editing.

-o --output

-o filename or --output filename writes all query output into file filename. This is equivalent to the vsq1 meta-command \o.

-P --pset

-P assignment or --pset assignment lets you specify printing options in the style of \pset on the command line. Note that you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write -P format=latex.
-p --port

-p port or --port port specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.

-q --quiet

-q or --quiet specifies that vsql do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this appears. This is useful with the -c option. Within vsql you can also set the QUIET variable to achieve the same effect.

-R --record-separator

-R separator or --record-separator separator specifies separator as the record separator. This is equivalent to the \pset recordsep command.

-S --single-line

-S --single-line runs in single-line mode where a newline terminates a SQL command, like the semicolon does.

Note: This mode is provided for those who insist on it, but you are not necessarily encouraged to use it, particularly if you mix SQL and meta-commands on a line. The order of execution might not always be clear to the inexperienced user.

-s --single-step

-s --single-step runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.

-T --table-attr

-T table-options or --table-attr table-options lets you specify options to be placed within the HTML table tag. See \pset for details.
-t --tuples-only

-t or --tuples-only disables printing of column names, result row count footers, and so on. This is equivalent to the vsql meta-command \t.

-V --version

-V or --version prints the vsql version and exits.

-v --variable --set

-v assignment, --variable assignment, and --set assignment perform a variable assignment, like the vsql meta-command \set.

Note: You must separate name and value, if any, by an equals sign (=) on the command line.

To unset a variable, omit the equal sign. To set a variable without a value, use the equals sign but omit the value. Make these assignments at a very early stage of start-up, so that variables reserved for internal purposes can get overwritten later.

-X --no-vsqlrc

-X --no-vsqlrc prevents the start-up file from being read: the system-wide vsqlrc file or the user's ~/.vsqlrc file.

-x --expanded

-x or --expanded enables extended table formatting mode. This is equivalent to the vsql meta-command \x.

Connecting From a Non-Cluster Host

You can use the Vertica vsql executable image on a non-cluster Linux host to connect to a Vertica database.
On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the vsql executable. See Installing the Client RPM on Red Hat and SUSE for details.

If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

```
$ scp host01:/opt/vertica/bin/vsql . $ ./vsql
```

If the non-cluster host is running a different version of Linux than your cluster hosts, and that operating system is not Red Hat version 5 64-bit or SUSE 10/11 64-bit, you must install the Vertica server RPM in order to get vsql. Download the appropriate rpm package from the Download tab of the myVertica portal then log into the non-cluster host as root and install the rpm package using the command:

```
# rpm -Uvh filename
```

In the above command, `filename` is the package you downloaded. Note that you do not have to run the `install_Vertica` script on the non-cluster host in order to use vsql.

Notes

- Use the same Command-Line Options that you would on a cluster host.

- You cannot run vsql on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run vsql.
**Meta-Commands**

Anything you enter in vsql that begins with an unquoted backslash is a vsql meta-command that is processed by vsql itself. These commands help make vsql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a vsql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you can quote it with a single quote. To include a single quote into such an argument, precede it by a backslash. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \digits, \0digits, and \0xdigits (the character with the given decimal, octal, or hexadecimal code).

If an unquoted argument begins with a colon (:), it is taken as a vsql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes (``) are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.

Some commands take a SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, FOO"BAR"BAZ is interpreted as fooBARbaz, and "A weird"" name" becomes A weird" name.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence `\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and vsql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

**Meta-Commands Quick Reference**

<table>

</table>
\connect

Establishes a connection to database \textit{db}, under the specified user \textit{user-name}. The previous connection is closed. If you omit specifying a database name, Vertica connects to the current database. If you omit specifying a user name argument, Vertica assumes the current user.

**Syntax**

\texttt{\c [connect] \ [db \ [user-name]]}

**Error Handling**

Errors that prevent execution include specifying an unknown user and denial of access to the specified database. Vertica handles errors differently, depending on whether this command is executed interactively in \texttt{vsql}, or in a script:

- **\texttt{VSQL} handling:** The current connection is maintained.
- **Script:** Processing immediately stops with an error. This is prevents scripts from acting on the wrong database.

\d Meta-Commands

Vertica supports a number of \texttt{\d} commands, which return information on different categories of database objects. For a full list, see \texttt{\d Reference} below.

**Syntax**

Unless otherwise noted, \texttt{\d} commands generally conform to the following syntax:

\texttt{\dCommand \ [ [schema.]pattern ]}

**Arguments**

You can supply most \texttt{\d} commands with a string pattern argument, which filters the results that the command returns. The pattern can optionally be qualified by a schema name.
schema

Valid for most \d commands, specifies to return only database objects in `schema`. For example, the following \dp command obtains privileges information for all V_MONITOR tables that contain the string `resource`:

```sql
=> \dp V_MONITOR.*resource*
```

<table>
<thead>
<tr>
<th>Grantee</th>
<th>Grantor</th>
<th>Privileges</th>
<th>Schema</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_rejections</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>disk_resource_rejections</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_usage</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_acquisitions</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_rejection_details</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_pool_move</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>host_resources</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>node_resources</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_queues</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_pool_status</td>
</tr>
</tbody>
</table>

(10 rows)

pattern

Returns only the database objects that match the specified string. Pattern strings can include one or more of two wildcards:

<table>
<thead>
<tr>
<th>Wildcard character</th>
<th>Represents...</th>
</tr>
</thead>
<tbody>
<tr>
<td>* (asterisk)</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>? (question mark)</td>
<td>Any single character</td>
</tr>
</tbody>
</table>

For example, the following \dt command returns tables that start with the string `store`:

```sql
=> \dt store*
```

<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Kind</th>
<th>Owner</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>store_orders</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>store_orders_2018</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>store_overseas</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_dimension</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_sales_fact</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
</tbody>
</table>

(6 rows)

\d Reference

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\d</td>
<td>Unqualified by a pattern argument, returns all tables with their schema</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>\d</td>
<td>names, owners, and comments. If qualified by a pattern argument, \d returns all matching tables and all columns in each table, with details about each column, such as data type, size, and default value.</td>
</tr>
<tr>
<td>\df</td>
<td>Returns all function names, the function return data type, and the function argument data type. Also returns the procedure names and arguments for all procedures that are available to the user.</td>
</tr>
<tr>
<td>\dj</td>
<td>Returns all projections showing the schema, projection name, owner, and node. The returned rows include superprojections, live aggregate projections, Top-K projections, and projections with expressions</td>
</tr>
<tr>
<td>\dn</td>
<td>Returns the schema names and schema owner</td>
</tr>
<tr>
<td>\dp</td>
<td>Returns the grantee, grantor, privileges, schema, and name for all table access privileges in each schema.</td>
</tr>
<tr>
<td>\dS</td>
<td>Unqualified by a pattern argument, returns all V_CATALOG and V_MONITOR system tables. To obtain system tables for just one schema, qualify the command with the schema name, as follows: \dS { V_CATALOG</td>
</tr>
<tr>
<td>\ds</td>
<td>Returns sequences and their parameters.</td>
</tr>
<tr>
<td>\dT</td>
<td>Returns all data types that Vertica supports.</td>
</tr>
<tr>
<td>\dt</td>
<td>Unqualified by a pattern argument, returns the same information as an unqualified \d command. If qualified by a pattern argument, \dt returns matching tables with the same level of detail as an unqualified \dt command.</td>
</tr>
<tr>
<td>\dtv</td>
<td>Returns tables and views.</td>
</tr>
<tr>
<td>\du</td>
<td>Returns database users and whether they are superusers.</td>
</tr>
<tr>
<td>\dv</td>
<td>Unqualified by a pattern argument, returns all views with their schema names, owners, and comments. If qualified by a pattern argument, \dv returns all matching views and the columns in each view, with each column's data type and size.</td>
</tr>
</tbody>
</table>

Note: \dT: returns no results if qualified with a pattern argument.
\edit

Edits the query buffer (or specified file) with an external editor. When the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of vsqI, where the whole buffer up to the first semicolon is treated as a single line. (Thus you cannot make scripts this way. Use \i for that.) If there is no semicolon, vsqI waits for one to be entered (it does not execute the query buffer).

Tip: vsqI searches the environment variables VSQL_EDITOR, EDITOR, and VISUAL (in that order) for an editor to use. If all of them are unset, vi is used on Linux systems, notepad.exe on Windows systems.

Syntax

\[edit [ file ]

\i

Reads and executes input from the specified file.

Note: To see the lines on the screen as they are read, set the variable ECHO to all.

Syntax

\i filename

Examples

The Vertica vsqI client on Linux supports backquote (backtick) expansion. For example:

1. Set an environment variable to a path that contains scripts you want to run:

   $ export MYSCRIPTS=/home/dbadmin/testscripts
2. Issue the vsql command.
   $ vsql

3. Use backquote expansion to include the path for running an existing script—for example, sample.sql.
   => \i `echo $MYSCRIPTS/sample.sql`

\locale

Displays or sets the locale setting for the current session.

Note: This command does not alter the default locale for all database sessions. To change the default for all sessions, set configuration parameter `DefaultSessionLocale`.

Syntax

\locale [Locale-identifier]

Arguments

| Locale-identifier | Specifies the ICU locale identifier to use, by default set to: en_US@collation=binary
|                  | If set to an empty string, Vertica sets locale to en_US_POSIX.
|                  | If you omit this argument, \locale returns the current locale setting.
|                  | For details on identifier options, see About Locale in the Administrator's Guide. For a complete list of locale identifiers, see the ICU Project. |

Examples

View the current locale setting:

=> \locale
en_US@collation=binary

Change the default locale for this session:
Notes

The server locale settings impact only the collation behavior for server-side query processing. The client application is responsible for ensuring that the correct locale is set in order to display the characters correctly. Below are the best practices recommended by Vertica to ensure predictable results:

- The locale setting in the terminal emulator for vsql (POSIX) should be set to be equivalent to session locale setting on server side (ICU) so data is collated correctly on the server and displayed correctly on the client.

- The vsql locale should be set using the POSIX LANG environment variable in terminal emulator. Refer to the documentation of your terminal emulator for how to set locale.

- Server session locale should be set using the set as described in Specify the Default Locale for the Database.

- All input data for vsql should be in UTF-8 and all output data is encoded in UTF-8.

- Non UTF-8 encodings and associated locale values are not supported.

\pset

Sets options that control how Vertica formats query result output.

Syntax

\pset output-option

Output Options

| Note: Unless otherwise specified, output options are valid for all formats. |
|---|---|
| format | Sets output format, where format-option is one of the |
### format-option

Following:

- **unaligned** writes all column data of each row on a single line, where each field is separated only by the current separator character. Use this output for use as input to other programs—for example, comma-delimited fields for CSV input.

- **aligned** (default): Renders column-aligned output.

- **html**: Renders output in HTML markup as a table.

- **latex**: Renders output in LaTeX markup.

### border int

Valid only if output format is set to html, specifies the table border, where **int** specifies the border type.

### expanded

Toggles between regular and expanded format. When expanded format is enabled, all output has two columns with the column name on the left and the data on the right. This mode is especially useful for wide tables.

### fieldsep 'arg'

Valid only if output format is set to unaligned, specifies the field separator, by default | (vertical bar).

For example, to specify tab as the field separator:

```
\pset fieldsep '\t'
```

### footer

Toggles display of the default footer:

(int rows)

### null 'string'

Specifies to represent column null values as **string**. By default, Vertica renders null values as an empty field, which might be mistaken as an empty string.

For example:

```
\pset null '(null)'
```

### pager [always]

Toggles use of a pager for query and vsql help output. If the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used.
When the pager is off, the pager is not used. When the pager is on, the pager is used only when appropriate; that is, the output is to a terminal and does not fit on the screen. (vsql does not do a perfect job of estimating when to use the pager.)

If qualified with the argument always, the pager is always used.

<table>
<thead>
<tr>
<th>recordsep 'char'</th>
<th>Valid only if output format is set to unaligned, specifies the character used to delimit table records (tuples), by default a newline character.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableattr html-attribute [...]</td>
<td>Specifies attributes to be placed inside the HTML table tag—for example, cellpadding or bgcolor.</td>
</tr>
</tbody>
</table>
| title ['title-str'] | Sets a title that precedes query result output, to title-str. HTML output renders this as follows:
  &lt;caption&gt;title-str&lt;/caption&gt;
  To remove the title, reissue the command omit the title-str argument. |
| trailingrecordsep | Toggles on or off the trailing record separator to use in unaligned output mode. |
| t[uples_only] | Toggles between tuples only and full display. Full display might show extra information such as column headers, titles, and various footers. In tuples only mode, only actual table data is shown. |

### Shortcuts

The following \pset commands have short-cuts:

<table>
<thead>
<tr>
<th>PSET command</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>\pset expanded</td>
<td>\x</td>
</tr>
<tr>
<td>\pset fieldsep 'arg'</td>
<td>\f</td>
</tr>
<tr>
<td>\pset format aligned</td>
<td>\a</td>
</tr>
<tr>
<td>\pset format html</td>
<td>\H</td>
</tr>
<tr>
<td>\pset tableattr html-attribute [...]</td>
<td>\T html-attribute [...]</td>
</tr>
<tr>
<td>\pset title title-str</td>
<td>\C ['title-str']</td>
</tr>
</tbody>
</table>
### PSET command

<table>
<thead>
<tr>
<th>PSET command</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>\pset tuples_only</td>
<td>\t</td>
</tr>
</tbody>
</table>

### Examples

See [Output Formatting Examples](#).

### \set

Sets an internal variable to one or more values. If multiple values are specified, they are concatenated. An unqualified `\set` command lists all internal variables.

To unset a variable, use `vsql meta-command \unset`.

### Syntax

```
\set [var [value]...]
```

### Arguments

| **var** | The name of an internal variable to set. Valid variable names are case sensitive and can contain characters, digits, and underscores. `vsql` treats several variables as special, which are described in [Variables](#).
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>value</strong></td>
<td>A value to set in variable <code>var</code>. If no value is specified, the variable is set to no value. If set to an empty string, the variable is set to no value. If you omit this argument, <code>\set</code> returns all internal variables.</td>
</tr>
</tbody>
</table>

If no arguments are supplied, `\set` returns all internal variables. For example:

```
=> \set
  VERSION = 'vsql'
  AUTOCOMMIT = 'off'
  VERBOSITY = 'default'
  PROMPT1 = '%/%R%# '
  PROMPT2 = '%/%R%# '
  PROMPT3 = '>> '
  ROWS_AT_A_TIME = '1000'
  DBNAME = 'dbadmin'
```
\timing

If set to on, returns how long (in milliseconds) each SQL statement runs. Results include:

- Length of time required to fetch the first block of rows
- Total time until the last block is formatted.

Unqualified, \timing toggles timing on and off. You can explicitly turn timing on and off by qualifying the command with options ON and OFF, respectively.

**Note:** You can also enable \timing from the command line using the vsql -i command.

**Syntax**

\timing [ON | OFF]

**Examples**

The following unqualified \timing commands toggle timing on and off:

```bash
=> \timing
Timing is on
=> \timing
Timing is off
```

The following example shows a SQL command with timing on:

```bash
=> \timing
Timing is on.
=> SELECT user_name, ssl_state, authentication_method, client_authentication_name, client_type
    FROM sessions
    WHERE session_id=(SELECT session_id FROM current_session);
```

```
  user_name | ssl_state | authentication_method | client_authentication_name | client_type 
  --------- | --------- | -------------------- | -------------------------- | ------------- 
  dbadmin   | None      | ImpTrust             | default: Implicit Trust    | vsql          
```

time: First fetch (1 row): 73.684 ms. All rows formatted: 73.770 ms
Variables

vsql provides variable substitution features similar to common Linux command shells. Variables are name/value pairs, where the value can be a string of any length. To set variables, use the vsql meta-command \set. For example, the following statement sets the variable fact to the value dim:

```vsql
=> \set fact dim
```

If you call \set on a variable and supply no value, the variable is set to an empty string.

Note: The arguments of \set are subject to the same substitution rules as with other commands. For example, \set dim :fact is a valid way to copy a variable.

Getting Variables

To retrieve the content of a given variable, precede the name with a colon and use it as the argument of any slash command. For example:

```vsql
=> \echo :fact
dim
```

An unqualified \set command returns all current variables and their values:

```
dbadmin=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%#'
PROMPT2 = '%/%R%#'
PROMPT3 = '>>'
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```

Deleting Variables

To unset (or delete) a variable, use the vsql meta-command \unset.
Variable Naming Conventions

VSQL internal variable names can contain letters, numbers, and underscores in any order and any number. Some variables are treated specially by vsql. They indicate certain option settings that can be changed at runtime by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended. By convention, all specially treated variables consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

SQL Interpolation

You can substitute ("interpolate") vsql variables into regular SQL statements. You do so by prepending the variable name with a colon (:). For example, the following statements query the table my_table:

```sql
=> \set fact 'my_table'
=> SELECT * FROM :fact;
```

The value of the variable is copied literally, so it can even contain unbalanced quotes or backslash commands. Make sure that it makes sense where you put it. Variable interpolation is not performed into quoted SQL entities. One exception applies: the contents of backquoted strings (``) are passed to a system shell, and replaced with the shell's output. See Using Backquotes to Read System Variables below.

Using Backquotes to Read System Variables

In vsql, the contents of backquotes are passed to the system shell to be interpreted (the same behavior as many UNIX shells). This is particularly useful in setting internal vsql variables, since you may want to access UNIX system variables (such as HOME or TMPDIR) rather than hard-code values.

For example, to set an internal variable to the full path for a file in your UNIX user directory, you can use backquotes to get the content of the system HOME variable, which is the full path to your user directory:

```sql
=> \set inputfile `echo $HOME/myinput.txt` \echo :inputfile
/home/dbadmin/myinput.txt
```
The contents of the backquotes are replaced with the results of running the contents in a system shell interpreter. In this case, the echo $HOME command returns the contents of the HOME system variable.

**AUTOCOMMIT**

When AUTOCOMMIT is set 'on', each SQL command is automatically committed upon successful completion; for example:

```
\set AUTOCOMMIT on
```

To postpone COMMIT in this mode, set the value as off.

```
\set AUTOCOMMIT off
```

If AUTOCOMMIT is empty or defined as off, SQL commands are not committed unless you explicitly issue COMMIT.

**Notes**

- AUTOCOMMIT is off by default.
- AUTOCOMMIT must be in uppercase, but the values, on or off, are case insensitive.
- In autocommit-off mode, you must explicitly abandon any failed transaction by entering ABORT or ROLLBACK.
- If you exit the session without committing, your work is rolled back.
- Validation on vsql variables is done when they are run, not when they are set.
- The COPY statement, by default, commits on completion, so it does not matter which AUTOCOMMIT mode you use, unless you issue COPY NO COMMIT. Please note that DDL statements are autocommitted.
- To tell if AUTOCOMMIT is on or off, issue the set command:

```
$ \set...
AUTOCOMMIT = 'off'
...
```

- AUTOCOMMIT is off if a SELECT * FROM LOCKS shows locks from the statement you just ran.
$ \texttt{set AUTOCOMMIT off} \\
$ \texttt{set} \\
... \\
\texttt{AUTOCOMMIT = 'off'} \\
... \\
\texttt{SELECT COUNT(*) FROM customer_dimension;} \\
\texttt{count} \\
------ \\
50000 \\
(1 row) \\
\texttt{SELECT node_names, object_name, lock_mode, lock_scope} \\
FROM LOCKS; \\
\texttt{node_names | object_name | lock_mode | lock_scope} \\
----------------- | ------------------ | ---------- | ------------------ \\
site01 | Table:customer_dimension | S | TRANSACTION \\
(1 row) \\

**DBNAME**

The name of the database to which you are currently connected. DBNAME is set every time you connect to a database (including program startup), but it can be unset.

**ECHO**

If set to all, all lines entered from the keyboard or from a script are written to the standard output before they are parsed or run.

To select this behavior on program start-up, use the switch -a. If set to queries, vsql merely prints all queries as they are sent to the server. The switch for this is -e.

**ECHO_HIDDEN**

When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the Vertica internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch -E.)

If you set the variable to the value noexec, the queries are just shown but are not actually sent to the server and run.

**ENCODING**

The current client character set encoding.
HISTCONTROL

If this variable is set to ignore space, lines that begin with a space are not entered into the history list. If set to a value of ignoredups, lines matching the previous history line are not entered. A value of ignore both combines the two options. If unset, or if set to any other value than those previously mentioned, all lines read in interactive mode are saved on the history list.

Source: Bash.

HISTSIZE

The number of commands to store in the command history. The default value is 500.

Source: Bash.

HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program startup), but can be unset.

IGNOREEOF

If unset, sending an EOF character (usually Control+D) to an interactive session of vsql terminates the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

Source: Bash.

ON_ERROR_STOP

By default, if a script command results in an error, for example, because of a malformed command or invalid data format, processing continues. If you set ON_ERROR_STOP to ‘on’ in a script and an error occurs during processing, the script terminates immediately.
If you set ON_ERROR_STOP to ‘on’ in a script, run the script from Linux using `vsql -f <filename>`, and an error occurs, vsql returns an error code 3 to Linux to indicate that the error occurred in a script.

To enable ON_ERROR_STOP:

```
=> \set ON_ERROR_STOP on
```

To disable ON_ERROR_STOP:

```
=> \set ON_ERROR_STOP off
```

**PORT**

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

**PROMPT1 PROMPT2 PROMPT3**

These specify what the prompts vsql issues look like. See Promoting for details.

**QUIET**

This variable is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

**ROWS_AT_A_TIME**

ROWS_AT_A_TIME is set by default to 1000, and retrieves results as blocks of rows of that size. The column formatting for the first block is used for all blocks, so in later blocks some entries could overflow.

When formatting results, Vertica buffers ROWS_AT_A_TIME rows in memory to calculate the maximum column widths. It is possible that rows after this initial fetch are not properly aligned if any of the field values are longer than those see in the first ROWS_AT_A_TIME rows. ROWS_AT_A_TIME can be unset with `vsql meta-command\unset` to guarantee perfect alignment. However, this requires re-buffering the entire result set in memory and might cause vsql to fail if the result set is too big.
SINGLELINE
This variable is equivalent to the command line option -S.

SINGLESTEP
This variable is equivalent to the command line option -s.

USER
The database user you are currently connected as. This is set every time you connect to a database (including program startup), but can be unset.

VERBOSITY
This variable can be set to the values default, verbose, or terse to control the verbosity of error reports.

VSQL_HOME
By default, the vsql program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.

In the following example, vsql reads configuration information out of /tmp/jsmith rather than out of ~.

```bash
# Make an alternate configuration file in /tmp/jsmith
mkdir -p /tmp/jsmith
echo "\echo Using VSQLRC in tmp/jsmith" > /tmp/jsmith/.vsqrlrc
# Note that nothing is echoed when invoked normally
vsq
# Note that the .vsqrlrc is read and the following is
# displayed before the vsql prompt
#
# Using VSQLRC in tmp/jsmith
VSQL_HOME=/tmp/jsmith vsq
```
VSQL_SSLMODE

VSQL_SSLMODE specifies how (or whether) clients (like admintools) use SSL when connecting to servers. The default value is prefer, meaning to use SSL if the server offers it. Legal values are require, prefer, allow, and disable. This variable is equivalent to the command-line -m option (or --sslmode).

Prompting

The prompts vsql issues can be customized to your preference. The three variables PROMPT1, PROMPT2, and PROMPT3 contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when vsql requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run a SQL COPY command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

| %M       | The full host name (with domain name) of the database server, or [local] if the connection is over a socket, or [local:/dir/name], if the socket is not at the compiled in default location. |
| %m       | The host name of the database server, truncated at the first dot, or [local]. |
| %>       | The port number at which the database server is listening. |
| %n       | The database session user name. |
| %/       | The name of the current database. |
| %~       | Like %/, but the output is ~ (tilde) if the database is your default database. |
| %#       | If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.) |
| %R       | In prompt 1 normally =, but ^ if in single-line mode, and ! if the session is |
disconnected from the database (which can happen if \connect fails). In prompt 2 the sequence is replaced by -, *, a single quote, a double quote, or a dollar sign, depending on whether vsql expects more input because the command wasn't terminated yet, because you are inside a /* ... */ comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything.

| %x | Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection). |
| %digits | The character with the indicated numeric code is substituted. If digits starts with 0x the rest of the characters are interpreted as hexadecimal; otherwise if the first digit is 0 the digits are interpreted as octal; otherwise the digits are read as a decimal number. |
| %:name: | The value of the vsq! variable name. See the section Variables for details. |
| %'command' | The output of command, similar to ordinary "back- tick" substitution. |
| %[ ... %] | Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[ and %]. Multiple pairs of these may occur within the prompt. The following example results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals: |

```bash
testdb=> \set PROMPT1 '%[033[1;33;40m]n@%R%#%[%033[0m]%' 
```

To insert a percent sign into your prompt, write %%. The default prompts are '%/%R%# ' for prompts 1 and 2, and '>> ' for prompt 3.

**Note:** See the [specification for terminal control sequences](#) (applicable to gnome-terminal and xterm).

---

**Command Line Editing**

vsql supports the tecla library for convenient line editing and retrieval.
The command history is automatically saved when vsql exits and is reloaded when vsql starts up. Tab-completion is also supported, although the completion logic makes no claim to be a SQL parser. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named .teclarc in your home directory:

```
bind ^I
```

Read the tecla documentation for further details.

## Notes

The vsql implementation of the tecla library deviates from the tecla documentation as follows:

- **Recalling Previously Typed Lines**
  
  Under pure tecla, all new lines are appended to a list of historical input lines maintained within the GetLine resource object. In vsql, only different, non-empty lines are appended to the list of historical input lines.

- **History Files**

  tecla has no standard name for the history file. In vsql, the file name is called ~/.vsql_hist.

- **International Character Sets (Meta keys and locales)**

  In vsql, 8-bit meta characters are no longer supported. Make sure that meta characters send an escape by setting their EightBitInput X resource to False. You can do this in one of the following ways:

  - Edit the ~/.Xdefaults file by adding the following line:

    ```
    XTerm*EightBitInput: False
    ```

  - Start an xterm with an -xrm '*EightBitInput: False' command-line argument.

- **Key Bindings:**

  The following key bindings are specific to vsql:

  - *Insert* switches between insert mode (the default) and overwrite mode.
  - *Delete* deletes the character to the right of the cursor.
  - *Home* moves the cursor to the front of the line.
- *End* moves the cursor to the end of the line.
- ^R Performs a history backwards search.

**vsq1 Environment Variables**

Set one or more of the following environment variables to be used by the defined properties automatically, each time you start vsq1:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAGER</td>
<td>If the query results do not fit on the screen, they are piped through this command. Typical values are <code>more</code> or <code>less</code>. The default is platform-dependent. The use of the pager can be disabled by using the <code>\pset</code> command.</td>
</tr>
<tr>
<td>VSQL_DATABASE</td>
<td>The database to which you are connecting. For example, VMart.</td>
</tr>
<tr>
<td>TMPDIR</td>
<td>Directory for storing temporary files. The default is platform-dependent. On Unix-like systems the default is <code>/tmp</code>.</td>
</tr>
<tr>
<td>VSQL_EDITOR</td>
<td>Editor used by the <code>\e</code> command. The variables are examined in the order listed; the first that is set is used.</td>
</tr>
<tr>
<td>VSQL_HOST</td>
<td>Host name or IP address of the Vertica node.</td>
</tr>
<tr>
<td>VSQL_PASSWORD</td>
<td>The database password. Using this environment variable increases site security by precluding the need to enter the database password on the command line.</td>
</tr>
<tr>
<td>VSQL_PORT</td>
<td>Port to use for the connection.</td>
</tr>
<tr>
<td>VSQL_SSLMODE</td>
<td>Specifies whether and how clients such as admintools use SSL when connecting to servers.</td>
</tr>
<tr>
<td>VSQL_USER</td>
<td>User name to use for the connection.</td>
</tr>
</tbody>
</table>
**Locales**

The default terminal emulator under Linux is gnome-terminal, although xterm can also be used. Vertica recommends that you use gnome-terminal with vsq1 in UTF-8 mode, which is its default.

**To Change Settings on Linux**

1. From the tabs at the top of the vsq1 screen, select Terminal.
2. Click Set Character Encoding.
3. Select Unicode (UTF-8).

   Note: This works well for standard keyboards. xterm has a similar UTF-8 option.

**To Change Settings on Windows Using PuTTy**

1. Right click the vsq1 screen title bar and select Change Settings.
2. Click Window and click Translation.
3. Select UTF-8 in the drop-down menu on the right.

**Notes**

- vsq1 has no way of knowing how you have set your terminal emulator options.
- The tecla library is prepared to do POSIX-type translations from a local encoding to UTF-8 on interactive input, using the POSIX LANG, etc., environment variables. This could be useful to international users who have a non-UTF-8 keyboard. See the tecla documentation for details.
Vertica recommends the following (or whatever other .UTF-8 locale setting you find appropriate):

```
export LANG=en_US.UTF-8
```

- The `vsql` locale command invokes and tracks the server `SET LOCALE TO` command, described in the SQL Reference Manual. `vsql` itself currently does nothing with this locale setting, but rather treats its input (from files or from tecla), all its output, and all its interactions with the server as UTF-8. `vsql` ignores the POSIX locale variables, except for any "automatic" uses in printf, and so on.

## Entering Data with vsql

You often need to insert literal data when using vsql. For example:

- Adding a row of data to a table using an `INSERT` statement.
- Adding multiple rows of data through a `COPY FROM STDIN` statement.

The following table lists the data types that Vertica supports, and the format you use to enter that data in queries when using vsql.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Inserting to vsql using</th>
<th>Example Use in INSERT INTO table...</th>
<th>For More Information See...</th>
</tr>
</thead>
</table>
| Binary types, such as BINARY and VARBINARY | Helper functions such as HEX_TO_BINARY, octal strings, specified data format in COPY statements, casting string values to binary. | VALUES(HEX_TO_BINARY('0x3D'), '\\141\\337\'); | • Binary Data Types  
• Loading Binary (Native) Data |
<p>| BOOLEAN | Literal values TRUE and FALSE or strings such as 'y', 't', 'true', or | VALUES(TRUE, 'f'); | Boolean Data Type |</p>
<table>
<thead>
<tr>
<th>Character data types such as CHAR or LONG VARCHAR</th>
<th>Strings enclosed in single quotes.</th>
<th>VALUES('my string');</th>
<th>Character Data Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date and time data types, such as TIMESTAMPTZ</td>
<td>Formatted text string</td>
<td>VALUES('16:43:00', '2016-09-15 04:55:00 PDT');</td>
<td>Date/Time Data Types</td>
</tr>
<tr>
<td>Date/Time Data Types</td>
<td></td>
<td></td>
<td>Date/Time Expressions</td>
</tr>
<tr>
<td>Numeric Data Types</td>
<td>Literal numeric values, including scientific notation, hexadecimal, and BINARY scaling.</td>
<td>VALUES(3.1415, 42, 6.0221409e23);</td>
<td>Numeric Data Types</td>
</tr>
<tr>
<td>UUID</td>
<td>Formatted text string</td>
<td>VALUES('12345678-1234-1234-1234-123456789012');</td>
<td>UUID Data Type</td>
</tr>
</tbody>
</table>

### Files

Before starting up, vsql attempts to read and execute commands from the system-wide vsqlrc file and the user's ~/.vsqlrc file. The command-line history is stored in the file ~/.vsql_history.

**Tip:** If you want to save your old history file, open another terminal window and save a copy to a different file name.

### Exporting Data Using vsql

You can use vsql for simple data-export tasks by changing its output format options so the output is suitable for importing into other systems (tab-delimited or comma-separated files, for example). These options can be set either from within an interactive vsql session, or through command-line arguments to the vsql command (making the export process suitable for
automation through scripting). After you have set vsql's options so it outputs the data in a format your target system can read, you run a query and capture the result in a text file.

The following table lists the meta-commands and command-line options that are useful for changing the format of vsql's output.

<table>
<thead>
<tr>
<th>Description</th>
<th>Meta-command</th>
<th>Command-line Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable padding used to align output.</td>
<td>\a</td>
<td>-A or --no-align</td>
</tr>
<tr>
<td>Show only tuples, disabling column headings and row counts.</td>
<td>\t</td>
<td>-t or --tuples-only</td>
</tr>
<tr>
<td>Set the field separator character.</td>
<td>\pset fieldsep</td>
<td>-F or --field-separator</td>
</tr>
<tr>
<td>Send output to a file.</td>
<td>\o</td>
<td>-o or --output</td>
</tr>
<tr>
<td>Specify a SQL statement to execute.</td>
<td>N/A</td>
<td>-c or --command</td>
</tr>
</tbody>
</table>

The following example demonstrates disabling padding and column headers in the output, and setting a field separator to dump a table to a tab-separated text file within an interactive session.

```sql
=> SELECT * FROM my_table;
a | b | c  
---+---+----
a | one | 1
b | two | 2
c | three | 3
d | four | 4
e | five | 5
(5 rows)
=> \a
Output format is unaligned.
=> \t
Showing only tuples.
=> \pset fieldsep '\t'
Field separator is "	".
=> \o dumpfile.txt
=> select * from my_table;
=> \o
=> \! cat dumpfile.txt
a  one 1
b  two 2
c  three 3
d  four 4
e  five 5
```
**Note:** You could encounter issues with empty strings being converted to NULLs or the reverse using this technique. You can prevent any confusion by explicitly setting null values to output a unique string such as NULLNULLNULL (for example, `\pset null 'NULLNULLNULL'`). Then, on the import end, convert the unique string back to a null value. For example, if you are copying the file back into a Vertica database, you would give the argument NULL 'NULLNULLNULL' to the COPY statement.

When logged into one of the database nodes, you can create the same output file directly from the command line by passing the right parameters to vsql:

```
$ vsql -U username -F ['$\t' -At -o dumpfile.txt -c "SELECT * FROM my_table;"
Password:
$ cat dumpfile.txt
a  one  1
b  two  2
c  three 3
d  four 4
e  five 5
```

If you want to convert null values to a unique string as mentioned earlier, you can add the argument `-P null='NULLNULLNULL'` (or whatever unique string you choose).

By adding the `-w` vsql command-line option to the example command line, you could use the command within a batch script to automate the data export. However, the script would contain the database password as plain text. If you take this approach, you should prevent unauthorized access to the batch script, and also have the script use a database user account that has limited access.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as `\t` for tab), or a backslash (`\`) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (`\t`), vertical tab (`\v`) and the octal value of vertical tab (`\013`).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F '$\t' -At -c "SELECT * FROM testtable;"
A  1  2  3
B  4  5  6

$ vsql -F '$\v' -At -c "SELECT * FROM testtable;"
A  1
  2
  3
```
Copying Data Using vsql

You can use vsql to copy data between two Vertica databases. This technique is similar to the technique explained in Exporting Data Using vsql, except instead of having vsql save data to a file for export, you pipe one vsql's output to the input of another vsql command that runs a COPY statement from STDIN. This technique can also work for other databases or applications that accept data from an input stream.

Note: The following technique only works for individual tables. To copy an entire database to another cluster, see Copying the Database to Another Cluster in the Administrator's Guide.

The easiest way to copy using vsql is to log in to a node of the target database, then issue a vsql command that connects to the source Vertica database to dump the data you want. For example, the following command copies the store.store_sales_fact table from the vmart database on node testdb01 to the vmart database on the node you are logged into:

```
$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
```

Note: The above example copies the data only, not the table design. The target table for the data copy must already exist in the target database. You can export the design of the table using EXPORT_OBJECTS or EXPORT_CATALOG.

If you are using the Bash shell, you can escape special delimiter characters. For example, `DELIMITER E'\t'` specifies tab. Shells other than Bash may have other string-literal syntax.
Monitoring Progress (optional)

You may want some way of monitoring progress when copying large amounts of data between Vertica databases. One way of monitoring the progress of the copy operation is to use a utility such as Pipe Viewer that pipes its input directly to its output while displaying the amount and speed of data it passes along. Pipe Viewer can even display a progress bar if you give it the total number of bytes or lines you expect to be processed. You can get the number of lines to be processed by running a separate vsq1 command that executes a SELECT COUNT query.

Note: Pipe Viewer isn't a standard Linux command, so you will need to download and install it yourself. See the Pipe Viewer page for download packages and instructions. Vertica does not support Pipe Viewer. Install and use it at your own risk.

The following command demonstrates how you can use Pipe Viewer to monitor the progress of the copy shown in the prior example. The command is complicated by the need to get the number of rows that will be copied, which is done using a separate vsq1 command within a Bash backquote string, which executes the string's contents and inserts the output of the command into the command line. This vsq1 command just counts the number of rows in the store.store_sales_fact table.

```
vsq1 -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact" \ 
| pv -lpetr -s `vsq1 -U username -w passwd -h testdb01 -d vmart -At -c "SELECT COUNT (*) FROM store.store_sales_fact;"` \ 
| vsq1 -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

While running, the above command displays a progress bar that looks like this:

```
0:00:39 [12.6M/s] [=================================>] 50% ETA 00:00:40
```

Output Formatting Examples

By default, Vertica formats query output as follows:

```
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
category_description
------------------------
Food
Medical
Misc
Non-food
(4 rows)
```
You can control the format of query output in various ways with the \pset command—for example, change the border:

```sql
=> \pset border 2
Border style is 2.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
+-----------------------------+
| category_description        |
+-----------------------------+
| Food                        |
| Medical                     |
| Misc                        |
| Non-food                    |
+-----------------------------+
(4 rows)
=> \pset border 0
Border style is 0.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
-----------------------------
| category_description        |
-----------------------------
Food
Medical
Misc
Non-food
(4 rows)
```

The following sequence of `pset` commands change query output in several ways:

- Set border style to 1.
- Remove column alignment.
- Change the field separator to a comma.
- Remove column headings

```sql
=> \pset border 1
Border style is 1.
=> \pset format unaligned
Output format is unaligned.
=> \pset fieldsep ','
Field separator is ",".
=> \pset tuples_only
Showing only tuples.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
1,Brand #2 bagels,Food
1,Brand #1 butter,Food
2,Brand #6 chicken noodle soup,Food
3,Brand #11 vanilla ice cream,Food
4,Brand #14 chocolate chip cookies,Food
4,Brand #12 rash ointment,Medical
6,Brand #18 bananas,Food
7,Brand #25 basketball,Misc
8,Brand #27 french bread,Food
9,Brand #32 clams,Food
```
The following example uses meta-commands to toggle output format—in this case, \a (alignment), \t (tuples only), and -x (extended display):

```plaintext
=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is off.

=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;

<table>
<thead>
<tr>
<th>product_key</th>
<th>product_description</th>
<th>category_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Brand #2 bagels</td>
<td>Food</td>
</tr>
<tr>
<td>1</td>
<td>Brand #1 butter</td>
<td>Food</td>
</tr>
<tr>
<td>2</td>
<td>Brand #6 chicken noodle soup</td>
<td>Food</td>
</tr>
<tr>
<td>3</td>
<td>Brand #11 vanilla ice cream</td>
<td>Food</td>
</tr>
<tr>
<td>4</td>
<td>Brand #14 chocolate chip cookies</td>
<td>Food</td>
</tr>
<tr>
<td>4</td>
<td>Brand #12 rash ointment</td>
<td>Medical</td>
</tr>
<tr>
<td>6</td>
<td>Brand #18 bananas</td>
<td>Food</td>
</tr>
<tr>
<td>7</td>
<td>Brand #25 basketball</td>
<td>Misc</td>
</tr>
<tr>
<td>8</td>
<td>Brand #27 french bread</td>
<td>Food</td>
</tr>
<tr>
<td>9</td>
<td>Brand #32 clams</td>
<td>Food</td>
</tr>
</tbody>
</table>

(10 rows)
```

The following example sets output format to HTML, so Vertica renders query results in HTML markup as a table:

```plaintext
=> \pset format html
Output format is html.
=> \pset tableattr 'border="2" cellpadding="3"
Table attribute is "border="2" cellpadding="3"."

=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 2;

```html
<table border="1" border="2" cellpadding="3">
<tr align="center">
<th>product_key</th>
<th>product_description</th>
<th>category_description</th>
</tr>
<tr align="top">
<td align="right">1</td>
<td align="left">Brand #2 bagels</td>
<td align="left">Food</td>
</tr>
<tr align="top">
<td align="right">1</td>
<td align="left">Brand #1 butter</td>
<td align="left">Food</td>
</tr>
</table>
<p>(2 rows)</p>
```
**Client Libraries**

The Vertica client driver libraries provide interfaces for connecting your client applications (or third-party applications such as Cognos and MicroStrategy) to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- Open Database Connectivity (ODBC)—the most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.

- Java Database Connectivity (JDBC)—used by clients written in the Java programming language.

- ActiveX Data Objects for .NET (ADO.NET)—used by clients developed using Microsoft's .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

**Client Driver Standards**

The Vertica client drivers are compatible with the following driver standards:

- The ODBC driver complies with version 3.5.1 of the ODBC standard.

- Vertica's JDBC driver is a type 4 driver that complies with the JDBC 3.0 standard. It is compiled using JDK version 1.5, and is compatible with client applications compiled using JDK versions 1.5 and 1.6.

- ADO.NET drivers conform to .NET framework 3.0 specifications.

The drivers do not support some of the optional features in the standards. See [ODBC Feature Support](#) and [JDBC Feature Support](#) and [Using ADO.NET](#) for details.
Client Driver and Server Version Compatibility

Usually, each version of the Vertica server is compatible with previous versions of the client drivers. This compatibility lets you upgrade your Vertica server without having to immediately upgrade your client software. However, some new features of the new server version may not be available through the old drivers.

Note: Vertica ODBC client drivers are backwards compatible to all Vertica server versions 7.1 and later. JDBC and ADO.NET client drivers are backwards compatible to all Vertica server versions 7.2 and later.

The following tables summarize the compatibility of each recent version of the client drivers with the Vertica server versions.

The following table indicates that, in general, all clients are forward compatible.

<table>
<thead>
<tr>
<th>Client</th>
<th>Client Driver Version</th>
<th>Compatible Server Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Clients</td>
<td>6.1.x</td>
<td>6.1.x, 7.0.x, 7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x</td>
</tr>
<tr>
<td></td>
<td>7.0.x</td>
<td>7.0.x, 7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x</td>
</tr>
<tr>
<td></td>
<td>7.1.x</td>
<td>7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x</td>
</tr>
<tr>
<td></td>
<td>7.2.x</td>
<td>7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x</td>
</tr>
<tr>
<td></td>
<td>8.0.x</td>
<td>8.0.x, 8.1.x, 9.0.x, 9.1.x</td>
</tr>
<tr>
<td></td>
<td>8.1.x</td>
<td>8.1.x, 9.0.x, 9.1.x</td>
</tr>
<tr>
<td></td>
<td>9.0.x</td>
<td>9.0.x, 9.1.x</td>
</tr>
<tr>
<td></td>
<td>9.1.x</td>
<td>9.1.x</td>
</tr>
</tbody>
</table>

The following table lists FIPS 140-2 compatible clients.

<table>
<thead>
<tr>
<th>Client</th>
<th>Client Driver Version</th>
<th>Compatible Server Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIPS-enabled ODBC</td>
<td>8.0.x</td>
<td>8.0.x, 8.1.x</td>
</tr>
<tr>
<td>FIPS-enabled ODBC</td>
<td>8.1.x</td>
<td>8.0.x, 8.1.x</td>
</tr>
</tbody>
</table>
The following table indicates that the ODBC client is backward compatible.

<table>
<thead>
<tr>
<th>Client</th>
<th>Client Driver Version</th>
<th>Compatible Server Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIPS-enabled ODBC</td>
<td>9.0.x</td>
<td>8.0.x, 8.1.x, 9.0.x</td>
</tr>
<tr>
<td>FIPS-enabled ODBC</td>
<td>9.1.x</td>
<td>8.0.x, 8.1.x, 9.0.x, 9.1.x</td>
</tr>
<tr>
<td>FIPS-enabled JDBC</td>
<td>8.1.x</td>
<td>8.1.x</td>

<tr>
<td>FIPS-enabled JDBC</td>
<td>9.1.x</td>
<td>8.1.x, 9.0.x, 9.1.x</td>
</tr>
</tbody>
</table>

The following table indicates that the JDBC and ADO.NET clients are backward compatible.

<table>
<thead>
<tr>
<th>Client</th>
<th>Client Driver Version</th>
<th>Compatible Server Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDBC and ADO.NET (backwards compatibility)</td>
<td>9.1.1</td>
<td>7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x</td>
</tr>
</tbody>
</table>

**Vertica ODBC/JDBC Client Installers**

The ODBC/JDBC client drivers are a separate installation from the ADO.NET drivers. (ADO.NET support is not available in Community Edition.) As noted in the compatibility table, the 6.x ODBC/JDBC client drivers do not support access to a non Vertica 6.x database and above. For example, you cannot use the new 6.x ODBC/JDBC client drivers to access a Vertica 5.x database. If you plan on having a mixed Vertica environment supporting both 5.x and 6.x Vertica database, consider keeping the 5.x drivers installed.
ODBC/JDBC Multiple Version Installations

The following ODBC/JDBC drivers are supported on a single machine:

- 4.x and 5.x ODBC/JDBC drivers can be installed on the same machine.
- 4.x and 6.x ODBC/JDBC drivers can be installed on the same machine.

It is not possible to have both 5.x and 6.x ODBC drivers on a single machine. If you install the 6.x version, it automatically overlays the existing 5.x installation, and any DSN defined against a 5.x Vertica database is not supported.

Vertica ADO.NET Client Installers

Prior to version 6.x, ADO.Net drivers must be uninstalled prior to installing a later version of the driver. The 6.x ADO.Net drivers require the Vertica database to be 6.0.0 or above. The ADO.NET 6.x driver only supports access to a Vertica 6.x server. The ADO.NET 4.x plug-in does not work with a Vertica 6.x server. If you plan on also using the ODBC bridge and you need to access both Vertica 5.x and 6.x databases, consider keeping the 5.x versions of the ODBC/JDBC drivers for the reasons stated previously.
Client Drivers

You must install the Vertica client drivers to access Vertica from your client application. The drivers create and maintain connections to the database and provide APIs that your applications use to access your data. The client drivers support connections using JDBC, ODBC, and ADO.NET.

Client Driver Standards

The client drivers support the following standards:

- ODBC drivers conform to ODBC 3.5.1 specifications.
- JDBC drivers conform to JDK 5 specifications.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

Installing the Client Drivers

How you install client drivers depends on the client's operating system:

- For Linux and UNIX clients, you must first install a Linux driver manager. After you have installed the driver manager, there are two different ways to install the client drivers:
  - On Red Hat Enterprise Linux 5, 64-bit and SUSE Linux Enterprise Server 10/11 64-bit, you can use the Vertica client RPM package to install the ODBC and JDBC drivers as well as the vsql client.
  - On other Linux platforms and UNIX-like platforms you can download the ODBC and JDBC drivers and install them individually.

Note: The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica Analytics Platform on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux, AIX, and HP-UX). To use JDBC, you need to add the JDBC client
driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)

- On Mac OS X clients, download the ODBC client driver .pkg file. The driver is compatible with both 32-bit and 64-bit applications.

- On Windows clients, download the 32-bit or 64-bit client installer. The installer provides the ODBC client driver, the ADO.NET client driver, the OLE DB client driver, the vsql client, the Microsoft Connectivity Pack, and the Visual Studio plug-in.

- There is a cross-platform JDBC client driver .jar file available for installation on all platforms.

The remainder of this section explain the requirements for the Vertica client drivers, and the procedure for downloading, installing, and configuring them.

Driver Prerequisites

The following topics describe the system requirements for the client drivers. You need to ensure that your client system meets these requirements before installing and using the client drivers.

ODBC Prerequisites

There are several requirements your client systems must meet before you can install the Vertica ODBC drivers.

Operating System

The Vertica ODBC driver requires a supported platform. The list of currently-supported platforms can be found at Vertica 9.1.x Client Drivers.

ODBC Driver Manager

The Vertica ODBC driver requires that the client system have a supported driver manager. See Installing Driver Managers on Linux and Other UNIX-like Platforms for details.
UTF-8, UTF-16 and UTF-32 Support

The Vertica ODBC driver is a universal driver that supports UTF-8, UTF-16, and UTF-32 encoding. The default setting depends on the client platform. For details, see Required ODBC Driver Configuration Settings for Linux and UNIX.

When using the driver with the DataDirect Connect driver manager, DataDirect Connect adapts to the ODBC driver's text encoding settings. You should configure the ODBC driver to use the encoding method that your application requires. This allows strings to be passed between the driver and the application without intermediate conversion.

- Programming ODBC Client Applications
- Creating an ODBC Data Source Name (DSN)

ADO.NET Prerequisites

The Vertica driver for ADO.NET requires the following software and hardware components:

Operating System

The Vertica ADO.NET driver requires a supported Windows operating system. The list of supported platforms can be found in the Supported Platforms document at http://vertica.com/docs.

Memory

Vertica suggests a minimum of 512MB of RAM.

.NET Framework

The requirements for the .NET framework for ADO.NET in Vertica can be found in the Supported Platforms document at http://vertica.com/docs.

- Programming ADO.NET Applications

Python Prerequisites

Python is a free, agile, object-oriented, cross-platform programming language designed to emphasize rapid development and code readability. Python has been released under several different open source licenses.

Vertica's ODBC driver is tested with multiple versions of Python. See Perl and Python Requirements for details.

Python Driver

Vertica requires the Vertica Python Client or the pyodbc driver module. See your system's Python documentation for installation and configuration information.

Supported Operating Systems

The Vertica ODBC driver requires one of the operating systems listed in ODBC Prerequisites. For usage and examples, see Programming Python Client Applications.

Perl Prerequisites

Perl is a free, stable, open source, cross-platform programming language licensed under its Artistic License, or the GNU General Public License (GPL).

Your Perl scripts access Vertica through its ODBC driver, using the Perl Database Interface (DBI) module with the ODBC Database Driver (DBD::ODBC). The Vertica ODBC driver is known to be compatible with these versions of Perl:

- 5.8
- 5.10

Later Perl versions may also work.
Perl Drivers

The following Perl driver modules have been tested with the Vertica ODBC driver:

- The DBI driver module, version 1.609
- The DBD::ODBC driver module, version 1.22

Other versions may also work.

Supported Client Systems

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC Prerequisites.

PHP Prerequisites

PHP is a widely-used general-purpose scripting language that is especially suited for Web development and can be embedded into HTML. PHP is licensed under the PHP License, an open-source BSD-style license certified by the Open Source Initiative.

PHP Modules

The following PHP modules are required:

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbdc (if you are using the iODBC driver)

Supported Client Systems

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC Prerequisites.
Upgrading the Client Drivers

The Vertica client drivers are usually updated for each new release of the Vertica server. The client driver installation packages include the version number of the corresponding Vertica server release. Usually, the drivers are forward-compatible with the next release, so your client applications are still be able to connect using the older drivers after you upgrade to the next version of Vertica Analytics Platform server. See Client Driver and Server Version Compatibility for details on which client driver versions work with each version of Vertica server.

Note: Vertica ODBC client drivers are backwards compatible to all Vertica server versions 7.1 and later. JDBC and ADO.NET client drivers are backwards compatible to all Vertica server versions 7.2 and later.

You should upgrade your clients as soon as possible after upgrading your server, to take advantage of new features and to maintain maximum compatibility with the server.

To upgrade your drivers, follow the same procedure you used to install them in the first place. The new installation will overwrite the old. See the specific instructions for installing the drivers on your client platform for any special instructions regarding upgrades.

Note: Installing new ODBC drivers does not alter existing DSN settings. You may need to change the driver settings in either the DSN or in the odbcinst.ini file, if your client system uses one. See Creating an ODBC Data Source Name for details.

Setting a Client Connection Label

You can set a client connection label when you connect to a Vertica database. You can also set or return the client connection label using the SET_CLIENT_LABEL and GET_CLIENT_LABEL functions.

Set the client connection label:

```sql
=> SELECT SET_CLIENT_LABEL('py_data_load_application');
SET_CLIENT_LABEL
-----------------------------------------------
client_label set to py_data_load_application
(1 row)
```

Return the current client connection label:

```sql
=> SELECT GET_CLIENT_LABEL();
GET_CLIENT_LABEL
```
The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions `GET_CLIENT_LABEL` and `SET_CLIENT_LABEL`.

When you use these two methods, make sure you pass the string value `APPLICATIONNAME` to both the setter and getter methods.

Use `setClientInfo()` to create a client label, and use `getClientInfo()` to return the client label:

```java
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        myProp.put("loginTimeout", "35");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://docc05.verticacorp.com:5433/doccdb", myProp);
            System.out.println("Connected!");
            conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
            System.out.println("New Conn label: " + conn.getClientInfo("APPLICATIONNAME"));
            conn.close();
        } catch (SQLTransientConnectionException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.println("Network connection issue: ");
            System.out.println(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.println("Could not log into database: ");
            System.out.println(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When you run this method, it prints the following result to the standard output:
Additional Parameter Settings

The following parameters can be set for the Vertica client drivers.

Logging Settings

These parameters control how messages between the client and server are logged. None of these settings are required. If they are not set, then the client library does not log any messages. They apply to both ADO.NET and ODBC.

- LogLevel—The severity of messages that are logged between the client and the server. The valid values are:
  - 0—No logging
  - 1—Fatal errors
  - 2—Errors
  - 3—Warnings
  - 4—Info
  - 5—Debug
  - 6—Trace (all messages)

The value you specify for this setting sets the minimum severity for a message to be logged. For example, setting LogLevel to 3 means that the client driver logs all warnings, errors, and fatal errors.

Note: On a Windows client, you have the option of directing ODBC or OLE DB log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. See Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs. for ODBC, or Register the OLE DB Driver as a Windows Event Log Provider, and Enable the Logs for OLE DB.
• **LogPath**—The absolute path of a directory to store log files. For example: `/var/log/verticaodbc`  

• **LogNamespace**—Limits logging to messages generated by certain objects in the client driver.

**Note:** These settings are also available for the Vertica JDBC driver through connection properties. See [Connection Properties](#) for details.

### ODBC-specific Settings

The following settings are used only by the Vertica ODBC client driver.

- **DriverManagerEncoding**—The UTF encoding standard that the driver manager uses. This setting needs to match the encoding the driver manager expects. The available values for this setting are:
  - UTF-8
  - UTF-16 (usually used by unixODBC)
  - UTF-32 (usually used by iODBC)

See the documentation for your driver manager to find the correct value for this setting.

**Note:** While both UTF-16 and UTF-8 are valid settings for DataDirect, Vertica recommends that you set the DataDirect driver manager encoding to UTF-16.

If you do not set this parameter, the ODBC driver defaults to the value shown in the following table. If your driver manager uses a different encoding, you must set this value for the ODBC driver to be able to work.

<table>
<thead>
<tr>
<th>Client Platform</th>
<th>Default Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIX 64-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>HP-UX 64-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Linux 32-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Linux 64-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Client Platform</td>
<td>Default Encoding</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>Linux Itanium 64-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>OS X</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Windows 32-bit</td>
<td>UTF-16</td>
</tr>
<tr>
<td>Windows 64-bit</td>
<td>UTF-16</td>
</tr>
</tbody>
</table>

- **ErrorMessagePath**—The absolute path to the parent directory that contains the Vertica client driver's localized error message files. These files are usually stored in the same directory as the Vertica ODBC driver files.

  Note: This setting is required. If you do not set it, then any error the ODBC driver encounters will result in an error message about a missing ODBCMessages.xml file.

- **ODBCInstLib**—The absolute path to the file containing the ODBC installer library (ODBCInst). This setting is required if the directory containing this library is not set in the LD_LIBRARY_PATH or LIB_PATH environment variables. The library files for the major driver manager are:

  - UnixODBC: libodbcinst.so
  - iODBC: libiodbcinst.so (libiodbcinst.2.dylib on OS X)
  - DataDirect: libodbcinst.so

  Note: On AIX platforms, you need give the path to the library archive, followed by the name of the library enclosed in parenthesis. For example: ODBCInstLib=/usr/lib64/libodbcinst.a(libodbcinst.so.1)

**ADO.NET-specific Settings**

This setting applies only to the ADO.NET client driver:

**C#PreloadLogging**—Tells the Vertica ADO.NET driver to begin logging as soon as possible, before the driver has fully loaded itself. Normally, logging only starts after the driver has fully loaded. Valid values for this setting are:

- 0—Do not start logging before the driver has loaded.
- 1—Start logging as soon as possible.
Using Legacy Drivers

The Vertica server supports connections from previous versions of the client drivers. For detailed information the compatibility between versions of the Vertica server and Vertica client, see Client Driver and Server Version Compatibility.

Modifying the Java CLASSPATH

The CLASSPATH environment variable contains the list of directories where the Java run time looks for library class files. For your Java client code to access Vertica, you need to add the directory where the Vertica JDBC .jar file is located.

Note: In your CLASSPATH, use the symbolic link vertica-jdbc-x.x.x.jar (where x.x.x is a version number) that points to the JDBC library .jar file, rather than the .jar file itself. Using the symbolic link ensures that any updates to the JDBC library .jar file (which will use a different filename) will not invalidate your CLASSPATH setting, since the symbolic link's filename will remain the same. You just need to update the symbolic link to point at the new .jar file.

Linux, AIX, HP-UX, and OS X

If you are using the Bash shell, use the export command to define the CLASSPATH variable:

```
# export CLASSPATH=/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If environment variable CLASSPATH is already defined, use the following command to prevent it from being overwritten:

```
# export CLASSPATH=$CLASSPATH:/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If you are using a shell other than Bash, consult its documentation to learn how to set environment variables.

You need to either set the CLASSPATH environment variable for every login session, or insert the command to set the variable into one of your startup scripts (such as ~/.profile or /etc/profile).
Windows

Provide the class paths to the .jar, .zip, or .class files.

C:> SET CLASSPATH=classpath1;classpath2...

For example:

C:> SET CLASSPATH=C:\java\MyClasses\vertica-jdbc-x.x.x.jar

As with the Linux/UNIX settings, this setting only lasts for the current session. To set the CLASSPATH permanently, set an environment variable:

1. On the Windows Control Panel, click System.

2. Click Advanced or Advanced Systems Settings.

3. Click Environment Variables.

5. In the Variable name box, type CLASSPATH.

6. In the Variable value box, type the path to the Vertica JDBC .jar file on your system (for example, C:\Program Files (x86)\Vertica\JDBC\vertica-jdbc-x.x.x.jar)

Specifying the Library Directory in the Java Command

There is an alternative way to tell the Java run time where to find the Vertica JDBC driver other than changing the CLASSPATH environment variable: explicitly add the directory containing the .jar file to the java command line using either the -cp or -classpath argument. For example, on Linux, start your client application using:

# java -classpath /opt/vertica/java/lib/vertica-jdbc-x.x.x.jar myapplication.class

Your Java IDE may also let you add directories to your CLASSPATH, or let you import the Vertica JDBC driver into your project. See your IDE documentation for details.
Installing the Client Drivers on Linux and UNIX-Like Platforms

This topic explains how to install the client drivers on Linux and UNIX-like platforms.

Installing Driver Managers on Linux and Other UNIX-like Platforms

If your client platform does not already have an ODBC driver manager, you need to install one before you can use the Vertica ODBC client driver. The driver manager provides an interface between your client operating system and the ODBC drivers. See Vertica 9.1.x Client Drivers for a list of driver managers that are supported on each of the client platforms.

Driver managers can be downloaded from your operating system specific repository and from the links below.

Vertica does not provide instructions for installing and configuring these third-party binaries. For download and configuration information, see the respective driver manager websites for installation and configuration information:

- UnixODBC: http://www.unixodbc.org/
- iODBC: http://www.iodbc.org

Installing the Client RPM on Red Hat and SUSE

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client driver RPM that installs both the ODBC and JDBC driver libraries and the vsql client.

Important: Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and vsql.

To install the client driver RPM package:

1. Open a Web browser and log in to the myVertica portal.
2. Click Downloads, and choose Client Drivers.
3. Download the client RPM file that matches your client platform's architecture.

   Note: The 64-bit client driver RPM installs both the 64-bit and 32-bit ODBC driver libraries on non-FIPS compliant systems.

4. If you did not directly download the RPM on the client system, transfer the file to the client.

5. Log in to the client system as root.

6. Install the RPM package you downloaded:

   # rpm -Uvh package_name.rpm

   Note: You receive one or more conflict error messages if there are existing Vertica client driver files on your system. This can happen if you are trying to install the client driver package on a system that has the server package installed, since the server package also includes the client drivers. In this case, you don't need to install the client drivers, and can instead use the drivers installed by the server package. If the conflict arises from an old driver installation or from a server installation for an older version, you can use the rpm command's --force switch to force it to overwrite the existing files with the files in the client driver package.

   Once you have installed the client package, you need to create a DSN (see Creating an ODBC DSN for Linux, AIX, and HP-UX) and set some additional configuration parameters (see Required ODBC Driver Configuration Settings for Linux and UNIX) to use ODBC. To use JDBC, you need to modify your class path (see Modifying the Java CLASSPATH) before you can use JDBC.

   You may also want to add the vsq1 client to your PATH environment variable so that you do not need to enter its full path to run it. You add it to your path by adding the following to the .profile file in your home directory or the global /etc/profile file:

   export PATH=$PATH:/opt/vertica/bin

### Installing JDBC Driver on Linux, AIX, and HP-UX

   Note: The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica Analytics Platform on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux, AIX, and HP-UX).
**DSN for Linux, AIX, and HP-UX.** To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see **Modifying the Java CLASSPATH**). (The JDBC client driver is not available on FIPS-compliant systems.)

**Note:** For additional details about supported platforms, see **Supported Platforms**.

The JDBC driver is available for download from myVertica portal. There is a single .jar file that works on all platforms and architectures. To download and install the file:

1. Open a Web browser and log in to myVertica portal.

2. Click the Download tab and locate and download the JDBC driver.

3. You need to copy the .jar file you downloaded to a directory in your Java CLASSPATH on every client system with which you want to access Vertica. You can either:

   - Copy the .jar file to its own directory (such as /opt/vertica/java/lib) and then add that directory to your CLASSPATH (recommended). See **Modifying the Java CLASSPATH** for details.

   - Copy the .jar file to directory that is already in your CLASSPATH (for example, a directory where you have placed other .jar files on which your application depends).

**Note:** In the directory where you copied the .jar file, you should create a symbolic link named `vertica_jdk_5.jar` to the .jar file. You can reference this symbolic link anywhere you need to use the name of the JDBC library without having to worry any future upgrade invalidating the file name. This symbolic link is automatically created on server installs. On clients, you need to create and manually maintain this symbolic link yourself if you installed the driver manually. The **Installing the Client RPM on Red Hat and SUSE** create this link when they install the JDBC library.

---

**Installing ODBC Drivers on Linux, AIX, and HP-UX**

**Note:** For additional details about supported platforms, see **Supported Platforms**.

Read **Driver Prerequisites** before you proceed.

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client RPM that installs both the ODBC and JDBC driver and the vsol client. See **Installing the Client RPM on Red Hat and SUSE**.
**Note:** The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica Analytics Platform on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see [Creating an ODBC DSN for Linux, AIX, and HP-UX](#)). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see [Modifying the Java CLASSPATH](#)). (The JDBC client driver is not available on FIPS-compliant systems.)

The ODBC driver installation packages are broken down by client platform on the [myVertica portal](#). The package's filename is named based on its operating system and architecture (for example, `vertica_9.1.xx_odbc_x86_64_linux.tar.gz`)

**Important:** Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsq1 and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, [Installing the FIPS Client Driver for ODBC and vsq1](#).

**Installation Procedure**

1. Open a Web browser and log in to myVertica portal.

2. Click the Download tab and locate and download the driver package that corresponds to your client system.

3. If you did not directly download to the client system, transfer the downloaded file to it.

4. Log in to the client system as root.

5. If the directory `/opt/vertica/` does not exist, create it:

   ```bash
   # mkdir -p /opt/vertica/
   ```

6. Copy the downloaded file to the `/opt/vertica/` directory. For example:

   ```bash
   # cp vertica_9.1.xx_odbc_x86_64_linux.tar.gz /opt/vertica/
   ```

7. Change to the `/opt/vertica/` directory:

   ```bash
   # cd /opt/vertica/
   ```

8. Uncompress the file you downloaded. For example:
$ tar vxzf vertica_9.1.xx_odbc_x86_64_linux.tar.gz

Two folders are created: one for the include file, and one for the library files. The path of the library file depends on the processor architecture: lib for 32-bit libraries, and lib64 for 64-bit libraries. So, a 64-bit driver client download creates the directories:

- /opt/vertica/include, which contains the header file
- /opt/vertica/lib64, which contains the library file

Post Driver Installation Configuration

You must configure the ODBC driver before you can use it. There are two required configuration files:

- The odbc.ini configuration file defines the Data Source Names (DSNs) that tell the ODBC how to access your Vertica databases. See Creating an ODBC Data Source Name for instructions to create this file.

- The vertica.ini configuration file defines some Vertica-specific settings required by the drivers. See Required ODBC Driver Configuration Settings for Linux and UNIX for instructions to create this file.

Note: If you are upgrading your ODBC driver, you must either update your DSNs to point to the newly-installed driver or create new DSNs. If your odbc.ini file references drivers defined in an odbcinst.ini file, you just need to update the odbcinst.ini file. See Creating an ODBC Data Source Name (DSN) for details.

Required ODBC Driver Configuration Settings for Linux and UNIX

In addition to DSN settings, Vertica provides additional ODBC client driver configuration parameters. These settings control the following:

- The text encoding used by the driver manager (for example, UTF-8 or UTF-16).

- The location of the directory containing the Vertica ODBC driver's error message files.

- Whether and how the ODBC driver logs messages.

On Linux and UNIX platforms, you must provide these additional settings manually so that the ODBC driver can function properly. To do so, edit the vertica.ini file to supply the necessary
additional configuration settings. You specify where the ODBC driver can find the vertica.ini file using an environment variable named VERTICAINI. See Required Settings.

Setting ODBC Driver Settings on Linux and UNIX-Like Platforms

Driver settings specific to Vertica are stored in a text file named vertica.ini (although you may choose a different file name). On Linux and UNIX platforms, you must edit the vertica.ini file to supply additional configuration settings before the ODBC driver can function properly. You tell the Vertica ODBC driver where to find the vertica.ini file using an environment variable named VERTICAINI.
Required Settings

On Linux and UNIX platforms, you must configure two settings in order for the ODBC driver to work correctly:

- `ErrorMessagesPath`
- `ODBCInstLib` (unless the driver manager's installation library is in a directory listed in the `LD_LIBRARY_PATH` or `LIB_PATH` environment variables).

If your driver manager does not use UTF-8 encoding, you need to set `DriverManagerEncoding` to the proper encoding.
Create a vertica.ini File

There is no standard location for the vertica.ini file—you can store the file anywhere that it is convenient for you on your client system. One possible location is in the /etc directory if you have multiple users on your client system that need to access it. You can also have a vertica.ini file in each user's home directory so users can alter their own settings. Wherever you store it, be sure users have read access to the file.

The format of the vertica.ini file is similar to the odbc.ini file, with a section followed by parameter definitions. Unlike the odbc.ini file, vertica.ini contains a single section named Driver:

```
[Driver]
```

Following the section definition, you add setting definitions, one per line. A setting definition consists of the setting name, followed by an equal sign (=), followed by the value. The value does not need quotes. For example, to set the ODBCInstLib setting, you add a line like this:

ODBCInstLib=/usr/lib64/libodbcinst.so

See Additional Parameter Settings for a list of the additional settings.
Set the VERTICAINI Environment Variable

You must set an environment variable named VERTICAINI to the absolute path of the vertica.ini file. The Vertica ODBC driver uses this variable to find the settings.

Where you set this variable depends on whether users on your client system need to have separate vertica.ini files. If you want to have a single, system-wide vertica.ini file, you can add a command to set VERTICAINI in /etc/profile or some other system-wide environment file. For example:

```bash
export VERTICAINI=/etc/vertica.ini
```

If users need individual vertica.ini files, set VERTICAINI in their ~/.profile or similar configuration file. For example:

```bash
export VERTICAINI=~/.vertica.ini
```
Example vertica.ini File

The following example vertica.ini file configures the ODBC driver to:

- use the 64-bit UNIXODBC driver manager.
- get its error messages from the standard Vertica 64-bit ODBC driver installation directory.
- log all warnings and more severe messages to log files stored in the temporary directory.

```
[Driver]
DriverManagerEncoding=UTF-16
ODBCInstLib=/usr/lib64/libodbcinst.so
ErrorMessagePath=/opt/vertica
LogLevel=4
LogPath=/tmp
```

Installing the FIPS Client Drivers

This topic details how to install the FIPS client drivers for JDBC and ODBC.

Installing the FIPS Client Driver for ODBC and vsql

Vertica offers a FIPS client for FIPS-compatible systems. A FIPS-compatible system is FIPS-enabled and includes the OpenSSL libraries.

The FIPS client supports ODBC and vsql and is offered in 64-bit only.

Prerequisites

Verify that your host system is running Red Hat Enterprise Linux 6.6.

The FIPS client installer checks your host system for the value of the sysctl parameter, crypto.fips_enabled. You must set this parameter to 1 (enabled). If your host is not enabled, the client does not install.

For other prerequisites, related specifically to ODBC, see ODBC Prerequisites.

Installing the FIPS Client

To install the FIPS client driver package:
1. Download the FIPS client package from the myVertica portal.

2. Log in to the client system as root.

3. Install the RPM package that you downloaded:

   # rpm -Uvh package_name.rpm

For ODBC, once you have installed the client package, you need to create a DSN and set some additional configuration parameters. For more information, see:

- Creating an ODBC DSN for Linux, AIX, and HP-UX
- Required ODBC Driver Configuration Settings for Linux and UNIX

You may also want to add the vsq1 client to your PATH environment variable so that you do not need to enter its full path to run it. To do so, add the following to the .profile file in your home directory or the global /etc/profile file:

   export PATH=$PATH:/opt/vertica/bin

Client Searches for OpenSSL Libraries

When you launch the client application to connect to the server, the client searches for and loads the OpenSSL libraries libcrypto.so.1.0 and libssl.so.1.0 (version 1.0.1e):

- The client first checks to see if LD_LIBRARY_PATH is set.

- If the LD_LIBRARY_PATH location does not include the libraries, it checks RunPath, either /opt/vertica/lib or within the ODBC or vsq1 directory structure (../lib).

Important: The LD_LIBRARY_PATH, if set, directs the search path for the OpenSSL libraries. Be aware that the client loads the libraries from any set or preset LD_LIBRARY_PATH location.

The following figure depicts the search for the OpenSSL libraries.
Installing the FIPS Client Driver for JDBC

Vertica offers a JDBC client driver that is compliant with the Federal Information Processing Standard (FIPS). Use this JDBC client driver to access systems that are FIPS-compatible. For more information on FIPS in Vertica, see Federal Information Processing Standard.

Implementing FIPS on a JDBC client requires a third-party JRE extension called BouncyCastle, a collection of APIs used for cryptography. Use BouncyCastle APIs with JDK 1.7 and 1.8, and Red Hat 6.6.
Important: When using the JDBC FIPS-compliant client, expect some time lag for the client to connect efficiently and securely. If necessary, increase your system's entropy to ensure a fast and secure connection.

You need to add the FIPS BouncyCastle jar as the JVM JSSE provider, as follows:

1. Download the BouncyCastle FIPS jar file bc-fips-1.0.0.jar from the BouncyCastle download page.

2. Add bc-fips-1.0.0.jar as a JRE library extension:
   ```
   <path to jre>/lib/ext/bc-fips-1.0.0.jar
   ```

3. Add BouncyCastle as an SSL security provider in <path to jre>/lib/security/java.security:
   ```
   security.provider.1=org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
   security.provider.2=com.sun.net.ssl.internal.ssl.Provider BCFIPS
   security.provider.3=sun.security.provider.Sun
   ```

4. Use the following JVM java-D system property command arguments to set the KeyStore and TrustStore files to BCFIPS:
   ```
   export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.keyStoreProvider=BCFIPS
   export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.trustStoreProvider=BCFIPS
   ```

   For information on setting the SSL Keystore and Truststore, see Configuring SSL for JDBC Clients.

5. Set the default type for the KeyStore implementation to BCFKS in <path to jre>/lib/security/java.security:
   ```
   keystore type=BCFKS
   ssl.keystore.type=BCFKS
   ```

Note: If you are using FIPS with BouncyCastle, you must create all client keys and certificates with the BCFKS store type, including the Vertica->Kafka key/certs.
6. On the command line, run the following command from `<path to jre>/lib/ext` to create the keystore and truststore. Make sure you use the BCFKS type:

```
$ <java bin path> keytool -keystore vertica.kafka.keystore.bcfks
   -storetype BCFKS
   -providername BCFIPS
   -providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
   -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
   -providerpath bc-fips-1.0.0.jar
   -alias CARoot
   -import -file (server.crt.der file path)
```

7. Enter the keystore password when prompted. The following message appears:

"Certificate was added to the keystore"

8. Run the java program with SSL DB:
   a. Copy the `vertica.kafka.keystore.bcfks` keyStore from `<path to jre>/lib/ext/` to the java program folder.
   b. Convert the Vertica server certificate to a form that java understands:
      i. `openssl x509 -in server.crt -out server.crt.der -outform der`
      ii. `<java bin path>/keytool -keystore verticastore -keypasswd -storepass password -importkeystore -noprompt -alias verticasql -import -file server.crt.der`
   c. Download the latest `vertica jdbc` driver from the [vertica.com download page](http://vertica.com).

9. After creation of `verticastore`, `keyStore`, and download `jar`, execute the following command to run java with debugging to test the implementation:

```
$ java -Djavax.net.debug=ssl -Djavax.net.ssl.keyStore='vertica.kafka.keystore.bcfks'
   -Djavax.net.ssl.keyStorePassword='password'
   -Djavax.net.ssl.trustStore='<path to verticastore>/verticastore'
   -Djavax.net.ssl.trustStorePassword='password'
   -cp .:vertica-jdbc-8.1.0-0.jar FIPSTest
```
Installing the Client Drivers and Tools on Windows

This section details how to install the client drivers and tools on Windows.

For connectivity through a JDBC connection, see Installing the JDBC Client Driver for Windows. For all other client drivers and tools, see The Vertica Client Drivers and Tools for Windows.

Installing the JDBC Client Driver for Windows

To install the Vertica JDBC driver on your Windows client system, you must first download the cross-platform JDBC driver .jar file to your system. Then, choose the method that the Windows Java installation will use to find it.

Important: If you are using Vertica client drivers for Windows that were released before Vertica 7.2.3, you must first uninstall the older drivers. This is true for the separate JDBC client driver download (the .jar file). This is also true for the client drivers included in the package, Client Drivers and Tools for Windows (an .exe file), which includes ODBC, vsq1, ADO.NET, OLEDB, the Visual Studio plugin, and SQL Server integration components. Once you have installed client versions 7.2.3, you do not need to uninstall for upgrades that follow. For example, upgrading from 8.1.x to 9.1.x would not require that you uninstall before upgrade.

Download the JDBC Driver for Windows

1. On your Windows client system, open a browser, and log in to the myVertica portal.

2. Install the Vertica JDBC driver for Windows:
   a. Navigate to the Downloads tab, and scroll to the Client Software section.
   b. Click the download link for the JDBC Driver for Windows installer.

3. Accept the license agreement, and wait for the download to complete.

Choose How Java Locates the JDBC Driver Library

For your Java client application to use the Vertica JDBC driver, the Java interpreter must be able to find the driver's library file. Choose one of these methods to tell the Java interpreter where to look for the library:
- Copy the JDBC .jar file you downloaded to the system-wide Java Extensions folder (C:\Windows\Sun\Java).

- Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).

- Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java command line.

**The Vertica Client Drivers and Tools for Windows**

You can obtain the Vertica Client Drivers and Tools for Windows installer through the myVertica portal. You can run the installer on either a 32-bit or 64-bit system, either as a regular Windows installer or silently.

**Components**

The Vertica Client Drivers and Tools for Windows installs the following components on your system:

- The ODBC Client Driver for Windows
- The OLE DB Client Driver for Windows
- The vsqI Client for Windows
- The ADO.NET Driver for Windows
- The Microsoft Connectivity Pack for Windows
- The Visual Studio Plug-in for Windows

Read Fully Update Your System before you proceed.

**System Prerequisites**

The Vertica Client Drivers and Tools for Windows released with Vertica Release 7.2. or later has basic system prerequisite requirements. The pack also requires that specific Microsoft components be installed for full integration.

For a list of all prerequisites, see Vertica 9.1.x Client Drivers in the Supported Platforms document.
**Important:** If you are using Vertica client drivers for Windows that were released before Vertica 7.2.3, you must first uninstall the older drivers. This is true for the separate JDBC client driver download (the .jar file). This is also true for the client drivers included in the package, Client Drivers and Tools for Windows (an .exe file), which includes ODBC, vsq1, ADO.NET, OLEDB, the Visual Studio plugin, and SQL Server integration components. Once you have installed client versions 7.2.3, you do not need to uninstall for upgrades that follow. For example, upgrading from 8.1.x to 9.1.x would not require that you uninstall before upgrade.
Fully Update Your System

Before you install the Vertica driver package, verify that your system is fully up to date with all Windows updates and patches. See the documentation for your version of Windows for instructions on how to run Windows update. The Vertica client libraries and vsql executable install updated Windows libraries that depend on Windows service packs. Be sure to resolve any issues that block the installation of Windows updates.

If your system is not fully up-to-date, you may receive error messages about missing libraries such as api-ms-win-crt-runtime-l1-1-0.dll when starting vsql.
.NET Framework

The .NET framework is not bundled into the Vertica Client Drivers and Tools for Windows. However, during installation, a web installer launches if Microsoft .NET 3.5 SP1 is not detected on your system. You then have the opportunity to download the framework. Also, if your operating system version includes .NET 3.5 SP1, but it is not turned on, the installer turns on the feature.

If you have Visual Studio 2010 or 2012 installed, your system already includes Microsoft .NET Framework 4.0 or 4.5, respectively. You also need Microsoft .NET 3.5 SP1 to use the Vertica Client Drivers and Tools for Windows integration features.

Use the following links to download the appropriate version of .NET framework directly from Microsoft:

- For .NET Framework 3.5 SP1:
  

- For .NET Framework 4.0:
  

- For .NET Framework 4.5:
  
Microsoft Visual Studio

Important: You must have Visual Studio and the matching SDK installed to use the Visual Studio plug-in.

After installing the plug-in, you can use it to access your Vertica database from within Visual Studio. If you do not have the SDK installed, download the SDK specific to your version of Visual Studio.

Note: For Visual Studio 2015, you do not need to download the SDK separately as it is included as an installation option with the Visual Studio installation. For more information, refer to the Microsoft documentation.

- For the Microsoft Visual Studio 2008 SDK:

- For the Microsoft Visual Studio 2008 SP1 SDK:

- For the Microsoft Visual Studio 2010 SDK:

- For the Microsoft Visual Studio 2010 SP1 SDK:

- For the Microsoft Visual Studio 2012 SDK:

- For the Microsoft Visual Studio 2013 SDK:

If the Microsoft Visual Studio SDK is missing when you begin the installation, a dialog box opens to tell you so. You can choose to ignore this dialog box.
Configuring BIDS or SSDT-BI Integration

The Vertica Client Drivers and Tools for Windows installer provides BIDS (Visual Studio 2008) or SSDT-BI (Visual Studio 2010, 2012, 2013, or 2015) integration. To use BIDS or SSDT-BI, follow this process:

1. Install the BIDS or SSDT-BI development tool add-on for Visual Studio.

2. Verify that SQL Server is installed on the same or a different machine.

3. Verify that the SQL Server Shared Features for BIDS or SSDT-BI have been activated.

You can then develop packages using BIDS or SSDT-BI, creating your projects using SQL Server’s SSIS, SSAS, SSRS features. To use these features, you must connect to Vertica through the Vertica ADO.NET driver (for SSIS and SSRS) or the OLE DB driver (for SSAS).

For more information, see Microsoft Components.
Microsoft SQL Server

Use SQL Server 2012, 2014 or 2016. The Vertica Client Drivers and Tools for Windows installer enables support for the following:

- **SQL Server 2012, 2014, and 2016:**
  - SQL Server Integration Services (SSIS)
  - SQL Server Reporting Services (SSRS)
  - SQL Server Analysis Services (SSAS)

**Note:** For SQL Server 2012, you can use either SQL Server 2012 or SQL Server 2012 SP1.

To use the enhanced Vertica .NET support, you must first install SQL Server. Then, you can install the Client Drivers and Tools for Windows. The following components must be installed on the SQL server:

<table>
<thead>
<tr>
<th>For...</th>
<th>Install...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSAS</td>
<td>The Analysis Services Instance Feature.</td>
</tr>
<tr>
<td>SSRS</td>
<td>The Reporting Services Instance Feature.</td>
</tr>
<tr>
<td>SSIS (Data Type Mappings)</td>
<td>The SQL Server Integration Services Shared Feature.</td>
</tr>
</tbody>
</table>
Download the Client Drivers and Tools for Windows

1. On your Windows client system, open a browser, and log in to the myVertica portal.

2. Install the Vertica Client Drivers and Tools for Windows:
   a. Navigate to the Downloads tab, and scroll to the Client Software section. Click the link for the Vertica Client Drivers download page.
   b. Click the download link for the Vertica Client Drivers and Tools installer.

3. Accept the license agreement, and wait for the download to complete.

Install or Upgrade the Client Drivers and Tools for Windows

As the Windows Administrator, double-click the installer to start the installation. Follow the prompts as the wizard guides you through each step of the process.

By default, the installer installs the client drivers and tools in C:\Program Files\Vertica Systems\. You have the option of changing this location during installation.

Note: The install wizard allows you to choose the components you want to install. Under your Windows Control Panel, the installer adds a program for each installed component. Among the programs the installer adds is a program named, Vertica Client Installer. You can right-click on the installer to modify, repair, or uninstall the Vertica client.

Important: The Vertica Microsoft Connectivity Pack is included as part of the Vertica Client Drivers and Tools for Windows. If you plan to use the Microsoft Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.
Upgrading the Client Drivers and Tools for Windows

You do not need to uninstall the Client Drivers and Tools for Windows before upgrading. The installation program upgrades the existing drivers and tools in place.

Important: If you are using Vertica client drivers for Windows that were released before Vertica 7.2.3, you must first uninstall the older drivers. This is true for the separate JDBC client driver download (the .jar file). This is also true for the client drivers included in the package, Client Drivers and Tools for Windows (an .exe file), which includes ODBC, vsqI, ADO.NET, OLEDB, the Visual Studio plugin, and SQL Server integration components. Once you have installed client versions 7.2.3, you do not need to uninstall for upgrades that follow. For example, upgrading from 8.1.x to 9.1.x would not require that you uninstall before upgrade.

Silently Install or Upgrade the Client Drivers and Tools for Windows

1. As a Windows Administrator, open a command-line session, and change directory to the folder that contains the installer.

2. Run the command:

   ```
   VerticaSetup.exe -q -install InstallFolder="C:\Program Files\Vertica Systems"
   ```

The client drivers and tools are silently installed in C:\Program Files\Vertica Systems\.
Upgrading the Client Drivers and Tools for Windows

You do not need to uninstall the Client Drivers and Tools for Windows before upgrading. The installation program upgrades the existing drivers and tools in place.

Important: If you are using Vertica client drivers for Windows that were released before Vertica 7.2.3, you must first uninstall the older drivers. This is true for the separate JDBC client driver download (the .jar file). This is also true for the client drivers included in the package, Client Drivers and Tools for Windows (an .exe file), which includes ODBC, vsq1, ADO.NET, OLEDB, the Visual Studio plugin, and SQL Server integration components. Once you have installed client versions 7.2.3, you do not need to uninstall for upgrades that follow. For example, upgrading from 8.1.x to 9.1.x would not require that you uninstall before upgrade.

Post-Installation Steps for ODBC Driver and vsq1 Client

After you install the Vertica Client Drivers and Tools for Windows, there are additional steps you must take for the ODBC driver and vsq1 client to function correctly.

- **ODBC Driver** — After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Windows Clients.

- **vsq1 Client** — The vsq1 client does not have a shortcut. Before you can start using vsq1, you must add the vsq1 executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating system you are running. To start vsq1 and show the help list, open a command window, and type `vsq1 -?` at the command prompt. See Using vsq1 for Windows Users for important details about using vsq1 in a Windows console.

Uninstalling, Modifying, or Repairing the Client Drivers and Tools

To uninstall, modify, or repair the client drivers and tools, run the Client Drivers and Tools for Windows installer.

The installer provides three options:
<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify</td>
<td>Remove installed client drivers and tools or install missing client drivers and tools.</td>
</tr>
<tr>
<td>Repair</td>
<td>Reinstall already-installed client drivers and tools.</td>
</tr>
<tr>
<td>Uninstall</td>
<td>Uninstall all of the client drivers and tools.</td>
</tr>
</tbody>
</table>
Silently Uninstall the Client Drivers and Tools

1. As a Windows Administrator, open a command-line session, and change directory to the folder that contains the installer.

2. Run the command:

   VerticaSetup.exe -q -uninstall

The client drivers and tools are silently uninstalled.

Components of the Client Drivers and Tools on Windows

The following sections describe the components in the Client Drivers and Tools for Windows in more detail:

- The ODBC Client Driver for Windows
- The vsql Client for Windows
- The Microsoft Connectivity Pack for Windows
- The OLE DB Client Driver for Windows
- The ADO.NET Driver for Windows
- The Visual Studio Plug-in for Windows

The ODBC Client Driver for Windows

The Vertica ODBC driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the Client Drivers downloads page.

After Installing the ODBC Driver

After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Windows Clients.
ODBC Driver Settings on Windows

ODBC driver settings are automatically configured using the Vertica Client Drivers and Tools installer on Windows. The values for the settings are stored in the Windows registry under the path `HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver`. It is not necessary to configure additional ODBC driver settings on Windows platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings using the Windows ODBC Data Source Configuration window.

See Additional Parameter Settings for a list of additional settings for the ODBC client driver. See Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs for information on how to send ODBC log entries to Event Tracing for Windows (ETW).

Diverting ODBC Log Entries to ETW

On Windows clients, you can direct Vertica to send ODBC log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.
Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs

To use ETW logging, you must register the ODBC driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

**Important:** If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

   **Important:** You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.

   a. For the 64-bit ODBC driver, run:

   ```
   wevtutil im "c:\Program Files\Vertica Systems\ODBC64\lib\VerticaODBC64.man"
   /resourceFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
   /messageFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
   ```

   b. For the 32-bit ODBC driver, run:

   ```
   wevtutil im "c:\Program Files (x86)\Vertica Systems\ODBC32\lib\VerticaODBC32.man"
   /resourceFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
   /messageFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
   ```

3. Run the command `wevtutil sl` to enable the logs.

   a. For 64-bit ODBC driver logs, run:

   ```
   wevtutil sl VerticaODBC64/e:true
   ```
b. For the 32-bit ODBC driver logs, run:

```
wevtutil sl VerticaODBC32/e:true
```

**Note:** Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.
Add the String Value LogType

By default, Vertica does not send ODBC log entries to ETW. To activate ETW, add the string LogType to your Windows registry, and set its value to ETW.

1. Start the registry editor by typing regedit.exe in the Windows Run command box.
2. Navigate to the correct location in the registry.

   HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver

3. Right-click in the right pane of the Registry Editor window. Select New and then select String Value.
4. Change the name of the string value from New Value #1 to LogType.
5. Double-click the new LogType entry. When prompted for a new value, enter ETW.
6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.
Event Viewer Log Levels

The LogLevel parameter setting is described in the section, Additional Parameter Settings. The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

<table>
<thead>
<tr>
<th>Vertica LogLevel Setting</th>
<th>Vertica LogLevel Description</th>
<th>Entries are sent to Event Viewer as log level...</th>
<th>Event Viewer Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(No logging)</td>
<td>0</td>
<td>(No logging)</td>
</tr>
<tr>
<td>1</td>
<td>Fatal Errors</td>
<td>1</td>
<td>Critical</td>
</tr>
<tr>
<td>2</td>
<td>Errors</td>
<td>2</td>
<td>Error</td>
</tr>
<tr>
<td>3</td>
<td>Warnings</td>
<td>3</td>
<td>Warning</td>
</tr>
<tr>
<td>4</td>
<td>Info</td>
<td>4</td>
<td>Information</td>
</tr>
<tr>
<td>5</td>
<td>Debug</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Trace (all messages)</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).

- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.
**Where to Find Logs in Event Viewer**

1. Launch the Windows Event Viewer.

2. From Event Viewer (Local), expand Applications and Services Logs.

3. Expand the folder that contains the log you want to review (for example, VerticaODBC64).

4. Select the Vertica ODBC log under the folder. Entries appear in the right pane.
Event Log Entry: Event ID

Once you have chosen an ODBC log in Event Viewer, note the value in the Event ID field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

The vsql Client for Windows

The Vertica vsql client for Windows is installed as part of the Client Drivers and Tools for Windows.

There is no shortcut for the vsql client. Before you can start using vsql, you must add the vsql executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating system you are running. After you have made the change to your PATH environment variable, start a command window and type vsql -? at the command prompt to start vsql and show the help list.

For information about editing the Window PATH environment variable, see How do I set or change the PATH system variable?

For important details about using vsql in a Windows console, see Using vsql for Windows Users.

Using vsql for Windows Users
Font

The default raster font does not work well with the ANSI code page. Set the console font to "Lucida Console."
Console Encoding

`vsql` is built as a "console application." The Windows console windows use a different encoding than the rest of the system, so take care when you use 8-bit characters within `vsql`. If `vsql` detects a problematic console code page, it warns you at startup.

To change the console code page, set the code page by entering `cmd.exe /c chcp 1252`.

**Note:** 1252 is a code page that is appropriate for European languages. Replace it with your preferred locale code page.
Running Under Cygwin

Verify that your cygwin.bat file does not include the "tty" flag. If the "tty" flag is included in your cygwin.bat file, then banners and prompts are not displayed in vsql.

To verify, enter:

```
set CYGWIN=binmode tty ntsec
```

To remove the "tty" flag, enter:

```
set CYGWIN=binmode ntsec
```

Additionally, when running under Cygwin, vsql uses Cygwin shell conventions as opposed to Windows console conventions.
Tab Completion

Tab completion is a function of the shell, not vsq1. Because of this, tab completion does not work the same way in Windows vsq1 as it does on Linux versions of vsq1.

On Windows, instead of using tab-completion, press F7 to pop-up a history window of commands. You can also press F8 after typing a few letters of a command to cycle through commands in the history buffer which begin with the same letters.

The Microsoft Connectivity Pack for Windows

The Vertica Microsoft Connectivity Pack for Windows provides a configuration file for you to access Microsoft Business Intelligence tools. The Connectivity Pack is installed as part of the Client Drivers and Tools for Windows.

To learn about which Microsoft components are configured with the Microsoft Connectivity Pack, see Microsoft Components.

Microsoft Components

This section describes the Microsoft Business Intelligence components you can use with Microsoft Visual Studio and Microsoft SQL Server. After configuration, you can use these Microsoft components to develop business solutions using your Vertica server.

Important: The Vertica Microsoft Connectivity Pack is included as part of the Vertica Client Drivers and Tools for Windows. If you plan to use the Microsoft Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.
Microsoft Component Configuration

The Vertica ADO.NET driver, the Visual Studio plug-in, and the OLE DB driver allow you to integrate your Vertica server with an environment that includes Microsoft components previously installed on your system. Additional tools are also available for integration with Microsoft SQL Server.

The available drivers provide integration with the following Microsoft components:

- Business Intelligence Development Studio (BIDS) for Visual Studio 2008 for use with SQL Server 2012. BIDS is a client-based application used to develop business intelligence solutions based on the Microsoft Visual Studio development environment. It includes additional project types specific to SQL Server Business Intelligence. As a developer, you can use BIDS to develop business solutions.

- SQL Server Analysis Services (SSAS) for SQL Server 2012, 2014, and 2016. Use SSAS for OLAP and data mining, while using Vertica as the source for cube creation.

- SQL Server Integration Services (SSIS) for SQL Server 2012, 2014, and 2016. SSIS provides SQL Server Type Mappings to map data types between Vertica and SQL Server. Use SSIS for data migration, data integration and workflow, and ETL.

The following figure displays the relationship between Microsoft components and Vertica dependencies.
BIDS and SSDT-BI

Business Intelligence Development Studio (BIDS) is available in Microsoft Visual Studio 2008 with additional project types that are specific to SQL Server business intelligence. BIDS is the primary environment that you use to develop business solutions that include Analysis Services, Integration Services, and Reporting Services projects.

Both BIDS and SSDT-BI are client-based applications that include additional project types specific to SQL Server Business Intelligence.

You can use the Visual Studio Shell Integration plug-in to browse a database from within the Visual Studio Server Explorer. This capability allows you to work outside of BIDS or SSDT-BI development to perform tasks, such as listing tables or inserting data. When you use Visual Studio in BIDS or SSDT-BI mode, you can develop business solutions using the data in your Vertica database. For example, you can create cubes or open tables.

Microsoft does not support the following configurations:

- You cannot use Microsoft Visual Studio 2008 with BIDS development to create a SQL Server 2012 Business Intelligence solution.

- You cannot use Microsoft Visual Studio 2010/2012/2013/2015 with SSDT-BI development to create a SQL Server 2008 Business Intelligence solution.
SQL Server Analysis Services (SSAS) Support

BIDS or SSDT-BI includes the Analysis Services project for developing online analytical processing (OLAP) for business intelligence applications. This project type includes templates for:

- Cubes
- Dimensions
- Data sources
- Data source views

It also provides the tools for working with these objects.

Note: OpenText recommends that you use the Vertica OLE DB driver when connecting to the Vertica server from SSAS due to improved performance.

You can find the OLE DB connection properties in OLE DB Connection Properties.
SQL Server Integration Services (SSIS) Support

BIDS or SSDT-BI includes the Integration Services project for developing ETL solutions. This project type includes templates for:

- Packages
- Data sources
- Data source views

It also provides the tools for working with these objects.

You can find support for using Vertica as a data source and target from both SSIS and the import/export wizard. You must install mapping files specific to Vertica on the Integration Server and BIDS or SSDT-BI workstation to enable this capability. The Vertica Client Drivers and Tools for Windows installs these mapping files as the "SQL Server Type Mappings" component(s) in both 32-bit and 64-bit versions.

Note: Always use the Vertica ADO.NET driver when connecting to the Vertica server from SSIS.
SQL Server Reporting Services (SSRS) Support

BIDS or SSDT-BI includes Report projects for developing reporting solutions.

You can use Vertica as a data source for Reporting Services. The installer implements various configuration file modifications to enable this capability on both the BIDS or SSDT-BI workstation and the Reporting Services server.

Compatibility Issues and Limitations

This section lists compatibility issues and limitations for integrating the Microsoft Connectivity Pack with Microsoft Visual Studio and Microsoft SQL Server.
BIDS and SSDT-BI Limitations

BIDS and SSDT-BI are 32-bit development environments for Analysis Services, Integration Services, and Reporting Services projects. They are not designed to run on the Itanium 64-bit architecture and thus are not installed on Itanium servers.
SSAS Limitations

- The SSAS Tabular Model is not supported.

- If, after installing the Vertica OLE DB driver, an SSAS cube build fails, restart the SSAS service.
SSIS Data Type Limitations

The following sections cover data type limitations when using SQL Server Integration Services (SSIS).
**Time Data Transfer**

When transferring time data, SSIS uses the `TimeSpan` data type that supports precision greater than six digits. The Vertica ADO.NET driver translates `TimeSpan` as an `Interval` data type that supports up to six digits. The Interval type is not converted to the `TimeSpan` type during transfer. As a result, if the time value has a precision of more than six digits, the data is truncated, not rounded.

For information on ADO.NET data types, refer to [ADO.NET Data Types](#).
DATE and DATETIME Precision

To function without errors, DATE and DATETIME have a range from 0001-01-01 00:00:00.0000000 to 9999-12-31 23:59:59.999999.

In SSIS, the DATETIME type (DT_TIMESTAMP) supports only a scale up to three decimal places for seconds. Any decimal places after that are automatically discarded. You can perform derived column transformations only on DATETIME values between January 1, 1753 through December 31, 9999.
**Numeric Precision**

The maximum and minimum decimal allowed is:

- **Max:** +79,228,162,514,264,337,593,543,950,335
- **Min:** -79,228,162,514,264,337,593,543,950,335

For example, if the scale is 16, the range of values is:

+/- 7,922,816,251,426.4337593543950335

The valid scale range is any number that is smaller than 29 and greater than 38. Using a scale between 29 and 38 does not generate an error.

Unsupported Floating Point Values

SQL Server does not support NaN, Infinity, or –Infinity values. These values are supported when you use SSIS to transfer between Vertica instances, but they are not supported with a SQL Server Destination.
String Conversion

The CHAR and VARCHAR data types used in SSIS are DT_WSTR, with a maximum length of 4000 characters.

In SSIS, Vertica strings are converted to Unicode strings in SSIS to handle multi-lingual data. You can convert these strings to ASCII using a Data Conversion Task.
**Scale**

Whenever you use a scale greater than 38, SSIS replaces it with a value of 4.
Interval Conversion

SSIS does not support interval types. It converts them to TIME and strips off the day component. Any package that has interval types greater than a day returns incorrect results.
Data Mapping Issues with SQL Server Import and Export Wizard

When you create an Integrated Services package (SSIS) using the SQL Server Import and Export Wizard, certain data types do not automatically map correctly. A mapping issue can occur when you use the wizard with:

- SQL Server Native OLE DB Provider for SQL Server 2008 or 2012
- SQL Server Native Client 10.0/11.0 Provider for SQL Server 2010/2012

To avoid this issue, manually change the type mappings with BIDS or SSDT-BI.
Data Transfer Failures

When using an Integrated Services package (SSIS) with the SQL Server OLE DB Provider for SQL Server 2008 or 2012, certain data type transfers can fail when transferring from Vertica to SQL Server. To avoid this issue, use either BIDS or SSDT-BI when transferring data.
Batch Insert of VARBINARY/LONG VARBINARY Data Types

Sometimes, one row of a batch insert of VARBINARY or LONG VARBINARY data types exceeds the data type limit:

- VARBINARY: 65 KB
- LONG VARBINARY: 32 MB

In such cases, all rows are rejected, rather than just the one row whose length exceeds the type limit. The batch insert fails with the message "row(s) are rejected".

To avoid this issue, use a predicate to filter out rows from the source that do not fit into the receiving database.
Boolean Queries in SQL Server Query Designer

When issuing a Boolean query in SQL Server Query Designer, you must enclose Boolean column values in quotes. Otherwise, you receive a SQL execution error (for example, someboolean = 'true').
SSRS Limitations

Data Connection Wizard Workaround

The SSRS Report Wizard provides a data connection wizard. After you select the wizard and enter all the connection information, the OK button is disabled. You cannot save your work and continue. The workaround is to not use the wizard and to use the following panel instead:

![Report Wizard - Query Designer](image)

Report Wizard - Query Designer

Vertica uses the Report Wizard's Generic Query Designer. Other data sources use a Graphical Query Designer that supports building queries visually. The Graphical Query Designer is a part of a package called Visual Data Tools (VDT). The Graphical Query Designer works only with Generic OLE DB providers and the built-in providers. You cannot use it with the Vertica Data Provider.

Report Builder

Report Builder is a web-based report design tool. It does not support creating reports using custom data extensions, so you cannot use it with Vertica. When you create a report using Report Builder, existing Vertica data sources appear in the list of available data sources. However, choosing a Vertica data source causes an error.

Schema Name Not Automatically Provided when Mapping Vertica Destination

Currently, when you map a Vertica destination, the schema name is not automatically provided. You must enter it manually or pick it from the drop-down menu as follows:
The OLE DB Client Driver for Windows

The Vertica OLE DB driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the Client Drivers downloads page.

The values for the OLE DB driver's settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver.

For information on how the OLE DB driver integrates with Microsoft components previously installed on your system, see Microsoft Component Configuration.

OLE DB Connection Properties

Use the Connection Manager to set the OLE DB connection string properties, which define your connection. You access the Connection Manager from within Visual Studio.

These connection parameters appear on the Connection page.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provider</td>
<td>Select the native OLE DB provider for the connection.</td>
<td>None</td>
</tr>
<tr>
<td>OLE DB Provider</td>
<td>Indicates Vertica OLE DB Provider.</td>
<td>None</td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server or file name</td>
<td>Enter the server or file name.</td>
<td>None</td>
</tr>
<tr>
<td>Location</td>
<td>Not supported.</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Use Windows NT Integrated Security</td>
<td>Not supported.</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Use a specific user name and password</td>
<td>Enter a user name and password. Connect with No Password: Select the Blank password check box. Save and Encrypt Password: Select Allow saving password.</td>
<td>None</td>
</tr>
<tr>
<td>Initial Catalog</td>
<td>The name of the database running on the server.</td>
<td>None</td>
</tr>
</tbody>
</table>

The All page from the Connection Manager dialog box includes all possible connection string properties for the provider.

The table that follows lists the connection parameters for the All page.

For OLE DB properties information specific to Microsoft, see the Microsoft documentation [OLE DB Properties](#).

<table>

<td>Makes a connection to the server whether or not the server uses SSL. The first attempt is made over a clear channel. If that attempt fails, a second attempt is over SSL.</td>
</tr>
<tr>
<td></td>
<td>disable</td>
<td>Never connects to the server using SSL. Typically, you use this setting for troubleshooting.</td>
</tr>
</tbody>
</table>

**Diverting OLE DB Log Entries to ETW**

On Windows clients, you can direct Vertica to send OLE DB log entries to Event Tracing for Windows (ETW). Once set, OLE DB log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.
Register the OLE DB Driver as a Windows Event Log Provider, and Enable the Logs

To use ETW logging, you must register the OLE DB driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

**Important:** If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

   **Important:** You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.
   a. For the 64-bit OLE DB driver, run:

   ```
   wevtutil im "c:\Program Files\Vertica Systems\OLEDB64\lib\VerticaOLEDB64.man"
   /resourceFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_oledb.dll"
   /messageFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_oledb.dll"
   ```
   b. For the 32-bit OLE DB driver, run:

   ```
   wevtutil im "c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\VerticaOLEDB32.man"
   /resourceFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_oledb.dll"
   /messageFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_oledb.dll"
   ```

3. Run the command `wevtutil sl` to enable the logs.
   a. For 64-bit OLE DB driver logs, run:

   ```
   wevtutil sl VerticaOLEDB64/e:true
   ```
b. For the 32-bit ODBC driver logs, run:

```
wevtutil sl VerticaOLEDB32/e:true
```

**Note:** Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.
Add the String Value LogType

By default, Vertica does not send OLE DB log entries to ETW. To activate ETW, add the string LogType to your Windows registry, and set its value to ETW.

1. Start the registry editor by typing regedit.exe in the Windows Run command box.

2. Navigate to the correct location in the registry.

   HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver

3. Right-click in the right pane of the Registry Editor window. Select New and then select String Value.

4. Change the name of the string value from New Value #1 to LogType.

5. Double-click the new LogType entry. When prompted for a new value, enter ETW.

6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.
**Event Viewer Log Levels**

The LogLevel parameter setting is described in the section, Additional Parameter Settings. The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

<table>
<thead>
<tr>
<th>Vertica LogLevel Setting</th>
<th>Vertica LogLevel Description</th>
<th>Entries are sent to Event Viewer as log level...</th>
<th>Event Viewer Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(No logging)</td>
<td>0</td>
<td>(No logging)</td>
</tr>
<tr>
<td>1</td>
<td>Fatal Errors</td>
<td>1</td>
<td>Critical</td>
</tr>
<tr>
<td>2</td>
<td>Errors</td>
<td>2</td>
<td>Error</td>
</tr>
<tr>
<td>3</td>
<td>Warnings</td>
<td>3</td>
<td>Warning</td>
</tr>
<tr>
<td>4</td>
<td>Info</td>
<td>4</td>
<td>Information</td>
</tr>
<tr>
<td>5</td>
<td>Debug</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Trace (all messages)</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).

- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.
Where to Find Logs in Event Viewer

1. Launch the Windows Event Viewer.

2. From Event Viewer (Local), expand Applications and Services Logs.

3. Expand the folder that contains the log you want to review (for example, VerticaOLEDB64).

4. Select the Vertica OLE DB log under the folder. Entries appear in the right pane.
Event Log Entry: Event ID

Once you have chosen an OLE DB log in Event Viewer, note the value in the Event ID field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

The ADO.NET Driver for Windows

The Vertica ADO.NET driver for Windows is installed as part of the Client Drivers and Tools for Windows.

The ADO.NET driver is installed in the ADO.NET folder of the installation folder. The driver is also installed into the Windows Global Assembly Cache (GAC).

For information on how the ADO.NET driver integrates with Microsoft components previously installed on your system, see Microsoft Components.

The Visual Studio Plug-in for Windows

The Visual Studio plug-in for Windows is installed as part of the Client Drivers and Tools for Windows.

For information on how the Visual Studio plug-in integrates with Microsoft components previously installed on your system, see Microsoft Components.

Visual Studio Limitations

Visual Studio 2012 May Require Update 3

You may need to install update 3 to Visual Studio 2012 if:

- You launch Server Explorer to view and work with your Vertica server, but the Vertica data source is not visible.
- You create a SSAS cube, connect to Vertica, and find either an empty list of tables or tables not functioning correctly.

This issue does not occur for other versions of Visual Studio supported by Vertica.

Results Viewer Limited to 655 Columns
The Visual Studio results viewer cannot execute a query that includes more than 655 columns. If a table includes more than 655 columns, select specific columns (up to 655 total) rather than selecting all columns.

**Manually Refresh Settings for Visual Studio**

If, after installing the Visual Studio plug-in, you do not see Vertica listed as a data provider, manually refresh.

To do so, run `devenv.exe`/setup, which you can find in the Visual Studio installation folder.

**SQL Pane Issues**

- **ALTER TABLE or CREATE TABLE**

  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and issue the ALTER TABLE or CREATE TABLE statement in the SQL pane. However, a message displays telling you that the statement is not supported. To resolve the error, click Continue, and the query executes.

- **Queries with Semicolons**

  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and execute a SQL query in the SQL pane. If you include a semicolon (;) with your query, the query executes, but the result returned cannot be edited. To avoid this issue, enter the same query in the SQL pane without the semicolon.

- **Quoting Boolean Values**

  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 to connect to the Vertica database and execute a SQL query in the SQL pane. When attempting to insert a value into a Boolean column without putting quotes around the value, subsequent execution of the SQL statement returns an error. To work around this issue, include quotes.

**Uninstalling Client Drivers and Tools for Windows Error**

There is a scenario where an uninstall of the Client Drivers and Tools for Windows package fails with a message that the .NET framework is required. What follows is the scenario that causes this issue.

1. You Install the Client Drivers and Tools for Windows.

2. You then install Visual Studio 2010 or 2012, which includes installation of the .NET framework 4.0 or 4.5.

3. You uninstall the .NET framework using the Windows Control Panel.
4. You then attempt to uninstall the Client Drivers and Tools for Windows. The uninstall fails with the message that .NET framework is required.

Perform the following to correct this issue:

1. Reinstall the .NET framework 4.0 or 4.5 manually, using the Windows Control Panel.
2. Uninstall the Client Drivers and Tools for Windows.

Installing the Client Drivers on Mac OS X

This section details how to install the client drivers on Mac OS X.

Installing the JDBC Driver on Mac OS X

To install the Vertica JDBC driver on your Mac OS X client system, download the cross-platform JDBC driver .jar file to your system and ensure OS X's Java installation can find it.

Downloading the JDBC Driver

To download the Vertica JDBC driver on Mac OS X:

1. On your Mac client system, open a browser and log into the myVertica portal.
2. Navigate to the Downloads page, scroll to the Client Software download section, and click the download link for the JDBC driver.
3. Accept the license agreement and wait for the download to complete.

Ensuring Java Can Find the JDBC Driver

In order for your Java client application to use the Vertica JDBC driver, the Java interpreter needs to be able to find its library file. Choose one of these methods to tell the Java interpreter where to look for the library:

- Copy the JDBC .jar file you downloaded to either the system-wide Java Extensions folder (/Library/Java/Extensions) or your user Java Extensions folder (/Users/username/Library/Java/Extensions).
Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).

Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java command line.

Installing the ODBC Driver on Mac OS X

You can obtain the Vertica ODBC driver for Mac OS X as a .pkg file through the myVertica portal. You can run the installer as a regular Mac OS X installer or silently. This driver is compatible with both 32-bit and 64-bit applications.

The installer is designed to be used with the standard iODBC Driver Manager included in Mac OS X. While Mac OS X ships with the iODBC Driver Manager already installed, you may choose to download the most recent version of the driver at the iODBC.org website.

By default, the installer installs the driver in the following location: /Library/Vertica/ODBC/lib/libverticaodbc.dylib. The installer also automatically registers a driver named "Vertica" with the iODBC Driver Manager.

To use the unixODBC Driver Manager instead of Apple's iODBC Driver Manager, see the unixODBC.org website.

Before You Download the Driver

If you installed a previous version of the Vertica ODBC driver for Mac OS X, your system may already have a registered driver named "Vertica." In this case, if you must remove or rename the older version of the driver before installing the Vertica ODBC driver .pkg.

To have multiple versions of the driver installed on your system at the same time, you must rename the currently installed version of the driver to something other than "Vertica." You can do so using the Apple ODBC Administrator Tool.

To rename the driver:

1. Using your web browser, download and install the Apple ODBC Administrator Tool.

2. Locate and open the ODBC Administrator Tool after installation:
   a. Navigate to Finder > Applications > Utilities.
   b. Open the ODBC Administrator Tool.
3. Click the Drivers tab, and then select the driver named "Vertica."

4. Click the Configure button. A dialog box opens.
   
   a. In Description, enter a new name for the driver, and then click OK. The dialog box closes.

   b. On the ODBC Administrator page, click Apply.

5. Exit the ODBC Administrator Tool.

Download the Driver

Follow these steps to download the Vertica ODBC driver for Mac OS X:

1. On your Mac OS X client system, open a browser, and log in to the myVertica portal.

2. Install the Vertica ODBC driver for Mac OS X:
   
   a. Navigate to the Downloads tab, and scroll to the Client Software section.

   b. Click the download link for the Mac OS X ODBC installer.

3. Accept the license agreement, and wait for the download to complete.

Install the Mac OS X ODBC Driver

As a Mac OS X Administrator, double-click the installer to start the installation. Follow the prompts as the wizard guides you through each step of the process.

Note: After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X Clients.

Silently Install the Mac OS X ODBC Driver

1. Log into the client Mac in one of two ways:
   
   ■ As an administrator account, if you are installing the driver for system-wide use

   ■ As the user who needs to use the Vertica ODBC driver

2. Open a terminal window. In the Finder, click Applications > Utilities > Terminal.

3. Install the .pkg file containing the ODBC driver using the command:
In the preceding .pkg command, change the path to that of the downloaded file, if:

- You downloaded the driver .pkg file to a directory other than your Downloads directory.
- You downloaded the driver using another user account.

Note: After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X Clients.

Uninstall the Mac OS X ODBC Driver

Uninstalling the Mac OS X ODBC Client-Driver does not remove any existing DSNs associated with the driver.

To uninstall:

1. Open a terminal window.
2. Enter the command:

```
sudo /Library/Vertica/ODBC/bin/Uninstall
```

Upgrade or Downgrade the Mac OS X ODBC Driver

All installations of the Vertica ODBC driver for Mac OS X are uniquely identified by a package ID and version number. The package ID does not change between versions, but the version number does. If you attempt multiple installations of the same version of the driver, a name collision error occurs. Therefore, multiple installations of the same version of the driver cannot coexist on a single operating system.

- **Upgrading**—Newly installed versions of the Vertica ODBC driver for Mac OS X automatically upgrade the relevant driver system settings. Any DSNs associated with a previous version of the driver are not affected, except that they begin using the newer version of the driver.

- **Downgrading**—Run the uninstall script to remove the current version of the Vertica ODBC driver for Mac OS X. Complete this step before installing an older driver version.
ODBC Driver Settings on Mac OS X

ODBC driver settings are automatically configured using the Vertica ODBC driver installer on Mac OS X. It is not necessary to configure additional ODBC driver settings on Mac OS X platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings by editing the VERTICAINI environment variable in each user's ~/.MacOSX/environment.plist file. See the Environment Variables entry in the Apple Developer's Library for more information.

See Additional Parameter Settings for a list of the additional settings.
Creating an ODBC Data Source Name (DSN)

A Data Source Name (DSN) is the logical name that is used by Open Database Connectivity (ODBC) to refer to the driver and other information that is required to access data from a data source. Whether you are developing your own ODBC client code or you are using a third-party tool that needs to access Vertica using ODBC, you need to configure and test a DSN. The method you use depends upon the client operating system you are using.

Refer to the following sections for information specific to your client operating system.

- Creating an ODBC DSN for Linux, AIX, and HP-UX
- Creating an ODBC DSN for Windows Clients
- Creating an ODBC DSN for Macintosh OS X Clients
- Data Source Name (DSN) Connection Properties
- Setting DSN Connection Properties

Creating an ODBC DSN for Linux, AIX, and HP-UX

You define DSN on Linux and other UNIX-like platforms in a text file. Your client's driver manager reads this file to determine how to connect to your Vertica database. The driver manager usually looks for the DSN definitions in two places:

- /etc/odbc.ini
- ~/.odbc.ini (a file named .odbc.ini in the user's home directory)

Users must be able to read the odbc.ini file in order to use it to connect to the database. If you use a global odbc.ini file, consider creating a UNIX group with read access to the file. Then, add the users who need to use the DSN to this group.

The structure of these files is the same—only their location differs. If both files are present, the ~/.odbc.ini file usually overrides the system-wide /etc/odbc.ini file.

Note: See your ODBC driver manager's documentation for details on where these files should be located and any other requirements.
odbc.ini File Structure

The odbc.ini is a text file that contains two types of lines:

- Section definitions, which are text strings enclosed in square brackets.
- Parameter definitions, which contain a parameter name, an equals sign (=), and then the parameter's value.

The first section of the file is always named [ODBC Data Sources], and contains a list of all the DSNs that the odbc.ini file defines. The parameters in this section are the names of the DSNs, which appear as section definitions later in the file. The value is a text description of the DSN and has no function. For example, an odbc.ini file that defines a single DSN named VerticaDSN could have this ODBC Data Sources section:

```
[ODBC Data Sources]
VerticaDSN = "vmartdb"
```

Appearing after the ODBC data sources section are sections that define each DSN. The name of a DSN section must match one of the names defined in the ODBC Data Sources section.

Configuring the odbc.ini file:

To create or edit the DSN definition file:

1. Using the text editor of your choice, open odbc.ini or ~/.odbc.ini.

2. Create an ODBC Data Sources section and define a parameter:
   - Whose name is the name of the DSN you want to create
   - Whose value is a description of the DSN

   For example, to create a DSN named VMart, you would enter:

   ```
   [ODBC Data Sources]
   VMart = "VMart database on Vertica"
   ```

3. Create a section whose name matches the DSN name you defined in step 2. In this section, you add parameters that define the DSN's settings. The most commonly-defined parameters are:
- **Description** – Additional information about the data source.

- **Driver** – The location and designation of the Vertica ODBC driver, or the name of a driver defined in the odbcinst.ini file (see below). For future compatibility, use the name of the symbolic link in the library directory, rather than the library file:
  - `/opt/vertica/lib`, on 32-bit clients
  - `/opt/vertica/lib64`, on 64-bit clients

For example, the symbolic link for the 64-bit ODBC driver library is:

```
/opt/vertica/lib64/libverticaodbc.so
```

The symbolic link always points to the most up-to-date version of the Vertica client ODBC library. Use this link so that you do not need to update all of your DSNs when you update your client drivers.

- **Database** – The name of the database running on the server. This example uses vmartdb for the vmartdb.

- **ServerName** — The name of the server where Vertica is installed. Use localhost if Vertica is installed on the same machine.

  You can provide an IPv4 address, IPv6 address, or host name.

  In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.

- **UID** — Either the database superuser (same name as database administrator account) or a user that the superuser has created and granted privileges. This example uses the user name dbadmin.

- **PWD** — The password for the specified user name. This example leaves the password field blank.

- **Port** — The port number on which Vertica listens for ODBC connections. For example, 5433.

- **ConnSettings** — Can contain SQL commands separated by a semicolon. These commands can be run immediately after connecting to the server.
SSLKeyFile — The file path and name of the client's private key. This file can reside anywhere on the system.

SSLCertFile — The file path and name of the client's public certificate. This file can reside anywhere on the system.

Locale — The default locale used for the session. By default, the locale for the database is: en_US@collation=binary (English as in the United States of America). Specify the locale as an ICU Locale. See the ICU User Guide (http://userguide.icu-project.org/locale) for a complete list of parameters that can be used to specify a locale.

PreferredAddressFamily:

The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are:

- ipv4—Connect to the server using IPv4.
- ipv6—Connect to the server using IPv6.
- none—Use the IP address provided by the DNS server.

For example:

```
[VMart]
Description = Vmart Database
Driver = /opt/vertica/lib64/libverticaodbc.so
Database = vmartdb
Servername = host01
UID = dbadmin
PWD =
Port = 5433
ConnSettings =
AutoCommit = 0
SSLKeyFile = /home/dbadmin/client.key
SSLCertFile = /home/dbadmin/client.crt
Locale = en_US@collation=binary
```

See Data Source Name (DSN) Connection Properties for a complete list of parameters including Vertica-specific ones.

Using an odbcinst.ini File

Instead of giving the path of the ODBC driver library in your DSN definitions, you can use the name of a driver defined in the odbcinst.ini file. This method is useful method if you have many DSNs and often need to update them to point to new driver libraries. It also allows you to set some additional ODBC parameters, such as the threading model.
Just as in the odbc.ini file, odbcinst.ini has sections. Each section defines an ODBC driver that can be referenced in the odbc.ini files.

In a section, you can define the following parameters:

- **Description** — Additional information about the data source.
- **Driver** — The location and designation of the Vertica ODBC driver, such as `/opt/vertica/lib64/libverticaodbc.so`

For example:

```
[Vertica]
Description = Vertica ODBC Driver
Driver = /opt/vertica/lib64/libverticaodbc.so
```

Then, in your odbc.ini file, use the name of the section you created in the odbcinst.ini file that describes the driver you want to use. For example:

```
[VMart]
Description = Vertica Vmart database
Driver = Vertica
```

If you are using the unixODBC driver manager, you should also add an ODBC section to override its standard threading settings. By default, unixODBC serializes all SQL calls through ODBC, which prevents multiple parallel loads. To change this default behavior, add the following to your odbcinst.ini file:

```
[ODBC]
Threading = 1
```

### Configuring Additional ODBC Settings

On Linux and UNIX systems, you need to configure some additional driver settings before you can use your DSN. See [Required ODBC Driver Configuration Settings for Linux and UNIX](https://www.vertica.com/docs/v9/HTML/Reference/ODBC/ODBC%20Driver%20Configuration%20Settings%20for%20Linux%20and%20UNIX.htm) for details.

### Testing an ODBC DSN Using Isql

The unixODBC driver manager includes a utility named isql, which is a simple ODBC command-line client. It lets you to connect to a DSN to send commands and receive results, similarly to vsql.

To use isql to test a DSN connection:
1. Run the following command:

```
$ isql -v DSNname
```

Where `DSNname` is the name of the DSN you created.

A connection message and a SQL prompt display. If they do not, you could have a configuration problem or you could be using the wrong user name or password.

2. Try a simple SQL statement. For example:

```
SQL> SELECT table_name FROM tables;
```

The `isql` tool returns the results of your SQL statement.

**Note:** If you have not set the ErrorMessagesPath in the additional driver configuration settings, any errors during testing will trigger a missing error message file ("The error message NoSQLGetPrivateProfileString could not be found in the en-US locale"). See [Required ODBC Driver Configuration Settings for Linux and UNIX](#) for more information.

---

### Creating an ODBC DSN for Windows Clients

To create a DSN for Microsoft Windows clients, you must perform the following tasks:

#### Setting Up an ODBC DSN

A *Data Source Name (DSN)* is the ODBC logical name for the drive and other information the database needs to access data. The name is used by Internet Information Services (IIS) for a connection to an ODBC data source.

This section describes how to use the Vertica ODBC Driver to set up an ODBC DSN. This topic assumes that the driver is already installed, as described in [Installing Client Drivers on Windows](#).

**To set up a DSN**

1. Open the ODBC Administrator. For example, you could navigate to Start > Control Panel > Administrative Tools > Data Sources (ODBC).
Note: The method you use to open the ODBC Administrator depends on your version of Windows. Differences between Windows versions and Start Menu customizations could require you to take a different action to open the ODBC Administrator.

2. Decide if you want all users on your client system to be able to access to the DSN for the Vertica database.
   - If you want all users to have access, then click the System DSN tab.
   - Otherwise, click the User DSN tab to create a DSN that is only usable by your Windows user account.

3. Click Add to create a new DSN to connect to the Vertica database.

4. Scroll through the list of drivers in the Create a New Data Source dialog box to locate the Vertica driver. Select the driver, and then click Finish.

   Note: If you have installed more than one version of the Vertica client drivers on your Windows client system, you may see multiple versions of the driver in this list. Choose the version that you know is compatible with your client application and Vertica Analytic Database server. If you are unsure, use the latest version of the driver.

The Vertica ODBC DSN configuration dialog box appears.

5. Click the More >>> button to view a description of the field you are editing and the connection string defined by the DSN.

6. Enter the information for your DSN. The following fields are required:
   - **DSN Name** — The name for the DSN. Clients use this name to identify the DSN to which they want to connect. The DSN name must satisfy the following requirements:
     - Its maximum length is 32 characters.
     - It is composed of ASCII characters except for the following: [ ] { } , ; ? * = ! @ \n     - It contains no spaces.
   - **Server** — The host name or IP address of the Vertica server to which you want to connect. Use localhost, if Vertica is installed on the same machine.

   You can provide an IPv4 address, IPv6 address, or host name.
In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.

The `PreferredAddressFamily` option is available on the Client Settings tab.

- **Backup Servers** — A comma-separated list of host names or IP addresses used to connect to if the server specified by the Server field is down. Optional.

- **Database** — The name of the Vertica database.

- **User Name** — The name of the user account to use when connecting to the database. If the application does not supply its own user name when connecting to the DSN, this account name is used to log into the database.

The rest of the fields are optional. See DSN Parameters for detailed information about the DSN parameters you can define.

7. If you want to test your connection:
   a. Enter at least a valid DSN name, Server name, Database, and either User name or select Windows authentication.
   b. If you have not selected Windows authentication, you can enter a password in the Password box. Alternately, you can select Password prompt to have the driver prompt you for a password when connecting.
   c. Click Test Connection.

8. When you have finished editing and testing the DSN, click OK. The Vertica ODBC DSN configuration window closes, and your new DSN is listed in the ODBC Data Source Administrator window.

9. Click OK to close the ODBC Data Source Administrator.

After creating the DSN, you can test it using Microsoft Excel 2007.

**Setting up a 32-Bit DSN on 64-Bit Versions of Microsoft Windows**

On 64-bit versions of Windows, the default ODBC Data Source Administrator creates and edits DSNs that are associated with the 64-bit Vertica ODBC library.
Attempting to use these 64-bit DSNs with a 32-bit client application results in an architecture mismatch error. Instead, you must create a specific 32-bit DSN for 32-bit clients by running the 32-bit ODBC Administrator usually located at:

c:\Windows\SysWOW64\odbcad32.exe

This administrator window edits a set of DSNs that are associated with the 32-bit ODBC library. You can then use your 32-bit client applications with the DSNs you create with this version of the ODBC administrator.

**Encrypting Passwords on ODBC DSN**

When you install an ODBC driver and create a Data Source Name (DSN) the DSN settings are stored in the registry, including the password. Encrypting passwords on ODBC DSN applies only to Windows systems.

Encrypting passwords on an ODBC data source name (DSN) provides security against unauthorized database access. The password is not encrypted by default and is stored in plain-text.

Note: Password encryption applies only to new or modified ODBC DSNs. If you have a DSN created in Version 8.0 or earlier and upgrade to 8.1, the password does not get encrypted regardless of the encryption settings.

**Enable Password Encryption**

Use the EncryptPassword parameter to enable or disable password encryption for an ODBC DSN:

- EncryptPassword = true enables password encryption
- EncryptPassword = false (default) disables password encryption

Set **EncryptPassword** in the Windows registry - HKEY_LOCAL_MACHINE > Software > Vertica > ODBC > Driver EncryptPassword=<true/false>.

Note: For 32 bit driver running on 64 bit windows verify password encryption here:

HKEY_LOCAL_MACHINE > Software > Wow6432Node > Vertica > ODBC > Driver > EncryptPassword=<true/false>

Encrypted passwords get updated in the following registry locations:

For a user DSN:
HKEY_CURRENT_USER-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD

For a system DSN:
HKEY_LOCAL_MACHINE-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD

Verify Password Encryption

Use Windows Registry editor to determine if password encryption is enabled based on the value of EncryptPassword. Depending on the type of DSN you installed, check the following:

For a user DSN: HKEY_CURRENT_USER > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For a system DSN: HKEY_LOCAL_MACHINE > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For each DSN, the value of the isPasswordEncrypted parameter indicates the status of the password encryption, where 1 indicates an encrypted password and 0 indicates an unencrypted password.

Testing an ODBC DSN Using Excel

You can use Microsoft Excel to verify that an application can connect to an ODBC data source or other ODBC application.

1. Open Microsoft Excel, and select Data > Get External Data > From Other Sources > From Microsoft Query.

2. When the Choose Data Source dialog box opens:
   a. Select New Data Source, and click OK.
   b. Enter the name of the data source.
   c. Select the Vertica driver.
   d. Click Connect.

3. When the Vertica Connection Dialog box opens, enter the connection information for the DSN, and click OK.
4. Click OK on the Create New Data Source dialog box to return to the Choose Data Source dialog box.

5. Select VMart_Schema*, and verify that the Use the Query Wizard check box is deselected. Click OK.

6. When the Add Tables dialog box opens, click Close.

7. When the Microsoft Query window opens, click the SQL button.

8. In the SQL window, write any simple query to test your connection. For example:

   ```
   SELECT DISTINCT calendar_year FROM date_dimension;
   ```

9. ■ If you see the caution, "SQL Query can't be represented graphically. Continue anyway?" click OK.
    ■ The data values 2003, 2004, 2005, 2006, 2007 indicate that you successfully connected to and ran a query through ODBC.

10. Select File > Return Data to Microsoft Office Excel.

11. In the Import Data dialog box, click OK.

    The data is now available for use in an Excel worksheet.

**Creating an ODBC DSN for Macintosh OS X Clients**

You can use the Vertica ODBC Driver to set up an ODBC DSN. This procedure assumes that the driver is already installed, as described in [Installing the ODBC Driver on Macintosh OS X](#).

### Setting Up a DSN

1. Using your web browser, download and install the Apple ODBC Administrator Tool.

2. Locate and open the ODBC Administrator Tool after installation:
   a. Navigate to Finder > Applications > Utilities.
   b. Open the ODBC Administrator Tool.
3. Click the Drivers tab, and verify that the Vertica driver is installed.

![ODBC Administrator](image)

4. Specify if you want all users on your client system to be able to access the DSN for the Vertica database:

   - If you want all users to have access, then click the System DSN tab.
   - Otherwise, click the User DSN tab to create a DSN that is only usable by your Macintosh user account.

5. Click Add... to create a new DSN to connect to the Vertica database.

6. Scroll through the list of drivers in the Choose A Driver dialog box to locate the Vertica driver. Select the driver, and then click OK. A dialog box opens that requests DSN parameter information.

7. In the dialog box, enter the Data Source Name (DSN) and an optional Description. To do so, click Add to insert keywords (parameters) and values that define the settings needed to connect to your database, including database name, server host, database user name (such as dbadmin), database password, and port. Then, click OK.
8. In the ODBC Administrator dialog box, click Apply.

   See Data Source Name (DSN) Connection Properties for a complete list of parameters including those specific to Vertica.

After configuring the ODBC Administrator Tool, you may need to configure additional driver settings before you can use your DSN, depending on your environment. See Additional ODBC Driver Configuration Settings for details.

Note: If you want to test your connection, use the iodbctest utility. For the procedure, see Testing a DSN Using iodbctest.

Testing an ODBC DSN Using iodbctest

The standard iODBC Driver Manager on OS X includes a utility named iodbctest that lets you test a DSN to verify that it is correctly configured. You pass this command a connection string in the same format that you would use to open an ODBC database connection. After configuring your DSN connection, you can run a query to verify that the connection works.

For example:

```
# iodbctest "DSN=VerticaDSN;UID=dbadmin;PWD=password"
iodBC Demonstration program
This program shows an interactive SQL processor
Driver Manager: 03.52.0607.1008
Driver: 07.01.0200 (verticaodbcw.so)
SQL> SELECT table_name FROM tables;
table_name
-----------------------------------------------
customer_dimension
product_dimension
promotion_dimension
date_dimension
vendor_dimension
employee_dimension
shipping_dimension
warehouse_dimension
inventory_fact
store_dimension
store_sales_fact
store_orders_fact
online_page_dimension
call_center_dimension
online_sales_fact
numbers
result set 1 returned 16 rows.
```
Data Source Name (DSN) Connection Properties

The following tables list the connection properties you can set in the DSNs for use with Vertica's ODBC driver.

Required Connection Properties

These connection properties are the minimum required to create a functioning DSN.

NOTE: If you use a host name (Servername) whose DNS entry resolves to multiple IP addresses, the client attempts to connect to the first IP address returned by the DNS. If a connection cannot be made to the first address, the client attempts to connect to the second, then the third, continuing until it either connects successfully or runs out of addresses.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver</td>
<td>The file path and name of the driver used.</td>
<td>none</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database running on the server.</td>
<td>none</td>
</tr>
<tr>
<td>Servername</td>
<td>The host name or IP address of any active node in a Vertica cluster. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6. You can also use the aliases &quot;server&quot; and &quot;host&quot; for this property.</td>
<td>none</td>
</tr>
<tr>
<td>UID</td>
<td>The database username.</td>

- Required ODBC Driver Configuration Settings for Linux and UNIX

Setting DSN Connection Properties

The properties in the following tables are common for all user and system DSN entries. The examples provided are for Windows clients.

To edit DSN properties:

- On UNIX and Linux client platforms, you can edit the odbc.ini file. The location of this file is specific to the driver manager. See Creating an ODBC DSN for Linux, AIX, and HP-UX.

- On Windows client platforms, you can edit some DSN properties using the Vertica ODBC client driver interface. See Creating an ODBC DSN for Windows Clients.

- You can also edit the DSN properties directly by opening the DSN entry in the Windows registry (for example, at HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI\DSNname). Directly editing the registry can be risky, so you should only use this method for properties that cannot be set through the ODBC driver's user interface, or via your client code.

- You can set properties in the connection string when opening a connection using the SQLDriverConnect() function:

```
sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=DSNName;Locale=en_GB@collation=binary", SQL_NTS, szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

Note: In the connection string ';' is a reserved symbol. If you need to set multiple properties as part of the ConnSettings property use '%$3B' in place of ';'. Also use '+=' instead of spaces.

For example:

```
sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=VerticaSQL;ConnSettings=set+search_path+to+a,b,c;set+locale=ch;SSLMode=prefer", SQL_NTS, szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

- Your client code can retrieve DSN property values after a connection has been made to Vertica using the SQLGetConnectAttr() and SQLGetStmtAttr() API calls. Some properties can be set and using SQLSetConnectAttr() and SQLSetStmtAttr().
For details of the list of properties specific to Vertica see ODBC Header Files specific to Vertica.
Programming ODBC Client Applications

Vertica provides an Open Database Connectivity (ODBC) driver that allows applications to connect to the Vertica database. This driver can be used by custom-written client applications that use the ODBC API to interact with Vertica. ODBC is also used by many third-party applications to connect to Vertica, including business intelligence applications and extract, transform, and load (ETL) applications.

This section details the process for configuring the Vertica ODBC driver. It also explains how to use the ODBC API to connect to Vertica in your own client applications.

This section assumes that you have already installed the ODBC libraries on your client system. If you have not, see Client Drivers.

ODBC Architecture

The ODBC architecture has four layers:

- **Client Application**

  Is an application that opens a data source through a Data Source Name (DSN). It then sends requests to the data source, and receives the results of those requests. Requests are made in the form of calls to ODBC functions.

- **Driver Manager**

  Is a library on the client system that acts as an intermediary between a client application and one or more drivers. The driver manager:

  - Resolves the DSN provided by the client application.
  - Loads the driver required to access the specific database defined within the DSN.
  - Processes ODBC function calls from the client or passing them to the driver.
  - Retrieves results from the driver.
  - Unloads drivers when they are no longer needed.

  On Windows and Mac client systems, the driver manager is provided by the operating system. On Linux and UNIX systems, you usually need to install a driver manager. See ODBC.
Prerequisites for a list of driver managers that can be used with Vertica on your client platform.

- **Driver**
  
  A library on the client system that provides access to a specific database. It translates requests into the format expected by the database, and translates results back into the format required by the client application.

- **Database**
  
  The database processes requests initiated at the client application and returns results.

**ODBC Feature Support**

The ODBC driver for Vertica supports the most of the features defined in the Microsoft ODBC 3.5 specifications. The following features are *not* supported:

- Updatable result sets
- Backwards scrolling cursors
- Cursor attributes
- More than one open statement per connection. For example you cannot execute a new statement while another statement has a result set open. If you need to execute multiple statements at once, open multiple database connections.
- Keysets
- Bookmarks

The Vertica ODBC driver accurately reports its capabilities. If you need to determine whether it complies with a specific feature, you should query the driver's capabilities directly using the SQLGetInfo() function.

**Vertica and ODBC Data Type Translation**

Most data types are transparently converted between Vertica and ODBC. This section explains several data types require special handling.

<th>ODBC C Typedef</th>
<th>C Type Identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>GEOGRAPHY</td>
<td>char[]</td>
<td>SQL_LONGVARCHAR</td>
<td>SQL_C_CHAR</td>
</tr>
<tr>
<td>UUID</td>
<td>SQLGUID (see note below)</td>
<td>SQL_GUID</td>
<td>SQL_C_GUID</td>
</tr>
</tbody>
</table>

### Notes

- The GEOMETRY and GEOGRAPHY data types are treated as LONG VARCHAR data by the ODBC driver.

- Vertica supports the standard interval data types supported by ODBC. See [Interval Data Types](#) in Microsoft's ODBC reference.

- Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with the earlier client driver versions that do not support the UUID data type (see [Client Driver and Server Version Compatibility](#) for the versions of the client drivers that Vertica supports). When one of these older clients queries tables with UUID columns in them, Vertica automatically translates the native UUID values to CHAR values. Also, when an older client inserts data into a UUID column, Vertica automatically converts the CHAR value sent by the client into a native UUID value. Vertica also reports the data type of these columns as CHAR when an older client queries a UUID column's metadata.

Using LONG VARCHAR and LONG VARBINARY Data Types with ODBC

The ODBC drivers support the LONG VARCHAR and LONG VARBINARY data types similarly to VARCHAR and VARBINARY data types. When binding input or output parameters to a LONG VARCHAR or LONG VARBINARY column in a query, use the SQL_LONGVARCHAR and SQL_LONGVARBINARY constants to set the column's data type. For example, to bind an input parameter to a LONG VARCHAR column, you would use a statement that looks like this:

```
rc = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR, 80000, 0, (SQLPOINTER)myLongString, sizeof(myLongString), NULL);
```

Note: Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

ODBC Header File Specific to Vertica

The Vertica ODBC driver provides a C header file named verticaodbc.h that defines several useful constants that you can use in your applications. These constants let you access and alter settings specific to Vertica.

This file's location depends on your client operating system:

- /opt/vertica/include on Linux and UNIX systems.
- C:\Program Files (x86)\Vertica\ODBC\include on Windows systems.

The constants defined in this file are listed below.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Associated Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL_ATTR_VERTICA_RESULT_BUFFER_SIZE</td>
<td>Sets the size of the buffer used when retrieving results from the server.</td>
<td>SQLSetConnectAttr() SQLGetConnectAttr()</td>
</tr>
</tbody>
</table>
Connecting to the Database

The first step in any ODBC application is to connect to the database. When you create the connection to a data source using ODBC, you use the name of the DSN that contains the details of the driver to use, the database host, and other basic information about connecting to the data source.

There are 4 steps your application needs to take to connect to a database:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Associated Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL_ATTR_VERTICA_DIRECT_BATCH_INSERT</td>
<td>Determines whether a batch is inserted directly into the ROS (1) or using AUTO mode (0). By default batches are inserted using AUTO. When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS. For details about load options, see <a href="#">Choosing a Load Method</a>.</td>
<td>SQLSetConnectAttr() SQLSetStmtAttr() SQLGetConnectAttr() SQLGetStmtAttr()</td>
</tr>
<tr>
<td>SQL_ATTR_VERTICA_LOCALE</td>
<td>Changes the locale from en_US@collation=binary to the ICU locale specified. See <a href="#">Setting the Locale for ODBC Sessions</a> for an example of using this parameter.</td>
<td>SQLSetConnectAttr() SQLGetConnectAttr()</td>
</tr>
</tbody>
</table>

Vertica Documentation
Connecting to Vertica
1. Call SQLAllocHandle() to allocate a handle for the ODBC environment. This handle is used to create connection objects and to set application-wide settings.

2. Use the environment handle to set the version of ODBC that your application wants to use. This ensures that the data source knows which API your application will use to interact with it.

3. Allocate a database connection handle by calling SQLAllocHandle(). This handle represents a connection to a specific data source.

4. Use the SQLConnect() or SQLDriverConnect() functions to open the connection to the database.

   Note: If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.

When creating the connection to the database, use SQLConnect() when the only options you need to set at connection time is the username and password. Use SQLDriverConnect() when you want to change connection options, such as the locale.

The following example demonstrates connecting to a database using a DSN named ExampleDB. After it creates the connection successfully, this example simply closes it.

```c
// Demonstrate connecting to Vertica using ODBC.  
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients  
#include <windows.h>
// SQL include files that define data types and ODBC API  
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Set the ODBC version we are going to use to  
    // 3.
```
Running the above code prints the following:

Allocated an environment handle.
Set application version to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Disconnecting and freeing handles.
See Setting the Locale for ODBC Sessions for an example of using SQLDriverConnect to connect to the database.

Notes

- If you use the DataDirect® driver manager, you should always use the SQL_DRIVER_NOPROMPT value for the SQLDriverConnect function's DriverCompletion parameter (the final parameter in the function call) when connecting to Vertica. Vertica's ODBC driver on Linux and UNIX platforms does not contain a UI, and therefore cannot prompt users for a password.

- On Windows client platforms, the ODBC driver can prompt users for connection information. See Prompting Windows Users for Missing Connection Properties for more information.

- If your database does not comply with your Vertica license agreement, your application receives a warning message in the return value of the SQLConnect() function. Always have your application examine this return value to see if it is SQL_SUCCESS_WITH_INFO. If it is, have your application extract and display the message to the user.

Enabling Native Connection Load Balancing in ODBC

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the DSN entry or in the connection string. The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.
// Demonstrate enabling native load connection balancing.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <assert.h>

// Only needed for Windows clients
#include <windows.h>

// SQL include files that define data types and ODBC API functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;

int main()
{
    SQLRETURN ret; /* Stores return value from ODBC API calls */
    SQLHENV hdlEnv; /* Handle for the SQL environment object */
    /* Allocate an a SQL environment object */
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));

    /* Set the ODBC version we are going to use to */
    /* 3. */
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
            (SQLPOINTER) SQL_OV_ODBC3,
            SQL_IS_UINTEGER);
    assert(SQL_SUCCEEDED(ret));

    /* Allocate a database handle. */
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));

    /* Connect four times. If load balancing is on, client should */
    /* connect to different nodes. */
    for (int x=1; x <= 4; x++)
    {
        /* Connect to the database using SQLDriverConnect. Set */
        /* ConnectionLoadBalance to 1 (true) to enable load */
        /* balancing. */
        cout << endl << "Connection attempt #" << x << "...;"
        const char *connStr = "DSN=VMart;ConnectionLoadBalance=1;"
            "UID=ExampleUser;PWD=password123";

        ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
            NULL, 0, NULL, SQL_DRIVER_NOPROMPT);
        if(!SQL_SUCCEEDED(ret))
        {
            cout << "failed. Exiting." << endl;
            exit(EXIT_FAILURE);
        }
        else{
            cout << "succeeded" << endl;
        }
    }

    /* We're connected. Query the v_monitor.current_session table to */
    /* find the name of the node we've connected to. */

    /* Set up a statement handle */
    SQLHSTMT hdlStmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
    assert(SQL_SUCCEEDED(ret));
}
ret = SQLExecDirect( hd1stmt, (SQLCHAR*)"SELECT node_name FROM "
"V_MONITOR.CURRENT_SESSION;", SQL_NTS );

if(SQL_SUCCEEDED(ret)) {
  // Bind variable to column in result set.
  SQLTCHAR node_name[256];
  ret = SQLBindCol(hd1stmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
                   sizeof(node_name), NULL);
  while(SQL_SUCCEEDED(ret = SQLFetchScroll(hd1stmt, SQL_FETCH_NEXT,1))) {
    // Print the bound variables, which now contain the values from the
    // fetched row.
    cout << "Connected to node " << node_name << endl;
  }
  // Free statement handle
  SQLFreeHandle(SQL_HANDLE_STMT,hd1stmt);
  cout << "Disconnecting." << endl;
  ret = SQLDisconnect( hd1Dbc );
  assert(SQL_SUCCEEDED(ret));
}
// When done, free all of the handles to close them
// in an orderly fashion.
cout << endl << "Freeing handles..." << endl;
SQLFreeHandle(SQL_HANDLE_DBC, hd1Dbc);
SQLFreeHandle(SQL_HANDLE_ENV, hd1Env);
cout << "Done!" << endl;
exit(EXIT_SUCCESS);
}

Running the above example produces output similar to the following:

Connection attempt #1... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Connection attempt #2... succeeded
Connected to node v_vmart_node0002
Disconnecting.

Connection attempt #3... succeeded
Connected to node v_vmart_node0003
Disconnecting.

Connection attempt #4... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Freeing handles...
Done!

ODBC Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration.
This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.

- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts. Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

### Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note: If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.
Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

**Using DNS Failover**

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

**Using the Backup Host List**

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the BackupServerNode parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the BackupServerNode connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```c++
// Demonstrate using connection failover.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <cassert.h>

// Only needed for Windows clients
// #include <windows.hgt;

// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;
```
int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hd1Env; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    assert(SQL_SUCCEEDED(ret));

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINT32);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    assert(SQL_SUCCEEDED(ret));

    /* DSN for this connection specifies a bad node, and good backup nodes:
    [VMartBadNode]
    Description=VMart Vertica Database
    Driver=/opt/vertica/lib64/libverticaodbc.so
    Database=VMart
    Servername=badnode.example.com
    BackupServerNode=vmart_node0002.example.com,vmart_node0003.example.com
    */

    // Connect to the database using SQLConnect
    cout << "Connecting to database." << endl;
    const char *dsnName = "VMartBadNode"; // Name of the DSN
    const char* userID = "ExampleUser"; // Username
    const char* passwd = "password123"; // password
    ret = SQLConnect(hd1Dbc, (SQLCHAR*)dsnName,
        SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        cout << "Could not connect to database." << endl;
        exit(EXIT_FAILURE);
    } else {
        cout << "Connected to database." << endl;
    }

    // We're connected. Query the v_monitor.current_session table to
    // find the name of the node we've connected to.

    // Set up a statement handle
    SQLHSTMT hd1Stmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hd1Dbc, &hd1Stmt);
    assert(SQL_SUCCEEDED(ret));

    ret = SQLExecDirect( hd1Stmt, (SQLCHAR*)"SELECT node_name FROM 
        "v_monitor.current_session;", SQL_NTS );
    if(SQL_SUCCEEDED(ret)) {
        // Bind variable to column in result set.
        SQLTCHAR node_name[256];
        ret = SQLBindCol(hd1Stmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
            sizeof(node_name), NULL);
        while(SQL_SUCCEEDED(ret = SQLFetchScroll(hd1Stmt, SQL_FETCH_NEXT,1))) {
            // Print the bound variables, which now contain the values from the
// fetched row.
    cout << "Connected to node " << node_name << endl;
  }
}

cout << "Disconnecting." << endl;
ret = SQLEndConnect( hdlDbc );
assert(SQL_SUCCEEDED(ret));

// When done, free all of the handles to close them
// in an orderly fashion.
cout << endl << "Freeing handles..." << endl;
SQLFreeHandle(SQL_HANDLE_STMT, hstmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdbc);
SQLFreeHandle(SQL_HANDLE_ENV, henv);
cout << "Done!" << endl;
exit(EXIT_SUCCESS);
}

When run, the example's output on the system console is similar to the following:

Connecting to database.
Connected to database.
Connected to node v_vmart_node002
Disconnecting.

Freeing handles...
Done!

Notice that the connection was made to the first node in the backup list (node 2).

Note: When native connection load balancing is enabled, the additional servers specified in
the BackupServerNode connection parameter are only used for the initial connection to a
Vertica host. If host redirects the client to another host in the database cluster to handle its
connection request, the second connection does not use the backup node list. This is rarely
an issue, since native connection load balancing is aware of which nodes are currently up in
the database. See Enabling Native Connection Load Balancing in ODBC

Prompting Windows Users for Missing Connection Properties

The Vertica Windows ODBC driver can prompt the user for connection information if required
information is missing. The driver displays the Vertica Connection Dialog if the client
application calls SQLDriverConnect to connect to Vertica and either of the following is true:
the DriverCompletion property is set to SQL_DRIVER_PROMPT.

- the DriverCompletion property is set to SQL_DRIVER_COMPLETE or SQL_DRIVER_COMPLETE_REQUIRED and the connection string or DSN being used to connect is missing the server, database, or port information.

If either of the above conditions are true, the driver displays a Vertica Connection Dialog to the user to prompt for connection information.

![Vertica Connection Dialog](image)

The dialog has all of the property values supplied in the connection string or DSN filled in.

**Note:** Your connection string at least needs to specify Vertica as the driver, otherwise Windows will not know to use the Vertica ODBC driver to try to open the connection.

The required fields on the connection dialog are Database, UID, Server, and Port. Once these are filled in, the form enables the OK button.

If the user clicks Cancel on the dialog, the SQLDriverConnect function call returns SQL_NO_DATA immediately, without attempting to connect to Vertica. If the user supplies incomplete or incorrect information for the connection, the connection function returns SQL_ERROR after the connection attempt fails.

**Note:** If the DriverCompletion property of the SQLDriverConnect function call is SQL_DRIVER_NOPROMPT, the ODBC driver immediately returns a SQL_ERROR indicating that it cannot connect because not enough information has been supplied and the driver is not allowed to prompt the user for the missing information.
Prompting Windows Users for Passwords

If the connection string or DSN supplied to the SQLDriverConnect function that client applications call to connect to Vertica lacks any of the required connection properties needed to connect, the Vertica’s Windows ODBC driver opens a dialog box to prompt the user to enter the missing information (see Prompting Windows Users for Missing Connection Properties). The user's password is not normally considered a required connection property, since Vertica user accounts may not have a password. If the password property is missing, the ODBC driver still tries to connect to Vertica without supplying a password.

You can use the PromptOnNoPassword DSN parameter to force ODBC driver to treat the password as a required connection property. This parameter is useful if you do not want to store passwords in DSN entries. Passwords saved in DSN entries are insecure, since they are stored as clear text in the Windows registry and therefore visible to other users on the same system.

There are two other factors which also decide whether the ODBC driver displays the Vertica Connection Dialog. These are (in order of priority):

- The SQLDriverConnect function call's DriverCompletion parameter.
- Whether the DSN or connection string contain a password

The following table shows how the PromptOnNoPassword DSN parameter, the DriverCompletion parameter of the SQLDriverConnect function, and whether the DSN or connection string contains a password interact to control whether the Vertica Connection dialog appears.

<table>
<thead>
<tr>
<th>PromptOnNoPassword Setting</th>
<th>DriverCompletion Value</th>
<th>DSN or Connection String Contains Password?</th>
<th>Vertica Connection Dialog Displays?</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>any value</td>
<td>SQL_DRIVER_PROMPT</td>
<td>any case</td>
<td>Yes</td>
<td>This DriverCompletion value forces the dialog to always appear, even if all required connection</td>
</tr>
<tr>
<td>PromptOnNoPassword Setting</td>
<td>DriverCompletion Value</td>
<td>DSN or Connection String Contains Password?</td>
<td>Vertica Connection Dialog Displays?</td>
<td>Notes</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------</td>
<td>---------------------------------------------</td>
<td>------------------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>any value</td>
<td>SQL_DRIVER_NOPROMPT</td>
<td>any case</td>
<td>No</td>
<td>This DriverCompletion value always prevents the dialog from appearing.</td>
</tr>
<tr>
<td>any value</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>Yes</td>
<td>No</td>
<td>Connection dialog displays if another required connection property is missing.</td>
</tr>
<tr>
<td>true</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>No</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>false (default)</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>No</td>
<td>No</td>
<td>Connection dialog displays if another required connection property is missing.</td>
</tr>
</tbody>
</table>

The following example code demonstrates using the PromptOnNoPassword DSN parameter along with a system DSN.

```sql
wstring connectionString = L"DSN=VerticaDSN;PromptOnNoPassword=1;";
retcode = SQLDriverConnect(
    hdbc,
    0,
    (SQLWCHAR*)connectString.c_str(),
    connectString.length(),
    OutConnStr,
    255,
    &OutConnStrLen,
```
No Password Entry vs. Empty Passwords

There is a difference between not having a password property in the connection string or DSN and having an empty password. The PromptOnNoPassword DSN parameter only has an effect if the connection string or DSN does not have a PWD property (which holds the user's password). If it does, even if it is empty, PromptOnNoPassword will not prompt the Windows ODBC driver to display the Vertica Connection Dialog.

This difference can cause confusion if you are using a DSN to provide the properties for your connection. Once you enter a password for a DSN connection in the Windows ODBC Manager and save it, Windows adds a PWD property to the DSN definition in the registry. If you later delete the password, the PWD property remains in the DSN definition—value is just set to an empty string. The PWD property is created even if you just use the Test button on the ODBC Manager dialog to test the DSN and later clear it before saving the DSN.

Once the password has been set, the only way to remove the PWD property from the DSN definition is to delete it using the Windows Registry Editor:

1. On the Windows Start menu, click Run.
2. In the Run dialog, type regedit, then click OK.
3. In the Registry Editor window, click Edit > Find (or press Ctrl+F).
4. In the Find window, enter the name of the DSN whose PWD property you want to delete and click OK.
5. If find operation did not locate a folder under the ODBC.INI folder, click Edit > Find Next (or press F3) until the folder matching your DSN's name is highlighted.

![Registry Editor](image)

6. Select the PWD entry and press Delete.

7. Click Yes to confirm deleting the value.

The DSN now does not have a PWD property and can trigger the connection dialog to appear when used along with PromptOnNoPassword=true and DriverConnect=SQL_DRIVER_COMPLETE.

**Setting the Locale for ODBC Sessions**

Vertica provides three ways to set the locale for an ODBC session:

- Specify the locale for all connections made using the DSN:
  - On Linux and other UNIX-like platforms: Creating an ODBC DSN for Linux, AIX, and HP-UX
  - On Windows platforms, set the locale in the ODBC DSN configuration editor's Locale field on the Server Settings tab. See Creating an ODBC DSN for Windows Clients for detailed information.
- Set the Locale connection parameter in the connection string in SQLDriverConnect() function.

For example:

```sql
SQLDriverConnect(conn, NULL, (SQLCHAR*)"DSN=Vertica;Locale=en_GB@collation=binary", SQL_NTS, szConnOut, sizeof(szConnOut), &iAvailable, SQL_DRIVER_NOPROMPT)
```

- Use the SQLSetConnectAttr() method with the SQL_ATTR_VERTICA_LOCALE constant and specify the ICU string as the attribute value. See the example below.

Notes

- Having the client system use a non-Unicode locale (such as setting LANG=C on Linux platforms) and using a Unicode locale for the connection to Vertica can result in errors such as "(10170) String data right truncation on data from data source." If data received from Vertica isn't in UTF-8 format. The driver allocates string memory based on the system's locale setting, and non-UTF-8 data can trigger an overrun. You can avoid these errors by always using a Unicode locale on the client system.

If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.

- ODBC applications can be in either ANSI or Unicode mode:
  - If Unicode, the encoding used by ODBC is UCS-2.
  - If ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 on the database server.

The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.

- If the end-user application is not already in UCS-2, the application is responsible for converting the input data to UCS-2, or unexpected results could occur. For example:
  - On non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
  - Or the symbol provided in the alternate encoding could be a valid UCS-2 symbol; in this case, incorrect data is inserted into the database.
ODBC applications should set the correct server session locale using SQLSetConnectAttr (if different from database-wide setting) in order to set the proper collation and string functions behavior on server.

The following example code demonstrates setting the locale using both the connection string and through the SQLSetConnectAttr() function.

```c
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
#include <windows.h>

// SQL include files that define data types and ODBC API
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

// Vertica-specific definitions. This include file is located as
// /opt/vertica/include on database hosts.
#include <verticaodbc.h>

int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdEnv);
    if (!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Set the ODBC version we are going to use to 3.
    ret = SQLSetEnvAttr(hdEnv, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_QV_ODBC3, SQL_IS_UINTEGER);
    if (!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC 3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application version to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdEnv, &hd1Dbc);
    if (!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.\n");
    }
    // Connect to the database using SQLDriverConnect
    printf("Connecting to database.\n");
    // Set the locale to English in Great Britain.
    const char *connStr = "DSN=ExampleDB;locale=en_GB;" "UID=dbadmin;PWD=password123";
    ret = SQLDriverConnect(hd1Dbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
                            NULL, 0, NULL, SQL_DRIVER_NOPROMPT);
```

Vertica Analytic Database (9.1.x)  Page 4653 of 6174
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Get the Locale
char locale[256];
SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale), 0);
printf("Locale is set to: %s\n", locale);
// Set the locale to a new value
const char* newLocale = "en_GB";
SQLSetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)newLocale, SQL_nts);

// Get the Locale again
SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale), 0);
printf("Locale is now set to: %s\n", locale);
// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
}

AUTOCOMMIT and ODBC Transactions

The AUTOCOMMIT connection attribute controls whether INSERT, ALTER, COPY and other
data-manipulation statements are automatically committed after they complete. By default,
AUTOCOMMIT is enabled—all statements are committed after they execute. This is often not
the best setting to use, since it is less efficient. Also, you often want to control whether a set of
statements are committed as a whole, rather than have each individual statement committed.
For example, you may only want to commit a series of inserts if all of the inserts succeed. With
AUTOCOMMIT disabled, you can roll back the transaction if one of the statements fail.

If AUTOCOMMIT is on, the results of statements are committed immediately after they are
executed. You cannot roll back a statement executed in AUTOCOMMIT mode.

For example, when AUTOCOMMIT is on, the following single INSERT statement is automatically
committed:

ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
"'Smith, Sam', '123-456-789');", SQL_nts);
If AUTOCOMMIT is off, you need to manually commit the transaction after executing a statement. For example:

```c
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500," " 'Smith, Sam', '123-456-789');", SQL_NTS);
// Other inserts and data manipulations
// Commit the statements(s)
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
```

The inserted row is only committed when you call SQLEndTran(). You can roll back the INSERT and other statements at any point before committing the transaction.

**Note:** Prepared statements cache the AUTOCOMMIT setting when you create them using SQLPrepare(). Later changing the connection's AUTOCOMMIT setting has no effect on the AUTOCOMMIT settings of previously created prepared statements. See Using Prepared Statements for details.

The following example demonstrates turning off AUTOCOMMIT, executing an insert, then manually committing the transaction.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
#include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
    }
    // Some insert
    ret = SQLExecDirect(hd1Dbc, (SQLCHAR*)"UPDATE customers SET value=500 WHERE id=500;", SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not execute direct statement.\n");
        exit(EXIT_FAILURE);
    }
    // Manually commit
    ret = SQLEndTran(SQL_HANDLE_DBC, hd1Dbc, SQL_COMMIT);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not commit the transaction.\n");
        exit(EXIT_FAILURE);
    }
    // Other inserts...
    return 0;
}
```
exit(EXIT_FAILURE);
}
else {
    printf("Allocated Database handle.\n");
}

// Connect to the database
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
               SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
               (SQLCHAR*)passwd, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Get the AUTOCOMMIT state
SQLINTEGER autoCommitState;
SQLGetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, &autoCommitState, 0, NULL);
printf("Autocommit is set to: %d\n", autoCommitState);

// Disable AUTOCOMMIT
printf("Disabling autocommit.\n");
ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF,
                        SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not disable autocommit.\n");
    exit(EXIT_FAILURE);
}

// Get the AUTOCOMMIT state again
SQLGetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, &autoCommitState, 0, NULL);
printf("Autocommit is set to: %d\n", autoCommitState);

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create a table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
              SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers 
    ""
    "(CustID int, CustName varchar(100), Phone_Number char(15));",
              SQL_NTS);

// Insert a single row.
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,
    ""
    "'Smith, Sam', '123-456-789');",
    SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not perform single insert.\n");
} else {
    printf("Performed single insert.\n");
}
// Need to commit the transaction before closing, since autocommit is
// disabled. Otherwise SQLDisconnect returns an error.
printf("Committing transaction.\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
   printf("Error committing transaction.\n");
   exit(EXIT_FAILURE);
}

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect(hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
   printf("Error disconnecting from database. Transaction still open?\n");
   exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
}

Running the above code results in the following output:

Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Autocommit is set to: 1
Disabling autocommit.
Autocommit is set to: 0
Performed single insert.
Committing transaction.
Free handles.

Note: You can also disable AUTOCOMMIT in the ODBC connection string. See Setting DSN Connection Properties for more information.

Retrieving Data Through ODBC

To retrieve data through ODBC, you execute a query that returns a result set (SELECT, for example), then retrieve the results using one of two methods:

- Use the SQLFetch() function to retrieve a row of the result set, then access column values in the row by calling SQLGetData().

- Use the SQLBindColumn() function to bind a variable or array to a column in the result set, then call SQLExtendedFetch() or SQLFetchScroll() to read a row of the result set and insert its values into the variable or array.
In both methods you loop through the result set until you either reach the end (signaled by the SQL_NO_DATA return status) or encounter an error.

Note: Vertica supports one cursor per connection. Attempting to use more than one cursor per connection will result in an error. For example, you receive an error if you execute a statement while another statement has a result set open.

The following code example demonstrates retrieving data from Vertica by:

1. Connecting to the database.
2. Executing a SELECT statement that returns the IDs and names of all tables.
3. Binds two variables to the two columns in the result set.
4. Loops through the result set, printing the ids and name values.

```c++
// Demonstrate running a query and getting results by querying the tables
// system table for a list of all tables in the current schema.
// Some standard headers
#include <stdlib.h>
#include <sstream>
#include <iostream>
#include <assert.h>

// Standard ODBC headers
#include <sql.h>
#include <sqlytypes.h>
#include <sqlext.h>

// Use std namespace to make output easier
using namespace std;

// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT i, MsgLen;
    SQLRETURN ret2;
    SQLCHAR SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER NativeError;
    i = 1;
    cout << endl;
    while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
        Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
        cout << "error record #" << i++ << endl;
        cout << "sqlstate: " << SqlState << endl;
        cout << "detailed msg: " << Msg << endl;
        cout << "native error code: " << NativeError << endl;
    }
}
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
```
ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
assert(SQL_SUCCEEDED(ret));
// Tell ODBC that the application uses ODBC 3.
ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
                   (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
assert(SQL_SUCCEEDED(ret));
// Allocate a database handle.
SQLHDBC hdlDbc;
ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
assert(SQL_SUCCEEDED(ret));
// Connect to the database
cout << "Connecting to database." << endl;
const char* dsnName = "ExampleDB";
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName, SQL_NTSQL,
                 (SQLCHAR*)userID, SQL_NTSQL,
                 (SQLCHAR*)passwd, SQL_NTSQL);
if (!SQL_SUCCEEDED(ret)) {
    cout << "Could not connect to database" << endl;
    reportError<SQLHDBC>(SQL_HANDLE_DBC, hdlDbc);
    exit(EXIT_FAILURE);
} else {
    cout << "Connected to database." << endl;
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
assert(SQL_SUCCEEDED(ret));
// Execute a query to get the names and IDs of all tables in the schema
// search p[ath] (usually public).
ret = SQLExecDirect( hdlStmt, (SQLCHAR*)"SELECT table_id, table_name "
                   "FROM tables ORDER BY table_name", SQL_NTSQL);
if (!SQL_SUCCEEDED(ret)) {
    // Report error an go no further if statement failed.
    cout << "Error executing statement." << endl;
    reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);
    exit(EXIT_FAILURE);
} else {

    // Query succeeded, so bind two variables to the two columns in the
    // result set,
    cout << "Fetching results..." << endl;
    SQLBIGINT table_id;  // Holds the ID of the table.
    SQLTCHAR table_name[256]; // buffer to hold name of table
    ret = SQLBindCol(hdlStmt, 1, SQL_C_SBIGINT, (SQLPOINTER)&table_id,
                    sizeof(table_id), NULL);
    ret = SQLBindCol(hdlStmt, 2, SQL_C_TCHAR, (SQLPOINTER)&table_name,
                    sizeof(table_name), NULL);

    // Loop through the results,
    while( SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT,1)) ) {
        // Print the bound variables, which now contain the values from the
        // fetched row.
        cout << table_id << " | " << table_name << endl;
    }
}
Running the example code in the vmart database produces output similar to this:

```c
// See if loop exited for reasons other than running out of data
if (ret != SQL_NO_DATA) {
    // Exit for a reason other than no more data... report the error.
    reportError<SQLHDBC>( SQL_HANDLE_STMT, hstmt );
}

// Clean up by shutting down the connection
cout << "Free handles." << endl;
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    cout << "Error disconnecting. Transaction still open?" << endl;
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hstmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

Loading Data Through ODBC

A primary task for many client applications is loading data into the Vertica database. There are several different ways to insert data using ODBC, which are covered by the topics in this section.
Using a Single Row Insert

The easiest way to load data into Vertica is to run an INSERT SQL statement using the SQLExecuteDirect function. However this method is limited to inserting a single row of data.

```sql
ret = SQLExecDirect(hstmt, (SQLTCHAR*)"INSERT into Customers values"
    "(1,'abca','efgh','1')", SQL_NTS);
```

Using Prepared Statements

Vertica supports using server-side prepared statements with both ODBC and JDBC. Prepared statements let you define a statement once, and then run it many times with different parameters. The statement you want to execute contains placeholders instead of parameters. When you execute the statement, you supply values for each placeholder.

Placeholders are represented by question marks (?) as in the following example query:

```
SELECT * FROM public.inventory_fact WHERE product_key = ?
```

Server-side prepared statements are useful for:

- Optimizing queries. Vertica only needs to parse the statement once.
- Preventing SQL injection attacks. A SQL injection attack occurs when user input is either incorrectly filtered for string literal escape characters embedded in SQL statements or user input is not strongly typed and thereby unexpectedly run. Since a prepared statement is parsed separately from the input data, there is no chance the data can be accidentally executed by the database.
- Binding direct variables to return columns. By pointing to data structures, the code doesn’t have to perform extra transformations.

The following example demonstrates a using a prepared statement for a single insert.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
#include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Some constants for the size of the data to be inserted.
#define CUST_NAME_LEN 50
```
```c
#define PHONE_NUM_LEN 15
#define NUM_ENTRIES 4

int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.
");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.
");
    }
    // Allocate a database handle.
    SQLDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    // Connect to the database
    printf("Connecting to database.
");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hd1Dbc, (SQLCHAR*)dsnName,
                     SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
                     (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.

exit(EXIT_SUCCESS);

Using Batch Inserts

You use batch inserts to insert chunks of data into the database. By breaking the data into batches, you can monitor the progress of the load by receiving information about any rejected rows after each batch is loaded. To perform a batch load through ODBC, you typically use a prepared statement with the parameters bound to arrays that contain the data to be loaded. For each batch, you load a new set of data into the arrays then execute the prepared statement.

When you perform a batch load, Vertica uses a COPY statement to load the data. Each additional batch you load uses the same COPY statement. The statement remains open until you end the transaction, close the cursor for the statement, or execute a non-INSERT statement.

Using a single COPY statement for multiple batches improves batch loading efficiency by:

- reducing the overhead of inserting individual batches
- combining individual batches into larger ROS containers
Note: If the database connection has AUTOCOMMIT enabled, then the transaction is automatically committed after each batch insert statement which closes the COPY statement. Leaving AUTOCOMMIT enabled makes your batch load much less efficient, and can cause added overhead in your database as all of the smaller loads are consolidated.

Even though Vertica uses a single COPY statement to insert multiple batches within a transaction, you can locate which (if any) rows were rejected due to invalid row formats or data type issues after each batch is loaded. See Finding the Number of Accepted Rows for details.

Note: While you can find rejected rows during the batch load transaction, other types of errors (such as running out of disk space or a node shutdown that makes the database unsafe) are only reported when the COPY statement ends.

Since the batch loads share a COPY statement, errors in one batch can cause earlier batches in the same transaction to be rolled back.

Batch Insert Steps

The steps your application needs to take in order to perform an ODBC Batch Insert are:

1. Connect to the database.
2. Disable autocommit for the connection.
3. Create a prepared statement that inserts the data you want to load.
4. Bind the parameters of the prepared statement to arrays that will contain the data you want to load.
5. Populate the arrays with the data for your batches.
6. Execute the prepared statement.
7. Optionally, check the results of the batch load to find rejected rows.
8. Repeat the previous three steps until all of the data you want to load is loaded.
9. Commit the transaction.
10. Optionally, check the results of the entire batch transaction.

The following example code demonstrates a simplified version of the above steps.
// Some standard headers
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
#include <windows.h>

// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

int main()
{
    // Number of data rows to insert
    const int NUM_ENTRIES = 4;

    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.
");
    }

    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.
");
    }

    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.
");
    }

    // Connect to the database
    printf("Connecting to database.
");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hd1Dbc, (SQLCHAR*)dsnName, SQL_NTS,
                     (SQLCHAR*)userID, SQL_NTS,
                     (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.
");
    }

    // Disable AUTOCOMMIT
    printf("Disabling autocommit.
");
ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not disable autocommit.\n");
    exit(EXIT_FAILURE);
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create a table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers", SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers 
" "(CustID int, CustName varchar(100), Phone_Number char(15))", SQL_NTS);

// Create the prepared statement. This will insert data into the table we created above.
printf("Creating prepared statement\n");
ret = SQLPrepare(hdlStmt, (SQLTCHAR*)"INSERT INTO customers (CustID, " "CustName, Phone_Number) VALUES(?,?,?)", SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not create prepared statement\n");
    exit(EXIT_FAILURE);
} else {
    printf("Created prepared statement.\n");
}

// This is the data to be inserted into the database.
SQLCHAR custNames[][50] = { "Allen, Anna", "Brown, Bill", "Chu, Cindy", "Dodd, Don"};
SQLINTEGER custIDs[] = { 100, 101, 102, 103};

// Bind the data arrays to the parameters in the prepared SQL statement. First is the custID.
ret = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_LONG, SQL_INTEGER, 0, 0, (SQLPOINTER)custIDs, sizeof(SQLINTEGER), NULL);
if(!SQL_SUCCEEDED(ret)) {

    exit(EXIT_FAILURE);
} else {
    printf("Bound CustIDs array to prepared statement\n");
}

// Bind CustNames
ret = SQLBindParameter(hdlStmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_VARCHAR, 50, 0, (SQLPOINTER)custNames, 50, NULL);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind custNames\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound CustNames array to prepared statement\n");
}

// Bind phoneNums
ret = SQLBindParameter(hdlStmt, 3, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_CHAR, 15, 0, (SQLPOINTER)phoneNums, 15, NULL);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind phoneNums\n");
    exit(EXIT_FAILURE);
}
} else {
    printf("Bound phoneNums array to prepared statement\n");
}

// Tell the ODBC driver how many rows we have in the array.
ret = SQLSetStmtAttr( hd1Stmt, SQL_ATTR_PARAMSET_SIZE, (SQLPOINTER)NUM_ENTRIES, 0 );
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind set parameter size\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound phoneNums array to prepared statement\n");
}

// Add multiple batches to the database. This just adds the same batch of data four times for simplicity's sake. Each call adds the 4 rows into the database.
for (int batchLoop=1; batchLoop<=5; batchLoop++) {
    // Execute the prepared statement, loading all of the data in the arrays.
    printf("Adding Batch #%d...", batchLoop);
    ret = SQLExecute(hdlStmt);
    if(!SQL_SUCCEEDED(ret)) {
        printf("not successful!\n");
    } else {
        printf("successful.\n");
    }
}

// Done with batches, commit the transaction
printf("Committing transaction\n");
ret = SQLExecOpt(hdlStmt, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not commit transaction\n");
} else {
    printf("Committed transaction\n");
}

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
}

The result of running the above code is shown below.

Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Creating prepared statement
Created prepared statement.
Bound CustIDs array to prepared statement
Bound CustNames array to prepared statement
Bound phoneNums array to prepared statement
Adding Batch #1...successful.
Adding Batch #2...successful.
Adding Batch #3...successful.
Adding Batch #4...successful.
Adding Batch #5...successful.
Committing transaction
Committed transaction
Free handles.

The resulting table looks like this:

```sql
=> SELECT * FROM customers;
CustID | CustName   | Phone_Number
-------+-----------+-------------
 100   | Allen, Anna| 1-617-555-1234
 101   | Brown, Bill| 1-781-555-1212
 102   | Chu, Cindy | 1-508-555-4321
 103   | Dodd, Don  | 1-617-555-4444
 100   | Allen, Anna| 1-617-555-1234
 101   | Brown, Bill| 1-781-555-1212
 102   | Chu, Cindy | 1-508-555-4321
 103   | Dodd, Don  | 1-617-555-4444
 100   | Allen, Anna| 1-617-555-1234
 101   | Brown, Bill| 1-781-555-1212
 102   | Chu, Cindy | 1-508-555-4321
 103   | Dodd, Don  | 1-617-555-4444
(20 rows)
```

Note: An input parameter bound with the SQL_C_NUMERIC data type uses the default numeric precision (37) and the default scale (0) instead of the precision and scale set by the SQL_NUMERIC_STRUCT input value. This behavior adheres to the ODBC standard. If you do not want to use the default precision and scale, use SQLSetDescField() or SQLSetDescRec() to change them in the statement's attributes.

Tracking Load Status (ODBC)

After loading a batch of data, your client application can get the number of rows that were processed and find out whether each row was accepted or rejected.
Finding the Number of Accepted Rows

To get the number of rows processed by a batch, you add an attribute named SQL_ATTR_PARAMS_PROCESSED_PTR to the statement object that points to a variable to receive the number rows:

```c
SQLULEN rowsProcessed;
SQLSetStmtAttr(hstmt, SQL_ATTR_PARAMS_PROCESSED_PTR, &rowsProcessed, 0);
```

When your application calls SQLExecute() to insert the batch, the Vertica ODBC driver saves the number of rows that it processed (which is not necessarily the number of rows that were successfully inserted) in the variable you specified in the SQL_ATTR_PARAMS_PROCESSED_PTR statement attribute.
Finding the Accepted and Rejected Rows

Your application can also set a statement attribute named SQL_ATTR_PARAM_STATUS_PTR that points to an array where the ODBC driver can store the result of inserting each row:

```c
SQLUSMALLINT rowResults[NUM_ENTRIES];
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAM_STATUS_PTR, rowResults, 0);
```

This array must be at least as large as the number of rows being inserted in each batch.

When your application calls SQLExecute to insert a batch, the ODBC driver populates the array with values indicating whether each row was successfully inserted (SQL_PARAM_SUCCESS or SQL_PARAM_SUCCESS_WITH_INFO) or encountered an error (SQL_PARAM_ERROR).

The following example expands on the example shown in Using Batch Inserts to include reporting the number of rows processed and the status of each row inserted.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
#include <windows.h>

// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT i, MsgLen;
    SQLRETURN ret2;
    SQLCHAR SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER NativeError;
    i = 1;
    printf("\n");
    while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
                          Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
        printf("error record %d\n", i);
        printf("sqlstate: %s\n", SqlState);
        printf("detailed msg: %s\n", Msg);
        printf("native error code: %d\n\n", NativeError);
        i++;
    }
}

// Add multiple batches to the database. This just adds the same // batch of data over and over again for simplicity's sake.
for (int batchLoop=1; batchLoop<=5; batchLoop++) {
    // Execute the prepared statement, loading all of the data // in the arrays.
printf("Adding Batch #%d...", batchLoop);
ret = SQLExecute(hdlStmt);
if(!SQLUCCEEDED(ret)) {
    reportError<SQLHDBC>( SQL_HANDLE_STMT, hdlStmt );
    exit(EXIT_FAILURE);
}
// Number of rows processed is in rowsProcessed
printf("Params processed: %d\n", rowsProcessed);
printf("Results of inserting each row:\n");
int i;
for (i = 0; i<NUM_ENTRIES; i++) {
    SQLUSMALLINT result = rowResults[i];
    switch(rowResults[i]) {
    case SQL_PARAM_SUCCESS:
    case SQL_PARAM_SUCCESS_WITH_INFO:
        printf(" Row %d inserted successfully\n", i+1);
        break;
    case SQL_PARAM_ERROR:
        printf(" Row %d was not inserted due to an error.", i+1);
        break;
    default:
    printf(" Row %d had some issue with it: %d\n", i+1, result);
    }
}
// Done with batches, commit the transaction
printf("Commit Transaction\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQLUCCEEDED(ret)) {
    reportError<SQLHDBC>( SQL_HANDLE_STMT, hdlStmt );
}

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect(hdlDbc);
if(!SQLUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
}

Running the example code produces the following output:

- Allocated an environment handle.
- Set application to ODBC 3.
- Allocated Database handle.
- Connecting to database.
- Connected to database.
- Creating table.
- Created table.
- Creating prepared statement
- Created prepared statement.
- Bound CustIDs array to prepared statement
- Bound CustNames array to prepared statement
Bound phoneNums array to prepared statement

Error Handling During Batch Loads

When loading individual batches, you can find information on how many rows were accepted and what rows were rejected (see Finding the Number of Accepted Rows for details). Other errors, such as disk space errors, do not occur while inserting individual batches. This behavior is caused by having a single COPY statement perform the loading of multiple consecutive batches. Using the single COPY statement makes the batch load process perform much faster. It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Your bulk loading application should check for errors when the COPY statement closes. Normally, you force the COPY statement to close by calling the SQLEndTran() function to end the transaction. You can also force the COPY statement to close by closing the cursor using the SQLCloseCursor() function, or by setting the database connection's AutoCommit property to true before inserting the last batch in the load.
**Note:** The COPY statement also closes if you execute any non-insert statement. However, having to deal with errors from the COPY statement in what might be an otherwise-unrelated query is not intuitive, and can lead to confusion and a harder to maintain application. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

**Using the COPY Statement**

The COPY statement lets you bulk load data from a file on stored on a database node into the Vertica database. This method is the most efficient way to load data into Vertica because the file resides on the database server. One drawback is that only a database superuser can use COPY, since it requires privilege in order to access the filesystem of the database node.

One drawback of using COPY instead of performing batch loads is that you can only get results of the load (the number of accepted and rejected rows) when the COPY statement has finished. With batch loads, you can monitor the progress as batches are inserted. The ability to monitor the progress of a load can be a useful feature if you want to stop loading if a large portion of the data is being rejected.

A primary concern when bulk loading data using COPY is deciding whether the data should be loaded directly into ROS using the DIRECT option, or by using the AUTO method (loading into WOS until it fills, then loading into ROS). You should load directly into the ROS when your transaction will load a large (more than 100MB of data or so) amount of data.

**Note:** The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the COPY command. Specify a local path and filename for these modifiers when executing a COPY query from the driver.

The following example loads data into the WOS (Write Optimized Store) until it fills, then stores additional data directly in ROS (Read Optimized Store).

```sql
ret=SQLExecDirect(hdlStmt, (SQLCHAR*)"COPY customers "
    "FROM '/data/customers.txt' AUTO",SQL_NTS);
```

The following example loads data into the ROS (Read Optimized Store).

```sql
ret=SQLExecDirect(hdlStmt, (SQLCHAR*)"COPY customers "
    "FROM '/data/customers.txt' DIRECT",SQL_NTS);
```

See the [COPY](https://docs.vertica.com/9.1.x/) statement in the SQL Reference Manual for more information about its syntax and use.

The following example demonstrates using the COPY command.
// Some standard headers
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
#include <windows.h>

// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

// Helper function to determine if an ODBC function call returned
// successfully.
bool notSuccess(SQLRETURN ret) {
    return (ret != SQL_SUCCESS && ret != SQL_SUCCESS_WITH_INFO);
}

int main() {
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(notSuccess(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
            (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(notSuccess(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hd1Dbc, (SQLCHAR*)dsnName,
            SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
            (SQLCHAR*)passwd, SQL_NTS);
    if(notSuccess(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }
    // Disable AUTOCOMMIT
    printf("Disabling autocommit.\n");
    ret = SQLSetConnectAttr(hd1Dbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);
    if(notSuccess(ret)) {
printf("Could not disable autocommit.\n");
exit(EXIT_FAILURE);
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
SQL_NTSEmpty);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers"
" (LastName char(50) NOT NULL, FirstName char(50), Email char(50), 
" Phone_Number char(15));",
SQL_NTSEmpty);

// Run the copy command to load data into ROS.
ret=SQLExecDirect(hdlStmt, (SQLCHAR*)"COPY customers 
" FROM '/data/customers.txt' DIRECT",
SQL_NTSEmpty);
if(notSuccess(ret)) {
    printf("Data was not successfully loaded.\n");
    exit(EXIT_FAILURE);
} else {
    // Get number of rows added.
    SQLLEN numRows;
    ret=SQLRowCount(hdlStmt, &numRows);
    printf("Successfully inserted %d rows.\n", numRows);
}

// Done with batches, commit the transaction
printf("Committing transaction\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(notSuccess(ret)) {
    printf("Could not commit transaction\n");
} else {
    printf("Committed transaction\n");
}

// Clean up
printf("Free handles.\n");
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

The example prints the following when run:

Allocated an environment handle.
Set application to ODBC 3.
Connecting to database.
Connected to database.
Disabling autocommit.
Successfully inserted 10001 rows.
Committing transaction
Committed transaction
Streaming Data From the Client Using COPY LOCAL

The LOCAL option of the SQL COPY statement lets you stream data from a file on a client system to your Vertica database. This statement works through the ODBC driver, making the task of transferring data files from the client to the server much easier.

The LOCAL option of COPY works transparently through the ODBC driver. Just have your client application execute a statement containing a COPY LOCAL statement, and the ODBC driver will read and stream the data file from the client to the server.

Note: The COPY LOCAL statement must be the first statement within a query containing multiple statements. If you attempt to use COPY LOCAL as the second or later statement, you will receive the error "COPY LOCAL statement must be the first statement in a multiple statement query."

This example demonstrates loading data from the client system using the COPY LOCAL statement:

```c
#include <stdio.h>
#include <stdlib.h>
#include <windows.h>
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UTFSTRING);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
}```
// Allocate a database handle.
SQLHDBC hdlDbc;
ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate a database handle.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Set application to ODBC 3.\n");
}

// Connect to the database
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
                 SQL_NTSS, (SQLCHAR*)userID, SQL_NTSS,
                 (SQLCHAR*)passwd, SQL_NTSS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Set up a statement handle
SQLHSTMT hd1Stmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hd1Stmt);

// Create table to hold the data
SQLExecDirect(hd1Stmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
              SQL_NTSS);
SQLExecDirect(hd1Stmt, (SQLCHAR*)"CREATE TABLE customers"
             "("Last_Name char(50) NOT NULL, First_Name char(50),Email char(50),"n"
             "Phone_Number char(15));",
              SQL_NTSS);

// Run the copy command to load data into ROS.
ret=SQLExecDirect(hd1Stmt, (SQLCHAR*)"COPY customers "
                 "FROM LOCAL '/home/dbadmin/customers.txt' DIRECT",
                 SQL_NTSS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Data was not successfully loaded.\n");
    exit(EXIT_FAILURE);
} else {
    // Get number of rows added.
    SQLLEN numRows;
    ret=SQLRowCount(hd1Stmt, &numRows);
    printf("Successfully inserted %d rows.\n", numRows);
}

// COPY commits automatically, unless it is told not to, so
// there is no need to commit the transaction.

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect( hd1Dbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
}
exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

This example is essentially the same as the example shown in Using the COPY Statement, except it uses the COPY statement's LOCAL option to load data from the client system rather than from the filesystem of the database node.

Note: On Windows clients, the path you supply for the COPY LOCAL file is limited to 216 characters due to limitations in the Windows API.

Programming JDBC Client Applications

The Vertica JDBC driver provides you with a standard JDBC API. If you have accessed other databases using JDBC, you should find accessing Vertica familiar. This section explains how to use the JDBC to connect your Java application to Vertica.

You must first install the JDBC client driver on all client systems that will be accessing the Vertica database. For installation instructions, see Installing the Vertica Client Drivers.

For more information about JDBC:

- Vertica Analytic Database JDBC Documentation (Vertica extensions)
- An Introduction to JDBC, Part 1

JDBC Feature Support

The Vertica JDBC driver complies with the JDBC 4.0 standards (although it does not implement all of the optional features in them). Your application can use the DatabaseMetaData class to determine if the driver supports a particular feature it wants to use. In addition, the driver implements the Wrapper interface, which lets your client code discover Vertica-specific
extensions to the JDBC standard classes, such as VerticaConnection and VerticaStatement classes.

Some important facts to keep in mind when using the Vertica JDBC driver:

- Cursors are forward only and are not scrollable. Result sets cannot be updated.
- A connection supports executing a single statement at any time. If you want to execute multiple statements simultaneously, you must open multiple connections.
- Because Vertica does not have stored procedures, CallableStatement is not supported. The DatabaseMetaData.getProcedures() and .getProcedureColumns() methods return information about SQL functions (including User Defined Functions) instead of stored procedures.

Multiple SQL Statement Support

The Vertica JDBC driver can execute strings containing multiple statements. For example:

```java
stmt.executeUpdate("CREATE TABLE t(a INT);INSERT INTO t VALUES(10);");
```

Only the Statement interface supports executing strings containing multiple SQL statements. You cannot use multiple statement strings with PreparedStatement. COPY statements that copy a file from a host file system work in a multiple statement string. However, client COPY statements (COPY FROM STDIN) do not work.

Multiple Batch Conversion to COPY Statements

The Vertica JDBC driver converts all batch inserts into Vertica COPY statements. If you turn off your JDBC connection's AutoCommit property, the JDBC driver uses a single COPY statement to load data from sequential batch inserts which can improve load performance by reducing overhead. See Batch Inserts Using JDBC Prepared Statements for details.

Multiple JDBC Version Support

The Vertica JDBC driver implements both JDBC 3.0 and JDBC 4.0 compliant interfaces. The interface that the driver returns to your application depends on the JVM version on which it is running. If your application is running on a 5.0 JVM, the driver supplies your application with JDBC 3.0 classes. If your application is running on a 6.0 or later JVM, the driver supplies it with JDBC 4.0 classes.
Multiple Active Result Sets (MARS)

The Vertica JDBC driver supports Multiple Active Result Sets (MARS). MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.
Creating and Configuring a Connection

Before your Java application can interact with Vertica, it must create a connection. Connecting to Vertica using JDBC is similar to connecting to most other databases.

Importing SQL Packages

Before creating a connection, you must import the Java SQL packages. A simple way to do so is to import the entire package using a wildcard:

```java
import java.sql.*;
```

You may also want to import the `Properties` class. You can use an instance of this class to pass connection properties when instantiating a connection, rather than encoding everything within the connection string:

```java
import java.util.Properties;
```

If your application needs to run in a Java 5 JVM, it uses the older JDBC 3.0-compliant driver. This driver requires that you to manually load the Vertica JDBC driver using the `Class.forName()` method:

```java
// Only required for old JDBC 3.0 driver
try {
    Class.forName("com.vertica.jdbc.Driver");
} catch (ClassNotFoundException e) {
    // Could not find the driver class. Likely an issue with finding the .jar file.
    System.err.println("Could not find the JDBC driver class.");
    e.printStackTrace();
    return; // Exit. Cannot do anything further.
}
```

Your application may run in a Java 6 or later JVM. If so, then the JVM automatically loads the Vertica JDBC 4.0-compatible driver without requiring the call to `Class.forName`. However, making this call does not adversely affect the process. Thus, if you want your application to be compatible with both Java 5 and Java 6 (or later) JVMs, it can still call `Class.forName`.

Opening the Connection

With SQL packages imported, you are ready to create your connection by calling the `DriverManager.getConnection()` method. You supply this method with at least the following information:
• The IP address or host name of a node in the database cluster:
  
  You can provide an IPv4 address, IPv6 address, or host name.

  In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.

• Port number for the database

• Name of the database

• Username of a database user account

• Password of the user (if the user has a password)

The first three parameters are always supplied as part of the connection string, a URL that tells the JDBC driver where to find the database. The format of the connection string is:

"jdbc:vertica://VerticaHost:portNumber/databaseName"

The first portion of the connection string selects the Vertica JDBC driver, followed by the location of the database.

You can provide the last two parameters, username and password, to the JDBC driver, in one of three ways:

• As part of the connection string. The parameters are encoded similarly to URL parameters:

  "jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password"

• As separate parameters to DriverManager.getConnection():

  ```java
  Connection conn = DriverManager.getConnection(
      "jdbc:vertica://VerticaHost:portNumber/databaseName",
      "username", "password");
  ```

• In a Properties object:

  ```java
  Properties myProp = new Properties();
  myProp.put("user", "username");
  myProp.put("password", "password");
  Connection conn = DriverManager.getConnection(
      "jdbc:vertica://VerticaHost:portNumber/databaseName", myProp);
  ```

Of these three methods, the Properties object is the most flexible because it makes passing additional connection properties to the getConnection() method easy. See Connection
Properties and Setting and Getting Connection Property Values for more information about the additional connection properties.

If there is any problem establishing a connection to the database, the getConnection() method throws a SQLException on one of its subclasses. To prevent an exception, enclose the method within a try-catch block, as shown in the following complete example of establishing a connection.

```java
import java.sql.*;
import java.util.Properties;

public class VerySimpleVerticaJDBCExample {
    public static void main(String[] args) {
        /*
         * If your client needs to run under a Java 5 JVM, it will use the older
         * JDBC 3.0-compliant driver, which requires you manually load the
         * driver using Class.forName
         */
        /*
         * try { Class.forName("com.vertica.jdbc.Driver"); } catch
         * (ClassNotFoundException e) { // Could not find the driver class.
         * Likely an issue // with finding the .jar file.
         * System.err.println("Could not find the JDBC driver class.");
         * e.printStackTrace(); return; // Bail out. We cannot do anything
         * further. }
         */
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        myProp.put("loginTimeout", "35");
        myProp.put("binaryBatchInsert", "true");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                    "jdbc:vertica://V_vmart_node0001.example.com:5433/vmart", myProp);
            System.out.println("Connected!");
            conn.close();
        } catch (SQLTransientConnectionException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
            System.out.print(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.print("Could not log into database: ");
            System.out.print(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```
Usage Considerations

- When you disconnect a user session, any uncommitted transactions are automatically rolled back.

- If your database is not compliant with your Vertica license terms, Vertica issues a SQLWarning when you establish the connection to the database. You can retrieve this warning using the `Connection.getWarnings()` method. See Managing Licenses in the Administrator's Guide for more information about complying with your license terms.

JDBC Connection Properties

You use connection properties to configure the connection between your JDBC client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number to use to connect to your database. They also let you tune the performance of your connection and enable logging.

You can set a connection property in any of three ways:

- Include the property name and value as part of the connection string you pass to the `DriverManager.getConnection()` method.

- Set the properties in a Properties object, and then pass it to the `DriverManager.getConnection()` method.

- Use the `VerticaConnection.setProperty()` method. With this approach, you can change only those connection properties that remain changeable after the connection has been established.

In addition, some of the standard JDBC connection properties have getters and setters on the `Connection` interface (such as `Connection.setAutocommit()`).

The following tables list the properties supported by the Vertica JDBC driver, and explain which are required in order for the connection to be established.

Connection Properties

The properties in the following table can only be set before you open the connection to the database. Two of them are required for every connection.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnSettings</td>
<td>A string containing SQL statements that the JDBC driver automatically runs after it connects to the database. You can use this property to set the locale or schema search path, or perform other configuration that the connection requires. Required?: No  Default Value: none</td>
</tr>
<tr>
<td>DisableCopyLocal</td>
<td>When set to true, disables file-based COPY LOCAL operations, including copying data from local files and using local files to store data and exceptions. You can use this property to prevent users from writing to and copying from files on a Vertica host, including an MC host. Required?: No  Default Value: false</td>
</tr>
<tr>
<td>Label</td>
<td>Sets a label for the connection on the server. This value appears in the client_label column of the V_MONITOR.SESSIONS system table. Required?: No  Default Value: jdbc-driver_version-random_number</td>
</tr>
<tr>
<td>LoginTimeout</td>
<td>The number of seconds Vertica waits for a connection to be established to the database before throwing a SQLException. Required?: No  Default Value: 0 (no TCP timeout)</td>
</tr>
<tr>
<td>SSL</td>
<td>When set to true, use SSL to encrypt the connection to the server. Vertica must be configured to handle SSL connections before you can establish an SSL-encrypted connection to it. See TLS/SSL Server Authentication in the Administrator's Guide. Required?: No  Default Value: false</td>
</tr>
<tr>
<td>Password</td>
<td>The password to use to log into the database. Required?: Yes  Default Value: none</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>User</strong></td>
<td>The database user name to use to connect to the database. Required?: Yes</td>
</tr>
<tr>
<td></td>
<td>Default Value: none</td>
</tr>
<tr>
<td><strong>ConnectionLoadBalance</strong></td>
<td>A Boolean value indicating whether the client is willing to have its connection redirected to another host in the Vertica database. This setting has an effect only if the server has also enabled connection load balancing. See About Native Connection Load Balancing in the Administrator's Guide for more information about native connection load balancing. Required?: No</td>
</tr>
<tr>
<td></td>
<td>Default Value: false</td>
</tr>
<tr>
<td><strong>BackupServerNode</strong></td>
<td>A string containing the host name or IP address of one or more hosts in the database. If the connection to the host specified in the connection string times out, the client attempts to connect to any host named in this string. The host name or IP address can also include a colon followed by the port number for the database. If no port number is specified, the client uses the standard port number (5433). Separate multiple host name or IP address entries with commas. Required?: No</td>
</tr>
<tr>
<td></td>
<td>Default Value: none</td>
</tr>
<tr>
<td><strong>PreferredAddressFamily</strong></td>
<td>The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>• ipv4—Connect to the server using IPv4.</td>
</tr>
<tr>
<td></td>
<td>• ipv6—Connect to the server using IPv6.</td>
</tr>
<tr>
<td></td>
<td>• none—Use the IP address provided by the DNS server.</td>
</tr>
<tr>

</table>
General Properties

The following properties can be set after the connection is established. None of these properties are required.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoCommit</td>
<td>Controls whether the connection automatically commits transactions. Set this parameter to false to prevent the connection from automatically committing its transactions. You often want to do this when you are bulk loading multiple batches of data and you want the ability to roll back all of the loads if an error occurs.</td>
</tr>
<tr>
<td></td>
<td>Previous Property NameNote: This property was called defaultAutoCommit in previous versions of the Vertica JDBC driver.</td>
</tr>
<tr>
<td></td>
<td>Set After Connection: Connection.setAutoCommit()</td>
</tr>
<tr>
<td></td>
<td>Default Value: true</td>
</tr>
<tr>
<td>DirectBatchInsert</td>
<td>Determines whether a batch insert stored data directly into ROS (true) or using AUTO mode (false).</td>
</tr>
<tr>
<td></td>
<td>When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS. For details about load options, see Choosing a Load Method.</td>
</tr>
<tr>
<td></td>
<td>Set After Connection: VerticaConnection.setProperty()</td>
</tr>
<tr>
<td></td>
<td>Default Value: false</td>

<tr>
<td>LogNameSpace</td>
<td>Restricts logging to just messages generated by a specific packages. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>• com.vertica — All messages generated by the JDBC driver</td>
</tr>
<tr>
<td></td>
<td>• com.vertica.jdbc — All messages generated by the top-level database.</td>
</tr>
</tbody>
</table>
### Property | Description
--- | ---
JDBC API | 
- `com.vertica.jdbc.kafka` — All messages generated by the JDBC KV API
- `com.vertica.jdbc.core` — Connection and statement settings
- `com.vertica.jdbc.io` — Client/server protocol messages
- `com.vertica.jdbc.util` — Miscellaneous utilities
- `com.vertica.jdbc.dataengine` — Query execution and result set iteration
- `com.vertica.dataengine` — Query execution and result set iteration

**Default Value:** none

| LogPath | Sets the path where the log file is written.  
**Default Value:** The current working directory |

### Kerberos Connection Parameters

Use the following parameters to set the service and host name principals for client authentication using Kerberos.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
</table>
| JAASConfigName              | Provides the name of the JAAS configuration that contains the JAAS Krb5LoginModule and its settings  
**Default Value:** verticajdbc |
| KerberosServiceName         | Provides the service name portion of the Vertica Kerberos principal, for example: `vertica/host@example.com`  
**Default Value:** vertica |
| KerberosHostname            | Provides the instance or host name portion of the Vertica Kerberos principal, for example: `vertica/host@example.com`  
**Default Value:** Value specified in the servername connection string property |
Routable Connection API Connection Parameters

Use the following parameters to set properties to enable and configure the connection for Routable Connection lookups.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EnableRoutableQueries</td>
<td>Enables Routable Connection lookup. See Routing JDBC Queries Directly to a Single Node</td>
</tr>
<tr>
<td></td>
<td>Default Value: false</td>
</tr>
<tr>
<td>FailOnMultiNodePlans</td>
<td>If the query plan requires more than one node, then the query fails. Only applicable when EnableRoutableQueries = true.</td>
</tr>
<tr>
<td></td>
<td>Default Value: true</td>
</tr>
<tr>
<td>MetadataCacheLifetime</td>
<td>The time in seconds to keep projection metadata. Only applicable when EnableRoutableQueries = true.</td>
</tr>
<tr>
<td></td>
<td>Default Value:</td>
</tr>
<tr>
<td>MaxPooledConnections</td>
<td>Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Only applicable when EnableRoutableQueries = true.</td>
</tr>
<tr>
<td></td>
<td>Default Value: 20</td>
</tr>
<tr>
<td>MaxPooledConnectionsPerNode</td>
<td>Per-node maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Only applicable when EnableRoutableQueries = true.</td>
</tr>
<tr>
<td></td>
<td>Default Value: 5</td>
</tr>
</tbody>
</table>

Note: You can also use VerticaConnection.setProperty() method to set properties that have standard JDBC Connection setters, such as AutoCommit.

For information about manipulating these attributes, see Setting and Getting Connection Property Values.

Setting and Getting Connection Property Values

You can set a connection property in any of three ways:
include the property name and value as part of the connection string you pass to the DriverManager.getConnection() method.

- Set the properties in a Properties object, and then pass it to the DriverManager.getConnection() method.

- Use the VerticaConnection.setProperty() method. With this approach, you can change only those connection properties that remain changeable after the connection has been established.

In addition, some of the standard JDBC connection properties have getters and setters on the Connection interface (such as Connection.setAutocommit()).

Setting Properties When Connecting

There are two ways you can set connection properties when creating a connection to Vertica:

- In the connection string, using the same URL parameter format that you can use to set the username and password. The following example sets the SSL connection parameter to true:

  "jdbc:vertica://VerticaHost:5433/db?user=UserName&password=Password&ssl=true"

Setting a host name using the setProperty() method overrides the host name set in a connection string as seen above. If this occurs, Vertica may not be able to connect to a host. For example, using the connection string above, the following overrides the VerticaHost name:

Properties props = new Properties();
props.setProperty("dataSource", dataSourceURL);
props.setProperty("database", database);
props.setProperty("user", user);
props.setProperty("password", password);
ps.setProperty("jdbcDriver", jdbcDriver);
props.setProperty("hostName", "NonVertica_host");

However, if a new connection or override connection is needed, you may enter a valid host name in the hostname properties object.

The NonVertica_host hostname overrides VerticaHost name in the connection string. To avoid this issue comment out the props.setProperty("hostName", "NonVertica_host"); line:

//props.setProperty("hostName", "NonVertica_host");
In a Properties object that you pass to the getConnection() call. You will need to import the java.util.Properties class in order to instantiate a Properties object. Then you use the put() method to add the property name and value to the object:

```java
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
myProp.put("LoginTimeout", "35");
Connection conn;
try {
    conn = DriverManager.getConnection(
        "jdbc:vertica://VerticaHost:/ExampleDB", myProp);
} catch (SQLException e) {
    e.printStackTrace();
}
```

Note: The data type of all of the values you set in the Properties object are strings, regardless of the property value's data type.

### Getting and Setting Properties After Connecting

The VerticaConnection.getProperty() method lets you get the value of some connection properties. You can use VerticaConnection.setProperty() method to change the value for properties that can be set after the database connection has been established. Since these methods are Vertica-specific, to use them you must cast your Connection object to the VerticaConnection interface. To cast to VerticaConnection, you must either import it into your client application or use a fully-qualified reference (com.vertica.jdbc.VerticaConnection). The following example demonstrates getting and setting the value of the DirectBatchInsert property.

```java
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class SetConnectionProperties {
    public static void main(String[] args) { // Note: If your application needs to run under Java 5, you need to
        // load the JDBC driver using Class.forName() here.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        // Set DirectBatchInsert to true initially
        myProp.put("DirectBatchInsert", "true");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Show state of the DirectBatchInsert property. This was set at the
When run, the example prints the following on the standard output:

DirectBatchInsert state: true
DirectBatchInsert state is now: false

Setting and Returning a Client Connection Label

The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions GET_CLIENT_LABEL and SET_CLIENT_LABEL.

When you use these two methods, make sure you pass the string value APPLICATIONNAME to both the setter and getter methods.

Use setClientInfo() to create a client label, and use getClientInfo() to return the client label:
When you run this method, it prints the following result to the standard output:

Connected!
New Conn Label: JDBC Client - Data Load

Setting the Locale for JDBC Sessions

You set the locale for a connection while opening it by including a SET LOCALE statement in the ConnSettings property, or by executing a SET LOCALE statement at any time after opening the connection. Changing the locale of a Connection object affects all of the Statement objects you instantiated using it.

You can get the locale by executing a SHOW LOCALE query. The following example demonstrates setting the locale using ConnSettings and executing a statement, as well as getting the locale:

```java
import java.sql.*;
import java.util.Properties;

public class GetAndSetLocale {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, you need to load the JDBC driver
        // using Class.forName here
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        // Set Locale to true en_GB on connection. After the connection
        // is established, the JDBC driver runs the statements in the
        // ConnSettings property.
        myProp.put("ConnSettings", "SET LOCALE TO en_GB");
    }
}
```
Connection conn;
try {
    conn = DriverManager.getConnection(
          "jdbc:vertica://VerticaHost:5433/ExampleDB",
          myProp);

    // Execute a query to get the locale. The results should
    // show "en_GB" as the locale, since it was set by the
    // conn settings property.
    Statement stmt = conn.createStatement();
    ResultSet rs = null;
    rs = stmt.executeQuery("SHOW LOCALE");
    System.out.print("Query reports that Locale is set to: ");
    while (rs.next()) {
        System.out.println(rs.getString(2).trim());
    }

    // Now execute a query to set locale.
    stmt.execute("SET LOCALE TO en_US");

    // Run query again to get locale.
    rs = stmt.executeQuery("SHOW LOCALE");
    System.out.print("Query now reports that Locale is set to: ");
    while (rs.next()) {
        System.out.println(rs.getString(2).trim());
    }

    // Clean up
    conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}

Running the above example displays the following on the system console:

| Query reports that Locale is set to: en_GB LEN |
| Query now reports that Locale is set to: en_US LEN |

Notes:

- JDBC applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. Failing to convert the data can result in errors or the data being stored incorrectly.

- The JDBC driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16.
Changing the Transaction Isolation Level

Changing the transaction isolation level lets you choose how transactions prevent interference from other transactions. By default, the JDBC driver matches the transaction isolation level of the Vertica server. The Vertica default transaction isolation level is READ_COMMITTED, which means any changes made by a transaction cannot be read by any other transaction until after they are committed. This prevents a transaction from reading data inserted by another transaction that is later rolled back.

Vertica also supports the SERIALIZABLE transaction isolation level. This level locks tables to prevent queries from having the results of their WHERE clauses changed by other transactions. Locking tables can have a performance impact, since only one transaction is able to access the table at a time.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

You can change the transaction isolation level connection property after the connection has been established using the Connection object's setter (setTransactionIsolation()) and getter (getTransactionIsolation()). The value for transaction isolation property is an integer. The Connection interface defines constants to help you set the value in a more intuitive manner:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection.TRANSACTION_READ_COMMITTED</td>
<td>2</td>
</tr>
<tr>
<td>Connection.TRANSACTION_SERIALIZABLE</td>
<td>8</td>
</tr>
</tbody>
</table>

Note: The Connection interface also defines several other transaction isolation constants (READ_UNCOMMITTED and REPEATABLE_READ). Since Vertica does not support these isolation levels, they are converted to READ_COMMITTED and SERIALIZABLE, respectively.

The following example demonstrates setting the transaction isolation level to SERIALIZABLE.

```java
import java.sql.*;
import java.util.Properties;

public class SetTransactionIsolation {
    public static void main(String[] args) {
```
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
Connection conn;
try {
    conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
    // Get default transaction isolation
    System.out.println("Transaction Isolation Level: "+ conn.getTransactionIsolation());
    // Set transaction isolation to SERIALIZABLE
    conn.setTransactionIsolation(Connection.TRANSACTION_SERIALIZABLE);
    // Get the transaction isolation again
    System.out.println("Transaction Isolation Level: "+ conn.getTransactionIsolation());
    conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}

Running the example results in the following being printed out to the console:

Transaction Isolation Level: 2
Transaction Isolation Level: 8

Using a Pooling Data Source

A pooling data source uses a collection of persistent connections in order to reduce the overhead of repeatedly opening network connections between the client and server. Opening a new connection for each request is costly for both the server and the client than keeping a small pool of connections open constantly, ready to be used by new requests. When a request comes in, one of the pre-existing connections in the pool is assigned to it. Only if there are no free connections in the pool is a new connection created. Once the request is complete, the connection returns to the pool and waits to service another request.

The Vertica JDBC driver supports connection pooling as defined in the JDBC 4.0 standard. If you are using a J2EE-based application server in conjunction with Vertica, it should already have a built-in data pooling feature. All that is required is that the application server work with the PooledConnection interface implemented by Vertica's JDBC driver. An application server's pooling feature is usually well-tuned for the works loads that the server is designed to handle. See your application server's documentation for details on how to work with pooled connections. Normally, using pooled connections should be transparent in your code—you will just open connections and the application server will worry about the details of pooling them.
If you are not using an application server, or your application server does not offer connection pooling that is compatible with Vertica, you can use a third-party pooling library, such as the open-source c3p0 or DBCP libraries, to implement connection pooling.

**Note:** The Vertica Analytic Database client driver's native connection load balancing feature works with third-party connection pooling supplied by application servers and third-party pooling libraries. See Enabling Native Connection Load Balancing in JDBC for more information.

---

**Enabling Native Connection Load Balancing in JDBC**

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true. The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```java
import java.sql.*;
import java.util.Properties;
import java.sql.*;
import java.util.Properties;

public class JDBCLoadingBalanceExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "example_password123");
        myProp.put("loginTimeout", "35");
        myProp.put("ConnectionLoadBalance", 1);
        Connection conn;
        for (int x=1; x <= 4; x++) {
            try {
                System.out.print("Connect attempt "+ x + "...");
                conn = DriverManager.getConnection("jdbc:vertica://node01.example.com:5433/vmart", myProp);
                // Execute SQL statements...
            } catch (SQLException e) {
                System.out.println("Error: " + e.getMessage());
            }
        }
    }
}
```
Running the above example produces the following output:

```
Connect attempt #1...Connected to node v_vmart_node0002
Connect attempt #2...Connected to node v_vmart_node0003
Connect attempt #3...Connected to node v_vmart_node0001
Connect attempt #4...Connected to node v_vmart_node0002
```

**JDBC Connection Failover**

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application’s connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host
specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.

- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts. Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note: If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.
Using DNS Failover

To use DNS failover, you need to change your DNS server’s settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the BackupServerNode parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the BackupServerNode connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```java
import java.sql.*;
import java.util.Properties;

public class ConnectionFailoverExample {
    public static void main(String[] args) {
        // Assume using JDBC 4.0 driver on JVM 6+. No driver loading needed.
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        // Set two backup hosts to be used if connecting to the first host
        // fails. All of these hosts will be tried in order until the connection
        // succeeds or all of the connections fail.
        myProp.put("BackupServerNode", "VerticaHost02,VerticaHost03");
        Connection conn;
        try {
            // The connection string is set to try to connect to a known
            // but non-existent node (in this case, a host that never existed).
            conn = DriverManager.getConnection("jdbc:vertica://BadVerticaHost:5433/vmart", myProp);
            System.out.println("Connected!");
            // Query system to table to see what node we are connected to.
            // Assume a single row in response set.
            Statement stmt = conn.createStatement();
        }...
ResultSet rs = stmt.executeQuery("SELECT node_name FROM v_monitor.current_session;");  
rs.next();
System.out.println("Connected to node " + rs.getString(1).trim());
// Done with connection.
conn.close();
}  
}  
}  

When run, the example outputs output similar to the following on the system console:

Connected!
Connected to node v_vmart_node0002

Notice that the connection was made to the first node in the backup list (node 2).

Notes

- When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in JDBC for more information.
JDBC Data Types

The JDBC driver transparently converts most Vertica data types to the appropriate Java data type. In a few cases, a Vertica data type cannot be directly translated to a Java data type; these exceptions are explained in this section.

The VerticaTypes Class

JDBC does not support all of the data types that Vertica supports. The Vertica JDBC client driver contains an additional class named VerticaTypes that helps you handle identifying these Vertica-specific data types. It contains constants that you can use in your code to specify Vertica data types. This class defines two different categories of data types:

- Vertica's 13 types of interval values. This class contains constant properties for each of these types. You can use these constants to select a specific interval type when instantiating members of the VerticaDayTimeInterval and VerticaYearMonthInterval classes:

```
// Create a day to second interval.
VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(
    VerticaTypes.INTERVAL_DAY_TO_SECOND, 10, 0, 5, 40, 0, 0, false);
// Create a year to month interval.
VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(
    VerticaTypes.INTERVAL_YEAR_TO_MONTH, 10, 6, false);
```

- Vertica UUID data type. One way you can use the VerticaTypes.UUID is to query a table's metadata to see if a column is a UUID. See UUID Values for an example.

See the JDBC Documentation for more information on this class.

Numeric Data Alias Conversion

The Vertica server supports data type aliases for integer, float and numeric types. The JDBC driver reports these as its basic data types (BIGINT, DOUBLE PRECISION, and NUMERIC), as follows:

<table>
<thead>
<tr>
<th>Vertica Server Types and Aliases</th>
<th>Vertica JDBC Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER INT</td>
<td>BIGINT</td>
</tr>
</tbody>
</table>
Vertica Server Types and Aliases | Vertica JDBC Type
---|---
INT8 | INT8
BIGINT | BIGINT
SMALLINT | SMALLINT
TINYINT | TINYINT
DOUBLE PRECISION | DOUBLE PRECISION
FLOAT5 | DOUBLE PRECISION
FLOAT8 | DOUBLE PRECISION
REAL | DOUBLE PRECISION
DECIMAL | DECIMAL
NUMERIC | NUMERIC
NUMBER | NUMERIC
MONEY | NUMERIC

If a client application retrieves the values into smaller data types, Vertica JDBC driver does not check for overflows. The following example demonstrates the results of this overflow.

```java
import java.sql.*;
import java.util.Properties;

public class JDBCDataTypes {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        // using Class.forName here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/VMart", myProp);
            Statement statement = conn.createStatement();
            // Create a table that will hold a row of different types of
            // numeric data.
            statement.executeUpdate("DROP TABLE IF EXISTS test_all_types cascade");
            statement.executeUpdate("CREATE TABLE test_all_types (" +
                                 + "c0 INTEGER, c1 TINYINT, c2 DECIMAL, " +
                                 + "c3 MONEY, c4 DOUBLE_PRECISION, c5 REAL")");
            // Add a row of values to it.
            statement.executeUpdate("INSERT INTO test_all_types VALUES(" +
                                    + "111111111111, 444, 55555555555.5555," +
                                    + "444, 5555555555555555.5555, "
```
+ "77777777.77, 88888888888888888.88, "
+ "10101010.1010101010101010")

// Query the new table to get the row back as a result set.
ResultSet rs = statement
   .executeQuery("SELECT * FROM test_all_types");

// Get the metadata about the row, including its data type.
ResultSetMetaData md = rs.getMetaData();

// Loop should only run once...
while (rs.next()) {
   // Print out the data type used to defined the column, followed
   // by the values retrieved using several different retrieval
   // methods.

   String[] vertTypes = new String[] {"INTEGER", "TINYINT",
      "DECIMAL", "MONEY", "DOUBLE PRECISION", "REAL"};

   for (int x=1; x<7; x++) {
      System.out.println("\n\nColumn "+ x "+ (" + vertTypes[x-1] + ")");
      System.out.println("\tgetColumnType()\t" + md.getColumnType(x));
      System.out.println("\tgetColumnTypeName()\t" + md.getColumnTypeName(x));
      System.out.println("\tgetShort()\t" + rs.getShort(x));
      System.out.println("\tgetLong()\t" + rs.getLong(x));
      System.out.println("\tgetInt()\t" + rs.getInt(x));
      System.out.println("\tgetByte()\t" + rs.getByte(x));
   }
}

rs.close();
statement.executeUpdate("drop table test_all_types cascade");
statement.close();
}
}

The above example prints the following on the console when run:

**Column 1 (INTEGER)**

- `getColumnType()` -5
- `getColumnTypeName()` BIGINT
- `getShort()` 455
- `getLong()` 111111111111
- `getInt()` -558038585
- `getByte()` -57

**Column 2 (TINYINT)**

- `getColumnType()` -5
- `getColumnTypeName()` BIGINT
- `getShort()` 444
- `getLong()` 444
- `getInt()` 444
- `getByte()` -68

**Column 3 (DECIMAL)**

- `getColumnType()` 2
- `getColumnTypeName()` NUMERIC
Using Intervals with JDBC

The JDBC standard does not contain a data type for intervals (the duration between two points in time). To handle Vertica's INTERVAL data type, you must use JDBC's database-specific object type.

When reading an interval value from a result set, use the ResultSet.getObject() method to retrieve the value, and then cast it to one of the Vertica interval classes: VerticaDayTimeInterval (which represents all ten types of day/time intervals) or VerticaYearMonthInterval (which represents all three types of year/month intervals).

**Note:** The units interval style is not supported. Do not use the SET INTERVALSTYLE statement to change the interval style in your client applications.

Using Intervals in Batch Inserts

When inserting batches into tables that contain interval data, you must create instances of the VerticaDayTimeInterval or VerticaYearMonthInterval classes to hold the data you want to insert. You set values either when calling the class's constructor, or afterwards using setters. You then insert your interval values using the PreparedStatement setObject() method. You can also use the .setString() method, passing it a string in "DD HH:MM:SS" or "YY-MM" format.
The following example demonstrates inserting data into a table containing a day/time interval and a year/month interval:

```java
import java.sql.*;
import java.util.Properties;
// You need to import the Vertica JDBC classes to be able to instantiate 
// the interval classes.
import com.vertica.jdbc.*;

public class IntervalDemo {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver 
        // using Class.forName here
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection( 
                "jdbc:vertica://VerticaHost:5433/VMart", myProp);
            // Create table for interval values
            Statement stmt = conn.createStatement();
            stmt.executeUpdate("DROP TABLE IF EXISTS interval_demo");
            stmt.executeUpdate("CREATE TABLE interval_demo(" 
                + "DayInt INTERVAL DAY TO SECOND, " 
                + "MonthInt INTERVAL YEAR TO MONTH")");
            // Insert data into interval columns using 
            // VerticaDayTimeInterval and VerticaYearMonthInterval 
            // classes.
            PreparedStatement pstmt = conn.prepareStatement( 
                "INSERT INTO interval_demo VALUES (?,?)");
            // Create instances of the Vertica classes that represent 
            // intervals.
            VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(10, 0, 
                5, 40, 0, 0, false);
            VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval( 
                10, 6, false);
            // These objects can also be manipulated using setters.
            dayInt.setHour(7);
            // Add the interval values to the batch
            ((VerticaPreparedStatement) pstmt).setObject(1, dayInt);
            ((VerticaPreparedStatement) pstmt).setObject(2, monthInt);
            pstmt.addBatch();
            // Set another row from strings.
            // Set day interval in "days HH:MM:SS" format
            pstmt.setString(1, "10 10:10:10");
            // Set year to month value in "MM-YY" format
            pstmt.setString(2, "12-09");
            pstmt.addBatch();
            // Execute the batch to insert the values.
            try {
                pstmt.executeBatch();
            } catch (SQLException e) {
                System.out.println("Error message: " + e.getMessage());
            }
        }
    }
}
```
Reading Interval Values

You read an interval value from a result set using the `ResultSet.getObject()` method, and cast the object to the appropriate Vertica object class: `VerticaDayTimeInterval` for day/time intervals or `VerticaYearMonthInterval` for year/month intervals. This is easy to do if you know that the column contains an interval, and you know what type of interval it is. If your application cannot assume the structure of the data in the result set it reads in, you can test whether a column contains a database-specific object type, and if so, determine whether the object belongs to either the `VerticaDayTimeInterval` or `VerticaYearMonthInterval` classes.

```java
// Retrieve the interval values inserted by previous demo.
// Query the table to get the row back as a result set.
ResultSet rs = stmt.executeQuery("SELECT * FROM interval_demo");
// If you do not know the types of data contained in the result set,
// you can read its metadata to determine the type, and use
// additional information to determine the interval type.
ResultSetMetaData md = rs.getMetaData();
while (rs.next()) {
    for (int x = 1; x <= md.getColumnCount(); x++) {
        // Get data type from metadata
        int colDataType = md.getColumnType(x);
        // You can get the type in a string:
        System.out.println("Column "+x+" is a "+md.getColumnTypeName(x));
        // Normally, you'd have a switch statement here to
        // handle all sorts of column types, but this example is
        // simplified to just handle database-specific types
        if (colDataType == Types.OTHER) {
            // Column contains a database-specific type. Determine
            // what type of interval it is. Assuming it is an
            // interval...
            Object columnVal = rs.getObject(x);
            if (columnVal instanceof VerticaDayTimeInterval) {
                // We know it is a date time interval
                VerticaDayTimeInterval interval =
                    (VerticaDayTimeInterval) columnVal;
                // You can use the getters to access the interval's
                // data
                System.out.println("Column "+x+"'s value is ");
                System.out.println(interval.getDay()+" Days ");
                System.out.println(interval.getHour()+" Hours ");
                System.out.println(interval.getMinute() + " Minutes");
            } else if (columnVal instanceof VerticaYearMonthInterval) {
                VerticaYearMonthInterval interval =
                    (VerticaYearMonthInterval) columnVal;
                System.out.println("Column "+x+"'s value is ");
                System.out.println(interval.getYear()+" Years ");
                System.out.println(interval.getMonth()+" Months");
            } else {
                System.out.println("Not an interval.");
            }
        }
    }
}
```
The example prints the following to the console:

Column 1 is a INTERVAL DAY TO SECOND
Column 1’s value is 10 Days 7 Hours 5 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2’s value is 10 Years 6 Months
Column 1 is a INTERVAL DAY TO SECOND
Column 1’s value is 10 Days 10 Hours 10 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2’s value is 12 Years 9 Months

Another option is to use database metadata to find columns that contain intervals.

```java
// Determine the interval data types by examining the database
// metadata.
DatabaseMetaData dbmd = conn.getMetaData();
ResultSet dbMeta = dbmd.getColumns(null, null, "interval_demo", null);
int colcount = 0;
while (dbMeta.next()) {
    // Get the metadata type for a column.
    int javaType = dbMeta.getInt("DATA_TYPE");
    System.out.println("Column " + ++colcount + " Type name is " +
        dbMeta.getString("TYPE_NAME"));

    if(javaType == Types.OTHER) {
        // The SQL_DATETIME_SUB column in the metadata tells you
        // Specifically which subtype of interval you have.
        // The VerticaDayTimeInterval.isDayTimeInterval()
        // methods tells you if that value is a day time.
        //
        int intervalType = dbMeta.getInt("SQL_DATETIME_SUB");
        if(VerticaDayTimeInterval.isDayTimeInterval(intervalType)) {
            // Now you know it is one of the 10 day/time interval types.
            // When you select this column you can cast to
            // VerticaDayTimeInterval.
            // You can get more specific by checking intervalType
            // against each of the 10 constants directly, but
            // they all are represented by the same object.
            System.out.println("column " + colcount + " is a " +
                "VerticaDayTimeInterval intervalType = "
                + intervalType);
        } else if(VerticaYearMonthInterval.isYearMonthInterval(
                    intervalType)) {
            //now you know it is one of the 3 year/month intervals,
            //and you can select the column and cast to
            // VerticaYearMonthInterval
            System.out.println("column " + colcount + " is a " +
```
"VerticaDayTimeInterval intervalType = " + intervalType);
    } else {
        System.out.println("Not an interval type.");
    }
}

UUID Values

UUID is a core data type in Vertica. However, it is not a core Java data type. You must use the java.util.UUID class to represent UUID values in your Java code. The JDBC driver does not translate values from Vertica to non-core Java data types. Therefore, you must send UUID values to Vertica using generic object methods such as PreparedStatement.setObject(). You also use generic object methods (such as ResultSet.getObject()) to retrieve UUID values from Vertica. You then cast the retrieved objects as a member of the java.util.UUID class.

The following example code demonstrates inserting UUID values into and retrieving UUID values from Vertica.

```java
package jdbc_uuid_example;

import java.sql.*;
import java.util.Properties;

public class VerticaUUIDExample {

    public static void main(String[] args) {

        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        Connection conn;

        try {
            conn = DriverManager.getConnection("jdbc:vertica://doch01:5433/VMart", myProp);
            Statement stmt = conn.createStatement();

            // Create a table with a UUID column and a VARCHAR column.
            stmt.execute("DROP TABLE IF EXISTS UUID_TEST CASCADE; ");
            stmt.execute("CREATE TABLE UUID_TEST (id UUID, description VARCHAR(25)); ");

            // Prepare a statement to insert a UUID and a string into the table.
            PreparedStatement ps = conn.prepareStatement("INSERT INTO UUID_TEST VALUES(?,?)");

            java.util.UUID uuid; // Holds the UUID value.

            for (Integer x = 0; x < 10; x++) {
                // Generate a random uuid
                uuid = java.util.UUID.randomUUID();
```
// Set the UUID value by calling setObject.
ps.setObject(1, uuid);
// Set the String value to indicate which UUID this is.
ps.setString(2, "UUID #" + x);
ps.execute();
}

// Query the uuid
ResultSet rs = stmt.executeQuery("SELECT * FROM UUID_TEST ORDER BY description ASC");
while (rs.next()) {
    // Cast the object from the result set as a UUID.
    uuid = (java.util.UUID) rs.getObject(1);
    System.out.println(rs.getString(2) + " : " + uuid.toString());
}
} catch (SQLException e) {
    e.printStackTrace();
}

The previous example prints output similar to the following:

<table>
<thead>
<tr>
<th>UUID #0</th>
<th>67b6dcb6-c28c-4965-b9f7-5c830a84664d</th>
</tr>
</thead>
<tbody>
<tr>
<td>UUID #1</td>
<td>485d3835-2887-4233-b003-392254fa97e0</td>
</tr>
<tr>
<td>UUID #2</td>
<td>81421f51-c803-473d-8cfc-2c184582a117</td>
</tr>
<tr>
<td>UUID #3</td>
<td>bec8b86a-b650-47b0-852c-8229155332d9</td>
</tr>
<tr>
<td>UUID #4</td>
<td>8ae5e3ec-d143-4ef7-8901-24f6d8b83abf</td>
</tr>
<tr>
<td>UUID #5</td>
<td>669696ce-5e86-4e87-b8d0-a937f5fc18d7</td>
</tr>
<tr>
<td>UUID #6</td>
<td>19609ec9-ec56-4444-9cfe-ad2b8de537dd</td>
</tr>
<tr>
<td>UUID #7</td>
<td>97182e1d-5c7e-4da1-9922-67e8b04fde173</td>
</tr>
<tr>
<td>UUID #8</td>
<td>c76c3a2b-a9ef-4d65-b2f7-7c637f872b3c</td>
</tr>
<tr>
<td>UUID #9</td>
<td>3cbbcd26-c177-4277-b3df-bf4d9389f69d</td>
</tr>
</tbody>
</table>

Determining Whether a Column has a UUID Data Type

JDBC does not support the UUID data type. This limitation means you cannot use the usual ResultSetMetaData.getColumnType() method to determine column's data type is UUID. Calling this method on a UUID column returns Types.OTHER. This value is also to identify interval columns. You can use two ways to determine if a column contains UUIDs:

- Use ResultSetMetaData.getColumnTypeName() to get the name of the column's data type. For UUID columns, this method returns the value "Uuid" as a String.

- Query the table's metadata to get the SQL data type of the column. If this value is equal to VerticaTypes.UUID, the column's data type is UUID.

The following example demonstrates both of these techniques:

// This example assumes you already have a database connection
// and result set from a query on a table that may contain a UUID.
// Get the metadata of the result set to get the column definitions
ResultSetMetaData meta = rs.getMetaData();
int colcount;
int maxcol = meta.getColumnCount();

System.out.println("Using column metadata:");
for (colcount = 1; colcount < maxcol; colcount++) {
    // .getColumnType() always returns "OTHER" for UUID columns.
    if (meta.getColumnType(colcount) == Types.OTHER) {
        // To determine that it is a UUID column, test the name of the column type.
        if (meta.getColumnTypeName(colcount).equalsIgnoreCase("uuid")) {
            // It's a UUID column
            System.out.println("Column " + colcount + " is UUID");
        }
    }
}

// You can also query the table's metadata to find its column types and compare
// it to the VerticaType.UUID constant to see if it is a UUID column.
System.out.println("Using table metadata:");
DatabaseMetaData dbmd = conn.getMetaData();
// Get the metadata for the previously-created test table.
ResultSet tableMeta = dbmd.getColumns(null, null, "UUID_TEST", null);
colcount = 0;
// Each row in the result set has metadata that describes a single column.
while (tableMeta.next()) {
    colcount++;
    // The SQL_DATA_TYPE column holds the Vertica database data type. You compare
    // this value to the VerticaTypes.UUID constant to see if it is a UUID.
    if (tableMeta.getInt("SQL_DATA_TYPE") == VerticaTypes.UUID) {
        // Column is a UUID data type...
        System.out.println("Column " + colcount + " is a UUID column.");
    }
}

This example prints the following to the console if it is run after running the prior example:

Using column metadata:
Column 1 is UUID
Using table metadata:
Column 1 is a UUID column.

Executing Queries Through JDBC

To run a query through JDBC:

2. Run the query.

The method you use to run the query depends on the type of query you want to run:
- a DDL query that does not return a result set.
- a DDL query that returns a result set.
- a DML query

**Executing DDL (Data Definition Language) Queries**

To run DDL queries, such as `CREATE TABLE` and `COPY`, use the `Statement.execute()` method. You get an instance of this class by calling the `createStatement` method of your connection object.

The following example creates an instance of the `Statement` class and uses it to execute a `CREATE TABLE` and a `COPY` query:

```java
Statement stmt = conn.createStatement();
stmt.execute("CREATE TABLE address_book (Last_Name char(50) default '', " +
                 "First_Name char(50),Email char(50),Phone_Number char(50))");
stmt.execute("COPY address_book FROM 'address.dat' DELIMITER ',' NULL 'null'");
```

**Executing Queries That Return Result Sets**

Use the `Statement` class's `executeQuery` method to execute queries that return a result set, such as `SELECT`. To get the data from the result set, use methods such as `getInt`, `getString`, and `getDouble` to access column values depending upon the data types of columns in the result set. Use `ResultSet.next` to advance to the next row of the data set.

```java
ResultSet rs = null;
rs = stmt.executeQuery("SELECT First_Name, Last_Name FROM address_book");
int x = 1;
while(rs.next()){
    System.out.println(x + ". " + rs.getString(1).trim() + " " + rs.getString(2).trim());
    x++;
}
```

*Note: The Vertica JDBC driver does not support scrollable cursors. You can only read forwards through the result set.*
Executing DML (Data Manipulation Language) Queries Using executeUpdate

Use the executeUpdate method for DML SQL queries that change data in the database, such as INSERT, UPDATE and DELETE which do not return a result set.

```java
stmt.executeUpdate("INSERT INTO address_book " +
    "VALUES ('Ben-Shachar', 'Tamar', 'tamar@example.com', " +
    "'555-380-6466')");
stmt.executeUpdate("INSERT INTO address_book (First_Name, Email) " +
    "VALUES ('Pete', 'pete@example.com')");
```

**Note:** The Vertica JDBC driver's Statement class supports executing multiple statements in the SQL string you pass to the execute method. The PreparedStatement class does not support using multiple statements in a single execution.
Loading Data Through JDBC

You can use any of the following methods to load data via the JDBC interface:

- Executing a SQL INSERT statement to insert a single row directly.
- Batch loading data using a prepared statement.
- Bulk loading data from files or streams using COPY.

When loading data into Vertica, you need to decide whether to write data to the Write Optimized Store (WOS) or the Read Optimized Store (ROS). By default, most data loading methods insert data into the WOS until it fills up, then insert any additional data directly into ROS containers (called AUTO mode). This is the best method to use when frequently loading small amounts of data (often referred to as trickle-loading). When performing less frequent large data loads (any loads over 100MB of data at once), you should change this behavior to insert data directly into the ROS.

The following sections explain in detail how you load data using JDBC.

Using a Single Row Insert

The simplest way to insert data into a table is to use the SQL INSERT statement. You can use this statement by instantiating a member of the Statement class, and use its `executeUpdate()` method to run your SQL statement.

The following code fragment demonstrates how you can create a Statement object and use it to insert data into a table named address_book:

```java
Statement stmt = conn.createStatement();
stmt.executeUpdate("INSERT INTO address_book "+
    "VALUES ("Smith", "John", "jsmith@example.com", " +
    "'555-123-4567')");
```

This method has a few drawbacks: you need convert your data to string and escape any special characters in your data. A better way to insert data is to use prepared statements. See Batch Inserts Using JDBC Prepared Statements.
Using LONG VARCHAR and LONG VARBINARY Data Types with JDBC

Using LONG VARCHAR and LONG VARBINARY data types in a JDBC client application is similar to using VARCHAR and VARBINARY data types. The JDBC driver transparently handles the conversion (for example, between a Java String object and a LONG VARCHAR). The following example code demonstrates inserting and retrieving a LONG VARCHAR string. It uses the JDBC Types class to determine the data type of the string returned by Vertica, although it does not actually need to know whether the database column is a LONG VARCHAR or just a VARCHAR in order to retrieve the value.

```java
import java.sql.*;
import java.util.Properties;

public class LongVarcharExample {
    public static void main(String[] args) {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();

            // How long we want the example string to be. This is larger than can fit into a traditional VARCHAR (which is limited to 65000).
            int length = 100000;

            // Create a table with a LONG VARCHAR column that can store the string we want to insert.
            stmt.execute("DROP TABLE IF EXISTS longtable CASCADE");
            stmt.execute("CREATE TABLE longtable (text LONG VARCHAR (" + length + ")");

            // Build a long string by appending an integer to a string builder
            // until we hit the size limit. Will result in a string containing 01234567890123....
            StringBuilder sb = new StringBuilder(length);
            for (int i = 0; i < length; i++)
                { sb.append( i % 10 );
            }
```
String value = sb.toString();

System.out.println("String value is "+value.length()+" characters long.");

// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement(""+"INSERT INTO longtable (text)" +" VALUES(?)");

try {
    // Insert LONG VARCHAR value
    System.out.println("Inserting LONG VARCHAR value");
    pstmt.setString(1, value);
    pstmt.addBatch();
    pstmt.executeBatch();

    // Query the table we created to get the value back.
    ResultSet rs = null;
    rs = stmt.executeQuery("SELECT * FROM longtable");

    // Get metadata about the result set.
    ResultSetMetaData rsmd = rs.getMetaData();
    // Print the type of the first column. Should be
    // LONG VARCHAR. Also check it against the Types class, to
    // recognize it programmatically.
    System.out.println("Column #1 data type is: "+
                       rsmd.getColumnTypeName(1));
    if (rsmd.getColumnType(1) == Types.LONGVARCHAR) {
        System.out.println("It is a LONG VARCHAR");
    } else {
        System.out.println("It is NOT a LONG VARCHAR");
    }

    // Print out the string length of the returned value.
    while (rs.next()) {
        // Use the same getString method to get the value that you
        // use to get the value of a VARCHAR.
        System.out.println("Returned string length: "+
                           rs.getString(1).length());
    }
} catch (SQLException e) {
    System.out.println("Error message: "+e.getMessage());
    return; // Exit if there was an error
}

// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}
octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).
Batch Inserts Using JDBC Prepared Statements

You can load batches of data into Vertica using prepared `INSERT` statements—server-side statements that you set up once, and then call repeatedly. You instantiate a member of the `PreparedStatement` class with a SQL statement that contains question mark placeholders for data. For example:

```
PreparedStatement pstmt = conn.prepareStatement(
    "INSERT INTO customers(last, first, id) VALUES(?,?,?)");
```

You then set the parameters using data-type-specific methods on the `PreparedStatement` object, such as `setString()` and `setInt()`. Once your parameters are set, call the `addBatch()` method to add the row to the batch. When you have a complete batch of data ready, call the `executeBatch()` method to execute the insert batch.

Behind the scenes, the batch insert is converted into a `COPY` statement. When the connection's `AutoCommit` parameter is disabled, Vertica keeps the `COPY` statement open and uses it to load subsequent batches until the transaction is committed, the cursor is closed, or your application executes anything else (or executes any statement using another `Statement` or `PreparedStatement` object). Using a single `COPY` statement for multiple batch inserts makes loading data more efficient. If you are loading multiple batches, you should disable the `AutoCommit` property of the database to take advantage of this increased efficiency.

When performing batch inserts, experiment with various batch and row sizes to determine the settings that provide the best performance.

The following example demonstrates using a prepared statement to batch insert data.

```
import java.sql.*;
import java.util.Properties;

public class BatchInsertExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        // Set streamingBatchInsert to True to enable streaming mode for batch inserts.
        // myProp.put("streamingBatchInsert", "True");

        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();
```

// Set AutoCommit to false to allow Vertica to reuse the same
// COPY statement
conn.setAutoCommit(false);

// Drop table and recreate.
stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
stmt.execute("CREATE TABLE customers (CustID int, Last_Name "+ "char(50), First_Name char(50), Email char(50), " "+ "Phone_Number char(12))");
// Some dummy data to insert.
String[] firstNames = new String[] { "Anna", "Bill", "Cindy", "Don", "Eric" };
String[] lastName = new String[] { "Allen", "Brown", "Chu", "Dodd", "Estavez" };
String[] emails = new String[] { "aang@example.com", "b.brown@example.com", "cindy@example.com", "d.d@example.com", "e.estavez@example.com" };
// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customers (CustID, Last_Name, " + "First_Name, Email, Phone_Number) " + "VALUES(?, ?, ?, ?, ?)")
// Add rows to a batch in a loop. Each iteration adds a
// new row.
for (int i = 0; i < firstNames.length; i++) {
    // Add each parameter to the row.
    pstmt.setInt(1, i + 1);
    pstmt.setString(2, lastName[i]);
    pstmt.setString(3, firstNames[i]);
    pstmt.setString(4, emails[i]);
    pstmt.setString(5, phoneNumbers[i]);
    // Add row to the batch.
    pstmt.addBatch();
}

try {
// Batch is ready, execute it to insert the data
    pstmt.executeBatch();
} catch (SQLException e) {
    System.out.println("Error message: " + e.getMessage());
    return; // Exit if there was an error
}

// Commit the transaction to close the COPY command
conn.commit();

// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, " "+ "Last_Name FROM customers ORDER BY CustID");
while (rs.next()) {
    System.out.println(rs.getInt(1) + " - " "+ rs.getString(2).trim() + " "+ rs.getString(3).trim());
}
// Cleanup
c conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}

The result of running the example code is:

1 - Anna Allen
2 - Bill Brown
3 - Cindy Chu
4 - Don Dodd
5 - Eric Estavez

Streaming Batch Inserts

By default, Vertica performs batch inserts by caching each row and inserting the cache when the user calls the `executeBatch()` method. Vertica also supports streaming batch inserts. A streaming batch insert adds a row to the database each time the user calls `addBatch()`. Streaming batch inserts improve database performance by allowing parallel processing and reducing memory demands.

**Note:** Once you begin a streaming batch insert, you cannot make other JDBC calls that require client-server communication until you have executed the batch or closed or rolled back the connection.

To enable streaming batch inserts, set the `streamingBatchInsert` property to True. The preceding code sample includes a line enabling `streamingBatchInsert` mode. Remove the `//` comment marks to enable this line and activate streaming batch inserts.

The following table explains the various batch insert methods and how their behavior differs between default batch insert mode and streaming batch insert mode.

<table>
<thead>
<tr>
<th>Method</th>
<th>Default Batch Insert Behavior</th>
<th>Streaming Batch Insert Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>addBatch()</code></td>
<td>Adds a row to the row cache.</td>
<td>Inserts a row into the database.</td>
</tr>
<tr>
<td><code>executeBatch()</code></td>
<td>Adds the contents of the row cache to the database in a single action.</td>
<td>Sends an end-of-batch message to the server and returns an array of integers indicating the success or failure of each <code>addBatch()</code> attempt.</td>
</tr>
</tbody>
</table>
clearBatch() | Clears the row cache without inserting any rows. | Not supported. Triggers an exception if used when streaming batch inserts are enabled.

### Notes

- Using the `PreparedStatement.setFloat()` method can cause rounding errors. If precision is important, use the `.setDouble()` method instead.

- The `PreparedStatement` object caches the connection's AutoCommit property when the statement is prepared. Later changes to the AutoCommit property have no effect on the prepared statement.

### Loading Batches Directly into ROS

When loading large batches of data (more than 100MB or so), you should load the data directly into ROS containers. Inserting directly into ROS is more efficient for large loads than AUTO mode, since it avoids overflowing the WOS and spilling the remainder of the batch to ROS. Otherwise, the Tuple Mover has to perform a moveout on the data in the WOS, while subsequent data is directly written into ROS containers causing your data to be segmented across storage containers.

When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS. For details about load options, see Choosing a Load Method.

To directly load batches into ROS, set the `directBatchInsert` connection property to true. See Setting and Getting Connection Property Values for an explanation of how to set connection properties. When this property is set to true, all batch inserts bypass the WOS and load directly into a ROS container.

If all of batches being inserted using a connection should be inserted into the ROS, you should set the `DirectBatchInsert` connection property to true in the `Properties` object you use to create the connection:

```java
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
// Enable directBatchInsert for this connection
myProp.put("DirectBatchInsert", "true");
Connection conn;
try {
    conn = DriverManager.getConnection(
        "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
    ...
```
If you will be using the connection for inserting both large and small batches (or you do not know the size batches you will be inserting when you create the Connection object), you can set the DirectBatchInsert property after the connection has been established using the VerticaConnection.setProperty method:

```java
((VerticaConnection)conn).setProperty("DirectBatchInsert", true);
```

See Setting and Getting Connection Property Values for a full example of setting DirectBatchInsert.

### Error Handling During Batch Loads

When loading individual batches, you can find how many rows were accepted and what rows were rejected (see Identifying Accepted and Rejected Rows for details). If you have disabled the AutoCommit connection setting, other errors (such as disk space errors, for example) do not occur while inserting individual batches. This behavior is caused by having a single SQL COPY statement perform the loading of multiple consecutive batches (which makes the load process more efficient). It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Therefore, your bulk loading application should be prepared to check for errors when the COPY statement closes. You can trigger the COPY statement to close by:

- ending the batch load transaction by calling `Connection.commit()`
- closing the statement using `Statement.close()`
- setting the connection’s AutoCommit property to true before inserting the last batch in the load

**Note:** The COPY statement also closes if you execute any non-insert statement or execute any statement using a different `Statement` or `PreparedStatement` object. Ending the COPY statement using either of these methods can lead to confusion and a harder-to-maintain application, since you would need to handle batch load errors in a non-batch load statement. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

### Identifying Accepted and Rejected Rows (JDBC)

The return value of `PreparedStatement.executeUpdate` is an integer array containing the success or failure status of inserting each row. A value 1 means the row was accepted and a value of -3 means that the row was rejected. In the case where an exception occurred during
the batch execution, you can also get the array using 
BatchUpdateException.getUpdateCounts().

The following example extends the example shown in Batch Inserts Using JDBC Prepared Statements to retrieve this array and display the results the batch load.

```java
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class BatchInsertErrorHandlingExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        // establish connection and make a table for the data.
        try {
            conn = DriverManager.getConnection("jdbc:vertica:///VerticaHost:5433/ExampleDB", myProp);
            // Disable auto commit
            conn.setAutoCommit(false);

            // Create a statement
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name char(50), First_Name char(50), Email char(50), " + "Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy", "Don", "Eric" };
            String[] emails = new String[] { "aang@example.com", "b.brown@example.com", "cindy@example.com", "d.d@example.com", "e.estavez@example.com" };

            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement("" + "INSERT INTO customers (CustID, Last_Name, "+ "First_Name, Email, Phone_Number) "+ "VALUES(?,?,?,?,?)");

            // Add rows to a batch in a loop. Each iteration adds a
            // new row.
            for (int i = 0; i < firstNames.length; i++) {
                // Add each parameter to the row.
                pstmt.setInt(i, i + 1);
            }
        }
    }
}
```
pstmt.setString(2, lastNames[i]);
pstmt.setString(3, firstNames[i]);
pstmt.setString(4, emails[i]);
pstmt.setString(5, phoneNumbers[i]);
// Add row to the batch.
pstmt.addBatch();
}

// Integer array to hold the results of inserting
// the batch. Will contain an entry for each row,
// indicating success or failure.
int[] batchResults = null;
try {
    // Batch is ready, execute it to insert the data
    batchResults = pstmt.executeBatch();
} catch (BatchUpdateException e) {
    // We expect an exception here, since one of the
    // inserted phone numbers is too wide for its column. All of the
    // rest of the rows will be inserted.
    System.out.println("Error message: " + e.getMessage());

    // Batch results isn't set due to exception, but you
    // can get it from the exception object.
    //
    // In your own code, you shouldn't assume the a batch
    // exception occurred, since exceptions can be thrown
    // by the server for a variety of reasons.
    batchResults = e.getUpdateCounts();
} // You should also be prepared to catch SQLExceptions in your own
// application code, to handle dropped connections and other general
// problems.

// Commit the transaction
conn.commit();

// Print the array holding the results of the batch insertions.
System.out.println("Return value from inserting batch: "
    + Arrays.toString(batchResults));
// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, "
    + "Last_Name FROM customers ORDER BY CustID");
while (rs.next()) {
    System.out.println(rs.getInt(1) + " - "
        + rs.getString(2).trim() + " "
        + rs.getString(3).trim());
}

// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}
Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server. Return value from inserting batch: [1, 1, -3, 1, 1]

1 - Anna Allen
2 - Bill Brown
4 - Don Dodd
5 - Eric Estavez

Notice that the third row failed to insert because its phone number is too long for the Phone_Number column. All of the rest of the rows in the batch (including those after the error) were correctly inserted.

Note: It is more efficient for you to ensure that the data you are inserting is the correct data type and width for the table column you are inserting it into than to handle exceptions after the fact.

Rolling Back Batch Loads on the Server

Batch loads always insert all of their data, even if one or more rows is rejected. Only the rows that caused errors in a batch are not loaded. When the database connection's AutoCommit property is true, batches automatically commit their transactions when they complete, so once the batch finishes loading, the data is committed.

In some cases, you may want all of the data in a batch to be successfully inserted—none of the data should be committed if an error occurs. The best way to accomplish this is to turn off the database connection's AutoCommit property to prevent batches from automatically committing themselves. Then, if a batch encounters an error, you can roll back the transaction after catching the BatchUpdateException caused by the insertion error.

The following example demonstrates performing a rollback if any error occurs when loading a batch.

```java
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class RollbackBatchOnError {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Disable auto-commit. This will allow you to roll back a
            // a batch load if there is an error.
            conn.setAutoCommit(false);
            // establish connection and make a table for the data.
        }
    }
}
```
Statement stmt = conn.createStatement();
// Drop table and recreate.
stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
stmt.execute("CREATE TABLE customers (CustID int, Last_Name
  + " char(50), First_Name char(50), Email char(50), "
  + " Phone_Number char(12))");

// Some dummy data to insert. The one row won't insert because
// the phone number is too long for the phone column.
String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
  "Don", "Eric" };
String[] lastNames = new String[] { "Allen", "Brown", "Chu",
  "Dodd", "Estavez" };?
String[] emails = new String[] { "aang@example.com",
  "b.brown@example.com", "cindy@example.com",
  "d.d@example.com", "e.estavez@example.com" };?
String[] phoneNumbers = new String[] { "123-456-789",
  "555-444-3333", "555-867-53094535", "555-555-1212",
  "781-555-0000" };?

// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO
customers (CustID, Last_Name, "
  + "First_Name, Email, Phone_Number) "
  + "VALUES(?,?,?,?,?)");

// Add rows to a batch in a loop. Each iteration adds a
// new row.
for (int i = 0; i < firstNames.length; i++) {
  // Add each parameter to the row.
  pstmt.setInt(1, i + 1);
  pstmt.setString(2, lastNames[i]);
  pstmt.setString(3, firstNames[i]);
  pstmt.setString(4, emails[i]);
  pstmt.setString(5, phoneNumbers[i]);
  // Add row to the batch.
  pstmt.addBatch();
}

// Integer array to hold the results of inserting
// the batch. Will contain an entry for each row,
// indicating success or failure.
int[] batchResults = null;
try {
  // Batch is ready, execute it to insert the data
  batchResults = pstmt.executeBatch();
  // If we reach here, we inserted the batch without errors.
  // Commit it.
  System.out.println("Batch insert successful. Committing.");
  conn.commit();
} catch (BatchUpdateException e) {
  System.out.println("Error message: " + e.getMessage());
  // Batch results isn't set due to exception, but you
  // can get it from the exception object.
  batchResults = e.getUpdateCounts();
  // Roll back the batch transaction.
  System.out.println("Rolling back batch insertion");
  conn.rollback();
}

} catch (SQLException e) {
  // General SQL errors, such as connection issues, throw
  // SQLExceptions. Your application should do something more
  // than just print a stack trace,
Running the above example prints the following on the system console:

```
Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server. Rolling back batch insertion
Return value from inserting batch: [1, 1, -3, 1, 1]
Customers table contains:
```

The return values indicate whether each rows was successfully inserted. The value 1 means the row inserted without any issues, and a -3 indicates the row failed to insert.

The customers table is empty since the batch insert was rolled back due to the error caused by the third column.

**Bulk Loading Using the COPY Statement**

One of the fastest ways to load large amounts of data into Vertica at once (bulk loading) is to use the **COPY statement**. This statement loads data from a file stored on a Vertica host (or in a data stream) into a table in the database. You can pass the COPY statement parameters that define the format of the data in the file, how the data is to be transformed as it is loaded, how to handle errors, and how the data should be loaded. See the COPY documentation in the SQL Reference Manual for details.

One parameter that is particularly important is the DIRECT option, which tells COPY to load the data directly into ROS rather than going through the WOS. You should use this option when you are loading large files (over 100MB) into the database. Without this option, your load may
fill the WOS and overflow into ROS, requiring the **Tuple Mover** to perform a Moveout on the data in the WOS. It is more efficient to directly load into ROS and avoid forcing a moveout.

Only a superuser can use the COPY statement to copy a file stored on a host, so you must connect to the database using a superuser account. If you want to have a non-superuser user bulk-load data, you can use COPY to load from a stream on the host (such as STDIN) rather than a file or stream data from the client (see **Streaming Data Via JDBC**). You can also perform a standard **batch insert using a prepared statement**, which uses the COPY statement in the background to load the data.

**Note:** When using this **COPY parameter** on any node, confirm that the source file is identical on all nodes. Using different files can produce inconsistent results.

The following example demonstrates using the COPY statement through the JDBC to load a file name `customers.txt` into a new database table. This file must be stored on the database host to which your application connects (in this example, a host named `VerticaHost`). Since the `customers.txt` file used in the example is very large, this example uses the DIRECT option to bypass WOS and load directly into ROS.

```java
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class COPYFromFile {
  public static void main(String[] args) {
    Properties myProp = new Properties();
    myProp.put("user", "ExampleAdmin"); // Must be superuser
    myProp.put("password", "password123");
    Connection conn;
    try {
      conn = DriverManager.getConnection("jdbc:vertica:///VerticaHost:5433/ExampleDB",myProp);
      // Disable AutoCommit
      conn.setAutoCommit(false);
      Statement stmt = conn.createStatement();
      // Create a table to hold data.
      stmt.execute("DROP TABLE IF EXISTS customers;");
      stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                      + " NOT NULL, First_Name char(50),Email char(50), "
                      + " Phone_Number char(15))");

      // Use the COPY command to load data. Load directly into ROS, since
      // this load could be over 100MB. Use ENFORCELENGTH to reject
      // strings too wide for their columns.
      boolean result = stmt.execute("COPY customers FROM "
                                + " '/data/customers.txt' DIRECT ENFORCELENGTH");

      // Determine if execution returned a count value, or a full result
      // set.
      if(result) {
        System.out.println("Got result set");
      } else {
        // Count will usually return the count of rows inserted.
      }
  }
}
```
System.out.println("Got count");
int rowCount = stmt.getUpdateCount();
System.out.println("Number of accepted rows = " + rowCount);

// Commit the data load
conn.commit();
} catch (SQLException e) {
    System.out.print("Error: ");
    System.out.println(e.toString());
    System.out.println(e.toString());
} } 

The example prints the following out to the system console when run (assuming that the customers.txt file contained two million valid rows):

Number of accepted rows = 2000000

**Streaming Data Via JDBC**

There are two options to stream data from a file on the client to your Vertica database:

- Use the VerticaCopyStream class to stream data in an object-oriented manner - details on the class are available in the JDBC Documentation
- Execute a **COPY LOCAL** SQL statement to stream the data

The topics in this section explain how to use these options.

**Using VerticaCopyStream**

The VerticaCopyStream class (details on the class are available in the JDBC Documentation) lets you stream data from the client system to a Vertica database. It lets you use the SQL **COPY statement** directly without having to copy the data to a host in the database cluster first. Using the COPY command to load data from the host requires superuser privileges to be able to access the host's filesystem. The COPY statement used to load data from a stream does not require superuser privileges so your client can connect using any user account that has INSERT privileges on the table that will receive the data.

To copy streams into the database:
1. Disable the database connections AutoCommit connection parameter.

2. Instantiate a VerticaCopyStreamObject, passing it at least the database connection objects and a string containing a COPY statement to load the data. This statement must copy data from the STDIN into your table. You can use whatever parameters are appropriate for your data load.

   **Note:** The VerticaCopyStreamObject constructor optionally takes a single InputStream object, or a List of InputStream objects. This option lets you pre-populate the list of streams to be copied into the database.

3. Call VerticaCopyStreamObject.start() to start the COPY statement and begin streaming the data in any streams you have already added to the VerticaCopyStreamObject.

4. Call VerticaCopyStreamObject.addStream() to add additional streams to the list of streams to send to the database. You can then call VerticaCopyStreamObject.execute() to stream them to the server.

5. Optionally, call VerticaCopyStreamObject.getRejects() to get a list of rejected rows from the last .execute() call. The list of rejects is reset by each call to .execute() or .finish().

   **Note:** If you used either the REJECTED DATA or EXCEPTIONS options in the COPY statement you passed to VerticaCopyStreamObject the object in step 2, .getRejects() returns an empty list. You can only use one method of tracking the rejected rows at a time.

6. When you are finished adding streams, call VerticaCopyStreamObject.finish() to send any remaining streams to the database and close the COPY statement.

7. Call Connection.commit() to commit the loaded data.
Getting Rejected Rows

The VerticaCopyStreamObject.getRejects() method returns a List containing the row numbers of rows that were rejected after the previous .execute() method call. Each call to .execute() clears the list of rejected rows, so you need to call .getRejects() after each call to .execute(). Since .start() and .finish() also call .execute() to send any pending streams to the server, you should also call .getRejects() after these methods as well.

The following example demonstrates loading the content of five text files stored on the client system into a table.

```java
import java.io.File;
import java.io.FileInputStream;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Iterator;
import java.util.List;
import java.util.Properties;
import com.vertica.jdbc.VerticaConnection;
import com.vertica.jdbc.VerticaCopyStream;

public class CopyMultipleStreamsExample {
    public static void main(String[] args) {
        // Note: If running on Java 5, you need to call Class.forName
        // to manually load the JDBC driver.
        // Set up the properties of the connection
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser"); // Must be superuser
        myProp.put("password", "password123");
        // When performing bulk loads, you should always disable the
        // connection's AutoCommit property to ensure the loads happen as
        // efficiently as possible by reusing the same COPY command and
        // transaction.
        myProp.put("AutoCommit", "false");
        Connection conn;
        try {
            conn = DriverManager.getConnection(  
                "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            Statement stmt = conn.createStatement();

            // Create a table to receive the data
            stmt.execute("DROP TABLE IF EXISTS customers");
            stmt.execute("CREATE TABLE customers (Last_Name char(50), "
                + "First_Name char(50),Email char(50), "
                + "Phone_Number char(15))");

            // Prepare the query to insert from a stream. This query must use
            // the COPY statement to load data from STDIN. Unlike copying from
            // a file on the host, you do not need superuser privileges to
            // copy a stream. All your user account needs is INSERT privileges
            // on the target table.
            String copyQuery = "COPY customers FROM STDIN "
        }
    }
}
```
```
// Create an instance of the stream class. Pass in the
// connection and the query string.
VerticaCopyStream stream = new VerticaCopyStream(
(VerticaConnection) conn, copyQuery);

// Keep running count of the number of rejects
int totalRejects = 0;

// start() starts the stream process, and opens the COPY command.
stream.start();

// If you added streams to VerticaCopyStream before calling start(),
// You should check for rejects here (see below). The start() method
// calls execute() to send any pre-queued streams to the server
// once the COPY statement has been created.

// Simple for loop to load 5 text files named customers-1.txt to
// customers-5.txt
for (int loadNum = 1; loadNum <= 5; loadNum++) {
   // Prepare the input file stream. Read from a local file.
   String filename = "C:\\Data\\customers-" + loadNum + ".txt";
   System.out.println("\n\nLoading file: " + filename);
   File inputFile = new File(filename);
   FileInputStream inputstream = new FileInputStream(inputFile);

   // Add stream to the VerticaCopyStream
   stream.addStream(inputstream);

   // call execute() to load the newly added stream. You could
   // add many streams and call execute once to load them all.
   // Which method you choose depends mainly on whether you want
   // the ability to check the number of rejections as the load
   // progresses so you can stop if the number of rejects gets too
   // high. Also, high numbers of InputStreams could create a
   // resource issue on your client system.
   stream.execute();

   // Show any rejects from this execution of the stream load
   // getRejects() returns a List containing the
   // row numbers of rejected rows.
   List<Long> rejects = stream.getRejects();

   // The size of the list gives you the number of rejected rows.
   int numRejects = rejects.size();
   totalRejects += numRejects;
   System.out.println("Number of rows rejected in load ",
      + loadNum + ": " + numRejects);

   // List all of the rows that were rejected.
   Iterator<Long> rejit = rejects.iterator();
   long linecount = 0;
   while (rejit.hasNext()) {
      System.out.print("Rejected row "+ ++linecount);
      System.out.println(" is row "+ rejit.next());
   }
}
```

long results = stream.finish();
System.out.println("Finish returned " + results);

// If you added any streams that hadn't been executed(),
// you should also check for rejects here, since finish()
// calls execute() to

// You can also get the number of rows inserted using
// getRowCount().
System.out.println("Number of rows accepted: "
        + stream.getRowCount());
System.out.println("Total number of rows rejected: " + totalRejects);

// Commit the loaded data
conn.commit();

} catch (Exception e) {
    e.printStackTrace();
}
}

Running the above example on some sample data results in the following output:

Loading file: C:\Data\customers-1.txt
Number of rows rejected in load #1: 3
Rejected row #1 is row 3
Rejected row #2 is row 7
Rejected row #3 is row 51
Loading file: C:\Data\customers-2.txt
Number of rows rejected in load #2: 5
Rejected row #1 is row 4143
Rejected row #2 is row 6132
Rejected row #3 is row 9998
Rejected row #4 is row 10000
Rejected row #5 is row 10050
Loading file: C:\Data\customers-3.txt
Number of rows rejected in load #3: 9
Rejected row #1 is row 14142
Rejected row #2 is row 16131
Rejected row #3 is row 19999
Rejected row #4 is row 20001
Rejected row #5 is row 20005
Rejected row #6 is row 20049
Rejected row #7 is row 20056
Rejected row #8 is row 20144
Rejected row #9 is row 20236
Loading file: C:\Data\customers-4.txt
Number of rows rejected in load #4: 8
Rejected row #1 is row 23774
Rejected row #2 is row 24141
Rejected row #3 is row 25906
Rejected row #4 is row 26130
Rejected row #5 is row 27317
Rejected row #6 is row 28121
Rejected row #7 is row 29321
Rejected row #8 is row 29998
Loading file: C:\Data\customers-5.txt
Number of rows rejected in load #5: 1
Rejected row #1 is row 39997
Finish returned 39995
Number of rows accepted: 39995
Total number of rows rejected: 26

**Note:** The above example shows a simple load process that targets one node in the Vertica cluster. It is more efficient to simultaneously load multiple streams to multiple database nodes. Doing so greatly improves performance because it spreads the processing for the load across the cluster.

**Using COPY LOCAL with JDBC**

To use COPY LOCAL with JDBC, just execute a **COPY LOCAL** statement with the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class (details on the class are available in the JDBC Documentation). However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a file (streamed over a network connection, for example).

You can use COPY LOCAL in a multiple-statement query. However, you should always make it the first statement in the query. You should not use it multiple times in the same query.

The following example code demonstrates using COPY LOCAL to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement, except for the use of the LOCAL option in the **COPY** statement, and the path to the data file is on the client system, rather than on the server.

**Note:** The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the copy local command. Specify a local path and filename for these modifiers when executing a COPY LOCAL query from the driver.

```java
import java.sql.*;
import java.util.Properties;

public class COPYLocal {
    public static void main(String[] args) {
        // Note: If using Java 5, you must call Class.forName to load the
        // JDBC driver.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser"); // Do not need to superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Disable AutoCommit
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
        }
    }
}
```
// Create a table to hold data.
stmt.execute("DROP TABLE IF EXISTS customers;");
stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                  + " NOT NULL, First_Name char(50),Email char(50), "
                  + " Phone_Number char(15))");

// Use the COPY command to load data. Load directly into ROS, since
// this load could be over 100MB. Use ENFORCELENGTH to reject
// strings too wide for their columns.
boolean result = stmt.execute("COPY customers FROM LOCAL "
                  + " 'C:\Data\customers.txt' DIRECT ENFORCELENGTH");

// Determine if execution returned a count value, or a full result
// set.
if (result) {
    System.out.println("Got result set");
} else {
    // Count will usually return the count of rows inserted.
    System.out.println("Got count");
    int rowCount = stmt.getUpdateCount();
    System.out.println("Number of accepted rows = " + rowCount);
}

conn.close();
}

} catch (SQLException e) {
    System.out.print("Error: ");
    System.out.println(e.toString());
    
}

The result of running this code appears below. In this case, the customers.txt file contains
10000 rows, seven of which get rejected because they contain data too wide to fit into their
database columns.

Got countNumber of accepted rows = 9993
Handling Errors

When the Vertica JDBC driver encounters an error, it throws a SQLException or one of its subclasses. The specific subclass it throws depends on the type of error that has occurred. Most of the JDBC method calls can result in several different types of errors, in response to which the JDBC driver throws a specific SQLException subclass. Your client application can choose how to react to the error based on the specific exception that the JDBC driver threw.

Note: The specific SQLException subclasses were introduced in the JDBC 4.0 standard. If your client application runs in a Java 5 JVM, it will use the older JDBC 3.0-compliant driver which lacks these subclasses. In that case, all errors throw a SQLException.

The hierarchy of SQLException subclasses is arranged to help your client application determine what actions it can take in response to an error condition. For example:

- The JDBC driver throws SQLTransientException subclasses when the cause of the error may be a temporary condition, such as a timeout error (SQLTimeoutException) or a connection issue (SQLTransientConnectionIssue). Your client application can choose to retry the operation without making any sort of attempt to remedy the error, since it may not reoccur.

- The JDBC driver throws SQLNonTransientException subclasses when the client needs to take some action before it could retry the operation. For example, executing a statement with a SQL syntax error results in the JDBC driver throwing the a SQLSyntaxErrorException (a subclass of SQLNonTransientException). Often, your client application just has to report these errors back to the user and have him or her resolve them. For example, if the user supplied your application with a SQL statement that triggered a SQLSyntaxErrorException, it could prompt the user to fix the SQL error.

See Vertica Analytic Database SQLState Mapping to Java Exception Classes for a list Java exceptions thrown by the JDBC driver.
## Vertica Analytic Database SQLState Mapping to Java Exception Classes

**Routing JDBC Queries Directly to a Single Node**

The JDBC driver has the ability to route queries directly to a single node using a special connection called a Routable Connection. This feature is ideal for high-volume "short" requests that return a small number of results that all exist on a single node. The common scenario for using this feature is to do high-volume lookups on data that is identified with a unique key. Routable queries typically provide lower latency and use less system resources than distributed queries. However, the data being queried must be segmented in such a way that the JDBC client can determine on which node the data resides.
Vertica Typical Analytic Query

Typical analytic queries require dense computation on data across all nodes in the cluster and benefit from having all nodes involved in the planning and execution of the queries.

Vertica Routable Query API Query

For high-volume queries that return a single or a few rows of data, it is more efficient to execute the query on the single node that contains the data.

To effectively route a request to a single node, the client must determine the specific node on which the data resides. For the client to be able to determine the correct node, the table must be segmented by one or more columns. For example, if you segment a table on a Primary Key (PK) column, then the client can determine on which node the data resides based on the Primary Key and directly connect to that node to quickly fulfill the request.
The Routable Query API provides two classes for performing routable queries: VerticaRoutableExecutor and VGet. VerticaRoutableExecutor provides a more expressive SQL-based API while VGet provides a more structured API for programmatic access.

- The VerticaRoutableExecutor class allows you to use traditional SQL with a reduced feature set to query data on a single node. Note that the client and server must be at at least Release 7.1 SP1 to use the VerticaRoutableExecutor.

  For joins, the table must be joined on a key column that exists in each table you are joining, and the tables must be segmented on that key. However, this is not true for unsegmented tables, which can always be joined (since all the data in an unsegmented table is available on all nodes).

- The VGet class does not use traditional SQL syntax. Instead, it uses a data structure that you build by defining predicates and predicate expressions and outputs and output expressions. This class is ideal for doing Key/Value type lookups on single tables.

  The data structure used for querying the table must provide a predicate for each segmented column defined in the projection for the table. You must provide, at a minimum, a predicate with a constant value for each segmented column. For example, an id with a value of 12234 if the table is segmented only on the id column. You can also specify additional predicates for the other, non-segmented, columns in the table. Predicates act like a SQL WHERE clause and multiple predicates/predicate expressions apply together with a SQL AND modifier. Predicates must be defined with a constant value. Predicate expressions can be used to refine the query and can contain any arbitrary SQL expressions (such as less than, greater than, and so on) for any of the non-segmented columns in the table.

Java documentation for all classes and methods in the JDBC Driver is available in the Vertica JDBC Documentation.

Note: The JDBC Routable Query API is read-only and requires JDK 1.6 or greater.

Creating Tables and Projections for use with the Routable Query API

For routable queries, the client must determine the appropriate node to get the data. The client does this by comparing all projections available for the table, and determining the best projection to use to find the single node that contains data. You must create a projection segmented by the key column(s) on at least one table to take full advantage of the routable query API. Other tables that join to this table must either have an unsegmented projection, or a projection segmented as described below.
Creating Tables for use with Routable Queries

To create a table that can be used with the routable query API, segment (by hash) the table on a uniformly distributed column. Typically, you segment on a primary key. For faster lookups, sort the projection on the same columns on which you segmented. For example, to create a table that is well suited to routable queries:

```
CREATE TABLE users (
  id INT NOT NULL PRIMARY KEY,
  username VARCHAR(32),
  email VARCHAR(64),
  business_unit VARCHAR(16))
ORDER BY id
SEGMENTED BY HASH(id)
ALL NODES;
```

This table is segmented based on the id column (and ordered by id to make lookups faster). To build a query for this table using the routable query API, you only need to provide a single predicate for the id column which returns a single row when queried.

However, you might add multiple columns to the segmentation clause. For example:

```
CREATE TABLE users2 (
  id INT NOT NULL PRIMARY KEY,
  username VARCHAR(32),
  email VARCHAR(64),
  business_unit VARCHAR(16))
ORDER BY id, business_unit
SEGMENTED BY HASH(id, business_unit)
ALL NODES;
```

In this case, you need to provide two predicates when querying the users2 table, as it is segmented on two columns, id and business_unit. However, if you know both id and business_unit when you perform the queries, then it is beneficial to segment on both columns, as it makes it easier for the client to determine that this projection is the best projection to use to determine the correct node.

Designing Tables for Single-node JOINs

If you plan to use the VerticaRoutableExecutor class and join tables during routable queries, then you must segment all tables being joined by the same segmentation key. Typically this key is a primary/foreign key on all the tables being joined. For example, the customer_key may be the primary key in a customers dimension table, and the same key is a foreign key in a sales...
fact table. Projections for a VerticaRoutableExecutor query using these tables must be segmented by hash on the customer key in each table.

If you want to join with small dimension tables, such as date dimensions, then it may be appropriate to make those tables unsegmented so that the date_dimension data exists on all nodes. It is important to note that when joining unsegmented tables, you still must specify a segmented table in the createRoutableExecutor() call.

Verifying Existing Projections for Tables

If tables are already segmented by hash (for example, on an ID column), then you can determine what predicates are needed to query the table by using the Vertica function GET_PROJECTIONS to view that table's projections. For example:

```sql
=> SELECT GET_PROJECTIONS ('users');
...
Projection Name: [Segmented] [Seg Cols] [ # of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-----------------------------------------------------------------------------------------------
public.users_b1 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
public.users_b0 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
```

For each projection, only the public.users.id column is specified, indicating your query predicate should include this column.

If the table is segmented on multiple columns, for example id and business_unit, then you need to provide both columns as predicates to the routable query.

Creating a Connection for Routable Queries

The JDBC Routable Query API provides the VerticaRoutableConnection (details are available in the JDBC Documentation) interface to connect to a cluster and allow for Routable Queries. This interface provides advanced routing capabilities beyond those of a normal VerticaConnection. The VerticaRoutableConnection provides access to the VerticaRoutableExecutor and VGet classes. See Defining the Query for Routable Queries using the VerticaRoutableExecutor Class and Defining the Query for Routable Queries Using the VGet Class respectively.

You enable access to this class by setting the EnableRoutableQueries JDBC connection property to true.

The VerticaRoutableConnection maintains an internal pool of connections and a cache of table metadata that is shared by all VerticaRoutableExecutor/VGet objects that are produced by the connection's createRoutableExecutor() /prepareGet() method. It is also a fully-
fledged JDBC connection on its own and supports all the functionality that a VerticaConnection supports. When this connection is closed, all pooled connections managed by this VerticaRoutableConnection and all child objects are closed too. The connection pool and metadata is only used by child Routable Query operations.

Example:

You can create the connection using a JDBC DataSource:

```java
com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
jdbcSettings.setDatabase("exampleDB");
jdbcSettings.setHost("v_vmart_node0001.example.com");
jdbcSettings.setUserID("dbadmin");
jdbcSettings.setPassword("password");
jdbcSettings.setEnableRoutableQueries(true);
jdbcSettings.setPort((short) 5433);

VerticaRoutableConnection conn;
conn = (VerticaRoutableConnection)jdbcSettings.getConnection();
```

You can also create the connection using a connection string and the DriverManager.getConnection() method:

```java
String connectionString = "jdbc:vertica://v_vmart_node0001.example.com:5433/exampleDB?user=dbadmin&password=&EnableRoutableQueries=true";
VerticaRoutableConnection conn = (VerticaRoutableConnection) DriverManager.getConnection(connectionString);
```

Both methods result in a conn connection object that is identical.

**Note:** Avoid opening many VerticaRoutableConnection connections because this connection maintains its own private pool of connections which are not shared with other connections. Instead, your application should use a single connection and issue multiple queries through that connection.

In addition to the setEnableRoutableQueries property that the Routable Query API adds to the Vertica JDBC connection class, the API also adds additional properties. The complete list is below.

- **EnableRoutableQueries:** Enables Routable Query lookup capability. Default is false.

- **FailOnMultiNodePlans:** If the plan requires more than one node, and FailOnMultiNodePlans is true, then the query fails. If it is set to false then a warning is generated and the query continues. However, latency is greatly increased as the Routable Query must first determine the data is on multiple nodes, then a normal query is run using
traditional (all node) execution and execution. Defaults to true. Note that this failure cannot occur on simple calls using only predicates and constant values.

- **MetadataCacheLifetime**: The time in seconds to keep projection metadata. The API caches metadata about the projection used for the query (such as projections). The cache is used on subsequent queries to reduce response time. The default is 300 seconds.

- **MaxPooledConnections**: Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Default 20.

- **MaxPooledConnectionsPerNode**: Per-node maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Default 5.

### Defining the Query for Routable Queries using the VerticaRoutableExecutor Class

The `VerticaRoutableExecutor` class is used to access table data directly from a single node. `VerticaRoutableExecutor` directly queries Vertica only on the node that has all the data needed for the query, avoiding the distributed planning and execution costs associated with a normal Vertica execution. You can use `VerticaRoutableExecutor` if you need to join tables or use a group by clause, as these operations are not possible using VGet.

When using the `VerticaRoutableExecutor` class, you must follow these rules:

- If joining tables, all tables being joined must be segmented (by hash) on the same set of columns referenced in the join predicate, unless the table being joined is unsegmented.

- When using multiple conditions in WHERE clauses, the WHERE clause must use AND between the conditions. Using OR in the WHERE clause causes the query to degenerate to a multi-node plan. OR, IN list, or range conditions on columns outside of the join condition are acceptable if the data exists on the same node.

- You can only execute a single statement per request. "Chained" SQL statements are not permitted.

- Your query may be used in a driver-generated subquery to help determine if the query can be executed on a single node. Therefore, you cannot include the semi-colon at the end of the statement and you cannot include SQL comments (using double-dashes, like so: `--`), as these would cause the driver-generated query to fail.
You create a VerticaRoutableExecutor by calling `createRoutableExecutor(schema, table)` on a connection object. If schema is set to null, then the search path is used to find the table.

VerticaRoutableExecutor Methods

VerticaRoutableExecutor has the following methods (more details on the class are available in the JDBC Documentation):

- `execute(query string, [ column, value | Map ])` - Runs the query. Accepts as input the query to be executed, and either:
  - The column and value when the lookup is being done on just a single value. For example:

    ```java
    String column = "customer_key";
    Integer value = 1;
    ResultSet rs = q.execute(query, column, value)
    ```

  - A Java map of the column names and corresponding values if the lookup is being done on one or more columns. For example: `ResultSet rs = q.execute(query, map);`. The table must have at least one projection segmented by a set of columns exactly matching the columns in the map. Note that each column defined in the map must have only one value. You cannot include more than one value for the same column. For example:

    ```java
    Map<String, Object> map = new HashMap<String, Object>();
    map.put("customer_key", 1);
    map.put("another_key", 42);
    ResultSet rs = q.execute(query, map);
    ```

The query being executed uses regular SQL. The SQL used must meet the rules of the VerticaRoutableExecutor class. For example, you can add limits and sorts, or use aggregate functions, provided the data exists on a single node.

Important: The JDBC client uses the column/value or map arguments to determine on which node to execute the query. You must make sure that the content of the query uses the same values that you provide in the column/value or map arguments.

Note: The following data types cannot be used as column values. Additionally, if a table is segmented on any columns with the following data types then the table cannot be queried using the Routable Query API:
Note: The driver does not verify the syntax of the query before it sends the query to the server. If your expression is incorrect, then the query fails.

- `close()` - Closes this VerticaRoutableExecutor by releasing resources used by this VerticaRoutableExecutor. It does not close the parent JDBC connection to Vertica.

- `getWarnings()` - Retrieves the first warning reported by calls on this VerticaRoutableExecutor. Additional warnings are chained and can be accessed with the JDBC `getNextWarning()` method.

Example Query Using VerticaRoutableExecutor

The following example details how to use VerticaRoutableExecutor to execute a query using both a JOIN clause and an aggregate function with a GROUP BY clause. The example also details how to create both a customer and a sales table, and how to segment the tables so they can be joined using the VerticaRoutableExecutor class. This example also uses the date_dimension table from the VMart schema to illustrate how you can also join data on unsegmented tables.

1. Create a table for customer details, and then create the projections which segment on the `customer_key`.

```sql
CREATE TABLE customers (customer_key INT, customer_name VARCHAR(128), customer_email VARCHAR (128));

CREATE PROJECTION cust_proj_b0 AS
(SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES;

CREATE PROJECTION cust_proj_b1 AS
(SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 1;

CREATE PROJECTION cust_proj_b2 AS
(SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 2;
```
2. Create a sales table, then create the projections which segment on the customer_key. Since both the customer and sales tables are segmented on the same key, you can join them with the VerticaRoutableExecutor Routable Query lookup.

```sql
CREATE TABLE sales (sale_key INT, customer_key INT, date_key INT, sales_amount FLOAT);

CREATE PROJECTION sales_proj_b0 AS
(SELECT *
  FROM sales)
SEGMENTED BY HASH (customer_key) ALL NODES;

CREATE PROJECTION sales_proj_b1 AS
(SELECT *
  FROM sales)
SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 1;

CREATE PROJECTION sales_proj_b2 AS
(SELECT *
  FROM sales)
SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 2;

SELECT start_refresh();
```

3. Add some sample data:

```sql
INSERT INTO customers VALUES (1, 'Fred', 'fred@example.com');
INSERT INTO customers VALUES (2, 'Sue', 'Sue@example.com');
INSERT INTO customers VALUES (3, 'Dave', 'Dave@example.com');
INSERT INTO customers VALUES (4, 'Ann', 'Ann@example.com');
INSERT INTO customers VALUES (5, 'Jamie', 'Jamie@example.com');
COMMIT;

INSERT INTO sales VALUES(1, 1, 1, '100.00');
INSERT INTO sales VALUES(2, 2, 2, '200.00');
INSERT INTO sales VALUES(3, 3, 3, '300.00');
INSERT INTO sales VALUES(4, 4, 4, '400.00');
INSERT INTO sales VALUES(5, 5, 5, '400.00');
INSERT INTO sales VALUES(6, 1, 15, '500.00');
INSERT INTO sales VALUES(7, 1, 15, '400.00');
INSERT INTO sales VALUES(8, 1, 35, '300.00');
INSERT INTO sales VALUES(9, 1, 35, '200.00');
COMMIT;
```

4. Create an unsegmented projection of the VMart date_dimension table for use in this example. Note you must run SELECT start_refresh(); to unsegment the existing data:

```sql
=> CREATE PROJECTION date_dim_unsegment AS
(SELECT *
```
Using the customer, sales, and date_dimension data, you can now create a Routable Query lookup that uses joins and a group by to query the customers table and return the total number of purchases per day for a given customer:

```java
import java.sql.*;
import java.util.HashMap;
import java.util.Map;
import com.vertica.jdbc.kv.*;

public class verticaKV_doc {
    public static void main(String[] args) {
        com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
        jdbcSettings.setDatabase("VMart");
        jdbcSettings.setHost("vertica.example.com");
        jdbcSettings.setUserID("dbadmin");
        jdbcSettings.setPassword("password");
        jdbcSettings.setEnableRoutableQueries(true);
        jdbcSettings.setFailOnMultiNodePlans(true);
        jdbcSettings.setPort((short) 5433);
        VerticaRoutableConnection conn;
        Map<String, Object> map = new HashMap<String, Object>();
        map.put("customer_key", 1);
        try {
            conn = (VerticaRoutableConnection) jdbcSettings.getConnection();
            String table = "customers";
            VerticaRoutableExecutor q = conn.createRoutableExecutor(null, table);
            String query = "select d.date, SUM(s.sales_amount) as Total ";
            query += " from customers as c ";
            query += " join sales as s ";
            query += " on s.customer_key = c.customer_key ";
            query += " join date_dimension as d ";
            query += " on d.date_key = s.date_key ";
            query += " where c.customer_key = " + map.get("customer_key") + " group by (d.date) order by Total DESC";
            ResultSet rs = q.execute(query, map);
            while(rs.next()) {
                System.out.print("Date: " + rs.getString("date") + ": ");
            }
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

The example code outputs:
Note that your dates may be different, because the VMart schema randomly generates the dates in the date_dimension table.

Defining the Query for Routable Queries Using the VGet Class

The VGet class (details on the class are available in the JDBC Documentation) is used to access table data directly from a single node when you do not need to join the data or use a group by clause. Like VerticaRoutableExecutor, VGet directly queries Vertica nodes that have the data needed for the query, avoiding the distributed planning and execution costs associated with a normal Vertica execution. However, VGet does not use SQL. Instead, you define predicates and values to perform Key/Value type lookups on a single table. VGet is especially suited to doing key/value-type lookups on single tables.

You create a VGet by calling prepareGet(schema, table/proj) on a connection object. prepareGet() takes the name of the schema and the name of a table or projection as arguments.

VGet Methods

VGet has the following methods:

- addPredicate(string, object) - adds a predicate column and a constant value to the query. You must include a predicate for each column on which the table is segmented. The predicate acts as the "WHERE" clause to the query. Multiple addPredicate() method calls are joined by AND modifiers. Note that the VGet retains this value after each call to execute. To remove it, use ClearPredicates().

Note: The following data types cannot be used as predicates. Additionally, if a table is segmented on any columns with the following data types then the table cannot be queried using the Routable Query API:

- interval
- timetz
- timestamptz
- `addPredicateExpression(string)` - Accepts arbitrary SQL expressions that operate on the table's columns as input to the query. Predicate expressions and predicates are joined by AND modifiers. You can use segmented columns in predicate expressions, but they must also be specified as a regular predicate with `addPredicate()`.

  Note: The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

- `addOutputColumn(string)` - Adds a column to be included in the output. By default the query runs as `SELECT *` and you do not need to define any output columns to return the data. If you add output columns then you must add all the columns you want returned.

  Note that the VGet retains this value after each call to execute. To remove it, use `ClearOutputs()`.

- `addOutputExpression(string)` - Accepts arbitrary SQL expressions that operate on the table's columns as output. Note that the VGet retains this value after each call to execute. To remove it, use `ClearOutputs()`.

  Note: The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

  Note: `addOutputExpression()` is not supported when querying Flex Tables. If you attempt to use `addOutputExpression()` on a Flex Table query, then a `SQLFeatureNotSupportedException` is thrown.

- `addSortColumn(string, SortOrder)` - Adds a sort order to an output column. The output column can be either the one returned by the default query (`SELECT *`) or one of the columns defined in `addOutputColumn` or `addOutputExpression`. You can defined multiple sort columns.

- `setLimit(int)` - Sets a limit on the number of results returned. A limit of 0 is unlimited.

- `clearPredicates()` - Removes predicates that were added by `addPredicate()` and `addPredicateExpression()`.

- `clearOutputs()` - Removes outputs added by `addOutput()` and `addOutputExpression()`.

- `clearSortColumns()` - Removes sort columns previously added by `addSortColumn()`.
execute() - Runs the query. Care must be taken to ensure that the predicate columns exist on the table and projection used by VGet, and that the expressions do not require multiple nodes to execute. If an expression is sufficiently complex as to require more than one node to execute, execute() throws a SQLException if the FailOnMultiNodePlans connection property is true.

close() - Closes this VGet by releasing resources used by this VGet. It does not close the parent JDBC connection to Vertica.

getWarnings() - Retrieves the first warning reported by calls on this VGet. Additional warnings are chained and can be accessed with the JDBC getNextWarning() method.

You call the execute() method to run query. By default, the VGet fetches all the columns of all the rows that satisfy the logical AND of all the predicates passed via the addPredicate() method. To further customize the get operation use the addOutputColumn(), addOutputExpression(), addPredicateExpression(), addSortColumn() and setLimit() methods.

Note: VGet operations span multiple JDBC connections (and multiple Vertica sessions) and do not honor the parent connection's transaction semantics. If consistency is required across multiple executions, the parent VerticaRoutableConnection's consistent read API can be used to guarantee all operations occur at the same epoch.

VGet is thread safe, but all methods are synchronized, so threads that share a VGet instance are never run in parallel. For better parallelism, each thread should have its own VGet instance. Different VGet instances that operate on the same table share pooled connections and metadata in a manner that enables a high degree of parallelism.

Example

You can query the table defined in Creating Tables and Projections for use with the Routable Query API with the following example code. The table defines an id column that is segmented by hash.

```java
import java.sql.*;
import com.vertica.jdbc.kv..parseLong();

public class verticaKV2 {  
    public static void main(String[] args) {  
        com.vertica.jdbc.DataSource jdbcSettings  
            = new com.vertica.jdbc.DataSource();  
        jdbcSettings.setDatabase("exampleDB");  
        jdbcSettings.setHost("v_vmart_node0001.example.com");  
        jdbcSettings.setUserID("dbadmin");  
        jdbcSettings.setPassword("password");
```
jdbcSettings.setEnableRoutableQueries(true);
jdbcSettings.setPort((short) 5433);

VerticaRoutableConnection conn;
try {
    conn = (VerticaRoutableConnection)
        jdbcSettings.getConnection();
    System.out.println("Connected.");
    VGet get = conn.prepareGet("public", "users");
    get.addPredicate("id", 5);
    ResultSet rs = get.execute();
    rs.next();
    System.out.println("ID: " +
        rs.getString("id"));
    System.out.println("Username: "
        + rs.getString("username");
    System.out.println("Email: "
        + rs.getString("email"));
    System.out.println("Closing Connection.");
    conn.close();
} catch (SQLException e) {
    System.out.println("Error! Stacktrace:");
    e.printStackTrace();
}

The output:

Connected.
ID: 5
Username: userE
Email: userE@example.com
Closing Connection.

Routable Query Performance and Troubleshooting

This topic details performance considerations and common issues you might encounter when using the routable query API.

Using Resource Pools with Routable Queries

Individual routable queries are serviced quickly since they directly access a single node and return only one or a few rows of data. However, by default, Vertica resource pools use an AUTO setting for the execution parallelism parameter. When set to AUTO, the setting is determined by the number of CPU cores available and generally results in multi-threaded execution of queries in the resource pool. It is not efficient to create parallel threads on the server because routable query operations return data so quickly and routable query operations...
only use a single thread to find a row. To prevent the server from opening unneeded processing threads, you should create a specific resource pool for routable query clients. Consider the following settings for the resource pool you use for routable queries:

- Set execution parallelism to 1 to force single-threaded queries. This setting improves routable query performance.
- Use CPU affinity to limit the resource pool to a specific CPU or CPU set. The setting ensures that the routable queries have resources available to them, but it also prevents routable queries from significantly impacting performance on the system for other general queries.
- If you do not set a CPU affinity for the resource pool, consider setting the maximum concurrency value of the resource pool to a setting that ensures good performance for routable queries, but does not negatively impact the performance of general queries.

Performance Considerations for Routable Query Connections

Because a VerticaRoutableConnection opens an internal pool of connections, it is important to configure MaxPooledConnections and MaxPooledConnectionsPerNode appropriately for your cluster size and the amount of simultaneous client connections. It is possible to impact normal database connections if you are overloading the cluster with VerticaRoutableConnections.

The initial connection to the initiator node discovers all other nodes in the cluster. The internal-pool connections are not opened until a VerticaRoutableExecutor or VGet query is sent. All VerticaRoutableExecutors/VGets in a connection object use connections from the internal pool and are limited by the MaxPooledConnections settings. Connections remain open until they are closed so a new connection can be opened elsewhere if the connection limit has been reached.

Troubleshooting Routable Queries

Routable query issues generally fall into two categories:

- Not providing enough predicates.
- Queries having to span multiple nodes.

Predicate Requirements

You must provide the same number of predicates that correspond to the columns of the table segmented by hash. To determine the segmented columns, call the Vertica function GET_PROJECTIONS. You must provide a predicate for each column displayed in the Seg Cols field.
For VGet, this means you must use `addPredicate()` to add each of the columns. For VerticaRoutableExecutor, this means you must provide all of the predicates and values in the map sent to `execute()`.

**Multi-node Failures**

It is possible to define the correct number of predicates, but still have a failure because multiple nodes contain the data. This failure occurs because the projection’s data is not segmented in such a way that the data being queried is contained on a single node. Enable logging for the connection and view the logs to verify the projection being used. If the client is not picking the correct projection, then try to query the projection directly by specifying the projection instead of the table in the create/prepare statement, for example:

- Using VerticaRoutableExecutor:
  ```java
  conn.createRoutableExecutor(schema, table/projection);
  ```

- Using VGet:
  ```java
  conn.prepareGet('schema','table/projection')
  ```

Additionally, you can use the `EXPLAIN` command in vsql to help determine if your query can run in single node. EXPLAIN can help you understand why the query is being run as single or multi-node.

**Pre-Segmenting Data Using VHash**

The VHash class is an implementation of the Vertica hash function for use with JDBC client applications.

Hash segmentation in Vertica allows you to segment a projection based on a built-in hash function. The built-in hash function provides even data distribution across some or all nodes in a cluster, resulting in optimal query execution.

Suppose you have several million rows of values spread across thousands of CSV files. Assume that you already have a table segmented by hash. Before you load the values into your database, you probably want to know to which node a particular value loads. For this reason, using VHash can be particularly helpful, by allowing you to pre-segment your data before loading.

The following example shows the VHash class hashing the first column of a file named "testFile.csv". The name of the first column in this file is `meterId`.

```java
Using VerticaRoutableExecutor:
```Java
conn.createRoutableExecutor(schema, table/projection);
```

Using VGet:
```
conn.prepareGet('schema','table/projection')
```

Additionally, you can use the EXPLAIN command in vsql to help determine if your query can run in single node. EXPLAIN can help you understand why the query is being run as single or multi-node.

**Pre-Segmenting Data Using VHash**

The VHash class is an implementation of the Vertica hash function for use with JDBC client applications.

Hash segmentation in Vertica allows you to segment a projection based on a built-in hash function. The built-in hash function provides even data distribution across some or all nodes in a cluster, resulting in optimal query execution.

Suppose you have several million rows of values spread across thousands of CSV files. Assume that you already have a table segmented by hash. Before you load the values into your database, you probably want to know to which node a particular value loads. For this reason, using VHash can be particularly helpful, by allowing you to pre-segment your data before loading.

The following example shows the VHash class hashing the first column of a file named "testFile.csv". The name of the first column in this file is `meterId`.
Segment the Data Using VHash

This example demonstrates how you can read the testFile.csv file from the local file system and run a hash function on the meteterId column. Using the database metadata from a projection, you can then pre-segment the individual rows in the file based on the hash value of meterId.

```java
import java.io.BufferedReader;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;
import java.io.FileReader;
import java.io.UnsupportedEncodingException;
import java.util.*;
import java.io.IOException;
import java.sql.*;
import com.vertica.jdbc.kv.VHash;

public class VerticaKVDoc {
    final Map<String, FileOutputStream> files;
    final Map<String, List<Long>> nodeToHashList;
    String segmentationMetadata;
    List<String> lines;

    public static void main(String[] args) throws Exception {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }

        Properties myProp = new Properties();
        myProp.put("user", "username");
        myProp.put("password", "password");

        VerticaKVDoc ex = new VerticaKVDoc();

        // Read in the data from a CSV file.
        ex.readLinesFromFile("C:\testFile.csv");

        try (Connection conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:portNumber/databaseName", myProp)) {
            // Compute the hashes and create FileOutputStreams.
            ex.prepareForHashing(conn);
        }

        // Write to files.
        ex.writeLinesToFiles();
    }

    public VerticaKVDoc() {
        files = new HashMap<String, FileOutputStream>();
    }
}
```
nodeToHashList = new HashMap<String, List<Long>>()

public void prepareForHashing(Connection conn) throws SQLException, FileNotFoundException {
    // Send a query to Vertica to return the projection segments.
    try (ResultSet rs = conn.createStatement().executeQuery(
        "SELECT get_projection_segments('public.projectionName')")
    ) {
        rs.next();
        segmentationMetadata = rs.getString(1);
    }
    // Initialize the data files.
    try (ResultSet rs = conn.createStatement().executeQuery(
        "SELECT node_name FROM nodes"
    )
    ) {
        while (rs.next()) {
            String node = rs.getString(1);
            files.put(node, new FileOutputStream(node + ".csv"));
        }
    }

    public void writeLinesToFiles() throws UnsupportedEncodingException, IOException {
        for (String line : lines) {
            long hashedValue = VHash.hashLong(getMeterIdFromLine(line));
            // Write the row data to that node’s data file.
            String node = VHash.getNodeFor(segmentationMetadata, hashedValue);
            FileOutputStream fos = files.get(node);
            fos.write(line.getBytes("UTF-8"));
        }
    }

    private long getMeterIdFromLine(String line) {
        // In our file, "meterId" is the name of the first column in the file.
        return Long.parseLong(line.split(",")[0]);
    }

    public void readLinesFromFile(String filename) throws IOException {
        lines = new ArrayList<String>();
        String line;
        try (BufferedReader reader = new BufferedReader(
            new FileReader(filename))) {
            while ((line = reader.readLine()) != null) {
                lines.add(line);
            }
        }
    }
}
Programming ADO.NET Applications

The Vertica driver for ADO.NET allows applications written in C# to read data from, update, and load data into Vertica databases. It provides a data adapter (Vertica Data Adapter) that facilitates reading data from a database into a data set, and then writing changed data from the data set back to the database. It also provides a data reader (VerticaDataReader) for reading data. The driver requires the .NET framework version 3.5+.

For more information about ADO.NET, see:

- Overview of ADO.NET
- .NET Framework Developer Guide

Note: All of the examples provided in this section are in C#.

ADO.NET Data Types

This table details the mapping between Vertica data types and .NET and ADO.NET data types.

<table>
<thead>
<tr>
<th>.NET Framework DbType</th>
<th>ADO.NET DbType</th>

**UUID Backwards Compatibility**

Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1.

**Note:** There are 13 VerticaType values for the 13 types of intervals. The specific VerticaType used determines the conversion rules that the driver applies. Year/Month intervals represented as 365/30 days.
Vertica maintains backwards compatibility with the earlier client driver versions that do not support the UUID data type (see Client Driver and Server Version Compatibility for the versions of the client drivers that Vertica supports). When one of these older clients queries tables with UUID columns in them, Vertica automatically translates the native UUID values to CHAR values. Also, when an older client inserts data into a UUID column, Vertica automatically converts the CHAR value sent by the client into a native UUID value. Vertica also reports the data type of these columns as CHAR when an older client queries a UUID column's metadata.

Setting the Locale for ADO.NET Sessions

- ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions as for ODBC apply if this encoding is violated.

- The ADO.NET driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16

- ADO.NET applications should set the correct server session locale by executing the SET LOCALE TO command in order to get expected collation and string functions behavior on the server.

- If there is no default session locale at the database level, ADO.NET applications need to set the correct server session locale by executing the SET LOCALE TO command in order to get expected collation and string functions behavior on the server. See the SET LOCALE command in the SQL Reference Manual

Connecting to the Database

This section describes:

- Using SSL: Installing SSL Certificates on Windows
- Opening and Closing the Database Connection (ADO.NET)
- ADO.NET Connection Properties
- Configuring Log Properties
Using SSL: Installing Certificates on Windows

You can optionally secure communication between your ADO.NET application and Vertica using SSL. The Vertica ADO.NET driver uses the default Windows key store when looking for SSL certificates. This is the same key store that Internet Explorer uses.

Before you can use SSL on the client side, you must implement SSL on the server. See TLS/SSL Server Authentication in the Administrator’s Guide, perform those steps, then return to this topic to install the SSL certificate on Windows.

To use SSL for ADO.NET connections to Vertica:

- Import the server and client certificates into the Windows Key Store.
- If required by your certificates, import the public certificate of your Certifying Authority.

Import the Server and Client Certificates into the Windows Key store:

1. Copy the server.crt file you generated when you enabled SSL on the server to your Windows Machine.
2. Double-click the certificate.
3. Let Windows determine the key type, and click Install.

Import the Public Certificate of Your CA:

You must establish a chain of trust for the certificates. You may need to import the public certificate for your Certifying Authority (CA) (especially if it is a self-signed certificate).

1. using the same certificate as above, double-click the certificate.
2. Select Place all certificates in the following store.
3. Click Browse, select Trusted Root Certification Authorities and click Next.
4. Click Install.

Enable SSL in Your ADO.NET Applications

In your connection string, be sure to enable SSL by setting the SSL property in VerticaConnectionStringBuilder to true, for example:
Opening and Closing the Database Connection (ADO.NET)

Before you can access data in Vertica through ADO.NET, you must create a connection to the database using the VerticaConnection class which is an implementation of System.Data.DbConnection. The VerticaConnection class takes a single argument that contains the connection properties as a string. You can manually create a string of property keywords to use as the argument, or you can use the VerticaConnectionStringBuilder class to build a connection string for you.

To download the ADO.NET driver, go to the Client Drivers Downloads page.

This topic details the following:

- Manually building a connection string and connecting to Vertica
- Using VerticaConnectionStringBuilder to create the connection string and connecting to Vertica
- Closing the connection

To Manually Create a Connection string:

See ADO.NET Connection Properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

1. For each property, provide a value and append the properties and values one after the other, separated by a semicolon. Assign this string to a variable. For example:

   ```
   String connectionString = "DATABASE=VMart;HOST=v_vmart_node0001;USER=dbadmin";
   ```

2. Build a Vertica connection object that specifies your connection string.

   ```
   VerticaConnection _conn = new VerticaConnection(connectionString);
   ```
3. Open the connection.

```csharp
_conn.Open();
```

4. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.

```csharp
VerticaCommand command = _conn.CreateCommand();
```

To Use the VerticaConnectionStringBuilder Class to Create a Connection String and Open a connection:

1. Create a new object of the VerticaConnectionStringBuilder class.

```csharp
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
```

2. Update your VerticaConnectionStringBuilder object with property values. See ADO.NET Connection Properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

```csharp
builder.Host = "v_vmart_node0001";
builder.Database = "VMart";
builder.User = "dbadmin";
```

3. Build a Vertica connection object that specifies your connection VerticaConnectionStringBuilder object as a string.

```csharp
VerticaConnection _conn = new VerticaConnection(builder.ToString());
```

4. Open the connection.

```csharp
_conn.Open();
```

5. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.

```csharp
VerticaCommand command = _conn.CreateCommand();
```

**Note:** If your database is not in compliance with your Vertica license, the call to `VerticaConnection.open()` returns a warning message to the console and the log. See
Managing Licenses in the Administrator's Guide for more information.

To Close the connection:

When you're finished with the database, close the connection. Failure to close the connection can deteriorate the performance and scalability of your application. It can also prevent other clients from obtaining locks.

```csharp
_conn.Close();
```

Example Usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            //Perform some operations
            _conn.Close();
        }
    }
}
```

**ADO.NET Connection Properties**

To download the ADO.NET driver, go to the Client Drivers Downloads page.

You use connection properties to configure the connection between your ADO.NET client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number, needed to connect to your database.

You can set a connection property in two ways:
- Include the property name and value as part of the connection string you pass to a VerticaConnection.

- Set the properties in a VerticaConnectionStringBuilder object, and then pass the object as a string to a VerticaConnection.

<table>

</tbody>
</table>
Enabling Native Connection Load Balancing in ADO.NET

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen. If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator’s Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the connection string or using the ConnectionStringBuilder(). The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```csharp
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
```

```csharp
static void Main(string[] args)
{
    VerticaConnectionStringBuilder builder =
        new VerticaConnectionStringBuilder();
    builder.Host = "v_vmart_node0001.example.com";
    builder.Database = "VMart";
    builder.User = "dbadmin";
    // Enable native client load balancing in the client,
    // must also be enabled on the server!
    builder.ConnectionLoadBalance = true;
    // Connect 3 times to verify a new node is connected
    // for each connection.
    for (int i = 1; i <= 4; i++)
    {
        try
        {
            VerticaConnection _conn =
                new VerticaConnection(builder.ToString());
            _conn.Open();
            if (i == 1)
            {
                // On the first connection, check the server policy for load balance
                VerticaCommand sqlcom = _conn.CreateCommand();
                sqlcom.CommandText =
                    "SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES";
                var returnVal = sqlcom.ExecuteScalar();
                Console.WriteLine("Status of load balancy policy on server: " +
                    returnVal.ToString() + "\n");
            }
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText =
                "SELECT node_name FROM V_MONITOR.CURRENT_SESSION";
            VerticaDataReader dr = command.ExecuteReader();
            while (dr.Read())
            {
                Console.Write("Connect attempt #" + i + ".");
                Console.WriteLine(" Connected to node " + dr[0]);
            }
            dr.Close();
            _conn.Close();
            Console.WriteLine("Disconnecting.\n");
        }
        catch (Exception e)
        {
            Console.WriteLine(e.Message);
        }
    }
}
```

Running the above example produces the following output:

```
Status of load balancy policy on server: roundrobin

Connect attempt #1... Connected to node v_vmart_node0001
Disconnecting.
```
Connect attempt #2... Connected to node v_vmart_node0002
Disconnecting.

Connect attempt #3... Connected to node v_vmart_node0003
Disconnecting.

Connect attempt #4... Connected to node v_vmart_node0001
Disconnecting.

ADO.NET Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.

- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts. Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.
Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note: If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS Failover

To use DNS failover, you need to change your DNS server’s settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the BackupServerNode parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.
The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```csharp
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
                new VerticaConnectionStringBuilder();
            builder.Host = "not.a.real.host:5433";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            builder.BackupServerNode =
                "another.broken.node:5433,v_vmart_node0002.example.com:5433";
            try
            {
                VerticaConnection _conn =
                    new VerticaConnection(builder.ToString());
                _conn.Open();
                VerticaCommand sqlcom = _conn.CreateCommand();
                sqlcom.CommandText = "SELECT node_name FROM current_session";
                var returnValue = sqlcom.ExecuteScalar();
                Console.WriteLine("Connected to node: "+
                                   returnValue.ToString() + "\n");
                _conn.Close();
                Console.WriteLine("Disconnecting.\n");
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
        }
    }
}
```

Notes

- When native connection load balancing is enabled, the additional servers specified in the `BackupServerNode` connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See [Enabling Native Connection Load Balancing in ADO.NET](https://docs.vertica.com/).
• Connections to a host taken from the BackupServerNode list are not pooled for ADO.NET connections.

### Configuring Log Properties (ADO.Net)

Log properties for ADO.Net are configured differently than they are other client drivers. On the other client drivers, log properties can be configured as one of the connection properties. The ADO.Net driver user the VerticaLogProperties class to configure the properties.

**VerticaLogProperties**

VerticaLogProperties is a static class that allows you to set and get the log settings for the ADO.net driver. You can control the log level, log path, and log namespace using this class. The log is created when the first connection is opened. Once the connection is opened, you cannot change the log path. It must be set prior to opening the connection. You can change the log level and log namespace at any time.

### Setting Log Properties

Setting the log properties is done using the three methods in the VerticaLogProperties class. The three methods are:

• **SetLogPath(String path, bool persist)**

• **SetLogNamespace(String lognamespace, bool persist)**

• **SetLogLevel(VerticaLogLevel loglevel, bool persist)**

Each of the methods requires a boolean persist argument. When set to true, the persist argument causes the setting to be written to the client’s Windows Registry, where it is used for all subsequent connections. If set to false, then the log property only applies to the current session.

**SetLogPath**

The SetLogPath method takes as its arguments a string containing the path to the log file and the persist argument. If the path string contains only a directory path, then the log file is created with the name vdp-driver-MM-dd_HH.mm.ss.log (where MM-dd_HH.mm.ss is the date and time the log was created). If the path ends in a filename, such as log.txt or log.log, then the log is created with that filename.
If `SetLogPath` is called with an empty string for the path argument, then the client executable's current directory is used as the log path.

If `SetLogPath` is not called and no registry entry exists for the log path, and you have called any of the other `VerticaLogProperties` methods, then the client executable's current directory is used as the log path.

When the persist argument is set to true, the path specified is copied to the registry verbatim. If no filename was specified, then the filename is not saved to the registry.

**Note:** The path must exist on the client system prior to calling this method. The method does not create directories.

**Example Usage:**

```csharp
    // set the log path
    string path = "C:\log";
    VerticalLogProperties.SetLogPath(path, false);
```

**SetLogNamespace**

The `SetLogNamespace` method takes as its arguments a string containing the namespace to log and the persist argument. The namespace string to log can be one of the following:

- **Vertica**
- **Vertica.Data.VerticaClient**
- **Vertica.Data.Internal.IO**
- **Vertica.Data.Internal.DataEngine**
- **Vertica.Data.Internal.Core**

Namespaces can be truncated to include multiple child namespaces. For example, you can specify "Vertica.Data.Internal" to log for all of the Vertica.Data.Internal namespaces.

If a log namespace is not set, and no value is stored in the registry, then the "Vertica" namespace is used for logging.

**Example Usage:**

```csharp
    // set namespace to log
    string lognamespace = "Vertica.Data.VerticaClient";
    VerticalLogProperties.SetLogNamespace(lognamespace, false);
```
SetLogLevel

The SetLogLevel method takes as its arguments a VerticaLogLevel type and the persist argument. The VerticaLogLevel argument can be one of:

- VerticaLogLevel.None
- VerticaLogLevel.Fatal
- VerticaLogLevel.Error
- VerticaLogLevel.Warning
- VerticaLogLevel.Info
- VerticaLogLevel.Debug
- VerticaLogLevel.Trace

If a log level is not set, and no value is stored in the registry, then VerticaLogLevel.None is used.

Example Usage:

```java
// set log level
VerticaLogLevel level = VerticaLogLevel.Debug;
VerticaLogProperties.SetLogLevel(level, false);
```

Getting Log Properties

You can get the log property values using the getters included in the VerticaLogProperties class. The properties are:

- LogPath
- LogNamespace
- LogLevel

Example Usage:

```java
// get current log settings
string logpath = VerticaLogProperties.LogPath;
VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
string logns = VerticaLogProperties.LogNamespace;
Console.WriteLine("Current Log Settings:");
Console.WriteLine("Log Path: " + logpath);
```
Console.WriteLine("Log Level: " + loglevel);
Console.WriteLine("Log Namespace: " + logns);

Setting and Getting Log Properties Example

This complete example shows how to set and get log properties:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {

            //configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            //get current log settings
            string logpath = VerticaLogProperties.LogPath;
            VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
            string logns = VerticaLogProperties.LogNamespace;
            Console.WriteLine("Old Log Settings:" );
            Console.WriteLine("Log Path: " + logpath);
            Console.WriteLine("Log Level: " + loglevel);
            Console.WriteLine("Log Namespace: " + logns);

            //set the log path
            string path = "C:\\log";
            VerticaLogProperties.SetLogPath(path, false);

            //set log level
            VerticaLogLevel level = VerticaLogLevel.Debug;
            VerticaLogProperties.SetLogLevel(level, false);

            //set namespace to log
            string lognamespace = "Vertica";
            VerticaLogProperties.SetLogNamespace(lognamespace, false);

            //open the connection
        }
    }
}
```

Vertica Documentation
Connecting to Vertica
VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();

// get new log settings

logpath = VerticaLogProperties.LogPath;
loglevel = VerticaLogProperties.LogLevel;
logns = VerticaLogProperties.LogNamespace;
Console.WriteLine("\nNew Log Settings:");
Console.WriteLine("Log Path: " + logpath);
Console.WriteLine("Log Level: " + loglevel);
Console.WriteLine("Log Namespace: " + logns);

// close the connection

_conn.Close(); 
}
}

The example produces the following output:

Old Log Settings:
Log Path:
Log Level: None
Log Namespace:
New Log Settings:
Log Path: C:\log
Log Level: Debug
Log Namespace: Vertica

Querying the Database Using ADO.NET

This section describes how to create queries to do the following:

- Inserting data into the database
- Read data from the database
- Load data into the database

Note: The ExecuteNonQuery() method used to query the database returns an int32 with the number of rows affected by the query. The maximum size of an int32 type is a constant and is defined to be 2,147,483,547. If your query returns more results than the int32 max, then ADO.NET throws an exception because of the overflow of the int32 type. However the query is still processed by Vertica even when the reporting of the return value fails. This is a limitation in .NET, as ExecuteNonQuery() is part of the standard ADO.NET interface.
Inserting Data (ADO.NET)

Inserting data can be done using the VerticaCommand class. VerticaCommand is an implementation of DbCommand. It allows you to create and send a SQL statement to the database. Use the CommandText method to assign a SQL statement to the command and then execute the SQL by calling the ExecuteNonQuery method. The ExecuteNonQuery method is used for executing statements that do not return result sets.

To Insert a Single Row of data:

1. Create a connection to the database.

2. Create a command object using the connection.

   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```

3. Insert data using an INSERT statement. The following is an example of a simple insert. Note that it does not contain a COMMIT statement because the Vertica ADO.NET driver operates in autocommit mode.

   ```csharp
   command.CommandText = 
   "INSERT into test values(2, 'username', 'email', 'password')";
   ```

4. Execute the query. The rowsAdded variable contains the number of rows added by the insert statement.

   ```csharp
   Int32 rowsAdded = command.ExecuteNonQuery();
   ```

   The ExecuteNonQuery() method returns the number of rows affected by the command for UPDATE, INSERT, and DELETE statements. For all other types of statements it returns -1. If a rollback occurs then it is also set to -1.

Example Usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
```
```csharp
using System;
using Vertica.

namespace Program
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "INSERT into test values(2, 'username', 'email', 'password')";
            Int32 rowsAdded = command.ExecuteNonQuery();
            Console.WriteLine( rowsAdded + " rows added!");
            _conn.Close();
        }
    }
}
```

**Using Parameters**

You can use parameters to execute similar SQL statements repeatedly and efficiently.
Using Parameters

VerticaParameters are an extension of the System.Data.DbParameter base class in ADO.NET and are used to set parameters in commands sent to the server. Use Parameters in all queries (SELECT/INSERT/UPDATE/DELETE) for which the values in the WHERE clause are not static; that is for all queries that have a known set of columns, but whose filter criteria is set dynamically by an application or end user. Using parameters in this way greatly decreases the chances of a SQL injection issue that can occur when simply creating a SQL query from a number of variables.

Parameters require that a valid DbType, VerticaDbType, or System type be assigned to the parameter. See SQL Data Types and ADO.NET Data Types for a mapping of System, Vertica, and DbType.

To create a parameter placeholder, place either the at sign (@) or a colon (:) character in front of the parameter name in the actual query string. Do not insert any spaces between the placeholder indicator (@ or :) and the placeholder.

**Note:** The @ character is the preferred way to identify parameters. The colon (:) character is supported for backward compatibility.

For example, the following typical query uses the string 'MA' as a filter.

```
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = 'MA';
```

Instead, the query can be written to use a parameter. In the following example, the string MA is replaced by the parameter placeholder @STATE.

```
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = @STATE;
```

For example, the ADO.net code for the prior example would be written as:

```
VerticaCommand command = _conn.CreateCommand();
command.CommandText = "SELECT customer_name, customer_address, customer_city, customer_state 
FROM customer_dimension WHERE customer_state = @STATE";
command.Parameters.Add(new VerticaParameter( "STATE", VerticaType.VarChar));
command.Parameters["STATE"].Value = "MA";
```

**Note:** Although the VerticaCommand class supports a Prepare() method, you do not need to call the Prepare() method for parameterized statements because Vertica automatically prepares the statement for you.

Creating and Rolling Back Transactions
Creating Transactions

Transactions in Vertica are atomic, consistent, isolated, and durable. When you connect to a database using the Vertica ADO.NET Driver, the connection is in autocommit mode and each individual query is committed upon execution. You can collect multiple statements into a single transaction and commit them at the same time by using a transaction. You can also choose to rollback a transaction before it is committed if your code determines that a transaction should not commit.

Transactions use the VerticaTransaction object, which is an implementation of DbTransaction. You must associate the transaction with the VerticaCommand object.

The following code uses an explicit transaction to insert one row each into tables of the VMart schema.
To Create a Transaction in Vertica Using the ADO.NET driver:

1. Create a connection to the database.

2. Create a command object using the connection.

   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```

3. Start an explicit transaction, and associate the command with it.

   ```csharp
   VerticaTransaction txn = _conn.BeginTransaction();
   command.Connection = _conn;
   command.Transaction = txn;
   ```

4. Execute the individual SQL statements to add rows.

   ```csharp
   command.CommandText =
       "insert into product_dimension values( ... )";
   command.ExecuteNonQuery();
   command.CommandText =
       "insert into store_orders_fact values( ... )";
   ```

5. Commit the transaction.

   ```csharp
   txn.Commit();
   ```
Rolling Back Transactions

If your code checks for errors, then you can catch the error and rollback the entire transaction.

```csharp
VerticaTransaction txn = _conn.BeginTransaction();
VerticaCommand command = new
    VerticaCommand("insert into product_dimension values( 838929, 5, 'New item 5')", _conn);
// execute the insert
command.ExecuteNonQuery();
command.CommandText = "insert into product_dimension values( 838929, 6, 'New item 6')";
// try insert and catch any errors
bool error = false;
try
{
    command.ExecuteNonQuery();
} catch (Exception e)
{
    Console.WriteLine(e.Message);
    error = true;
}
if (error)
{
    txn.Rollback();
    Console.WriteLine("Errors. Rolling Back.");
} else
{
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
}
```
Commit and Rollback Example

This example details how you can commit or rollback queries during a transaction.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            bool error = false;
            VerticaCommand command = _conn.CreateCommand();
            VerticaCommand command2 = _conn.CreateCommand();
            VerticaTransaction txn = _conn.BeginTransaction();
            command.Connection = _conn;
            command.Transaction = txn;
            command.CommandText = "insert into test values(1, 'test', 'test', 'test')";
            Console.WriteLine(command.CommandText);
            try
            {
                command.ExecuteNonQuery();
            } catch (Exception e)
            {
                Console.WriteLine(e.Message);
                error = true;
            }
            command.CommandText = "insert into test values(2, 'ear', 'eye', 'nose', 'extra')";
            Console.WriteLine(command.CommandText);
            try
            {
                command.ExecuteNonQuery();
            } catch (Exception e)
            {
                Console.WriteLine(e.Message);
                error = true;
            }
            if (error)
            {
                txn.Rollback();
                Console.WriteLine("Errors. Rolling Back.");
            }
        }
    }
```
else
{
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
    _conn.Close();
}

The example displays the following output on the console:

```sql
insert into test values(1, 'test', 'test', 'test')
insert into test values(2, 'ear', 'eye', 'nose', 'extra')
[42601]ERROR: INSERT has more expressions than target columns
Errors. Rolling Back.
```

See Also

- Setting the Transaction Isolation Level
Setting the Transaction Isolation Level

You can set the transaction isolation level on a per-connection and per-transaction basis. See Transaction for an overview of the transaction isolation levels supported in Vertica. To set the default transaction isolation level for a connection, use the `IsolationLevel` keyword in the `VerticaConnectionStringBuilder` string (see Connection String Keywords for details). To set the isolation level for an individual transaction, pass the isolation level to the `VerticaConnection.BeginTransaction()` method call to start the transaction.
To set the Isolation Level on a connection-basis:

1. Use the VerticaConnectionStringBuilder to build the connection string.

2. Provide a value for the IsolationLevel builder string. It can take one of two values: IsolationLevel.ReadCommited (default) or IsolationLevel.Serializeable. For example:

   ```csharp
   VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
   builder.Host = "192.168.1.100";
   builder.Database = "VMart";
   builder.User = "dbadmin";
   VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
   _conn1.Open();
   ```
To set the Isolation Level on a Transaction basis:

1. Set the IsolationLevel on the BeginTransaction method, for example

```java
VerticaTransaction txn = _conn.BeginTransaction(IsolationLevel.Serializable);
```
Example usage:

The following example demonstrates:

- getting the connection's transaction isolation level.
- setting the connection's isolation level using connection property.
- setting the transaction isolation level for a new transaction.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
            _conn1.Open();
            VerticaTransaction txn1 = _conn1.BeginTransaction();
            Console.WriteLine("\n Transaction 1 Transaction Isolation Level: "+
            txn1.IsolationLevel.ToString());
            txn1.Rollback();
            VerticaTransaction txn2 = _conn1.BeginTransaction(IsolationLevel.Serializable);
            Console.WriteLine("\n Transaction 2 Transaction Isolation Level: "+
            txn2.IsolationLevel.ToString());
            txn2.Rollback();
            VerticaTransaction txn3 = _conn1.BeginTransaction(IsolationLevel.ReadCommitted);
            Console.WriteLine("\n Transaction 3 Transaction Isolation Level: "+
            txn3.IsolationLevel.ToString());
            _conn1.Close();
        }
    }
}
```

When run, the example code prints the following to the system console:

```
Transaction 1 Transaction Isolation Level: ReadCommitted
Transaction 2 Transaction Isolation Level: Serializable
Transaction 3 Transaction Isolation Level: ReadCommitted
```
Reading Data (ADO.Net)

To read data from the database use VerticaDataReader, an implementation of DbDataReader. This implementation is useful for moving large volumes of data quickly off the server where it can be run through analytic applications.

Note: A VerticaCommand cannot execute anything else while it has an open VerticaDataReader associated with it. To execute something else, close the data reader or use a different VerticaCommand object.

To Read Data From the Database Using VerticaDataReader:

1. Create a connection to the database.

2. Create a command object using the connection.

   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```

3. Create a query. This query works with the example VMart database.

   ```csharp
   command.CommandText = 
   "SELECT fat_content, product_description " + 
   "FROM (SELECT DISTINCT fat_content, product_description" + 
   " FROM product_dimension " + 
   " WHERE department_description " + " " + " + " + " " + "IN ('Dairy') " + 
   "ORDER BY fat_content) AS food " + 
   "LIMIT 10;";
   ```

4. Execute the reader to return the results from the query. The following command calls the ExecuteReader method of the VerticaCommand object to obtain the VerticaDataReader object.

   ```csharp
   VerticaDataReader dr = command.ExecuteReader();
   ```

5. Read the data. The data reader returns results in a sequential stream. Therefore, you must read data from tables row-by-row. The following example uses a while loop to accomplish this:

   ```csharp
   Console.WriteLine("\n\nFat Content\tProduct Description\n----------------\t----------------------\n");
   ```
```csharp
int rows = 0;
while (dr.Read())
{
    Console.WriteLine("  + dr[0] + " \t + dr[1]);
    ++rows;
}
Console.WriteLine("--------\n (" + rows + " rows)\n");

6. When you're finished, close the data reader to free up resources.

dr.Close();
```

**Example Usage:**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "SELECT fat_content, product_description " +
                "FROM (SELECT DISTINCT fat_content, product_description" +
                " FROM product_dimension " +
                " WHERE department_description " +
                " IN ('Dairy') " +
                " ORDER BY fat_content) AS food " +
                "LIMIT 10;";
            VerticaDataReader dr = command.ExecuteReader();
            Console.WriteLine("\n\n Fat Content \t Product Description\n");
            Console.WriteLine("--------\t ------------------\n");
            int rows = 0;
            while (dr.Read())
            {
                Console.WriteLine("  + dr[0] + " \t + dr[1]);
                ++rows;
            }
            Console.WriteLine("--------\n (" + rows + " rows)\n");
            dr.Close();
            _conn.Close();
        }
    }
```
Loading Data Through ADO.Net

This section details the different ways that you can load data in Vertica using the ADO.NET client driver:

- Using the Vertica Data Adapter
- Example Batch Insert Using Parameters and Transactions
- Streaming Data Via ADO.NET

Using the Vertica Data Adapter

The Vertica data adapter (VerticaDataAdapter) enables a client to exchange data between a data set and a Vertica database. It is an implementation of DbDataAdapter. You can use VerticaDataAdapter to simply read data, or, for example, read data from a database into a data set, and then write changed data from the data set back to the database.
Batching Updates

When using the `Update()` method to update a dataset, you can optionally use the `UpdateBatchSize()` method prior to calling `Update()` to reduce the number of times the client communicates with the server to perform the update. The default value of `UpdateBatchSize` is 1. If you have multiple `rows.Add()` commands for a data set, then you can change the batch size to an optimal size to speed up the operations your client must perform to complete the update.
Reading Data From Vertica Using the Data adapter:

The following example details how to perform a select query on the VMart schema and load the result into a DataTable, then output the contents of the DataTable to the console.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            // Try/Catch any exceptions
            try
            {
                using (_conn)
                {
                    // Create the command
                    VerticaCommand command = _conn.CreateCommand();
                    command.CommandText = "select product_key, product_description " +
                                         "from product_dimension where product_key < 10";

                    // Associate the command with the connection
                    command.Connection = _conn;

                    // Create the DataAdapter
                    VerticaDataAdapter adapter = new VerticaDataAdapter();
                    adapter.SelectCommand = command;

                    // Fill the DataTable
                    DataTable table = new DataTable();
                    adapter.Fill(table);

                    // Display each row and column value.
                    int i = 1;
                    foreach (DataRow row in table.Rows)
                    {
                        foreach (DataColumn column in table.Columns)
                        {
                            Console.Write(row[column] + "\t");
                        }
                        Console.WriteLine();
                    }
                }
            }
        }
    }
}
}  
Console.WriteLine();  
i++;  
}  
Console.WriteLine(i + " rows returned.");  
}  
}  
catch (Exception e)  
{  
    Console.WriteLine(e.Message);  
}  
_conn.Close();  
}  
}
Reading Data From Vertica into a Data set and Changing data:

The following example shows how to use a data adapter to read from and insert into a dimension table of the VMart schema.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
using Vertica.Data.VerticaClient
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            // Try/Catch any exceptions
            try
            {
                using (_conn)
                {

                    //Create a data adapter object using the connection
                    VerticaDataAdapter da = new VerticaDataAdapter();

                    //Create a select statement that retrieves data from the table
                    da.SelectCommand = new VerticaCommand("select * from product_dimension where product_key < 10",
                                                        _conn);
                    da.SelectCommand.Parameters.Add(new VerticaParameter("key", VerticaType.BigInt));
                    da.SelectCommand.Parameters.Add(new VerticaParameter("desc", VerticaType.VarChar));
                    da.SelectCommand.Parameters[0].SourceColumn = "product_key";
                    da.SelectCommand.Parameters[1].SourceColumn = "product_version";
                    da.TableMappings.Add("product_key", "product_key");
```
using Batch Inserts and Prepared Statements

You can load data in batches using a prepared statement with parameters. You can also use transactions to rollback the batch load if any errors are encountered.

If you are loading large batches of data (more than 100MB), then consider using a direct batch insert.

The following example details using data contained in arrays, parameters, and a transaction to batch load data.

The test table used in the example is created with the command:

```sql
=> CREATE TABLE test (id INT, username VARCHAR(24), email VARCHAR(64), password VARCHAR(8));
```
Example Batch Insert Using Parameters and Transactions

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            // Create arrays for column data
            int[] ids = {1, 2, 3, 4};
            string[] usernames = {"user1", "user2", "user3", "user4"};
            string[] emails = {"user1@example.com", "user2@example.com", "user3@example.com", "user4@example.com"};
            string[] passwords = {"pass1", "pass2", "pass3", "pass4"};
            // create counters for accepted and rejected rows
            int rows = 0;
            int rejRows = 0;
            bool error = false;
            // Create the transaction
            VerticaTransaction txn = _conn.BeginTransaction();
            // Create the parameterized query and assign parameter types
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "insert into TEST values (@id, @username, @email, @password)";
            command.Parameters.Add(new VerticaParameter("id", VerticaType.BigInt));
            command.Parameters.Add(new VerticaParameter("username", VerticaType.VarChar));
            command.Parameters.Add(new VerticaParameter("email", VerticaType.VarChar));
            command.Parameters.Add(new VerticaParameter("password", VerticaType.VarChar));
            // Prepare the statement
            command.Prepare();
            // Loop through the column arrays and insert the data
            for (int i = 0; i < ids.Length; i++)
            {
                command.Parameters["id"].Value = ids[i];
                command.Parameters["username"].Value = usernames[i];
                command.Parameters["email"].Value = emails[i];
                command.Parameters["password"].Value = passwords[i];
                try
                {
                    rows += command.ExecuteNonQuery();
                }
                catch (Exception e)
```
{  
    Console.WriteLine("\nInsert failed - \n" + e.Message + "\n");  
    ++rejRows;  
    error = true;  
}

if (error) {  
    // Roll back if errors  
    Console.WriteLine("Errors. Rolling Back Transaction.");  
    Console.WriteLine(rejRows + " rows rejected.");  
    txn.Rollback();  
} else {  
    // Commit if no errors  
    Console.WriteLine("No Errors. Committing Transaction.");  
    txn.Commit();  
    Console.WriteLine("Inserted " + rows + " rows.");  
}

_conn.Close();
Loading Batches Directly into ROS

When loading large batches of data (more than 100MB or so), you should load the data directly into ROS containers. Inserting directly into ROS is more efficient for large loads than AUTO mode, since it avoids overflowing the WOS and spilling the remainder of the batch to ROS.

Otherwise, the Tuple Mover has to perform a moveout on the data in the WOS, while subsequent data is directly written into ROS containers. This results in the data from your batch being segmented across containers.

When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS. For details about load options, see Choosing a Load Method.

To directly load batches into ROS, set the DirectBatchInsert connection property to true. See Opening and Closing the Database Connection for details on all of the connection properties. When the DirectBatchInsert property is set to true, all batch inserts bypass the WOS and load directly into a ROS container.
Example usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            builder.DirectBatchInsert = true;
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            //Perform some operations
            _conn.Close();
        }
    }
}
```

Streaming Data Via ADO.NET

There are two options to stream data from a file on the client to your Vertica database through ADO.NET:

- Use the `VerticaCopyStream` ADO.NET class to stream data in an object-oriented manner
- Execute a `COPY LOCAL` SQL statement to stream the data

The topics in this section explain how to use these options.
Streaming From the Client Via VerticaCopyStream

The VerticaCopyStream class lets you stream data from the client system to a Vertica database. It lets you use the SQL COPY statement directly without having to copy the data to a host in the database cluster first by substituting one or more data stream(s) for STDIN.

Notes:

- Use Transactions and disable auto commit on the copy command for better performance.
- Disable auto commit using the copy command with the 'no commit' modifier. You must explicitly disable commits. Enabling transactions does not disable autocommit when using VerticaCopyStream.
- The copy command used with VerticaCopyStream uses copy syntax.
- VerticaCopyStream.rejects is zeroed every time execute is called. If you want to capture the number of rejects, assign the value of VerticaCopyStream.rejects to another variable before calling execute again.
- You can add multiple streams using multiple AddStream() calls.
Example usage:

The following example demonstrates using VerticaCopyStream to copy a file stream into Vertica.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            // Configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            // open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            try
            {
                using (_conn)
                {
                    // Start a transaction
                    VerticaTransaction txn = _conn.BeginTransaction();

                    // Create a table for this example
                    VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS copy_table", _conn);
                    command.ExecuteNonQuery();
                    command.CommandText = "CREATE TABLE copy_table (Last_Name char(50), " + "First_Name char(50),Email char(50), " + "Phone_Number char(15))"; 
                    command.ExecuteNonQuery();
                    // Create a new filestream from the data file
                    string filename = "C:/customers.txt";
                    Console.WriteLine("\nLoading File: " + filename);
                    FileStream inputfile = File.OpenRead(filename);
                    // Define the copy command
                    string copy = "copy copy_table from stdin record terminator E'\n' delimiter '|' + " enforce length " + " no commit";
                    // Create a new copy stream instance with the connection and copy statement
                    VerticaCopyStream vcs = new VerticaCopyStream(_conn, copy);

                    // Start the VerticaCopyStream process
                    vcs.Start();
                    // Add the file stream
                }
            }
        }
    }
}
```
```csharp
vcs.AddStream(inputfile, false);

// Execute the copy
vcs.Execute();

// Finish stream and write out the list of inserted and rejected rows
long rowsInserted = vcs.Finish();
IList<long> rowsRejected = vcs.Rejects;
// Does not work when rejected or exceptions defined
Console.WriteLine("Number of Rows inserted: ", rowsInserted);
Console.WriteLine("Number of Rows rejected: ", rowsRejected.Count);
if (rowsRejected.Count > 0)
{
    for (int i = 0; i < rowsRejected.Count; i++)
    {
        Console.WriteLine("Rejected row #\{0\} is row \{1\}", i, rowsRejected[i]);
    }
}

// Commit the changes
txn.Commit();

} catch (Exception e)
{
    Console.WriteLine(e.Message);
}

//close the connection
_conn.Close();
```
Using Copy with ADO.NET

To use COPY with ADO.NET, just execute a COPY statement and the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class. However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a local file (streamed over a network connection, for example).

The following example code demonstrates using COPY to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement and the path to the data file is on the client system, rather than on the server.

To load data that is stored on a database node, use a VerticaCommand object to create a COPY command:

1. Create a connection to the database through the node on which the data file is stored.
2. Create a command object using the connection.

   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```

3. Copy data. The following is an example of using the COPY command to load data. It uses the LOCAL modifier to copy a file local to the client issuing the command.

   ```csharp
   command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'
                       + " record terminator E'\n' delimiter '|'
                       + " enforcelength ";
   Int32 insertedRows = command.ExecuteNonQuery();
   Console.WriteLine(insertedRows + " inserted.");
   ```
Example Usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            // Configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            // Open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            try
            {
                using (_conn)
                {
                    // Start a transaction
                    VerticaTransaction txn = _conn.BeginTransaction();

                    // Create a table for this example
                    VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS lcopy_table");
                    command.ExecuteNonQuery();
                    command.CommandText = "CREATE TABLE IF NOT EXISTS lcopy_table (Last_Name char(50), 
                    First_Name char(50), Email char(50), " 
                    + "Phone_Number char(15))";
                    command.ExecuteNonQuery();
                    // Define the copy command
                    command.CommandText = "copy lcopy_table from
                    '/home/dbadmin/customers.txt'" 
                    + " record terminator E\n' delimiter '|'" 
                    + " enforce_length " 
                    + " no commit";
                    // Execute the copy
                    Int32 insertedRows = command.ExecuteNonQuery();
                    Console.WriteLine(insertedRows + " inserted.");
                    // Commit the changes
                    txn.Commit();
                }
            }
            catch (Exception e)
            {
                Console.WriteLine("Exception: "+ e.Message);
            }
        }
    }
}
```
Handling Messages (ADO.NET)

You can capture info and warning messages that Vertica provides to the ADO.NET driver by using the InfoMessage event on the VerticaConnection delegate class. This class captures messages that are not severe enough to force an exception to be triggered, but might still provide information that can benefit your application.

To Use the VerticalInfoMessageEventHander class:

1. Create a method to handle the message sent from the event handler:

   ```csharp
   static void conn_InfoMessage(object sender, VerticalInfoMessageEventArgs e)
   {
       Console.WriteLine(e.SqlState + "\: " + e.Message);
   }
   ```

2. Create a connection and register a new VerticalInfoMessageHandler delegate for the InfoMessage event:

   ```csharp
   _conn.InfoMessage += new VerticalInfoMessageEventHandler(conn_InfoMessage);
   ```

3. Execute your queries. If a message is generated, then the event handle function is run.

4. You can unsubscribe from the event with the following command:

   ```csharp
   _conn.InfoMessage -= new VerticalInfoMessageEventHandler(conn_InfoMessage);
   ```

Example usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
```
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
  class Program
  {

    // define message handler to deal with messages

    static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
    {
      Console.WriteLine(e.SqlState + "": " + e.Message);
    }

    static void Main(string[] args)
    {

      //configure connection properties

      VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
      builder.Host = "192.168.1.10";
      builder.Database = "VMart";
      builder.User = "dbadmin";

      //open the connection

      VerticaConnection _conn = new VerticaConnection(builder.ToString());
      _conn.Open();

      //create message handler instance by subscribing it to the InfoMessage event of the connection

      _conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);

      //create and execute the command

      VerticaCommand cmd = _conn.CreateCommand();
      cmd.CommandText = "drop table if exists fakeTable";
      cmd.ExecuteNonQuery();

      //close the connection

      _conn.Close();
    }
  }
}

This examples displays the following when run:

00000: Nothing was dropped
Getting Table Metadata (ADO.Net)

You can get the table metadata by using the GetSchema() method on a connection and loading the metadata into a DataTable:

```csharp
DataTable table = _conn.GetSchema("Tables", new string[] { database_name, schema_name, table_name, table_type });
```

For example:

```csharp
DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });
```

`database_name`, `schema_name`, `table_name` can be set to `null`, be a specific name, or use a LIKE pattern.

`table_type` can be one of:

- "SYSTEM TABLE"
- "TABLE"
- "GLOBAL TEMPORARY"
- "LOCAL TEMPORARY"
- "VIEW"
- `null`

If `table_type` is set to `null`, then the metadata for all metadata tables is returned.

Example Usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            //configure connection properties
        }
    }
}
```
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.1.10";
builder.Database = "VMart";
builder.User = "dbadmin";

//open the connection
VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();

//create a new data table containing the schema
DataTable table = _conn.GetSchema("Tables", new string[] {null, null, null, "SYSTEM TABLE"});

//print out the schema
foreach (DataRow row in table.Rows) {
    foreach (DataColumn col in table.Columns) {
        Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
    }
    Console.WriteLine("=----------------------------------");
}

//close the connection
_conn.Close();
Programming Python Client Applications

To use Python with Vertica, you must either install the Vertica Python Client (see Python Client Documentation) or install the pyodbc module and a Vertica ODBC driver on the machine where Python is installed. See Python Prerequisites.

Python on Linux

Most Linux distributions come with Python preinstalled. If you want a more recent version, you can download and build it from the source code, though sometimes RPMs are also available. See the Python Web site and click an individual release for details. See also Python documentation.

To determine the Python version on your Linux operating systems, type the following at a command prompt:

```bash
# python -V
```

The system returns the version; for example:

```
Python 3.3.4
```

Python on Windows

Windows operating systems do not include Python by default. There are several different distributions of Python for windows:

- The ActiveState Web site distributes a free Windows installer for Python called ActivePython.

- The official Python.org site has installer packages for several versions of Python.

If you need installation instructions for Windows, see Using Python on Windows at python.org.
Python and Unicode

When you are using Python, be sure that all of your components are using the same unicode text encoding. By default, the DSN Parameter `ColumnsAsChar` causes the ODBC driver to report CHAR and VARCHAR values as SQL_WCHAR. The driver returns these values to the driver manager in the encoding expected by the driver manager, as controlled by the `DriverManagerEncoding` parameter in `vertica.ini`. Similarly, your Python application must use the encoding expected by the driver manager. If any of these components use different encodings, your output can become garbled.

The Vertica Python Client

Vertica has a native Python client you can use to communicate with your Vertica database. Before you can connect to Vertica using Python, you need to download the Python Client. See the Vertica Python Client Documentation, for download and installation instructions.

Using pyodbc and Vertica

Before you can connect to Vertica using pyodbc, you need to download the pyodbc module, which communicates with iODBC/unixODBC driver on UNIX operating systems and the ODBC Driver Manager for Windows operating systems.

The pyodbc module is an open source, MIT-licensed Python module, letting you use ODBC to connect to almost any database from Windows, Linux, Mac OS/X, and other operating systems. Vertica supports multiple versions of pyodbc. See Python Prerequisites for additional details.

Download the source distribution from the pyodbc Web site, unpack it and build it. Note that you need the unixODBC development package (in addition to the regular build tools) to build pyodbc. For example, on RedHat/CentOS run: `yum install unixODBC-devel`, and on Ubuntu run: `sudo apt-get install unixodbc-dev`. See the pyodbc wiki for detailed instructions.

Python Clients and the UUID Data Type

Both the Vertica Python client and Vertica ODBC driver (that pyodbc interacts with) do not support Vertica's native UUID data type. Values retrieved using these drivers from a
UUID column are converted to strings. When your client queries the metadata for a UUID column, the drivers report its data type as a string. Convert any UUID values that you want to insert into a UUID column to strings. Vertica automatically converts these values into the native UUID data type before inserting them into a table.

- Python Database API Specification v2.0
- Python documentation

Configuring the ODBC Run-Time Environment on Linux

To configure the ODBC run-time environment on Linux:

1. Create the odbc.ini file if it does not already exist.

2. Add the ODBC driver directory to the LD_LIBRARY_PATH system environment variable:

```bash
export LD_LIBRARY_PATH=/path-to-vertica-odbc-driver:$LD_LIBRARY_PATH
```

**Important:** If you skip Step 2, the ODBC manager cannot find the driver in order to load it.

These steps are relevant only for unixODBC and iODBC. See their respective documentation for details on odbc.ini.

Querying the Database Using Python and pyodbc

The example session below uses pyodbc with the Vertica ODBC driver to connect Python to the Vertica database.
Note: SQLFetchScroll and SQLFetch functions cannot be mixed together in iODBC code. When using pyodbc with the iODBC driver manager, skip cannot be used with the fetchall, fetchone, and fetchmany functions.

Example Script

The following example script shows how to query Vertica using Python 3, pyodbc, and an ODBC DSN.

```python
import pyodbc
cnxn = pyodbc.connect("DSN=VerticaDSN", ansi=True)
cursor = cnxn.cursor()
# create table
cursor.execute("CREATE TABLE TEST("
    "C_ID INT,"
    "C_FP FLOAT,"
    "C_VARCHAR VARCHAR(100),"
    "C_DATE DATE, C_TIME TIME,"
    "C_TS TIMESTAMP,"
    "C_BOOL BOOL")")
cursor.execute("INSERT INTO test VALUES(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 09:00:09','t')")
cursor.execute("INSERT INTO test VALUES(2,3.4,'zxcasdqwe09876543','1991-11-11','00:00:01','1981-12-31 19:19:19','f')")
cursor.execute("SELECT * FROM TEST")
rows = cursor.fetchall()
for row in rows:
    print(row, end='\n')
cursor.execute("DROP TABLE TEST CASCADE")
cursor.close()
cnxn.close()
```

The resulting output displays:

```
(2, 3.4, 'zxcasdqwe09876543', datetime.date(1991, 11, 11), datetime.time(0, 0, 1), datetime.datetime(1981, 12, 31, 19, 19, 19), False)
(1, 1.1, 'abcdefg1234567890', datetime.date(1901, 1, 1), datetime.time(23, 12, 34), datetime.datetime(1901, 1, 1, 9, 0, 9), True)
```

Notes

SQLPrimaryKeys returns the table name in the primary (pk_name) column for unnamed primary constraints. For example:
**Unnamed primary key:**

```sql
CREATE TABLE schema.test(c INT PRIMARY KEY);
```

**SQLPrimaryKeys**

```
"TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>, "SCHEMA", "TEST", "C", 1, "TEST"
```

**Named primary key:**

```sql
CREATE TABLE schema.test(c INT CONSTRAINT pk_1 PRIMARY KEY);
```

**SQLPrimaryKeys**

```
"TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>, "SCHEMA", "TEST", "C", 1, "PK_1"
```

[[[Undefined variable _Branding_Variables._Company_Acronym]]] recommends that you name your constraints.

### Programming Perl Client Applications

The Perl programming language has a Database Interface module (DBI) that creates a standard interface for Perl scripts to interact with databases. The interface module relies on Database Driver modules (DBDs) to handle all of the database-specific communication tasks. The result is an interface that provides a consistent way for Perl scripts to interact with many different types of databases.

Your Perl script can interact with Vertica using the Perl DBI module along with the DBD::ODBC database driver to interface to Vertica's ODBC driver. See the CPAN pages for Perl's DBI and DBD::ODBC modules for detailed documentation.
Important: With Perl ODBC clients, Vertica allows a forked process (a child process) to drop the parent connection to the Vertica server when the child process completes and exits. Vertica allows this behavior regardless of the setting of the Perl DBI AutoInactiveDestroy attribute. To change the default setting so that Vertica honors the setting of the Perl DBI AutoInactiveDestroy attribute, add the parameter `CleanupInForkChild` to your `vertica.ini` file, and set its value to `1`. When the Perl DBI AutoInactiveDestroy attribute is set to `1`, and the Vertica parameter `CleanupInForkChild` is set to `1`, Vertica does not drop the parent connection upon child process completion.

Perl Client Prerequisites

In order run a Perl client script that connects to Vertica, your client system must have:

- The Vertica ODBC drivers installed and configured. See Installing the Vertica Client Drivers for details.

- A Data Source Name (DSN) containing the connection parameters for your Vertica. See Creating an ODBC Data Source Name. (Optionally, your Perl script can connect to Vertica without using a DSN as described in Connecting From Perl Without a DSN).

- A supported version of Perl installed

- The DBI and DBD::ODBC Perl modules (see below)

Supported Perl Versions

Vertica supports Perl versions 5.8 and 5.10. Versions later than 5.10 may also work.
Perl on Linux

Most Linux distributions come with Perl preinstalled. See your Linux distribution's documentation for details of installing and configuring its Perl package is it is not already installed.

To determine the Perl version on your Linux operating systems, type the following at a command prompt:

```
# perl -v
```

The system returns the version; for example:

```
This is perl, v5.10.0 built for x86_64-linux-thread-multi
```

Perl on Windows

Perl is not installed by default on Windows platforms. There are several different Perl packages you can download and install on your Windows system:

- **ActivePerl** by Activestate is a commercially-supported version of Perl for Windows platforms.
- **Strawberry Perl** is an open-source port of Perl for Windows.

The Perl Driver Modules (DBI and DBD::ODBC)

Before you can connect to Vertica using Perl, your Perl installation needs to have the Perl Database Interface module (DBI) and the Database Driver for ODBC (DBD::ODBC). These modules communicate with iODBC/unixODBC driver on UNIX operating systems or the ODBC Driver Manager for Windows operating systems.

Vertica supports the following Perl modules:

- **DBI version 1.609 (DBI-1.609.tar.gz)**
- **DBD::ODBC version 1.22 (DBD-ODBC-1.22.tar.gz)**

Later versions of DBI and DBD::ODBC may also work.

DBI is installed by default with many Perl installations. You can test whether it is installed by executing the following command on the Linux or Windows command line:
If the command exits without printing anything, then DBI is installed. If it prints an error, such as:

```
Can't locate DBI.pm in @INC (@INC contains: /usr/local/lib64/perl5/usr/local/share/perl5 /
/usr/lib64/perl5/vendor_perl /usr/share/perl5/vendor_perl
/usr/lib64/perl5 /usr/share/perl5 .) at -e line 1.
BEGIN failed--compilation aborted at -e line 1.
```

then DBI is not installed.

Similarly, you can see if DBD::ODBC is installed by executing the command:

```
# perl -e "use DBD::ODBC;"
```

You can also run the following Perl script to determine if DBI and DBD::ODBC are installed. If they are, the script lists any available DSNs.

```perl
#!/usr/bin/perl
use strict;
# Attempt to load the DBI module in an eval using require. Prevents
# script from erroring out if DBI is not installed.

eval {
    require DBI;
    DBI->import();
};
if ($@) {
    # The eval failed, so DBI must not be installed
    print "DBI module is not installed\n";
} else {
    # Eval was successful, so DBI is installed
    print "DBI Module is installed\n";
    # List the drivers that DBI knows about.
    my @drivers = DBI->available_drivers;
    print "Available Drivers: \n";
    foreach my $driver (@drivers) {
        print "\t$driver\n";
    }
    # See if DBD::ODBC is installed by searching driver array.
    if (grep {/ODBC/i} @drivers) {
        print "\nDBD::ODBC is installed.\n";
        # List the ODBC data sources (DSNs) defined on the system
        print "Defined ODBC Data Sources:\n";
        my @dsn = DBI->data_sources('ODBC');
        foreach my $dsn (@dsn) {
            print "\t$dsn\n";
        }
    } else {
        print "DBD::ODBC is not installed\n";
    }
}
```
The exact output of the above code will depend on the configuration of your system. The following is an example of running the code on a Windows computer:

<table>
<thead>
<tr>
<th>DBI Module is installed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available Drivers:</td>
</tr>
<tr>
<td>ADO</td>
</tr>
<tr>
<td>DBM</td>
</tr>
<tr>
<td>ExampleP</td>
</tr>
<tr>

</tr>
<tr>
<td>dbi:ODBC:VerticaDSN</td>
</tr>
</tbody>
</table>

### Installing Missing Perl Modules

If Perl's DBI or DBD::ODBC modules are not installed on your client system, you must install them before your Perl scripts can connect to Vertica. How you install modules depends on your Perl configuration:

- For most Perl installations, you use the `cpan` command to install modules. If the `cpan` command alias isn't installed on your system, you can try to start CPAN by using the command:

  ```bash
  perl -MCORE -e "shell();"
  ```

- Some Linux distributions provide Perl modules as packages that can be installed with the system package manager (such as yum or apt). See your Linux distribution's documentation for details.

- On ActiveState Perl for Windows, you use the Perl Package Manager (PPM) program to install Perl modules. See the [Activestate's PPM documentation](#) for details.

**Note:** Installing Perl modules usually requires administrator or root privileges. If you do not have these permissions on your client system, you need to ask your system administrator to install these modules for you.
Connecting to Vertica Using Perl

You use the Perl DBI module's `connect` function to connect to Vertica. This function takes a required data source string argument and optional arguments for the username, password, and connection attributes.

The data source string must start with "dbi:ODBC:", which tells the DBI module to use the DBD::ODBC driver to connect to Vertica. The remainder of the string is interpreted by the DBD::ODBC driver. It usually contains the name of a DSN that contains the connection information needed to connect to your Vertica database. For example, to tell the DBD::ODBC driver to use the DSN named VerticaDSN, you use the data source string:

```
"dbi:ODBC:VerticaDSN"
```

The username and password parameters are optional. However, if you do not supply them (or just the username for a passwordless account) and they are not set in the DSN, attempting to connect always fails.

The `connect` function returns a database handle if it connects to Vertica. If it does not, it returns `undef`. In that case, you can access the DBI module's error string property (`$DBI::errstr`) to get the error message.

**Note:** By default, the DBI module prints an error message to STDERR whenever it encounters an error. If you prefer to display your own error messages or handle errors in some other manner, you may want to disable these automatic messages by setting DBI's `PrintError` connection attribute to false. See Setting Perl DBI Connection Attributes for details. Otherwise, users may see two error messages: the one that DBI prints automatically, and the one that your script prints on its own.

The following example demonstrates connecting to Vertica using a DSN named VerticaDSN. The call to `connect` supplies a username and password. After connecting, it calls the database handle's `disconnect` function, which closes the connection.

```perl
#!/usr/bin/perl -w
use strict;
use DBI;
#
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```
Setting ODBC Connection Parameters in Perl

To set ODBC connection parameters, replace the DSN name with a semicolon delimited list of parameter name and value pairs in the source data string. Use the DSN parameter to tell DBD::ODBC which DSN to use, then add in other the other ODBC parameters you want to set. For example, the following code connects using a DSN named VerticaDSN and sets the connection's locale to en_GB.

```
#!/usr/bin/perl -w
use strict;
use DBI;

# Instead of just using the DSN name, use name and value pairs.
my $dbh = DBI->connect("dbi:ODBC:DSN=VerticaDSN;Locale=en_GB@collation=binary","ExampleUser","password123");
unless (defined $dbh) {
  # Connection failed.
  die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```

See Data Source Name (DSN) Connection Properties for a list of the connection parameters you can set in the source data string.

Setting Perl DBI Connection Attributes

The Perl DBI module has attributes that you can use to control the behavior of its database connection. These attributes are similar to the ODBC connection parameters (in several cases, they duplicate each other's functionality). The DBI connection attributes are a cross-platform way of controlling the behavior of the database connection.

You can set the DBI connection attributes when establishing a connection by passing the DBI `connect` function a hash containing attribute and value pairs. For example, to set the DBI connection attribute AutoCommit to false, you would use:

```
# Create a hash that holds attributes for the connection
my $attr = {AutoCommit => 0};
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);
```

See the DBI documentation's Database Handle Attributes section for a full description of the attributes you can set on the database connection.

After your script has connected, it can access and modify the connection attributes through the database handle by using it as a hash reference. For example:
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "
";

The following example demonstrates setting two connection attributes:

- **RaiseError** controls whether the DBI driver generates a Perl error if it encounters a database error. Usually, you set this to true (1) if you want your Perl script to exit if there is a database error.

- **AutoCommit** controls whether statements automatically commit their transactions when they complete. DBI defaults to Vertica's default AutoCommit value of true. Always set AutoCommit to false (0) when bulk loading data to increase database efficiency.

```perl
#!/usr/bin/perl
use strict;
use DBI;

# Create a hash that holds attributes for the connection
my $attr = {
    RaiseError => 1, # Make database errors fatal to script
    AutoCommit => 0, # Prevent statements from committing
    # their transactions.
};

# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);

if (defined $dbh->err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}

print "Connected!\n";

# The database handle lets you access the connection attributes directly:
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
print "The RaiseError attribute is: " . $dbh->{RaiseError} . "\n";
# And you can change values, too...
$dbh->{AutoCommit} = 1;
print "The AutoCommit attribute is now: " . $dbh->{AutoCommit} . "\n";
$dbh->disconnect();
```

The example outputs the following when run:

```
Connected!The AutoCommit attribute is: 0
The RaiseError attribute is: 1
The AutoCommit attribute is now: 1
```

**Connecting From Perl Without a DSN**

If you do not want to set up a Data Source Name (DSN) for your database, you can supply all of the information Perl's DBD::ODBC driver requires to connect to your Vertica database in the data source string. This source string must the DRIVER= parameter that tells DBD::ODBC which
driver library to use in order to connect. The value for this parameter is the name assigned to
the driver by the client system's driver manager:

- On Windows, the name assigned to the Vertica ODBC driver by the driver manager is
  Vertica.

- On Linux and other UNIX-like operating systems, the Vertica ODBC driver's name is assigned
  in the system's odbcinst.ini file. For example, if your /etc/odbcinst.ini contains the
  following:

  ```
  [Vertica]
  Description = Vertica ODBC Driver
  Driver = /opt/vertica/lib64/libverticaodbc.so
  ```

  you would use the name Vertica. See Creating an ODBC DSN for Linux, AIX, and HP-UX for
  more information about the odbcinst.ini file.

You can take advantage of Perl's variable expansion within strings to use variables for most of
the connection properties as the following example demonstrates.

```perl
#!/usr/bin/perl
use strict;
use DBI;
my $server='VerticaHost';
my $port = '5433';
my $database = 'VMart';
my $user = 'ExampleUser';
my $password = 'password123';
# Connect without a DSN by supplying all of the information for the connection.
# The DRIVER value on UNIX platforms depends on the entry in the odbcinst.ini
# file.
my $dbh = DBI->connect("dbi:ODBC:DRIVER={Vertica};Server=$server;" .
    "Port=$port;Database=$database;UID=$user;PWD=$password")
  or die "Could not connect to database: ". DBI::errstr;
print "Connected!\n";
$dbh->disconnect();
```

**Note:** Surrounding the driver name with braces {{ and }} in the source string is optional.

### Executing Statements Using Perl

Once your Perl script has connected to Vertica (see Connecting to Vertica Using Perl), it can
execute simple statements that return a value rather than a result set by using the Perl DBI
module's `do` function. You usually use this function to execute DDL statements or data loading
statements such as `COPY` (see Using COPY LOCAL to Load Data in Perl).
#!/usr/bin/perl
use strict;
use DBI;

# Disable autocommit
my $attr = {AutoCommit => 0};

# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);

unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}

# You can use the `do` function to perform DDL commands.
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");  
# Create a table to hold data.
$dbh->do("CREATE TABLE TEST ( 
    C_ID INT, \ 
    C_FP FLOAT,\ 
    CVARCHAR VARCHAR(100),\ 
    C_DATE DATE, C_TIME TIME,\ 
    C_TS TIMESTAMP,\ 
    C_BOOL BOOL)\");

# Commit changes and exit.
$dbh->commit();
$dbh->disconnect();

Note: The `do` function returns the number of rows that were affected by the statement (or -1 if the count of rows doesn't apply or is unavailable). Usually, the only time you need to consult this value is after you deleted a number of rows or if you used a bulk load command such as `COPY`. You use other DBI functions instead of `do` to perform batch inserts and selects (see Batch Loading Data Using Perl and Querying Using Perl for details).

### Batch Loading Data Using Perl

To load large batches of data into Vertica using Perl:

1. Set DBI’s AutoCommit connection attribute to false to improve the batch load speed. See Setting Perl DBI Connection Attributes for an example of disabling AutoCommit.

2. Call the database handle’s `prepare` function to prepare a SQL INSERT statement that contains placeholders for the data values you want to insert. For example:

```perl
# Prepare an INSERT statement for the test table
$sth = $dbh->prepare("INSERT INTO test_table (?,?,?,?)\");
```

The `prepare` function returns a statement handle that you will use to insert the data.
3. Assign data to the placeholders. There are several ways to do this. The easiest is to populate an array with a value for each placeholder in your INSERT statement.

4. Call the statement handle's execute function to insert a row of data into Vertica. The return value of this function call lets you know whether Vertica accepted or rejected the row.

5. Repeat steps 3 and 4 until you have loaded all of the data you need to load.

6. Call the database handle's commit function to commit the data you inserted.

The following example demonstrates inserting a small batch of data by populating an array of arrays with data, then looping through it and inserting each row.

```perl
#!/usr/bin/perl
use strict;
use DBI;

# Create a hash reference that holds a hash of parameters for the connection.
my $attr = {AutoCommit => 0, # Turn off autocommit
            PrintError => 0 # Turn off automatic error printing.
            # This is handled manually.
        };

# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);
if (defined DBI::err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}

print "Connection AutoCommit state is: ". $dbh->{AutoCommit} . "\n";

# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;") or die "Could not drop table";
$dbh->do("CREATE TABLE TEST( 
    C_ID INT, 
    C_FP FLOAT,
    CVARCHAR VARCHAR(100),
    C_DATE DATE, C_TIME TIME,
    C_TS TIMESTAMP,
    C_BOOL BOOL")" or die "Could not create table";

# Populate an array of arrays with values. One of these rows contains data that will not be successfully inserted. Another contains an undef value, which gets inserted into the database as a NULL.
my @data = ( [1,1.111,'Hello World!','2001-01-01','01:01:01', '2001-01-01 01:01:01','t'],
            [2,2.22222,'How are you?','2002-02-02','02:02:02', '2002-02-02 02:02:02','f'],
            ['bad value',2.22222,'How are you?','2002-02-02','02:02:02', '2002-02-02 02:02:02','f'],
            [4,4.22222,undef,'2002-02-02','02:02:02', '2002-02-02 02:02:02','f'],
        );

# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_catched("INSERT INTO test values(?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {
    $rowcount++;
    # Insert the row
    my $retval = $sth->execute(@$tuple);

    # See if the row was successfully inserted.
    if ($retval == 1) {
        # Value of 1 means the row was inserted (1 row was affected by insert)
        print "Row $rowcount successfully inserted\n";
    } else {
        print "Inserting row $rowcount failed";
        # Error message is not set on some platforms/versions of DBUI. Check to
        # ensure a message exists to avoid getting an uninitialized var warning.
        if ($sth->err) {
            print ": " . $sth->errstr();
        }
        print "\n";
    }
}
# Commit changes. With AutoCommit off, you need to use commit for batched
# data to actually be committed into the database. If your Perl script exits
# without committing its data, Vertica rolls back the transaction and the
# data is not committed.
$dbh->commit();
$dbh->disconnect();

The previous example displays the following when successfully run:

Connection AutoCommit state is: 0
Row 1 successfully inserted
Row 2 successfully inserted
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An
error occurred during query execution: Row rejected by server; see
server log for details (SQL-01000)
Row 4 successfully inserted

Note that one of the rows was not inserted because it contained a string value that could not
be stored in an integer column. See Conversions Between Perl and Vertica Data Types for
details of data type handling in Perl scripts that communicate with Vertica.

Using COPY LOCAL to Load Data in Perl

If you have delimited files (for example, a file with comma-separated values) on your client
system that you want to load into Vertica, you can use the COPY LOCAL statement to directly
load the file’s contents into Vertica instead of using Perl to read, parse, and then batch insert
the data. You execute a COPY LOCAL statement to load the file from the local filesystem. The
result of executing the statement is the number of rows that were successfully inserted.
Note: The COPY LOCAL statement must be the first statement within a query containing multiple statements. If you attempt to use COPY LOCAL as the second or later statement, you will receive the error "COPY LOCAL statement must be the first statement in a multiple statement query."

The following example code demonstrates loading a file named data.txt and located in the same directory as the Perl file into Vertica using a COPY LOCAL statement.

#!/usr/bin/perl
use strict;
use DBI;
# Filesystem path handling module
use File::Spec;
# Create a hash reference that holds a hash of parameters for the # connection.
my $attr = {AutoCommit => 0}; # Turn off AutoCommit
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr) or die "Failed to connect: $DBI::errstr";
print "Connected!\n";
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS Customers CASCADE;");
# Create a table to hold data.
$dbh->do("CREATE TABLE Customers( 
    ID INT, 
    FirstName VARCHAR(100),
    LastName VARCHAR(100),
    Email VARCHAR(100),
    Birthday DATE)");
# Find the absolute path to the data file located in the current working # directory and named data.txt
my $currDir = File::Spec->rel2abs(File::Spec->curdir());
my $dataFile = File::Spec->catfile($currDir, 'data.txt');
print "Loading file $dataFile\n";
# Load local file using copy local. Return value is the # of rows affected # which equates to the number of rows inserted.
my $rows = $dbh->do("COPY Customers FROM LOCAL '$dataFile' DIRECT") or die $dbh->errstr;
print "Copied $rows rows into database.\n";
$dbh->commit();
# Prepare a query to get the first 15 rows of the results
my $sth = $dbh->prepare("SELECT * FROM Customers WHERE ID < 15 ORDER BY ID");

$sth->execute() or die "Error querying table: ". $dbh->errstr;
my @row; # Pre-declare variable to hold result row used in format statement.
# Use Perl formats to pretty print the output. Declare the heading for the # form.
format STDOUT_TOP = ID First Last EMail Birthday == ===== ===== ===== ========
format STDOUT = @> @<<<<<<<<<<< @<<<<<<<<<<< @<<<<<<<<<<< @<<<<<<<<<<< @<<<<<<<<<<< @row
# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
    write; # Format command does the work of extracting the columns from
    # the @row array and writing them out to STDOUT.
}
# Call commit to prevent Perl from complaining about uncommitted transactions
# when disconnecting
$dbh->commit();
$dbh->disconnect();

The data.txt file is a text file containing a row of data on each line. The columns are delimited by pipe (|) characters. This is the default format that the COPY command accepts, which makes the COPY LOCAL statement in the example code simple. See the COPY statement entry in the SQL Reference Manual for handling data files that are in different formats. Here is an example of the content in this file:

<table>
<thead>
<tr>
<th>ID</th>
<th>First</th>
<th>Last</th>
<th>Email</th>
<th>Birthday</th>
</tr>

</tbody>
</table>

The example code produces the following output when run on a large sample file:
Note: Loading a single, large data file into Vertica through a single data connection is less efficient than loading a number of smaller files onto multiple nodes in parallel. Loading onto multiple nodes prevents any one node from becoming a bottleneck.

Querying Using Perl

To query Vertica using Perl:

1. Prepare a query statement using the Perl DBI module's `prepare` function. This function returns a statement handle that you use to execute the query and get the result set.

2. Execute the prepared statement by calling the `execute` function on the statement handle.

3. Retrieve the results of the query from the statement handle using one of several methods, such as calling the statement handle's `fetchrow_array` function to retrieve a row of data, or `fetchAll_array` to get an array of arrays containing the entire result set (not a good idea if your result set may be very large!).

The following example demonstrates querying the table created by the example shown in Batch Loading Data Using Perl. It executes a query to retrieve all of the content of the table, then repeatedly calls the statement handle's `fetchrow_array` function to get rows of data in an array. It repeats this process until `fetchrow_array` returns `undef`, which means that there are no more rows to be read.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1}; # Make errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them, getting each row as an array
while ($row = $sth->fetchrow_array()) {
    # The @row array contains the column values for this row of data
    # Loop through the column values
    foreach my $column (@row) {
        if (!defined $column) {
            # NULLs are signaled by undefs. Set to NULL for clarity
            $column = "NULL";
        }
        print "$column\t"; # Output the column separated by a tab
    }
    print "\n";
}
```
$dbh->disconnect();

The example prints the following when run:

```
1  1.111  Hello World!  2001-01-01  01:01:01  2001-01-01  01:01:01  1
2  2.22222  How are you?  2002-02-02  02:02:02  2002-02-02  02:02:02  0
4  4.22222  NULL  2002-02-02  02:02:02  2002-02-02  02:02:02  0
```

## Binding Variables to Column Values

Another method of retrieving the query results is to bind variables to columns in the result set using the statement handle's `bind_columns` function. You may find this method convenient if you need to perform extensive processing on the returned data, since your code can use variables rather than array references to access the data. The following example demonstrates binding variables to the result set, rather than looping through the row and column values.

```perl
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1}; # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN32","ExampleUser","password123", $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
$sth->execute();
# Create a set of variables to bind to the column values.
my ($C_ID, $C_FP, $C_VARCHAR, $C_DATE, $C_TIME, $C_TS, $C_BOOL);
# Bind the variable references to the columns in the result set.
$sth->bind_columns($C_ID, $C_FP, $C_VARCHAR, $C_DATE, $C_TIME, $C_TS, $C_BOOL);

# Now, calling fetch() to get a row of data updates the values of the bound variables.  Continue calling fetch until it returns undefined.
while ($sth->fetch()) {
  # Note, you should always check that values are defined before using them,
  # since NULL values are translated into Perl as undefined. For this example, just check the VARCHAR column for undefined values.
  if (!defined $C_VARCHAR) {
    $C_VARCHAR = "NULL";
  }
  # Just print values separated by tabs.
  print "$C_ID\t$C_FP\t$C_VARCHAR\t$C_DATE\t$C_TIME\t$C_TS\t$C_BOOL\n";
}
$dbh->disconnect();
```

The output of this example is identical to the output of the previous example.
Preparing, Querying, and Returning a Single Row

If you expect a single row as the result of a query (for example, when you execute a `COUNT (*)` query), you can use the DBI module's `selectrow_array` function to combine executing a statement and retrieving an array as a result.

The following example shows using `selectrow_array` to execute and get the results of the `SHOW LOCALE` statement. It also demonstrates changing the locale using the `do` function.

```perl
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1}; # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);
# Demonstrate setting/getting locale.
# Use selectrow_array to combine preparing a statement, executing it, and
# getting an array as a result.
my @localerv = $dbh->selectrow_array("SHOW LOCALE;");
# The locale name is the 2nd column (array index 1) in the result set.
print "Locale: $localerv[1]\n";
# Use do() to execute a SQL statement to set the locale.
$dbh->do("SET LOCALE TO en_GB");
# Get the locale again.
@localerv = $dbh->selectrow_array("SHOW LOCALE;");
print "Locale is now: $localerv[1]\n";
$dbh->disconnect();
```

The result of running the example is:

```
Locale: en_US@collation=binary (LEN_KBINARY)
Locale is now: en_GB (LEN)
```

Executing Queries and ResultBufferSize Settings

When you call the `execute()` function on a prepared statement, the client library retrieves results up to the size of the result buffer. The result buffer size is set using ODBC's `ResultBufferSize` setting.

Vertica does not allow multiple active queries per connection. However, you can simulate multiple active queries by setting the result buffer to be large enough to accommodate the entire results from the first query. To ensure that the ODBC client driver's buffer is large enough to store result set for first query you can set `ResultBufferSize` to 0. Setting this parameter to 0 makes the result buffer size unlimited. The ODBC driver allocates enough memory to read the entire result set. With the entire result set from the first query stored in the result set buffer, the database connection is free to perform another query. Your client can
execute this second query even though it has not processed the entire result set from the first query.

However, if you set the ResultBufferSize to 0, you may find that your calls to execute() result in the operating system killing your Perl client script. The operating system may terminate your script if the ODBC driver allocates too much memory to store a large result set.

A workaround for this behavior is to limit the number of rows returned by your query. Then you can set the ResultBufferSize to a value that accommodates this limited result set. For example, you can estimate the amount of memory needed to store a single row of your query result. Then use the LIMIT and OFFSET clauses to get a specific number of rows that will fit into the space you allocated using ResultBufferSize. If the results of your query is able to fit within the limited result set buffer, you can then perform additional queries with the same database connection. This solution makes your code more complex as you will need to perform multiple queries to get the entire result set. Also, it is not appropriate in cases where you need to operate on an entire result set at once, rather than just a portion of it at a time.

A better solution is to use separate database connections for each query you want to perform. The overhead of the additional database connection is small compared to the resources needed to process large data sets.

Conversions Between Perl and Vertica Data Types

Perl is a loosely-typed programming language that does not assign specific data types to values. It converts between string and numeric values based on the operations being performed on the values. For this reason, Perl has little problem extracting most string and numeric data types from Vertica. All interval data types (DATE, TIMESTAMP, etc.) are converted to strings. You can use several different date and time handling Perl modules to manipulate these values in your scripts.

Vertica NULL values translate to Perl's undefined (undef) value. When reading data from columns that can contain NULL values, you should always test whether a value is defined before using it.

When inserting data into Vertica, Perl's DBI module attempts to coerce the data into the correct format. By default, it assumes column values are VARCHAR unless it can determine that they are some other data type. If given a string value to insert into a column that has an integer or numeric data type, DBI attempts to convert the string's contents to the correct data type. If the entire string can be converted to a value of the appropriate data type, it inserts the value into the column. If not, inserting the row of data fails.

DBI transparently converts integer values into numeric or float values when inserting into column of FLOAT, NUMERIC, or similar data types. It converts numeric or floating values to integers only when there would be no loss of precision (the value to the right of the decimal
point is 0). For example, it can insert the value 3.0 into an INTEGER column since there is no loss of precision when converting the value to an integer. It cannot insert 3.1 into an INTEGER column, since that would result in a loss of precision. It returns an error instead of truncating the value to 3.

The following example demonstrates some of the conversions that the DBI module performs when inserting data into Vertica.

```perl
#!/usr/bin/perl
use strict;
use DBI;

# Create a hash reference that holds a hash of parameters for the # connection.
my $attr = {AutoCommit => 0, # Turn off autocommit
            PrintError => 0}; # Turn off print error. Manually handled

# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);
if (defined DBI::err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}

print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";

# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");
$dbh->do("CREATE TABLE TEST ( 
        C_ID INT, 
        C_FP FLOAT, 
        C_VARCHAR VARCHAR(100), 
        C_DATE DATE, 
        C_TIME TIME, 
        C_TS TIMESTAMP, 
        C_BOOL BOOL)");

# Populate an array of arrays with values.
my @data = (
    [1.111,'Matching datatypes','2001-01-01','01:01:01', '01:01:01','t'],
    [2.0,2,"Ints <-> floats","2002-02-02","02:02:02", '02:02:02',1],
    [3.1,3,"float -> int only* works when there is no loss of precision. 
   *this row will fail to insert: 
    [3.1,3,"float -> int with trunc?","2003-03-03","03:03:03","03:03:03",1],
    [4.4,"Strings -> numbers", '2004-04-04','04:04:04', '04:04:04',0],
    [5.5,"Strings -> numbers", '2005-05-05', '05:05:05', '05:05:05',0],
    [6.6.3.14159, '2006-06-06', '06:06:06', '06:06:06',0],
    [7.7, 'Date/time formats', '07/07/2007', '07:07:07',]
```
# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT INTO test values (?,?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {
    $rowcount++;
    # Insert the row
    my $retval = $sth->execute($tuple);
    # See if the row was successfully inserted.
    if ($retval == 1) {
        # Value of 1 means the row was inserted (1 row was affected by insert)
        print "Row $rowcount successfully inserted\n";
    } else {
        print "Inserting row $rowcount failed with error " .
             "$sth->state . " . $sth->errstr . "\n";
    }
}
# Commit the data
$dbh->commit();
# Prepare a query to get the content of the table
$sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
$sth->execute() or die "Error: " . $dbh->errstr;
my @row; # Need to pre-declare to use in the format statement.
# Use Perl formats to pretty print the output.
format STDOUT_TOP = Int Float VarChar Date Time Timestamp Bool
               +==== ========== ============ =========== =========== ===========
format STDOUT = @>> @<<< @<<<<<<<<<<<<<<<<< @<<<<<< @<<<<<< @<<<<<<<<< @<<<<
@row
.
# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
    write; # Format command does the work of extracting the columns from
    # the array.
}
# Commit to stop Perl complaining about in-progress transactions.
$dbh->commit();
$dbh->disconnect();

The example produces the following output when run:

Connection AutoCommit state is: 0
Row 1 successfully inserted
Row 2 successfully inserted
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An error occurred during query execution: Row rejected by server; see server log for details (SQL-01000)
Row 4 successfully inserted
Inserting row 5 failed with error 01000 [Vertica][VerticaDSII] (20) An error occurred during query execution: Row rejected by server; see server log for details (SQL-01000)
Row 6 successfully inserted
Row 7 successfully inserted
Perl Unicode Support

Perl supports Unicode data with some caveats. See the perlunicode and the perlunitut (Perl Unicode tutorial) manual pages for details. (Be sure to see the copies of these manual pages included with the version of Perl installed on your client system, as the support for Unicode has changed in recent versions of Perl.) Perl DBI and DBD::ODBC also support Unicode, however DBD::ODBC must be compiled with Unicode support. See the DBD::ODBC documentation for details. You can check the DBD::ODBC-specific connection attribute named odbc_has_unicode to see if Unicode support is enabled in the driver.

The following example Perl script demonstrates directly inserting UTF-8 strings into Vertica and then reading them back. The example writes a text file with the output, since there are may problems displaying Unicode characters in terminal windows or consoles.

```perl
#!/usr/bin/perl
use strict;
use DBI;
# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
  # Connetion failed.
  die "Failed to connect: $DBI::errstr"
}
# Output to a file. Displaying Unicode characters to a console or terminal
# window has many problems. This outputs a UTF-8 text file that can
# be handled by many Unicode-aware text editors:
open OUTFILE, '>:utf8', "unicodeout.txt";
# See if the DBD::ODBC driver was compiled with Unicode support. If this returns
# 1, your Perl script will get get strings from the driver with the UTF-8
# flag set on them, ensuring that Perl handles them correctly.
print OUTFILE "Was DBD::ODBC compiled with Unicode support? ".
    $dbh->{odbc_has_unicode}. "\n"

# Create a table to hold VARCHAR
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;")

# Create a table to hold data. Remember that the width of the VARCHAR column
# is the number of bytes set aside to store strings, which often does not equal
# the number of characters it can hold when it comes to Unicode!
$dbh->do("CREATE TABLE test( _VARCHAR VARCHAR100 )");
print OUTFILE "Inserting data...\n"
# Use Do to perform simple inserts
$dbh->do("INSERT INTO test VALUES('Hello')");
```
# This string contains several non-latin accented characters and symbols, encoded
# with Unicode escape notation. They are converted by Perl into UTF-8 characters
$dbh->do("INSERT INTO test VALUES(’My favorite band is ” .
 “\N{U+00DC}ml\N{U+00E4}t \N{U+00F6}v\N{U+00EB}ll” .
 “ \N{U+263A}’");
# Some Chinese (Simplified) characters. This again uses escape sequence
# that Perl translates into UTF-8 characters.
$dbh->do("INSERT INTO test VALUES(’\x{4F60}\x{597D}’)");
print OUTFILE "Getting data...
";
# Prepare a query to get the content of the table
my $sth = $dbh->prepare_cached("SELECT * FROM test");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them
while (my @row = $sth->fetchrow_array()) {
    # Loop through the column values
    foreach my $column (@row) {
        print OUTFILE "$column\t"
    }
    print OUTFILE "\n"
}
close OUTFILE;
$dbh->disconnect();

Viewing the unicodeout.txt file in a UTF-8-capable text editor or viewer displays:

Was DBD::ODBC compiled with Unicode support? 1
Inserting data...
Getting data...
My favorite band is Ümläüt Övërkill Ø
你好
Hello

Note: Terminal windows and consoles often have problems properly displaying Unicode characters. That is why the example writes the output to a text file. With some text editors, you may need to manually set the encoding of the text file to UTF-8 in order for the characters to properly appear (and the font used to display text must have a full Unicode character set). If the character still do not show up, it may be that your version of DBD::ODBC was not compiled with UTF-8 support.

- Unicode Character Encoding
- Required ODBC Driver Configuration Settings for Linux and UNIX
Programming PHP Client Applications

You can connect to Vertica through PHP-ODBC using the Unix ODBC or iODBC library. In order to use PHP with Vertica, you must install the following packages (and their dependencies):

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbc (if you are using the iODBC driver)

PHP on Linux

PHP is available with most Linux operating systems as a module for the Apache web server. Check your particular Linux repository for PHP RPMs or Debian packages. You can also build PHP from source. See the PHP web site for documentation and source downloads.

PHP on Windows

PHP is available for windows for both the Apache and IIS web servers. You can download PHP for Windows and view installation instructions at the PHP web site.

The PHP ODBC Drivers

PHP supports both the UnixODBC drivers and iODBC drivers. Both drivers use PHP's ODBC database abstraction layer.
Setup

You must read Programming ODBC Client Applications before connecting to Vertica through PHP. The following example ODBC configuration entries detail the typical settings required for PHP ODBC connections. The driver location assumes you have copied the Vertica drivers to /usr/lib64.

Example odbc.ini

```
[ODBC Data Sources]
VerticaDSNunixodbc = exampledb
VerticaDNSiodbc = exampledb2

[VerticaDSNunixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
UserName = dbadmin
Password =
Port = 5433

[VerticaDNSiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
UserName = dbadmin
Password =
Port = 5433
```

Example odbcinst.ini

```
# Vertica
[VerticaDSNunixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so

[VerticaDNSiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so

[ODBC]
Threading = 1
```
Verify the Vertica UnixODBC or iODBC Library

Verify the Vertica UnixODBC library can load all dependant libraries with the following command (assuming you have copies the libraries to /usr/lib64):

For example:

```
ldd /usr/lib64/libverticaodbc.so
```

You must resolve any "not found" libraries before continuing.

Test Your ODBC Connection

Test your ODBC connection with the following.

```
isql -v VerticaDSN
```

PHP Unicode Support

PHP does not offer native Unicode support. PHP only supports a 256-character set. However, PHP provides the UTF-8 functions `utf8_encode()` and `utf8_decode()` to provide some basic Unicode functionality.

See the PHP manual for `strings` for more details about PHP and Unicode.

Querying the Database Using PHP

The example script below details the use of PHP ODBC functions to connect to the Vertica Analytics Platform.

```php
<?php
# Turn on error reporting
error_reporting(E_ERROR | E_WARNING | E_PARSE | E_NOTICE);
# A simple function to trap errors from queries
function errortrap_odbc($conn, $sql) {
    if(!$rs = odbc_exec($conn, $sql)) {
        echo "<br/>Failed to execute SQL: $sql<br/>" . odbc_errormsg($conn);
    } else {
        echo "<br/>Success: " . $sql;
    }
    return $rs;
?>
```
Example Output

The following is the example output from the script.

```
Success: CREATE TABLE TEST (C_ID INT, C_FP FLOAT, CVARCHAR VARCHAR(100), C_DATE DATE, C_TIME TIME, C_TS TIMESTAMP, C_BOOL BOOL)
Success: INSERT INTO test values(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 09:00:09','t')
Success: odbc_execute.
Success: SELECT * FROM TEST
Array

  [C_ID] => 1
```
Managing Query Execution Between the Client and Vertica

The following topics describe techniques that help you manage query execution between your client and your Vertica database.

**ResultBufferSize**

By default, Vertica uses the ResultBufferSize parameter to determine the maximum size (in bytes) of a result set that a client can retrieve from a server. When ResultBufferSize is enabled, Vertica sends rows of data directly to the client making the query. The number of rows returned to the client at each fetch of data depends on the size (in bytes) of the ResultBufferSize parameter.

Sometimes, the size of the result set requested by the client is greater than what the ResultBufferSize parameter allows. In such cases, Vertica retrieves only a portion of the result set at a time. Each fetch of data returns the amount of data equal to the size set by the ResultBufferSize parameter. Ultimately, as the client iterates over the individual fetches of data, the entire result set is returned.
Benefits of ResultBufferSize

If you are concerned with the effect of your queries on network latency, ResultBufferSize may provide an advantage over MARS. MARS requires that the client wait until all rows of data are written to the server before the client can retrieve the data. This delay may cause latency issues for your network while waiting for the results to be stored.

In addition, MARS requires that you send two separate requests to return rows of data. The first request performs the query execution which stores the result set on the server. The second request retrieves the data rows that are stored on the server. With ResultBufferSize, you only need to send one request. This request both executes and retrieves the data rows of interest.

Query Execution with ResultBufferSize

The following graphic shows how Vertica returns rows of data from a database to the client with ResultBufferSize enabled:
The query execution performs the following steps:

1. The client sends a query, such as a **SELECT** statement, to the server. In the preceding graphic, the first query is named Query 1.
2. The server receives the client's request and begins to send both a description of the result set and the requested rows of data back to the client.

3. After all possible rows are returned to the client, the execution is complete. The size of the data set returned equals either that of the data that was requested or the maximum amount of data that ResultBufferSize parameter can retrieve. If the ResultBufferSize maximum size is not yet reached, Vertica can execute Query 2.

The server can accept Query 2 and perform the same steps that it did for Query 1. If the results for Query 1 had reached the maximum ResultBufferSize allowable, Vertica could not execute Query 2 until the client freed the results from Query 1.

After Query 2 runs, you cannot view the results you retrieved for Query 1, unless you execute Query 1 again.

**Setting an Unlimited Buffer Size**

Setting ResultBufferSize to 0 tells the client driver to use an unlimited result set buffer. With this setting, the client library allocates as much memory as it needs to read the entire result set of a query. You may choose to set ResultBufferSize to 0 if you want to simulate having multiple active queries over a single database connection at the same time. With an unlimited buffer size, your client can run a query and have its entire result set stored in memory. This ends the first query, so your client can execute a second query before it fully processes the results of the first query.

A drawback of this method is that your query may consume too much memory if your queries return large result sets. This over-allocation of memory can result in the operating system terminating your client. Due to this risk, consider using multiple database connections instead of trying to reuse a single connection for multiple queries. The overhead of multiple database connections is small compared to the overall amount of resources required to process a large data set.

**Multiple Active Result Sets (MARS)**

You can only enable MARS when you connect to Vertica using a JDBC client connection. MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.
MARS is set at the session level and must be enabled for every new session. When MARS is enabled, ResultBufferSize is disabled. No error is returned, however the ResultBufferSize parameter is ignored.

Benefits of MARS

In comparison with ResultBufferSize, MARS enables you to store multiple result sets from different queries at the same time. You can also send new queries before all of the results of a previous result set have been returned to the client. This allows applications to decouple query execution from result retrieval so that, on a single connection, you can process different results at the same time.

When you enable ResultBufferSize, you must wait until all result sets have been returned to the client before a new query can be executed.

Another benefit of MARS is that it allows you to free up query resources faster than ResultBufferSize allows. While a query is running, resources are held by that query session. When ResultBufferSize is enabled, a client that is performing slowly might read a single row of a result set and then have to stop to retrieve the next row. This prevents the query from finishing quickly and, therefore, prevents the resources used from being freed up for other applications. With MARS, the speed of the client is irrelevant to the reading of rows. As soon as the results are written to the MARS storage, the resources are freed and the speed at which the client retrieves rows no longer matters.

Query Execution with MARS

The following graphic demonstrates how multiple queries to the server are handled when MARS is enabled:
Query 1:

1. Query 1 is sent to the server.

2. Query 1's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.

3. Query 1 completes and its results are saved on the server.
a. You can now send commands to retrieve the rows of Query 1's result set. These rows are stored on the server. Retrieved rows are sent to the client along with the status of the result set. By keeping track of the status of the result set, Vertica is able to keep track of which rows have been retrieved from the server.

4. Now that Query 1 has successfully completed, and its result sets are being stored on the server, Query 2 can be executed.

Query 2:

1. Query 2 is sent to the server.

2. Query 2's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.

3. Query 2 completes and its results are stored on the server. Both Query 1 and Query 2 now have result sets stored on the server.

4. You can now send retrieval requests to both Query 1 and Query 2's result sets that are stored on the server. Whenever a retrieval request is made for rows from Query 1, the request is sent and rows and the result set status are sent to the client. The same occurs for Query 2.

Once all rows have been read by the client, the MARS storage on the server closes the active results session. The MARS storage on the server is then freed to store more data. The MARS storage also closes and frees once your session is finished.

Enabling and Disabling MARS

You can enable and disable MARS in two different ways:

1. To enable MARS using the JDBC client connection properties, see JDBC Connection Properties.

2. To enable MARS using the SET SESSION command, see SET SESSION MULTIPLEACTIVERESULTSETS.

Management API

The Management API is a REST API that you can use to view and manage Vertica databases with scripts or applications that accept REST and JSON. The response format for all requests is JSON.

**cURL**

cURL is a command-line tool and application library used to transfer data to or from a server. It uses URL syntax, such as HTTP and HTTPS. All API requests sent to a Vertica server must be made using HTTPS. A request made using HTTP will fail.

There are four HTTP requests that can be passed using `cURL` to call API methods:

<table>
<thead>
<tr>
<th>Request</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>Retrieves data.</td>
</tr>
<tr>
<td>PUT</td>
<td>Updates data.</td>
</tr>
<tr>
<td>POST</td>
<td>Creates new data.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Deletes data.</td>
</tr>
</tbody>
</table>

**Syntax**

curl https://<NODE>:5444/

**Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-h</code> <code>---help</code></td>
<td>Lists all available command-line options.</td>
</tr>
<tr>
<td><code>-H</code> <code>---header</code></td>
<td>Allows you to use custom headers in your command. This is useful for sending a request that requires a VerticaAPIKEY.</td>
</tr>
</tbody>
</table>

```bash
curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/
```
-k --insecure

Allows SSL connections without certificate validation.

curl -k https://<NODE>:5444/

-X --request

Specifies the custom request used when communicating with a server.

curl -X REQUEST https://<NODE>:5444/

Can be one of the following values:

- GET
- PUT
- POST
- DELETE

Note: If no request is specified, cURL automatically defaults to the GET request.

There are many more options available to add to your cURL query. For a comprehensive list with descriptions, visit the cURL Documentation Website.

**General API Information**

These API calls can interact with either standard Vertica nodes or Management Console nodes.

<table>
<thead>
<tr>
<th>GET /</th>
<th>Returns the agent-specific information useful for version checking and service discovery.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET api</td>
<td>Returns a list of api objects and properties.</td>
</tr>
</tbody>
</table>
GET /

Returns API version information and a list of links to child resources for the Management API.

Resource URL

https://<NODE>:5444/

Authentication

Not required.

Parameters

None.

Example Request

<table>
<thead>
<tr>

Rest APIs for the Agent

These API calls interact with standard Vertica nodes.
Backup and Restore

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET backups</td>
<td>Returns all the backups that have been created for all vbr configuration files (*.ini) that are located in the /opt/vertica/config directory.</td>
</tr>
<tr>
<td>POST backups/:config_script_base</td>
<td>Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).</td>
</tr>
<tr>
<td>GET backups/:config_script_base/:archive_id</td>
<td>Returns details for a specific backup archive.</td>
</tr>
<tr>
<td>POST restore/:archive_id</td>
<td>Restores a backup.</td>
</tr>
</tbody>
</table>

Databases

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET databases</td>
<td>Returns a list of databases, their properties, and current status.</td>
</tr>
<tr>
<td>POST databases</td>
<td>Creates a new database by supplying a valid set of parameters.</td>
</tr>
<tr>
<td>GET databases/:database_name</td>
<td>Returns details about a specific database.</td>
</tr>
<tr>
<td>PUT databases/:database_name</td>
<td>Starts, stops, rebalances, or runs Workload Analyzer on a database.</td>
</tr>
<tr>
<td>DELETE databases/:database_name</td>
<td>Deletes an existing database.</td>
</tr>
<tr>
<td>GET databases/:database_name/configuration</td>
<td>Returns the current configuration parameters from the database.</td>
</tr>
<tr>
<td>PUT databases/:database_name/configuration</td>
<td>Sets one or more configuration parameters in the database.</td>
</tr>
<tr>
<td><strong>GET databases/:database_name/hosts</strong></td>
<td>Returns hosts details for a specific database.</td>
</tr>
<tr>
<td>--------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>POST databases/:database_name/hosts</strong></td>
<td>Adds a new host to the database.</td>
</tr>
<tr>
<td><strong>DELETE databases/:database_name/hosts/:host_id</strong></td>
<td>Removes a host from the database.</td>
</tr>
<tr>
<td><strong>POST databases/:database_name/hosts/:host_id/process</strong></td>
<td>Starts the database process on a specific host.</td>
</tr>
<tr>
<td><strong>DELETE databases/:database_name/hosts/:host_id/process</strong></td>
<td>Stops the database on a specific host.</td>
</tr>
<tr>
<td><strong>POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new</strong></td>
<td>Replaces a host with a standby host in the database.</td>
</tr>
<tr>
<td><strong>GET databases/:database_name/license</strong></td>
<td>Returns the Vertica license that the specified database is using.</td>
</tr>
<tr>
<td><strong>PUT databases/:database_name/license</strong></td>
<td>Upgrades the license in the database.</td>
</tr>
<tr>
<td><strong>GET databases/:database_name/licenses</strong></td>
<td>Returns all the feature licenses that the specified database is using.</td>
</tr>
<tr>
<td><strong>GET databases/:database_name/nodes</strong></td>
<td>Returns a list of nodes for the specified database.</td>
</tr>
<tr>
<td><strong>GET databases/:database_name/nodes/:node_id</strong></td>
<td>Returns details on a specific node for the specified database.</td>
</tr>
<tr>
<td><strong>POST databases/:database_name/process</strong></td>
<td>Starts the specified database.</td>
</tr>
<tr>
<td><strong>GET databases/:database_name/process</strong></td>
<td>Returns the state of the database as either UP or DOWN.</td>
</tr>
<tr>
<td><strong>DELETE databases/:database_name/process</strong></td>
<td>Stops the specified database on all hosts.</td>
</tr>
<tr>
<td><strong>POST databases/:database_name/rebalance/process</strong></td>
<td>Rebalances the specified database. This option can have a long run time.</td>
</tr>
</tbody>
</table>
POST databases/:database_name/wla/process | Runs the analyze workload action against the specified database. This option can have a long run time.

**Hosts**

| GET hosts | Returns a list of hosts in this cluster. |
| GET hosts/:hostid | Returns details for a specific host in this cluster. |

**Jobs**

| GET jobs | Returns a list of jobs the agent is tracking, along with their current status and exit codes. |
| GET jobs/:id | Returns the details (the saved output) for a specific job. |

**Licenses**

| POST licenses | Uploads and applies a new license to this cluster. |
| GET licenses | Returns the license field that databases created on this cluster use. |

**Nodes**

| GET nodes | Returns a list of nodes in this cluster. |
| GET nodes/:nodeid | Returns details for a specific node in this cluster. |
## Webhooks

<table>
<thead>
<tr>
<th>Method</th>
<th>Endpoint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>webhooks</td>
<td>Returns a list of active webhooks.</td>
</tr>
<tr>
<td>POST</td>
<td>webhooks/subscribe</td>
<td>Creates a new webhook.</td>
</tr>
<tr>
<td>DELETE</td>
<td>webhooks/:subscriber_id</td>
<td>Deletes an existing webhook.</td>
</tr>
</tbody>
</table>
VerticaAPIKey

The Management API requires an authentication key, named VerticaAPIKEY, to access some API resources. You can manage API keys by using the apikeymgr command-line tool.

API key management tool

**optional arguments:**
- **-h**, **--help** show this help message and exit
- **--user REQUESTOR** The name of the person requesting the key
- **--app APPLICATION** The name of the application that will use the key
- **--delete** Delete the key for the given R & A
- **--create** Create a key for the given R & A
- **--update** Update a key for the given R & A
- **--migrate** migrate the keyset to the latest format
- **--secure {restricted,normal,admin}** Set the keys security level
- **--list** List all the keys known

Example Request

To create a new VerticaAPIKEY for the dbadmin user with admin access, enter the following:

```
$ apikeymgr --user dbadmin --app vertica --create --secure admin
```

**Response:**

```
Requestor : dbadmin
Application: vertica
API Key : ValidAPIKey
Synchronizing cluster...
```

Backup and Restore

You can use these API calls to perform backup and restore tasks for your database.

<p>| GET backups | Returns all the backups that have been created for all vbr configuration files (*.ini) that are located in the /opt/vertica/config directory. |
| POST | Creates a new backup as defined by the given vbr configuration script |</p>
<table>
<thead>
<tr>
<th>backups/:config_script_base</th>
<th>base (filename without the .ini extension).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>GET</strong> backups/:config_script_base/:archive_id</td>
<td>Returns details for a specific backup archive.</td>
</tr>
<tr>
<td><strong>POST</strong> restore/:archive_id</td>
<td>Restores a backup.</td>
</tr>
</tbody>
</table>
GET backups

Returns a list of all backups created for vbr configuration (*.ini) files that reside in /opt/vertica/config and provides details about each backup.

Resource URL

https://<NODE>:5444/backups

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/backups |

Response:

```
[{
  "backups": [],
  "config_file": "/opt/vertica/config/backup3.ini",
  "num_backups": 1
}, {
  "backups": [
    {
      "backup": "backup3_20140707_114852",
      "epoch": "61",
      "hosts": "v_vmart_node0001(10.20.100.247)",
      "objects": ""
    }
  ]
}]
```
"objects": "",
},
{
  "backup": "backup_archive20140707_113645",
  "epoch": "60",
  "hosts": "v_vmart_node0001(10.20.100.247)",
  "objects": ""
}
],
"config_file": "/opt/vertica/config/backup.ini",
"num_backups": 2
}
POST backups/:config_script_base

Creates a new backup job for the backup defined in the vbr configuration script :config_script_base. The vbr configuration script must reside in /opt/vertica/configuration. The :config_script_base value does not include the .ini filename extension.

To determine valid :config_script_base values, see GET backups.

Returns a job ID that you can use to determine the status of the job.

Resource URL

https://<NODE>:5444/backups/:config_script_base

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

| POST | https://<NODE>:5444/backups/backup3 |

Response:

```json
{
    "id": "CreateBackup-VMart-1404750602.03",
    "url": "/jobs/CreateBackup-VMart-1404750602.03"
}
```
GET backups/:config_script_base/:archive_id

Returns details on a specific backup. You must provide the :config_script_base. This value is the name of a vbr config file (without the .ini filename extension) that resides in /opt/vertica/config. The :archive_id is the value of the backup field that the GET backups command returns.

Resource URL

https://<NODE>:5444/backups/:config_script_base/:archive_id

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

```
GET https://<NODE>:5444/backups/backup3/backup3_20140707_123254
```

Response:

```
{
    "backup": "backup3_20140707_123254",
    "config_file": "/opt/vertica/config/backup3.ini",
    "epoch": "62",
    "hosts": "v_vmart_node0001(10.20.100.247)",
    "objects": ""
}
```
POST restore/:archive_id

Creates a new restore job to restore the database from the backup archive identified by :archive_id. The :archive_id is the value of a backup field that the GET backups command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/restore/:archive_id

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

| POST | https://<NODE>:5444/restore/backup3_20140707_132904 |

Response:

```
{
  "id": "RestoreBackup-VMart-1404760113.71",
  "url": "/jobs/RestoreBackup-VMart-1404760113.71"
}
```

Databases

You can use these API calls to interact with your database.

<p>| GETdatabases | Returns a list of databases, their properties, and current status. |</p>
<table>
<thead>
<tr>
<th>HTTP Method</th>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST</td>
<td>databases</td>
<td>Creates a new database by supplying a valid set of parameters.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name</td>
<td>Returns details about a specific database.</td>
</tr>
<tr>
<td>PUT</td>
<td>databases/:database_name</td>
<td>Starts, stops, rebalances, or runs Workload Analyzer on a database.</td>
</tr>
<tr>
<td>DELETE</td>
<td>databases/:database_name</td>
<td>Deletes an existing database.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/configuration</td>
<td>Returns the current configuration parameters from the database.</td>
</tr>
<tr>
<td>PUT</td>
<td>databases/:database_name/configuration</td>
<td>Sets one or more configuration parameters in the database.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/hosts</td>
<td>Returns hosts details for a specific database.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/hosts</td>
<td>Adds a new host to the database.</td>
</tr>
<tr>
<td>DELETE</td>
<td>databases/:database_name/hosts/:host_id</td>
<td>Removes a host from the database.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/hosts/:host_id/process</td>
<td>Starts the database process on a specific host.</td>
</tr>
<tr>
<td>DELETE</td>
<td>databases/:database_name/hosts/:host_id/process</td>
<td>Stops the database on a specific host.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/hosts/:host_id/replace_with/:host_id_new</td>
<td>Replaces a host with a standby host in the database.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/license</td>
<td>Returns the Vertica license that the specified database is using.</td>
</tr>
<tr>
<td>PUT</td>
<td>databases/:database_name/license</td>
<td>Upgrades the license in the database.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/licenses</td>
<td>Returns all the feature licenses that the specified database is using.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/nodes</td>
<td>Returns a list of nodes for the specified database.</td>
</tr>
<tr>
<td>Method</td>
<td>Endpoint</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/nodes/:node_id</td>
<td>Returns details on a specific node for the specified database.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/process</td>
<td>Starts the specified database.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/process</td>
<td>Returns the state of the database as either UP or DOWN.</td>
</tr>
<tr>
<td>DELETE</td>
<td>databases/:database_name/process</td>
<td>Stops the specified database on all hosts.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/rebalance/process</td>
<td>Rebalances the specified database. This option can have a long run time.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/wla/process</td>
<td>Runs the analyze workload action against the specified database. This option can have a long run time.</td>
</tr>
</tbody>
</table>
GETdatabases

Returns a list of databases, their current status, and database properties.

Resource URL

https://<NODE>:5444/databases

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/databases |

An example of the full request using cURL:

curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/databases

Response:

```json
{
   "body": [
      {
         "href": "/databases/VMart",
         "mime-type": [
            "application/vertica.database.json-v2"
         ],
         "name": "VMart",
         "port": "5433",
         "status": "UP"
      },
      {
         "href": "/databases/testDB",
         "mime-type": [
            "application/vertica.database.json-v2"
         ]
      }
   ]
}
```
"name": "testDB",
"port": "5433",
"status": "DOWN"
}
],
"href": "/databases",
"links": [
  "/:database_name"
],
"mime-type": "application/vertica.databases.json-v2"
}
POST databases

Creates a job to create a new database with the provided parameters.

**Important:** You must stop any running databases on the nodes on which you want to create the new database. If you do not, database creation fails.

Returns a job ID that can be used to determine the status of the job. See GET jobs.

**Resource URL**

https://<NODE>:5444/database

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the database to create.</td>
</tr>
<tr>
<td>passwd</td>
<td>Password for the new database.</td>
</tr>
<tr>
<td>only</td>
<td>Optional list of hostnames to include in the database. By default, all nodes in the cluster are added to the database.</td>
</tr>
<tr>
<td>exclude</td>
<td>Optional list of hostnames to exclude from the database.</td>
</tr>
<tr>
<td>catalog</td>
<td>Path of the catalog directory.</td>
</tr>
<tr>
<td>data</td>
<td>Path of the data directory.</td>
</tr>
<tr>
<td>port</td>
<td>Port where the database listens for client connections. Default is 5433.</td>
</tr>
</tbody>
</table>

**Example Request**

```plaintext
```
Response:

```json
{
    "userid": "dbadmin"
}
```
**GET databases/:database_name**

Returns details about a specific database. The :database_name is the value of the name field that the GETdatabases command returns.

**Resource URL**

```
https://<NODE>:5444/databases/:database_name
```

**Authentication**

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

```
GET https://<NODE>:5444/databases/VMart
```

**Response:**

```
{
  "body": {
    "database_id": "VMart",
    "id": "VMart",
    "nodes": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003",
    "nodes_new": [
      {
        "catalog_base": "/home/dbadmin",
        "data_base": "/home/dbadmin",
        "host": "10.20.100.247",
        "id": "v_vmart_node0001"
      },
      {
        "catalog_base": "/home/dbadmin",
        "data_base": "/home/dbadmin",
        "host": "10.20.100.248",
        "id": "v_vmart_node0002"
      },
      {
```
"catalog_base": "/home/dbadmin",
"data_base": "/home/dbadmin",
"host": "10.20.100.249",
"id": "v_vmart_node0003"
}
],
"path": "/home/dbadmin/VMart",
"port": "5433",
"restartpolicy": "ksafe",
"status": "UP"
},
"href": "/databases/VMart",

  "/configuration",
  "/hosts",
  "/license",
  "/nodes",
  "/process",
  "/rebalance/process",
  "/status",
  "/wla/process"
],
"mime-type": "application/vertica.database.json-v2"}
PUT databases/:database_name

Creates a job to run the action specified by the action parameter against the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/databases/:database_name

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have normal level security or higher.

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
<tr>
<td>action</td>
<td>Can be one of the following values:</td>
</tr>
<tr>
<td></td>
<td>• start — Start the database.</td>
</tr>
<tr>
<td></td>
<td>• stop — Stop the database.</td>
</tr>
<tr>
<td></td>
<td>• rebalance — Rebalance the database.</td>
</tr>
<tr>
<td></td>
<td>• wla — Run Work Load Analyzer against the database.</td>
</tr>
</tbody>
</table>

Example Request

PUT

Response:
{  
  "id": "StopDatabase-testDB-2014-07-20 13:28:49.321744",
  "url": "/jobs/StopDatabase-testDB-2014-07-20 13:28:49.321744"
}

DELETE databases/:database_name

Creates a job to delete (drop) an existing database on the cluster. To perform this operation, you must first stop the database. The :database_name is the value of the name field that the GETdatabases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

Parameters

None.

Example Request

```
DELETE  https://<NODE>:5444/databases/TestDB
```

Response:

```
{
  "id": "DropDatabase-TestDB-2014-07-18 12:50:33.332383",
  "url": "/jobs/DropDatabase-TestDB-2014-07-18 12:50:33.332383"
}
```
GET databases/:database_name/configuration

Returns a list of configuration parameters for the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Resource URL

https://<NODE>:5444/databases/:database_name/configuration

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
</tbody>
</table>

Example Request

<table>
<thead>
<tr>
<th>Method</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>https://&lt;NODE&gt;:5444/databases/testDB/configuration</td>
</tr>
</tbody>
</table>

Response:

This API call returns over 100 configuration parameters. The following response is a small subset of the total amount returned.

```json
[
  {

PUT databases/:database_name/configuration

Sets one or more configuration parameters for the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns. Returns the parameter name, the requested value, and the result of the attempted change (Success or Failed).

Resource URL

https://<NODE>:5444/databases/:database_name/configuration

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have admin level security.

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
<tr>
<td>parameter_</td>
<td>A parameter name and value combination for the parameter to be changed.</td>
</tr>
<tr>
<td>parameter_</td>
<td>Values must be URL encoded.</td>
</tr>
<tr>
<td>parameter_</td>
<td>You can include multiple name/value pairs to set multiple parameters with</td>
</tr>
<tr>
<td>parameter_</td>
<td>a single API call.</td>
</tr>
</tbody>
</table>

Example Request

<table>
<thead>
<tr>
<th>PUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>https://&lt;NODE&gt;:5444/databases/testDB/configuration?user_id=dbadmin&quot;&amp;&quot;passwd=vertica &quot;&amp;&quot;JavaBinaryForUDx=%2Fusr%2Fbin%2Fjava&quot;&amp;&quot;TransactionIsolationLevel=SERIALIZABLE</td>
</tr>
</tbody>
</table>

Response:

[
  {
    "key": "JavaBinaryForUDx",
    "result": "Success",
    "value": "/usr/bin/java"
]
},
{
  "key": "TransactionIsolationLevel",
  "result": "Success",
  "value": "SERIALIZABLE"
}
]
GET databases/:database_name/hosts

Returns the hostname/IP address, node name, and UP/DOWN status of each host associated with the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Resource URL

https://<NODE>:5444/databases/:database_name/hosts

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET     | https://<NODE>:5444/databases/VMart/hosts |

Response:

```json
{
  "body": [
    {
      "hostname": "10.20.100.247",
      "nodename": "v_vmart_node0001",
      "status": "UP",
    },
    {
      "hostname": "10.20.100.248",
      "nodename": "v_vmart_node0002",
      "status": "UP",
      "ts": "2014-07-18T13:12:31.904209"
    },
    {
      "hostname": "10.20.100.249",
      "nodename": "v_vmart_node0003",
      "status": "UP",
```
**POST databases/:database_name/hosts**

Creates a job to add a host to the database identified by :database_name. This host must already be part of the cluster. The :database_name is the value of the name field that the GETdatabases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

**Resource URL**

```
https://<NODE>:5444/:database_name/hosts
```

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
<tr>
<td>hostname</td>
<td>The hostname to add to the database. This host must already be part of the cluster.</td>
</tr>
</tbody>
</table>

**Example Request**

```
```

**Response:**

```
{
   "id": "AddHostToDatabase-testDB-2014-07-20 12:24:04.088812",
   "url": "/jobs/AddHostToDatabase-testDB-2014-07-20 12:24:04.088812"
}
```
 DELETE databases/:database_name/hosts/:host_id

Creates a job to remove the host identified by :host_id from the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns. The :host_id is the value of the host field returned by GET databases/:database_name.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/databases/:database_name/hosts/:host_id

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have admin level security.

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
</tbody>
</table>

Example Request

DELETE

Response:

```json
{
  "id": "RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235",
  "url": "/jobs/RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235"
}
```
POST databases/:database_name/hosts/:host_id/process

Creates a job to start the vertica process for the database identified by :database_name on the host identified by :host_id. The :database_name is the value of the name field that the GETdatabases command returns. The :host_id is the value of the host field returned by GET databases/:database_name.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/:database_name/hosts/:host_id/process

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

Response:

```json
{
   "id": "StartDatabase-testDB-2014-07-20 13:14:03.968340",
   "url": "/jobs/StartDatabase-testDB-2014-07-20 13:14:03.968340"
}
```
GET databases/:database_name/license

Returns details about the database license being used by the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Resource URL

https://<NODE>:5444/:database_name/license

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
</tbody>
</table>

Example Request

<table>
<thead>
<tr>
<th>Method</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>https://&lt;NODE&gt;:5444/VMart/license</td>
</tr>
</tbody>
</table>

Response:

```json
{
   "body": {
      "details": {
         "assigned_to": "Vertica Systems, Inc.",
         "grace_period": 0,
         "is_ce": false,
         "is_unlimited": false,
         "name": "vertica",
         "not_after": "Perpetual",
         "not_before": "2007-08-03"
      },
      "last_audit": {
         "database_size_bytes": "814060522"
      }
   }
}
```
"license_size_bytes": "536870912000",
"usage_percent": "0.00151630588248372"
},
"href": "/databases/VMart/license",
"links": [],
"mime-type": "application/vertica.license.json-v2"}
GET databases/:database_name/licenses

Returns details about all license being used by the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Resource URL

https://<NODE>:5444/:database_name/licenses

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
</tbody>
</table>

Example Request

<table>
<thead>
<tr>
<th>request</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>https://&lt;NODE&gt;:5444/VMart/licenses</td>
</tr>
</tbody>
</table>

Response:

```json
{
    "body": [
        {
            "details": {
                "assigned_to": "Vertica Systems, Inc.",
                "audit_date": "2014-07-19 21:35:25.111312",
                "is_ce": "False",
                "name": "vertica",
                "node_restriction": "",
                "not_after": "Perpetual",
                "not_before": "2007-08-03",
                "size": "500GB"
            },
            "last_audit": {
```
DELETE databases/:database_name/hosts/:host_id/process

Creates a job to stop the vertica process for the database identified by :database_name on the host identified by :host_id. The :database_name is the value of the name field that the GETdatabases command returns. The :host_id is the value of the host field returned by GET databases/:database_name.

Returns a job ID that can be used to determine the status of the job. See GET jobs.

Note: If stopping the database on the hosts causes the database to no longer be k-safe, then the all database nodes may shut down.

Resource URL

https://<NODE>:5444/databases/:database_name/hosts/:host_id/process

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

| DELETE | DELETE databases/testDB/hosts/192.168.232.181/process |

Response:

```json
{
  "id": "StopDatabase-testDB-2014-07-20 13:02:08.453547",
  "url": "/jobs/StopDatabase-testDB-2014-07-20 13:02:08.453547"
}
```
POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new

Creates a job to replace the host identified by hosts/:host_id with the host identified by replace_with/:host_id. Vertica performs these operations for the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns. The :host_id is the value of the host field as returned by GET databases/:database_name. You can find valid replacement hosts using GET hosts. The replacement host cannot already be part of the database. You must stop the vertica process on the host being replaced.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/databases/:database_name/hosts/:host_id/replace_with/:host_id_new

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
</tbody>
</table>

Example Request

<table>
<thead>
<tr>
<th>POS</th>
<th>Request</th>
</tr>
</thead>
</table>

Response:

```
{
}
```
GET databases/:database_name/nodes

Returns a comma-separated list of node IDs for the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Resource URL

https://<NODE>:5444/:database_name/nodes

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/VMart/nodes |

Response:

```
[  
  {  
    "database_id": "VMart",
    "node_id": "v_vmart_node001,v_vmart_node002,v_vmart_node003",
    "status": "Unknown"
  }
]
```
GET databases/:database_name/nodes/:node_id

Returns details about the node identified by :node_id. The :node_id is one of the node IDs returned by GET databases/:database_name/nodes.

Resource URL

https://<NODE>:5444/:database_name/nodes/:node_id

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/databases/VMart/nodes/v_vmart_node0001 |

Response:

```json
{
    "db": "VMart",
    "host": "10.20.100.247",
    "name": "v_vmart_node0001",
    "state": "UP"
}
```
POST databases/:database_name/process

Creates a job to start the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Returns a job ID that can be used to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/databases/:database_name/process

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>epoch</td>
<td>Start the database from this epoch.</td>
</tr>
<tr>
<td>include</td>
<td>Include only these hosts when starting the database. Use a comma-separated list of hostnames.</td>
</tr>
</tbody>
</table>

Example Request

<table>
<thead>
<tr>
<th>Method</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST</td>
<td>https://&lt;NODE&gt;:5444/databases/:testDB/process</td>
</tr>
</tbody>
</table>

An example of the full request using cURL:

curl -X POST -H "VerticaApiKeyId: ValidAPIKey" https://<NODE>:5444/:testDB/process

Response:

```
{
  "id": "StartDatabase-testDB-2014-07-20 12:41:46.061408",
  "url": "#/jobs/StartDatabase-testDB-2014-07-20 12:41:46.061408"
}
```
GET databases/:database_name/process

Returns a state of UP or DOWN for the database identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Resource URL

https://<NODE>:5444/databases/:database_name/process

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/databases/VMart/process |

Response:

```
{
    "state": "UP"
}
```
DELETE databases/:database_name/process

Creates a job to stop the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/databases/:database_name/process

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
</tbody>
</table>

Example Request

| DELETE     | https://<NODE>:5444/databases/testDB/process?user_id=dbadmin""&"passwd=vertica |

An example of the full request using cURL:

```
```

Response:

```
{
   "id": "StopDatabase-testDB-2014-07-20 12:46:04.406637",
   "url": "/jobs/StopDatabase-testDB-2014-07-20 12:46:04.406637"
}
```
POST databases/:database_name/rebalance/process

Creates a job to run a rebalance on the database identified by host identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/databases/:database_name/rebalance/process

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

<table>
<thead>
<tr>
<th>user_id</th>
<th>A database username.</th>
</tr>
</thead>
<tbody>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
</tbody>
</table>

Example Request

| POST | https://<NODE>:5444/databases/testDB/rebalance/process |

Response:

```json
{
   "id": "RebalanceData-testDB-2014-07-20 21:42:45.731038",
   "url": "/jobs/RebalanceData-testDB-2014-07-20 21:42:45.731038"
}
```
POST databases/:database_name/wla/process

Creates a job to run Workload Analyzer on the database identified by host identified by :database_name. The :database_name is the value of the name field that the GETdatabases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/databases/:database_name/wla/process

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
</tbody>
</table>

Example Request

<table>
<thead>
<tr>
<th>method</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST</td>
<td>https://&lt;NODE&gt;:5444/databases/testDB/wla/process</td>
</tr>
</tbody>
</table>

Response:

```
{
}
```

Hosts

You can use these API calls to get information on the hosts in your cluster.
<table>
<thead>
<tr>
<th><strong>GET hosts</strong></th>
<th>Returns a list of hosts in this cluster.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>GET hosts/:hostid</strong></td>
<td>Returns details for a specific host in this cluster.</td>
</tr>
</tbody>
</table>
GET hosts

Returns a list of the hosts in the cluster and the hardware, software, and network details about each host.

Resource URL

https://<NODE>:5444/hosts

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/hosts |

Response:

```json

"/:hostid"
],
"mime-type": "application/vertica.hosts.json-v2"}
GET hosts/:hostid

Returns hardware, software, and network details about the host identified by :host_id. You can find :host_id for each host using GET hosts.

Resource URL

https://<NODE>:5444/hosts/:hostid

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET       | https://<NODE>:5444/hosts/10.20.100.247 |

Response:

{
   "body": {
      "cpu_info": {
         "cpu_type": "Intel(R) Xeon(R) CPU E5-2695 v2 @ 2.40GHz",
         "number_of_cpus": 2
      },
      "hostname": "v_vmart_node0001.example.com",
      "max_user_proc": "3833",
      "nics": [
         {
            "broadcast": "10.20.100.255",
            "ipaddr": "10.20.100.247",
            "name": "eth0",
            "netmask": "255.255.255.0",
            "speed": "unknown"
         },
         {
            "broadcast": "255.255.255.255",
            "ipaddr": "127.0.0.1",
         }
      ]
   }
}
Jobs
You can use these API calls to get information on your database's jobs.

<table>
<thead>
<tr>
<th>GET jobs</th>
<th>Returns a list of jobs the agent is tracking, along with their current status and exit codes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET jobs/:id</td>
<td>Returns the details (the saved output) for a specific job.</td>
</tr>
</tbody>
</table>
GET jobs

Returns a list of jobs being tracked by the agent and job details. Jobs always start immediately. The is_running field is a Boolean value. If is_running is false, then the job is complete.

The exit_code details the status of the job. The exit_code is different for certain types of jobs:

- For Backup jobs:
  - 0 indicates success.
  - Any other number indicates a failure.

- For all other jobs:
  - -9 indicates success.
  - Any other number indicates a failure.

You can see details about failures in /opt/vertica/log/agentStdMsg.log.

Resource URL

https://<NODE>:5444/jobs

Authentication

Requires a VerticaAPIKey in the request header. The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/jobs |
Response:

```json
{
  "body": [
    {
      "exit_code": 0,
      "id": "CreateBackup-VMart-1405012447.75",
      "is_running": false,
      "status": "unused",
      "ts": "1405012461.18"
    },
    {
      "exit_code": 1,
      "id": "CreateBackup-VMart-1405012454.88",
      "is_running": false,
      "status": "unused",
      "ts": "1405012455.18"
    }
  ],
  "href": "/jobs",
  "links": [
    "/:jobid"
  ],
  "mime-type": "application/vertica.jobs.json-v2"
}
```
GET jobs/:id

Gets the details for a specific job with the provided :id. You can determine the list of job :ids using GET jobs.

Details for a specific job are the same as the details provided for all jobs by GET jobs.

Note: You must URL encode the :id as some IDs may contain spaces or other special characters.

Resource URL

https://<NODE>:5444/jobs/:id

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/jobs/CreateBackup-VMart-1405012454.88 |

Licenses

You can use these API calls to manage licenses for your database.

| POST licenses | Uploads and applies a new license to this cluster. |
| GET licenses  | Returns the license field that databases created on this cluster use. |
POST licenses

Uploads and applies a license file to this cluster.

You must provide the license file as an HTTP POST form upload, identified by the name *license*. For example, you can use cURL:

```
curl -k --request POST -H "VerticaApiKey:ValidAPIKey" \https://v_vmart_node0001:5444/licenses --form "license=@vlicense.dat"
```

Resource URL

https://<NODE>:5444/licenses

Authentication

Requires a *VerticaApiKey* in the request header.

The API key must have admin level security.

Parameters

None.

Example Request

```
| POST      | https://<NODE>:5444/licenses |
```

Response:

There is no HTTP body response for successful uploads. A successful upload returns an HTTP 200/OK header.
GET licenses

Returns any license files that are used by this cluster when creating databases. License files must reside in /opt/vertica/config/share.

Resource URL

https://<NODE>:5444/licenses

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET       | https://<NODE>:5444/licenses |

Response:

```json
{
    "body": [
        {
            "comment": "Vertica license is valid",
            "end": "Perpetual",
            "grace": "0",
            "size": "1TB CE Nodes 3",
            "start": "2011-11-22",
            "status": true,
            "vendor": "Vertica Community Edition"
        }
    ],
    "href": "/license",
    "links": [],
    "mime-type": "application/vertica.license.json-v2"
}
```
Nodes

You can use these API calls to retrieve information on the nodes in your cluster.

<table>
<thead>
<tr>
<th>API Call</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET nodes</td>
<td>Returns a list of nodes in this cluster.</td>
</tr>
<tr>
<td>GET nodes/:nodeid</td>
<td>Returns details for a specific node in this cluster.</td>
</tr>
</tbody>
</table>
GET nodes

Returns a list of nodes associated with this cluster.

Resource URL

https://<NODE>:5444/nodes

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/nodes |

Response:

```json
{
    "body": [
        "node0001",
        "node0002",
        "node0003",
        "v_testdb_node0001",
        "v_testdb_node0002",
        "v_testdb_node0003",
        "v_vmart_node0001",
        "v_vmart_node0002",
        "v_vmart_node0003"
    ],
    "href": "/nodes",
    "links": [
        "/:nodeid"
    ],
    "mime-type": "application/vertica.nodes.json-v2"
}
```
GET nodes/:nodeid

Returns details about the node identified by :node_id. You can find the :node_id for each node using GET nodes.

In the body field, the following information is detailed in comma-separated format:

- Node Name
- Host Address
- Catalog Directory
- Data Directory

Resource URL

https://<NODE>:5444/nodes/:node_id

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/nodes/v_vmart_node0001 |

Response:

```json
{
  "body": [
    "v_vmart_node0001",
    "10.20.100.247,/home/dbadmin,/home/dbadmin",
  ],
  "href": "/nodes/v_vmart_node0001",
  "links": []
}
```
Webhooks

You can use these API calls to obtain information on, create, or delete webhooks.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET <code>webhooks</code></td>
<td>Returns a list of active webhooks.</td>
</tr>
<tr>
<td>POST <code>webhooks/subscribe</code></td>
<td>Creates a new webhook.</td>
</tr>
<tr>
<td>DELETE <code>webhooks/:subscriber_id</code></td>
<td>Deletes an existing webhook.</td>
</tr>
</tbody>
</table>
GET webhooks

Returns a list of active webhooks for this cluster.

Resource URL

https://<NODE>:5444/webhooks

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

GET  https://<NODE>:5444/webhooks

Response:

{
   "body": [
   {
      "host": "192.168.232.1",
      "id": "79c1c8a18be02804b3d2f48ea6462909",
      "port": 80,
      "timestamp": "2014-07-20 22:54:09.829642",
      "url": "/gettest.htm"
   },
   {
      "host": "192.168.232.1",
      "id": "9c32cb0f3d2f9a7cb10835f1732fd4a7",
      "port": 80,
      "timestamp": "2014-07-20 22:54:09.829707",
      "url": "/getwebhook.php"
   }
   ],
   "href": "/webhooks",
   "links": [
      "/subscribe",
      "/:subscriber_id"
   ]}
},
  "mime-type": "application/vertica.webhooks.json-v2"
}
POST webhooks/subscribe

Creates a subscription for a webhook.

Resource URL

https://<NODE>:5444/webhooks/subscribe

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

<table>
<thead>
<tr>
<th>url</th>
<th>A URL to an application that accepts JSON messages from this cluster.</th>
</tr>
</thead>
</table>

Example Request

Response:

The response is not JSON encoded. The only text response is the ID of the webhook subscription. Additionally, an HTTP 200/OK header indicates success.

79c1c8a18be02804b3d2f462909
DELETE webhooks/:subscriber_id

Deletes the webhook identified by :subscriber_id. The :subscriber_id is the value of the id field that the GET webhooks command returns.

Resource URL

https://<NODE>:5444/webhooks/:subscriber_id

Authentication

Requires a VerticaAPIKey in the request header.
The API key must have restricted level security or higher.

Parameters

None.

Example Request

| DELETE | https://<NODE>:5444/webhooks/79c1c8a18be02804b3d2f48ea6462909 |

Response:

There is no HTTP body response for successful deletes. A successful delete returns an HTTP 200/OK header.

Rest APIs for the Management Console

These API calls interact with Management Console nodes.

Alerts

| GET alerts | Returns alerts for the current user. |
### Time Information

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET mcTimeInfo</td>
<td>Returns the current time for the MC server and the timezone of the location where the MC server is located.</td>
</tr>
</tbody>
</table>

### MC-User-ApKey

The MC-User-ApKey is a user-specific key used with Management Console. Users must have an MC-User-ApKey to interact with MC using the Rest API. All users with roles other than None automatically receive an MC-User-ApKey.

This key grants users the same rights through the API that they have available through their MC roles. To interact with the MC, users pass the key in the request header for the API.

### View the MC-User-ApKey

If you are the database administrator, you can view the MC-User-ApKey for all users. Individual users can view their own keys.

1. Connect to MC and go to MC Settings > User Management.
2. Select the user to view and click Edit. The user's key appears in the User API Key field.

### GET alerts

Returns a list of MC alerts, their current status, and database properties.

### Resource URL

https://<MC_NODE>:5450/webui/api/alerts
# Authentication

Requires an **MC-User-Apikey** in the request header.

## Filter Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| **types** | The type of alert to retrieve. Valid values are:  
  - info  
  - notice  
  - warning  
  - error  
  - critical  
  - alert  
  - emergency |
| **category** | For information, see [Thresholds Category Filter](#). |
| **db_name** | For information, see [Database Name Category Filter](#). |
| **limit** | The maximum number of alerts to retrieve. If the limit is lower than the number of existing alerts, Vertica retrieves the most recent alerts. Used with the type parameter, Vertica retrieves up to the limit for each type. For example, for a limit of five and types of critical and emergency, you could receive up to ten total alerts. |
| **time_from** | The timestamp start point from which to retrieve alerts. You can use this parameter in combination with the **time_to** parameter to retrieve alerts for a specific time range. Values must be passed in the following format: `yyyy-MM-ddTHH:mm`.  
  If you provide only the **time_from** parameter, and omit the **time_to** parameter, the response contains all alerts generated from the **time_from** parameter to the current time. |
| **time_to** | The timestamp end point from which to retrieve alerts. You can use this |
parameter in combination with the time_from parameter to retrieve alerts for a specific time range. Values must be passed in the following format: yyyy-MM-ddTHH:mm.

If you provide only the time_to parameter, and omit the time_from parameter, the response contains all alerts generated from the earliest possible time to the time passed in time_to.

Example Request

GET https://<MC_NODE>:5450/webui/api/alerts

Request Alerts Using cURL

This example shows how you can request alerts using cURL. In this example, the limit parameter is set to '2' and the types parameters is set to info and notice:

Response:

```json
[
  {
    "alerts": [
      {
        "id":5502,
        "markedRead":false,
        "eventTypeCode":0,
        "create_time":"2016-02-02 05:12:10.0",
        "updated_time":"2016-02-02 15:50:20.511",
        "severity":"warning",
        "status":1,
        "nodeName":"v_vmart_node0001",
        "databaseName":"VMart",
        "databaseId":1,
        "clusterName":"1449695416208_cluster",
        "description":"Warning: Low disk space detected (73% in use)",
        "summary":"Low Disk Space",
        "internal":false,
        "count":3830
      },
      {
        "id":5501,
        "markedRead":false,
        "eventTypeCode":2,
        "create_time":"2016-02-02 05:12:02.31",
        "updated_time":"2016-02-02 05:12:02.31",
```
Request Alerts Within a Time Range

These examples show various ways in which you can request the same alert as in the preceding example, but within specified time ranges.

Request the alert within a specific time range, using the `time_from` and `time_to` parameters:

```bash
```

Request the alert from a specific start time to the present using the `time_from` parameter:

```bash
```

Request the alert to a specific end point using the `time_to` parameter. When you use the `time_to` parameter without the `time_from` parameter, the `time_from` parameter defaults to the oldest alerts your MC contains:

```bash
```

GET mcTimeInfo

Returns the current time for the MC server and the timezone where the MC server is located.

Resource URL

https://<MC_NODE>:5450/webui/api/mcTimeInfo
Authentication

Requires an **MC-User-Apkey** in the request header.

Parameters

None.

Example Request

| GET | https://<MC_NODE>:5450/webui/api/mcTimeInfo |

This example shows how you can request MC time information using cURL:

```
```

Response:

```
{"mc_current_time":"Tue, 2000-01-01 01:02:03 -0500","mc_timezone":"US/Eastern"}
```

Thresholds Category Filter

Returns a list of alerts related to threshold settings in MC.

Resource URL

https://<MC_NODE>:5450/webui/api/alerts?category=thresholds

Authentication

Requires an **MC-User-Apkey** in the request header.
Example Request

| GET | https://<MC_NODE>:5450/webui/api/alerts?category=thresholds |

This example shows how you can request alerts on thresholds using cURL:

```
```

Response:

```
[
  {"alerts":[
    {
      "id":33,
      "markedRead":false,

See Also

- Combining Sub-Category Filters with Category Filters

Database Name Category Filter

Returns a list of MC alerts for a specific database.

Resource URL

https://<MC_NODE>:5450/webui/api/alerts?db_name=<database_name>
**Authentication**

Requires an **MC-User-Apikey** in the request header.

**Example Request**

```
GET https://<MC_NODE>:5450/webui/api/alerts?db_name="mydb"
```

This example shows how you can view alerts on a specific database using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?db_name="mydb"
```

**Response:**

```

Combining Sub-Category Filters with Category Filters

You can combine category filters with sub-category filters, to obtain alert messages for specific thresholds you set in MC. You can also use sub-category filters to obtain information about alerts on specific resource pools in your database.

Sub-Category Filters

You can use the following sub-category filters with the category filters. Sub-category filters are case sensitive and must be lowercase.

<table>
<thead>
<tr>
<th>Sub-Category Filter</th>
<th>Alerts Related to Threshold Value Set For:</th>
</tr>
</thead>
<tbody>
<tr>
<td>threshold_node_cpu</td>
<td>Node CPU</td>
</tr>
<tr>
<td>threshold_node_memory</td>
<td>Node Memory</td>
</tr>
<tr>
<td>threshold_node_disk_usage</td>
<td>Node Disk Usage</td>
</tr>
<tr>
<td>threshold_node_diskio</td>
<td>Node Disk I/O</td>
</tr>
<tr>
<td>threshold_node_cpuio</td>
<td>Node CPU I/O Wait</td>
</tr>
<tr>
<td>threshold_node_rebootrate</td>
<td>Node Reboot Rate</td>
</tr>
<tr>
<td>threshold_netio</td>
<td>Network I/O Error</td>
</tr>
<tr>
<td>threshold_query_queued</td>
<td>Queued Query Number</td>
</tr>
<tr>
<td>threshold_query_failed</td>
<td>Failed Query Number</td>
</tr>
<tr>
<td>threshold_query_spilled</td>
<td>Spilled Query Number</td>
</tr>
<tr>
<td>threshold_query_retried</td>
<td>Retried Query Number</td>
</tr>
<tr>
<td>threshold_query_runtime</td>
<td>Query Running Time</td>
</tr>
</tbody>
</table>
Resource Pool-Specific Sub-Category Filters

To retrieve alerts for a specific resource pool, you can use sub-category filters in combination with the following category filters:

- thresholds
- rp_name

If you use these sub-category filters without the rp_name filter, the query retrieves alerts for all resource pools in your database.

<table>
<thead>
<tr>
<th>Sub-Category Filter</th>
<th>Alerts Related to Threshold Value Set For:</th>
</tr>
</thead>
<tbody>
<tr>
<td>threshold_rp_query_max_time</td>
<td>Queries reaching the maximum allowed execution time.</td>
</tr>
<tr>
<td>threshold_rp_query_resource_reject</td>
<td>The number of queries with resource rejections.</td>
</tr>
<tr>
<td>threshold_rp_query_queue_time</td>
<td>The number of queries that ended because of queue time exceeding a limit.</td>
</tr>
<tr>
<td>threshold_rp_query_run_time</td>
<td>The number of queries that ended because of run time exceeding a limit.</td>
</tr>
<tr>
<td>threshold_rp_memory</td>
<td>The minimum allowed resource pool size.</td>
</tr>
<tr>
<td>threshold_rp_max_memory</td>
<td>The maximum allowed resource pool size.</td>
</tr>
</tbody>
</table>

Authentication

Requires an MC-User-Apikey in the request header.

Example Request

```bash
```
Combine the Thresholds Category Filter with a Sub-Category Filter

This example shows how you can request alerts using cURL with the thresholds category filter and a sub-category filter. You apply the following filters:

- thresholds
- threshold_node_cpu

```
```

Response:

```
[  
  { 
    "alerts": [  
      {  
        "id": 11749,

      }  
    ]  
  }  
]
```
Request an Alert On a Specific Resource Pool

This example shows how you can request alerts using cURL on a specific resource pool. The name of the resource pool is `resourcepool1`. You apply the following filters:

- thresholds
- `rp_name`
- `threshold_rp_query_run_time`

```bash
```

Response:

```json
[
  {
    "alerts": [
      {
        "id": 6525,
        "markedRead": false,

Using Eon Mode

You can operate your Vertica database in Eon Mode instead of in Enterprise Mode. In Enterprise Mode, the original Vertica "share nothing" configuration, each database node stores a portion of the data and performs a portion of the computation. In Eon Mode, computational processes are separated from a communal (shared) storage layer, which enables rapid scaling of computational resources as demand changes.

An Eon Mode database must be deployed on Amazon Web Services. You can use the Management Console to provision an Eon Mode database. (Enterprise Mode also supports deployment on AWS and also supports on-premise hardware and other cloud platforms.)

Vertica does not support upgrading or reviving a database running on any previous beta version to the current version. New databases created in Eon Mode in Vertica version 9.1 and later can be upgraded and revived.
Creating a Database in Eon Mode

Vertica provides three fulfillment methods that use CloudFormation Templates (CFTs) in the AWS Marketplace.

- Deploy Management Console into new VPC
- Deploy Management Console into existing VPC
- Management Console with 3 Vertica nodes

To deploy a Vertica Management Console on an AWS instance, use one of the first two fulfillment methods. The CFT that powers these two fulfillment methods prompts you for options that provision an AWS EC2 instance with the Management Console running on it.

- Using the Management Console interface, create and configure an Eon Mode database. The Management Console provisions the AWS EC2 instances for you.

- Configure and start your new Eon Mode database. For more information on creating databases using the Management Console, see Provision a New Vertica Cluster and Database on AWS Resources.

- To provision the Management Console running on a first AWS EC2 instance and provision a three-node Eon Mode database cluster running on an additional three AWS EC2 instances, use the third fulfillment method: Management Console with 3 Vertica nodes.

Use the Management Console to monitor and manage your Eon Database.

Important: Eon Mode databases can only be created on clusters residing on AWS resources.

For detailed instructions, see

- Overview of Vertica on Amazon Web Services (AWS) for installation procedures for Vertica on AWS resources. You can automatically deploy AWS resources and a Vertica cluster using a CloudFormation template and step-by-step wizards in MC.

- Provision a New Vertica Cluster and Database on AWS Resources for creating Eon Mode database clusters with MC.

- Creating a Database for instructions on how to create a Vertica database using the command line.
Browsing S3 Data Using External Tables

You might want to browse the data in a large data lake that is already stored on S3. Instead of loading data into Vertica, you can read it in place at query time using external tables.

You can create external tables to query Parquet, ORC, text, and delimited data stored in S3 buckets. External tables work the same way in Eon Mode as they do in Enterprise Mode, with one exception: users who are not superusers must have read access to an S3 storage location to run queries. You can create a USER storage location on S3 for this purpose.

The following example illustrates the steps to create a USER storage location, give a user access to it, and create an external table (as that user).

1. Define the AWS credentials associated with the S3 bucket where you will create the storage location:

   ```sql
   => ALTER SESSION SET AWSAuth='ID:secret';
   ```

2. As a superuser, create a USER storage location on the same bucket that holds the data.

   ```sql
   => CREATE LOCATION 's3://datalake' SHARED USAGE 'USER' LABEL 's3user';
   
   The only storage locations you can create on S3 are USER locations. You must create it as a shared location.
   ```

3. As a superuser, give access to the roles or users who will run queries against external tables.

   ```sql
   --- If you have not already created a role:
   => CREATE ROLE ExtUsers;
   --- Assign users to this role using GRANT (Role).
   => GRANT READ ON LOCATION 's3://datalake' TO ExtUsers;
   ```

4. As a user who has that role, create the external table in the usual way.

   ```sql
   => CREATE EXTERNAL TABLE sales (itemID INT, date DATE, price FLOAT) 
      AS COPY FROM 's3://datalake/sales/*.parquet' PARQUET;
   ```

See Creating External Tables for more information about creating and using external tables. If your data is in ORC or Parquet format, you can take advantage of partitioning to limit the data that Vertica reads during query execution. See Using Partition Columns.
Loading Data from an S3 Bucket

You can load data from an S3 bucket using COPY FROM. Before you can load data from S3, you must set certain configuration parameters.

Important: When loading data from S3, the maximum key length is 1K (1024 bytes). The input url argument for the S3 source (which can contain multiple delimited URLs) can be no larger than 1MB.

Setting Parameters

To read from S3 you need to provide Vertica with certain information, such as the S3 region and a credential to use for authentication. There are two different ways of setting these parameters:

- COPY from S3 depends on the configuration parameters described in AWS Parameters. You can set parameters globally using SET_CONFIG_PARAMETER or for the current session using ALTER SESSION SET.

- The deprecated UDSource depends on the session parameters described in AWS Library User-Defined Session Parameters, which you can set only at the session level using ALTER SESSION SET UDPARAMETER.

If you use ALTER SESSION SET to set AWS parameters, Vertica also sets the corresponding UDSource parameters as if you had also used ALTER SESSION SET UDPARAMETER. Therefore, a best practice when making session-level changes is to use ALTER SESSION SET with the AWS parameters instead of using ALTER SESSION SET UDPARAMETER with the AWS Library parameters, even if you are using the UDSource.

The following example shows how to set parameters using these methods.

```sql
--- set global default region
=> SELECT SET_CONFIG_PARAMETER('AWSRegion','us-west-1');

--- set credentials in the session only (also applies to UDSource)
=> ALTER SESSION SET AWSAuth='ID:secret';

--- alternate way to set credentials, for UDSource only (not copy from S3)
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='aws-id';
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='aws-key';
```

Vertica can read from buckets in only one AWS region at a time. To load from more than one region, change the region value for the session between loads.
Using COPY

Before you can read data from S3, you must create an IAM role for your EC2 instances to use, and grant that role permission to access your S3 resources. For more information about IAM roles, see Amazon's Web Services documentation.

You must set the AWSRegion configuration parameter to your S3 bucket's region. If you do not set the correct region, you might experience a delay before the load fails because Vertica retries several times before giving up.

The following example shows how to load data from buckets in different regions.

```sql
=> SELECT SET_CONFIG_PARAMETER('AWSRegion','us-west-1');
=> COPY sales FROM 's3://AWS_Data_1/sales.parquet' PARQUET;
=> ALTER SESSION SET AWSRegion='us-east-1');
=> COPY sales FROM 's3://AWS_Data_2/sales.orc', 's3://AWS_Data_3/sales.orc' ORC;
```

For more information, see Specifying COPY FROM Options.

Verifying the Load

You can verify that ROS files were created in the communal storage location using the AWS CLI:

```
$ aws s3 ls S3://testdb/  
   PRE 024/  
   PRE 028/  
   PRE 030/  
   PRE 034/  
   PRE 036/  
```

You can also use the AWS web interface by navigating to the bucket and viewing its contents.
Managing an Eon Mode Database in MC

Vertica Management Console with Provisioning is a deployment of Management Console (MC), a database health and activity monitoring tool. MC provides in-browser wizards you can follow to deploy Vertica cluster instances and create an Eon Mode database on them.

You can use MC to manage and monitor your database and its resources. See Using Management Console for the full guide on how to use MC to monitor your database.

When you create an Eon Mode database using Vertica Management Console with Provisioning, MC detects that your database is running in Eon Mode. When it does so, MC provides you with some tasks and monitoring tools that are specific to Eon Mode.

Access MC

The URL for MC includes the IP address of the host on which MC is installed, followed by the MC port:

https://xx.xxx.xxx.xxx:5450/webui/

If you created your database using the using Vertica Management Console with Provisioning, MC is already fully deployed. To locate the link through the AWS Console, go to the CloudFormation Stacks page. The URL is listed under your stack's Outputs tab, labeled Management Console.

Log into MC using the MC credentials you created during installation. After login, MC displays the MC Home page.

To get started in MC with a few important database tasks, see Fast Tasks.

Manage Your Cluster

Use the MC to manage clusters that are on an AWS environment, without having to go through the AWS console or a command line.

To see all monitored clusters on the Infrastructure page, on the MC Home page click View Your Infrastructure. To view the Cluster page, click the cluster you want to manage and click Manage in the dialog that appears.
On Cluster page, you can:

- Stop, start, reboot, add, or terminate individual instances in your cluster.
- Stop, start, or reboot the entire cluster.
- Terminate the database. This terminates all cluster instances, and all AWS resources associated with the cluster.

For more detail on these cluster management tasks, see Viewing and Managing Your Cluster.

**Monitor Storage Usage and Subscription Status**

To view storage usage and subscription charts for any Eon Mode database you monitor, click View Your Infrastructure on the MC Home page. Then click the Storage View tab.

Use the Storage View tab in MC to monitor the size and storage capacity of your databases. You can use this page to determine if you should downsize databases that are taking up more of your storage capacity and costs, or if you need to increase storage resources for a database that has been growing.

The Storage View tab also gives insight into Eon Mode database node-shard subscriptions. Subscriptions verify that your database is K-safe, and control your nodes' readiness to serve queries.

To see bar chart visualizations for subscriptions, click the Details link for any Eon Mode database listed on the Storage View tab.

To learn more about monitoring storage in MC, see Monitoring Database Storage. To understand how to read the subscription charts in MC, go to Monitoring Subscription Status in Eon Mode.

**Monitor Depot Activity**

The depot (see Eon Mode Architecture) improves query performance by preventing your queries from having to go to communal storage every time you run a query. Instead, the queries access the depot, which contains local copies of your data.
Use the Depot Activity page to monitor query activity, churn, and settings for your database's depot. To view this page, click the Activity tab at the bottom of your database's Overview page, then select Depot Activity Monitoring from the chart list. See Monitoring Depot Activity in MC for more on monitoring using this page.

- Fast Tasks
Shutting Down and Reviving An Eon Mode Database

An Eon Mode database keeps an up-to-date version of its data and metadata in its communal storage location. After you shut down the database, it continues to reside in communal storage. You can keep this storage in S3 and terminate compute nodes. When you are ready to use it again, you can revive the database and provision new compute nodes. Vertica uses the existing data to restore the database in the same state it was in before you shut it down. You do not need to wait for data to be copied; queries initially fetch data from communal storage as the compute nodes begin to fill their depots.

With the Vertica Management Console on AWS, you can use a wizard to provision a new cluster and revive a database onto it from a browser. See Reviving an Eon Mode Database in MC for the Management Console revive process.

Databases can be revived using admintools (described below) or through Management Console.

Important: If you need to revive your database on a previously existing cluster, you must revive it using admintools, not MC. For example, use admintools if you stopped a cluster whose hosts use instance storage where data is not persistently stored, and plan to bring back the database on the same cluster.

Vertica persists catalog data in S3, updating it every few minutes. Nonetheless, before shutting down your database you should make sure your metadata is up to date on communal storage. To do so, see Synchronizing Metadata.

Revive the Database Using Admintools

Use the following process to revive your Eon Mode database on an existing cluster using admintools.

Caution: Using the same communal storage location for multiple running databases causes data corruption. To avoid corruption, never use the revive functionality to simultaneously run the same Eon Mode database on different clusters.

Prerequisites:
- Communal storage location (an AWS S3 bucket) of the stopped Eon Mode database you plan to revive

- Username and password of the Eon Mode database you plan to revive

- AWS cluster with no other running databases, whose hosts are in the same region as your communal storage location's S3 bucket (To use a cluster in a new region, you must first clone the previous communal storage location to an S3 bucket in the new region)

- Amazon key pair for SSH access to an instance in the AWS cluster

- IP addresses of all hosts on the cluster

To revive the database:

1. SSH to a cluster host as an administrator.

2. To revive the database, run the following:

```
$ admintools -t revive_db --communal-storage-location=s3://<directory> -s $HOSTLIST --force -d $DATABASENAME
```

Initial queries after revive will read from communal storage, which may take longer. As the database begins to fetch data to depot storage, queries will run faster.

**Synchronizing Metadata**

If you revive a database, it will use the synced catalog maintained in communal storage. The catalog contains your database's metadata.

When an Eon Mode database is running, Vertica automatically syncs the catalog every five minutes. Therefore it is not typically necessary to intervene in the synchronization process. However, before shutting down it is a good idea to make sure that the persistent copy of the catalog contains all recent changes. You can use the following processes to make sure the database's catalog will be up to date when you revive.

You can check when the catalog was last synchronized, manually sync the catalog, or customize the catalog sync interval.
Check When the Catalog Was Last Synchronized

While the database is still running:
The following system tables are only available when the database is up.
Use the system table CATALOG_SYNC_STATE to see how recently each node synced its catalog to communal storage. Checking this requires the database to still be running.

```sql
=> SELECT * FROM catalog_sync_state;
```

The system table CATALOG_TRUNCATION_STATUS also indicates how up to date the catalog is on communal storage. It is completely up to date when the current catalog version is the same as the catalog truncation version. Checking this requires the database to still be running.

```sql
=> SELECT * FROM catalog_truncation_status;
```

When the database is not currently running:
If your database is not currently running, a JSON file containing additional cluster information is located in communal storage. This file indicates the catalog truncation version and timestamp of the last sync to communal storage:

/metadata.databasename/cluster_config.json

Manually Sync the Catalog

The sync_catalog function immediately synchronizes the catalog on all nodes or a specific node.

```sql
=> SELECT sync_catalog();
```

Customize Catalog Sync Interval

Use the CatalogSyncInterval parameter to set a time interval for which the metadata is pushed to communal storage:

```sql
=> ALTER DATABASE mydb SET CatalogSyncInterval = 10 minutes
```
Welcome to the Vertica on the Cloud guide. This section explains how you can create Vertica clusters on different cloud platforms.

This document assumes that you are familiar with the cloud environment on which you will create your Vertica cluster.
Vertica on Amazon Web Services

Welcome to the Vertica on Amazon Web Services (AWS) guide. This section explains how to create and manage Vertica clusters on AWS.

When you launch a cluster on AWS resources and are ready to create your database, consider whether to run it in Eon Mode or Enterprise Mode. The differences in these two modes lay in their architecture, deployment, and scalability:

- The Enterprise Mode database architecture distributes data across local nodes, and works on-premise or in the cloud. Create an Enterprise Mode database on a cluster of predetermined size, which is good for running large queries quickly. Because it persistently stores its data locally, you do not need access to shared storage on Amazon S3 to use an Enterprise Mode database.

- The Eon Mode database architecture leverages the flexibility of EC2 instances and the persistence of Amazon S3. Eon Mode databases are ideal when you want to frequently scale up your cluster in order to run many short, concurrent queries. Because an Eon Mode database stores its data in a persistent location outside of its local nodes, you can rapidly adjust the size of your cluster without interrupting ongoing workloads.

Eon Mode separates the computational processes from the communal storage layer of your database. This separation gives you the ability to store your data in a single location (on AWS) and elastically vary the number of compute nodes connected to that location according to your computational needs.

Vertica provides CloudFormation Templates (CFTs) through the AWS Marketplace. These CFTs also deploy Management Console.

Note: For detailed information about which CFT to use, see Creating a Database in Eon Mode.

After you provide parameters to the template, you create a stack to provision the AWS resources for your Vertica system. Now use Management Console (MC) to create and manage clusters and databases.

You can install an Eon Mode database using in-browser wizards provided by Management Console, available through the AWS Marketplace or using admintools. You can only create Eon Mode databases on clusters that reside on AWS resources.

See Using Eon Mode for more about Eon Mode database concepts.
In This Section

Overview of Vertica on Amazon Web Services (AWS)

Vertica clusters on AWS can operate on EC2 instances automatically provisioned using a CloudFormation Template, or manually deployed from Amazon Machine Images (AMIs). You can create a database in either Eon Mode or Enterprise Mode in a Vertica cluster in AWS.

CloudFormation Templates

Vertica provides Cloud Formation Templates (CFTs) through the AWS Marketplace. After you provide a few parameters to the template, create a stack to automatically provision the AWS resources for your Vertica system.

After creating the stack, use the Management Console (MC) to create and manage clusters and databases. See Provision a New Vertica Cluster and Database on AWS Resources.

Available Products

Using the license models and CFTs described in CloudFormation Template (CFT) Overview, you can install the following products:

- Vertica BYOL, Amazon Linux 2.0
- Vertica by the Hour, Amazon Linux 2.0
- Vertica BYOL, Red Hat
- Vertica by the Hour, Red Hat

See Launching MC and AWS Resources with a CloudFormation Template for information on installing these products.
Vertica AMI Operating Systems for AWS

Vertica provides Vertica and Management Console AMIs in the following operating systems.

- Red Hat 7.4
- Amazon Linux 2.0

You can use the AMI to deploy MC hosts or cluster hosts.

**Important:** When using Amazon Linux 2.0, you must compile C++ UDX libraries with a gcc version 4.8. For more information see Setting Up a Development Environment.

Supported Instance Types

Vertica supports a range of Amazon Web Services (AWS) instance types, each optimized for different purposes. Choose the instance type that best matches your performance and price needs as a user. Pricing information can be found on the AWS Marketplace:

<table>
<thead>
<tr>
<th>Optimization</th>
<th>Type</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>
Vertica AMI Sleep C-States

By default, the following instances have their processor C-states set to a value of 1 in the Vertica AMI:

- c4.8xlarge
- d2.8xlarge
- m4.10xlarge

This measure is meant to improve performance by limiting the sleep states an instance running Vertica will use.

For more information about sleep states, visit the AWS Documentation.

AWS Features Supported by Vertica

Vertica supports the following AWS features:

- Enhanced Networking: Vertica recommends that you use the AWS enhanced networking for optimal performance. For more information, see Enabling Enhanced Networking on Linux Instances in a VPC in the AWS documentation.

- Command Line Interface: Use the Amazon command-line interface (CLI) with your Vertica AMIs. For more information see the AWS Documentation.
Elastic Load Balancing: Use elastic load balancing (ELB) for queries up to one hour. When enabling ELB, configure the timer to 3600 seconds. For more information see the Amazon documentation.

Installing Vertica with CloudFormation Templates

Vertica provides CloudFormation Templates (CFTs) on the AWS Marketplace that allow you to get a cluster up and running quickly. Using the template allows you to automatically provision your AWS resources and launch a Vertica cluster and Management Console, with minimal configuration required.

If you prefer to deploy a VPC, instances, and related resources manually, see Install Vertica with Manually Deployed AWS Resources.

CloudFormation Template (CFT) Overview

With Vertica on AWS, use CloudFormation Templates (CFTs) to easily manage provisioning the AWS resources with a running Vertica system.

To access Vertica CFTs, go to the AWS Marketplace. Licensing models for CFTs are:

- Bring Your Own License (BYOL) - By default free CE license is installed with 3 nodes and 1 TB. To extend nodes or size, you can purchase the vertica BYOL license.

  Outside of the BYOL license on CFTs, you can also access the Community Edition without a license file. Simply leave the license field blank if you are using Management Console, or specify CE in the --license parameter during installation if you are using a command line (see Installing Vertica with the Installation Script).

- By the Hour - a pay-as-you-go model where you pay for only the number of hours you use for each node. One advantage of using the Paid Listing is that all charges appear on your Amazon AWS bill. This offers an alternative to purchasing a full Vertica license. This eliminates the need to compute potential storage needs in advance.

Available Vertica CFTs are:
- **Management Console with 3 Vertica nodes**: The easiest way to deploy Vertica. Note that this CFT deploys an Eon Mode database by default. However, this environment can also be used to create an Enterprise Mode database. For more information see [Creating a Database](#).

- **Deploy Management Console into new VPC**: This CFT deploys all required AWS resources and installs the Vertica Management Console (MC). After stack creation completes, log into the MC to provision a Vertica database cluster.

- **Deploy Management Console into existing VPC**: This CFT deploys the Vertica Management Console (MC) in an already-existing VPC and Subnet. After stack creation completes, the MC is available. Log in to MC to provision either a Vertica Enterprise database cluster or an Eon Mode database cluster.

  For this CFT, you must first set up the VPC, subnet and related network resources. For more information about the correct configuration of these resources for Vertica, see the [AWS documentation](#) and the following topics:
  - [Creating a Virtual Private Cloud](#)
  - [Configuring the Network](#)

For supported operating systems for these CFTs see [Vertica AMI Operating Systems for AWS](#).

### Available Products

Using the license models and CFTs described above, you can install the following products:

- **Vertica BYOL, Amazon Linux 2.0**
- **Vertica by the Hour, Amazon Linux 2.0**
- **Vertica BYOL, Red Hat**
- **Vertica by the Hour, Red Hat**

See [Launching MC and AWS Resources with a CloudFormation Template](#) for information on installing these products.
Launching MC and AWS Resources with a CloudFormation Template

Launch Vertica Management Console (MC) and its associated AWS resources using CloudFormation templates (CFTs) that are available through the AWS Marketplace. For an overview of available CFTs, see CloudFormation Template (CFT) Overview.

Use MC to deploy Vertica cluster instances and create an Eon Mode or Enterprise Mode database. You can also use MC to manage and monitor your databases.

Prerequisites

- AWS account with permissions to create a VPC, subnet, security group, EC2 instances, and IAM roles (For more information about AWS accounts, see the AWS documentation)

- Amazon key pair for SSH access to an EC2 instance (See the AWS documentation for key pairs)

Launch

Starting in the AWS Marketplace, you launch the provisioning instance from which you can install Vertica.

1. Log in to the AWS Marketplace with an AWS account (see the Prerequisites section above).

2. Search for "Vertica" in the AWS Marketplace and select a Vertica CFT. Each CFT leads you to a product overview page, with pricing estimates. (Also see CloudFormation Template (CFT) Overview for an overview of available templates and products).

3. Click Continue to Subscribe.

4. On the next page, select your launch settings based on your requirements for deployment.

5. If you have not agreed to Vertica EULA terms on the AWS Marketplace before, click Accept Software Terms to subscribe.

6. Click Launch with CloudFormation Console. The CloudFormation Console opens.
7. The CloudFormation Console automatically supplies the URL in the Specify an Amazon S3 template URL field. Click Next.

8. Follow the CloudFormation workflow and enter the parameters (collectively called a stack).

   **Important:** Take note of the username and password you set for Management Console during this step. You cannot recover or reset these credentials after you create the stack.

9. After confirming the details you have provided for your new stack, click Create. The AWS console brings you to the Stacks page, where you can view the progress of the creation process. The process takes several minutes.

10. The Outputs tab displays information about accessing your environment after the process completes.

**Access Management Console**

You will use Management Console to provision a Vertica cluster and database on the AWS resources you just launched.

1. On the CloudFormation Stacks page, select your new stack and view the Outputs tab. This tab provides information about accessing your environment, as well as documentation and licensing resources.

2. Click the Access Management Console URL. This link takes you to the MC login page.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ManagementConsole</td>
<td><a href="https://example.com:5450/webui">https://example.com:5450/webui</a> (login: username, password: ********)</td>
<td>Access Vertica Management Console for provision...</td>
</tr>
<tr>
<td>EULA</td>
<td><a href="http://www.example.com/terms_of_service.html">http://www.example.com/terms_of_service.html</a></td>
<td>End User License Agreement</td>
</tr>
<tr>
<td>Documentation</td>
<td><a href="https://example.com/vertica_docs">https://example.com/vertica_docs</a></td>
<td>Vertica Documentation</td>
</tr>
<tr>
<td>MCSSSH</td>
<td>( ssh -i example_keyfile.pem@cluster )</td>
<td>SSH to Management Console instance.</td>
</tr>
</tbody>
</table>

3. To log in, enter the MC username and password that you created using the CloudFormation Console.

   After login, MC displays the home page, with options to provision a new cluster or database or import existing ones. If you chose a CFT that also creates a database, your new database is also displayed on the home page.
This page also provides a Resources section with links to online training, blogs, community, and help resources.

Next Steps

You have successfully launched Management Console on AWS resources.

If you have not yet provisioned a Vertica cluster and database, follow the steps in Provision a New Vertica Cluster and Database on AWS Resources in the Using Management Console guide.

For information about managing your cluster using MC, see Managing Database Clusters.

See the Administrator's Guide for information about general use and maintenance of a Vertica database.

Install Vertica with Manually Deployed AWS Resources

Vertica provides an AMI that you can install on AWS resources that you manually deploy. This section will guide you through configuring your network settings on AWS, launching and preparing EC2 instances using the Vertica AMI, and creating a Vertica cluster on those EC2 instances.

Choose this method of installation if you are familiar with configuring AWS and have many specific AWS configuration needs. (To automatically deploy AWS resources and a Vertica cluster instead, see Installing Vertica with CloudFormation Templates.

Configure Your Network

Before you create your cluster, you must configure the network on which Vertica will run. Vertica requires a number of specific network configurations to operate on AWS. You may also have specific network configuration needs beyond the default Vertica settings.

The following sections explain which Amazon EC2 features you need to configure for instance creation.
Creating a Placement Group, Key Pair, and Virtual Private Cloud

Part of configuring your network for AWS is to create the following:

- **Placement Group**
- **Key Pair**
- **Virtual Private Cloud (VPC)**

Create a Placement Group

A placement group is a logical grouping of instances in a single Availability Zone. Placement Groups are required for clusters and all Vertica nodes must be in the same Placement Group.

Vertica recommends placement groups for applications that benefit from low network latency, high network throughput, or both. To provide the lowest latency, and the highest packet-per-second network performance for your Placement Group, choose an instance type that supports enhanced networking.

For information on creating placement groups see the AWS documentation.

Create a Key Pair

You need a key pair to access your instances using SSH. Create the key pair using the AWS interface and store a copy of your key (*.pem) file on your local machine. When you access an instance, you need to know the local path of your key.

Use a key pair to:

- Authenticate your connection as dbadmin to your instances from outside your cluster.
- Install and configure Vertica on your AWS instances.

See the AWS documentation for information on creating a key pair.

Create a Virtual Private Cloud (VPC)

You create a Virtual Private Cloud (VPC) on Amazon so that you can create a network of your EC2 instances. Your instances in the VPC all share the same network and security settings.

A Vertica cluster on AWS must be logically located in the same network. Create a VPC to ensure the nodes in your cluster can communicate with each other in AWS.
Create a single public subnet VPC with the following configurations:

- Assign a Network Access Control List (ACL) that is appropriate to your situation. The default ACL does not provide a high level of security.

- Enable DNS resolution and enable DNS hostname support for instances launched in this VPC.

- Add the required network inbound and outbound rules to the Network ACL associated to the VPC.

**Note:** A Vertica cluster must be operated in a single availability zone.

See the AWS documentation for information on creating a VPC.

### Network ACL Settings

Vertica requires the following basic network access control list (ACL) settings on an AWS instance running the Vertica AMI. Vertica recommends that you secure your network with additional ACL settings that are appropriate to your situation; the default ACL does not provide a high level of security.

#### Inbound Rules

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port Range</th>
<th>Use</th>
<th>Source</th>
<th>Allow/Deny</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSH</td>
<td>TCP (6)</td>
<td>22</td>
<td>SSH (Optional -- for access to your cluster from outside your VPC)</td>
<td>User Specific</td>
<td>Allow</td>
</tr>
<tr>
<td>Custom TCP Rule</td>
<td>TCP (6)</td>
<td>5450</td>
<td>MC (Optional -- for MC running outside of your VPC)</td>
<td>User Specific</td>

<tr>
<td>Custom TCP Rule</td>
<td>TCP (6)</td>
<td>0 - 65535</td>
<td>Ephemeral Ports</td>
<td>0.0.0.0/0</td>
<td>Allow</td>
</tr>
</tbody>
</table>

You can use the entire port range specified in the table above, or find your specific ephemeral ports by entering the following command:

```
cat /proc/sys/net/ipv4/ip_local_port_range
```

### More Information

For detailed information on network ACLs within AWS, refer to [Amazon's documentation](https://aws.amazon.com/documentation/).  
For detailed information on ephemeral ports within AWS, refer to [Amazon's documentation](https://aws.amazon.com/documentation/).

### Creating and Assigning an Internet Gateway

When you create a VPC, an internet gateway is automatically assigned to it. You can use that gateway, or you can assign your own. If you are using the default internet gateway, continue with the next procedure, [Creating a Security Group](#).

Otherwise, create an internet gateway specific to your needs. Associate your internet gateway with your VPC and subnet.

### More Information

For information about what an internet gateway is, as well as how to create one, visit the [AWS documentation](https://aws.amazon.com/documentation/).
Assigning an Elastic IP Address

An elastic IP is an unchanging IP address that you can use to connect to your cluster externally. Vertica recommends you assign a single elastic IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using their internal IP addresses dictated by your VPC settings.

Create an elastic IP address.

More Information

For information about what an elastic IP is, as well as how to create one, visit the AWS documentation.

Creating a Security Group

The Vertica AMI has specific security group requirements. When you create a Virtual Private Cloud (VPC), AWS automatically creates a default security group and assigns it to the VPC. You can use the default security group, or you can name and assign your own.

Create and name your own security group with the following basic security group settings. You may make additional modifications based on your specific needs.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

All ports must have a rule to open in the subnetCDIR level to allow nodes to be interconnected. For example, 10.11.12.0/24.

**Note:** In Management Console (MC), the Java IANA discovery process uses port 7 once to detect if an IP address is reachable before the database import operation. Vertica tries port 7 first. If port 7 is blocked, Vertica switches to port 22.
| All UDP | UDP | 0-65535 | Anywhere | 0.0.0.0/0 |

More Information

For information about what a security group is, as well as how to create one, visit the AWS documentation.

Deploying AWS Instances for a Vertica Database Cluster

Once you have configured your network, you are ready to create your AWS instances and install vertica. Follow these procedures to install and run Vertica on AWS.

Configuring and Launching an Instance

Once you have configured your network settings on AWS, you are ready to configure and launch the instances that you will install Vertica onto. An Elastic Compute Cloud (EC2) instance without a Vertica AMI is similar to a traditional host. Just like with an on-premises cluster, you must prepare and configure your cluster and network at the hardware level before you can install Vertica.

When you create an EC2 instance on AWS using a Vertica AMI, the instance includes the Vertica software and the recommended configuration. The Vertica AMI acts as a template, requiring fewer configuration steps. Vertica recommends that you use the Vertica AMI as is—without modification.

Choose a Fulfillment Method

Vertica provides three fulfillment methods that use CloudFormation Templates (CFTs) in the AWS Marketplace.

- **Deploy Management Console into new VPC**
- **Deploy Management Console into existing VPC**
- **Management Console with 3 Vertica nodes**

To deploy a Vertica Management Console on an AWS instance, use one of the first two fulfillment methods. The CFT that powers these two fulfillment methods prompts you for options that provision an AWS EC2 instance with the Management Console running on it.
- Using the Management Console interface, create and configure an Eon Mode database. The Management Console provisions the AWS EC2 instances for you.

- Configure and start your new Eon Mode database. For more information on creating databases using the Management Console, see Provision a New Vertica Cluster and Database on AWS Resources.

- To provision the Management Console running on a first AWS EC2 instance and provision a three-node Eon Mode database cluster running on an additional three AWS EC2 instances, use the third fulfillment method: Management Console with 3 Vertica nodes.

Configure EC2 Instances in AWS

1. Select the Vertica AMI from the AWS marketplace.

2. Select the desired fulfillment method.

3. Configure the following:
   - A supported instance type
   - The number of instances you want to launch. A Vertica cluster uses identically configured instances of the same type. You cannot mix instance types.
   - A VPC

   Note: Not all data centers support VPC. If you receive an error message that states "VPC is not currently supported...", choose a different region and zone (for example, choose us-east-1e rather than us-east-1c).

   - Placement Group

Add Storage to Your Instances

- Add a number of drives equal to the number of physical cores in your instance. For example, for a c3.8xlarge instance, add eight drives. For an r3.4xlarge, add four drives.

- Do not store your information on the root volume.

- For optimal performance with EBS volumes, Amazon recommends that you configure them in a RAID 0 array on each node in your cluster.

- Create your storage when you create your instances. This allows AWS to optimize storage performance.
Configure Security Group

1. Choose between your previously configured security group or the default security group.

2. Choose the key value pairs you intend to use with Vertica.

Launch Instances

Verify that your instances are running.

Connecting to an Instance

Using your private key, connect to your cluster through the instance you attached an elastic IP to.

1. As the dbadmin user, type the following command, substituting your ssh key:

   ```bash
   # ssh --ssh-identity <ssh key> dbadmin@elasticipaddress
   ```

2. Select Instances from the Navigation panel.

3. Select the instance that is attached to the Elastic IP.

4. Click Connect.

5. On Connect to Your Instance, choose one of the following options:

   - A Java SSH Client directly from my browser—Add the path to your private key in the field Private key path, and click Launch SSH Client.
   - Connect with a standalone SSH client—Follow the steps required by your standalone SSH client.

Connecting to an Instance from Windows Using Putty

If you connect to the instance from the Windows operating system, and plan to use Putty:

1. Convert your key file using PuTTYgen.

2. Connect with Putty or WinSCP (connect via the elastic IP), using your converted key (i.e.,
3. Move your key file (the *pem file) to the root dir using Putty or WinSCP.

Preparing Instances

After you create your instances, you need to prepare them for cluster formation. Prepare your instances by adding your AWS .pem key and your Vertica license.

By default, each AMI includes a Community Edition license. Once Vertica is installed, you can find the license at this location:

```
/opt/vertica/config/licensing/vertica_community_edition.license.key
```

1. As the dbadmin user, copy your *pem file (from where you saved it locally) onto your primary instance.

   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the `install_vertica` script fails with a message similar to the following:

   **FATAL (19):** Failed Login Validation 10.0.3.158, cannot resolve or connect to host as root.

   If you receive a failure message, enter the following command to correct permissions on your *pem file:

   ```
   chmod 600 /<name-of-pem>.pem
   ```

2. Copy your Vertica license over to your primary instance, placing it in your home directory or other known location.

Change Instances on AWS

You can change instance types on AWS. For example, you can downgrade a c3.8xlarge instance to c3.4xlarge. See Supported Instance Types for a list of valid AWS instances.

When you change AWS instances you may need to:

- Reconfigure memory settings
- Reset memory size in a resource pool
- Reset number of CPUs in a resource pool
Reconfigure memory settings

If you change to an AWS instance type that requires a different amount of memory, you may need to recompute the following and then reset the values:

- **All Systems**
- **max_map_count**

**Note:** You may need root user permissions to reset these values.

Reset memory size in a resource pool

If you used absolute memory in a resource pool, you may need to reconfigure the memory using the `MEMORYSIZE` parameter in `ALTER RESOURCE POOL`.

**Note:** If you set memory size as a percentage when you created the original resource pool, you do not need to change it here.

Reset number of CPUs in a resource pool

If your new instance requires a different number of CPUs, you may need to reset the CPUAFFINITYSET parameter in `ALTER RESOURCE POOL`.

Configuring Storage

Vertica recommends that you do not store your information on the root volume, especially your data and catalog directories. Instead, use dedicated EBS volumes for node storage. When configuring your storage, make sure to use a supported file system.

**Note:** When customizing an Eon mode cluster on AWS, note that Eon has been performance tested with a per-node EBS volume of up to 2TB. See Using Eon Mode.

For best performance, you can combine multiple EBS volumes into RAID-0. Vertica provides a shell script, which automates the storage configuration process.
Determining Volume Names

Before you combine volumes for storage, make note of your volume names so that you can alter the configure_aws_software_raid.sh shell script. You can find your volumes with the following commands:

cd /dev
ls

Your volumes start with xvd.

Important: Ignore your root volume. Do not include any of your root volumes in the RAID creation process.

Combining Volumes for Storage

Follow these sample steps to combine your EBS volumes into RAID 0 using the configure_aws_software_raid.sh shell script.

1. Edit the /opt/vertica/sbin/configure_aws_software_raid.sh shell file as follows:
   a. Comment out the safety exit command at the beginning.
   b. Change the sample volume names to your own volume names, which you noted previously. Add more volumes, if necessary.

2. Run the /opt/vertica/sbin/configure_aws_software_raid.sh shell file. Running this file creates a RAID 0 volume and mounts it to /vertica/data.

3. Change the owner of the newly created volume to dbadmin with chown.

4. Repeat steps 1-3 for each node on your cluster.

More Information

For more information about EBS storage, refer to the Amazon documentation.

Creating a Cluster

On AWS you use the install_vertica to combine instances and create a cluster. Check your My Instances page on AWS for a list of current instances and their associated IP addresses. You need these IP addresses when you run install_vertica.
Create a cluster as follows:

1. While connected to your primary instance, enter the following command to combine your instances into a cluster. Substitute the IP addresses for your instances and include your root *pem file name.

   ```
   $ sudo /opt/vertica/sbin/install_vertica --hosts 10.0.11.164,10.0.11.165,10.0.11.166
   --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity
   ~/<name-of-pem>.pem --license <license.file>
   ```

   **Note:** If you are using Community Edition, which limits you to three instances, you can specify `-L CE` with no license file.

   When you issue `install_vertica` or `update_vertica` on a Vertica AMI script, `--point-to-point` is the default. This parameter configures Spread to use direct point-to-point communication between all Vertica nodes, which is a requirement for clusters on AWS.

2. After combining your instances, Vertica recommends deleting your *pem key from your cluster to reduce security risks. The example below uses the shred command to delete the file:

   ```
   $ shred examplekey.pem
   ```

3. After creating one or more clusters, **Create a database**.

For complete information on the `install_vertica` script and its parameters, see [Installing Vertica with the Installation Script](#).

**Important:** Stopping or rebooting an instance or cluster without first shutting down the database down, may result in disk or database corruption. To safely shut down and restart your cluster, see [Operating the Database](#).

Checking Open Ports Manually Using the Netcat Utility

Once your cluster is up and running, you can check ports manually through the command line using the netcat (nc) utility. What follows is an example using the utility to check ports.

Before performing the procedure, choose the private IP addresses of two nodes in your cluster.

The examples given below use nodes with the private IPs:

```
10.0.11.60 10.0.11.61
```
Install the nc utility on your nodes. Once installed, you can issue commands to check the ports on one node from another node.

1. To check a TCP port:

   a. Put one node in listen mode and specify the port. In the following sample, we’re putting IP 10.0.11.60 into listen mode for port 4804.

      ```
      [root@ip-10-0-11-60 ~]# nc -l 4804
      ```

   b. From the other node, run nc specifying the IP address of the node you just put in listen mode, and the same port number.

      ```
      [root@ip-10-0-11-61 ~]# nc 10.0.11.60 4804
      ```

   c. Enter sample text from either node and it should show up on the other. To cancel once you have checked a port, enter Ctrl+C.

      ```
      Note: To check a UDP port, use the same nc commands with the –u option.
      ```

      ```
      [root@ip-10-0-11-60 ~]# nc -u -l 4804
      [root@ip-10-0-11-61 ~]# nc -u 10.0.11.60 4804
      ```

Exporting Data From Amazon S3 Using the AWS Library

The Vertica library for Amazon Web Services (AWS) is a set of functions and configurable session parameters. These parameters allow you to directly exchange data between Vertica and Amazon S3 storage without any third-party scripts or programs.

To use the AWS library, you must have access to an Amazon S3 storage account.

To load data from S3 in text, delimited, or Parquet format, you can use COPY FROM instead of using this library. See Specifying COPY FROM Options for more information.
In This Section

- Configure the AWS Library
- Exporting Data to Amazon S3 From Vertica

Configuring the Vertica Library for Amazon Web Services

Configure the Vertica library for Amazon Web Services (AWS) by setting session parameters with your AWS access key credentials and region. You can set your session parameters directly, or you can store your credentials in a table and set them with the AWS_SET_CONFIG function.

Because the AWS library is configured with session parameters, you must reconfigure the library with each new session.

**Important:** Your AWS access key ID and secret access key are different from your account access credentials. For more information about AWS access keys, visit the AWS documentation.

Setting AWS Authentication Parameters

This section describes the authentication parameters you need to set to access AWS and work with the data in your Vertica database.

**Note:** This only covers the AWS parameters for authentication. See AWS Library User-Defined Session Parameters for information on other AWS parameters.

Authentication parameters for AWS are:

- **aws_id:** The 20-character AWS access key used to authenticate your account.

- **aws_secret:** The 40-character AWS secret access key used to authenticate your account.

- **aws_session_token:** The AWS temporary security token generated by running the AWS STS command `get-session-token`. This AWS STS command generates temporary credentials you can use to implement multi-factor authentication for security purposes. See Implementing Multi-factor Authentication.
Vertica Documentation
Using Vertica on the Cloud

Implementing Multi-factor Authentication
Implement multi-factor authentication as follows:
1. Run the AWS STS command get-session-token, this returns the following:
$ Credentials": {
"SecretAccessKey": "bQid6jNuSWRqUzkIJCFG7c71gDHZY3h7aDSW2DU6",
"SessionToken":
"FQoDYXdzEBcaDKM1mWpeu88nDTTFICKsAbaiIDTWe4BTh33tnUvo9F/8mZicKKLLy7WIcpT4FLfr6ltIm242/U2CI9G/
XdC6eoysUi3UGH7cxdhjxAW4fjgCKKYuNL764N2xn0issmIuJOku3GTDyc4U4iNlWyEng3SlshdiqVlk1It2Mk0isEQXKtx
F9VgfncDQBxjZUCkYIzseZw5pULa9YQcJOzl+Q2JrdUCWu0iFspSUJPhOguH+wTqiM2XdHL5hcUcomqm41gU=",
"Expiration": "2018-04-12T01:58:50Z",
"AccessKeyId": "ASIAJ4ZYGTOSVSLUIN7Q"
}
}

For more information on get-session-token see the AWS documentation.
1. Using the SecretAccessKey returned from get-sessiontoken, set your temporary aws_
secret:
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_
secret='bQid6jNuSWRqUzkIJCFG7c71gDHZY3h7aDSW2DU6';

2. Using the SessionToken returned from get-session-token, set your temporary aws_
session_token:
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_session_
token='FQoDYXdzEBcaDKM1mWpeu88nDTTFICKsAbaiIDTWe4B
Th33tnUvo9F/8mZicKKLLy7WIcpT4FLfr6ltIm242/U2CI9G/XdC6eoysUi3UGH7cxdhjxAW4fjgCKKYuNL764N2xn0issmI
uJOku3GTDy
c4U4iNlWyEng3SlshdiqVlk1It2Mk0isEQXKtxF9VgfncDQBxjZUCkYIzseZw5pULa9YQcJOzl+Q2JrdUCWu0iFspSUJPhOg
uH+wTq
iM2XdHL5hcUcomqm41gU=';

3. Using the AccessKeyID returned from get-session-token, set your temporary aws_id:
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='ASIAJ4ZYGTOSVSLUIN7Q';

Note the Expiration value returned indicates when the temporary credentials expire. In this
example expiration occurs April 12, 2018 at 01:58:50.
These examples show how to implement multifactor authentication using session parameters.
You can use either of the following methods to securely set and store your AWS account
credentials:

Vertica Analytic Database (9.1.x)

Page 4987 of 6174


- Configuring Session Parameters Directly
- Configuring Session Parameters Using Keychains

Note: To increase security, configure session parameters directly to avoid storing credentials within Vertica.

AWS Access Key Requirements

To communicate with AWS, your access key must have the following permissions:

- s3:GetObject
- s3:PutObject
- s3:ListBucket

For security purposes, Vertica recommends that you create a separate access key with limited permissions specifically for use with the Vertica Library for AWS.

Configuring Session Parameters Directly

These examples show how to set the session parameters for AWS using your own credentials:

- **aws_id** — This value is your AWS access key ID.

  ```
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_id='AKABCOEXAMPLEPKPXYZQ';
  ```

- **aws_secret** — This value is your AWS secret access key.

  ```
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='CEXAMPLE3tEXAMPLE1wEXAMPLEFrFEXAMPLE6+Yz';
  ```

- **aws_region** - This value is the AWS region associated with the S3 bucket you intend to access. Left unconfigured, aws_region will default to us-east-1. It identifies the default server used by Amazon S3.

  ```
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_region='us-east-1';
  ```

**Important:** Parameter values are case sensitive.

Note the following when using `ALTER SESSION`: 
Using `ALTER SESSION` to change the values of AWS Parameters also changes the values of corresponding UDParameters.

- Setting a UDParameter changes only the UDParameter.
- Setting a configuration parameter changes both the AWS parameter and UDParameter.

## Configuring Session Parameters Using Credentials Stored in a Table

You can place your credentials in a table and secure them with a row-level access policy. You can then call your credentials with the AWS_SET_CONFIG scalar meta-function. This approach allows you to store your credentials on your cluster for future session parameter configuration. You must have dbadmin access to create access policies.

1. Create a table with rows or columns corresponding with your credentials:

   ```sql
   => CREATE TABLE keychain(accesskey varchar, secretaccesskey varchar);
   ```

2. Store your credentials in the corresponding columns:

   ```sql
   => COPY keychain FROM STDIN;
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   => AEXAMPLEI5EXAMPLEYXQ|CCEXAMPLEtFjTEXAMPLEiEXAMPLE6+Yz
   => \.
   ```

3. Set a row-level access policy appropriate to your security situation.

4. With each new session, configure your session parameters by calling the AWS_SET_CONFIG parameter in a SELECT statement:

   ```sql
   => SELECT AWS_SET_CONFIG('aws_id', accesskey), AWS_SET_CONFIG('aws_secret', secretaccesskey)
       FROM keychain;
   aws_set_config | aws_set_config
                   --------------------------------
   aws_id         | aws_secret
   (1 row)
   ```

**Important:** Vertica recommends that you *not* use the AWS_SET_CONFIG function to configure your library directly, for example:

```sql
=> select aws_set_config('aws_id', 'actual_ID');
=> select aws_set_config('aws_secret', 'actual_secret');
```
When you do so, your credentials are recorded in the server log.

5. After you have configured your session parameters, verify them:

```sql
=> SHOW SESSION UDPARAMETER ALL;
```

Exporting Data to Amazon S3 From Vertica

After you configure the library for Amazon Web Services (AWS), you can export Vertica data to Amazon S3 by calling the S3EXPORT() transform function. S3EXPORT() writes data to files, based on the URL you provide. Vertica performs all communication over HTTPS, regardless of the URL type you use. Vertica does not support virtual host style URLs. If you use HTTPS URL constructions, you must use path style URLs.

Note: If your S3 bucket contains a period in its path, then you should set the prepend_hash parameter to True.

You can control the output of S3EXPORT() in the following ways:

- Adjust the base query provided to S3EXPORT
- Adjust the parameters of S3EXPORT
- Adjust the partition of your result set with the OVER() clause

Adjust the Query Provided to S3EXPORT

By adjusting the query given to S3EXPORT(), you can export anything from tables to reporting queries.

This example exports a whole table:
This example exports the results of a query:

```sql
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object') OVER(PARTITION BEST) FROM exampleTable;
rows | url
----------------------------------------
 606 | https://exampleBucket/object
(1 row)
```

**Adjust the Partition of Your Result Set with the OVER Clause**

Use the OVER clause to control your export partitions. Using the OVER() clause without qualification results in a single partition processed by the initiator for all of the query data. This example shows how to call the function with an unqualified OVER() clause:

```sql
=> SELECT S3EXPORT(customer_name, annual_income USING PARAMETERS url='s3://exampleBucket/object')
       OVER()
       FROM public.customer_dimension
       WHERE (customer_gender, annual_income) IN
           (SELECT customer_gender, MAX(annual_income)
            FROM public.customer_dimension
            GROUP BY customer_gender);
rows | url
----------------------------------------
  25 | https://exampleBucket/object
(1 row)
```

You can also use window clauses, such as window partition clauses and window order clauses, to manage exported objects.

This example shows how you can use a window partition clause to partition S3 objects based on company values:

```sql
=> SELECT S3EXPORT(name, company USING PARAMETERS url='s3://exampleBucket/object',
   delimiter=',') OVER(PARTITION BY company) AS MEDIAN
                          FROM exampleTable;
```

Adding Nodes to a Running AWS Cluster

There are three main steps to adding a node to a database cluster:

1. Provision the host in AWS. Hosts are also known as instances.
2. Add the host to the cluster.
3. Add the node to the database.

If you are managing your database cluster in AWS using the Vertica Management Console, the Add Instance wizard performs all three steps. See the instructions in the Managing AWS Instances section of Viewing and Managing Your Cluster.

Otherwise, use the procedures described in the following topics to add instances/nodes to an AWS cluster:

- Launching New Instances to Add to an Existing Cluster
- Including New Instances as Cluster Nodes
- Adding Nodes and Rebalancing the Database

The procedures assume you have an AWS cluster up and running and have most-likely accomplished each of the following:

- Created a database.
- Defined a database schema.
- Loaded data.
- Run the database designer.
- Connected to your database.
In This Section

- Launching New Instances to Add to an Existing Cluster
- Including New Instances as Cluster Nodes
- Adding Nodes and Rebalancing the Database

Launching New Instances to Add to an Existing Cluster

Perform the procedure in Configuring and Launching an Instance to create new instances that you then will add to your existing cluster. Be sure to choose the same details you chose when you created the original instances (VPC, placement group, subnet, and security group).

Including New Instances as Cluster Nodes

The Instances page lists the instances and their associated IP addresses. You need the IP addresses when you run the install_vertica script.

If you are configuring EBS volumes, be sure to configure the volumes on the node before you add the node to your cluster.

To add the new instances as nodes to your existing cluster:

1. Configure and launch your new instances.

2. Connect to the instance that is assigned to the Elastic IP. See Connecting to an Instance if you need more information.

3. Run the vertica installation script to add the new instances as nodes to your cluster. Specify the internal IP addresses for your instances and your *pem file name.

   sudo /opt/vertica/sbin/install_vertica --add-hosts <instance-ip> --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-pem>.pem
Adding Nodes and Rebalancing the Database

Once you have added the new instances to your existing cluster, you add them as nodes to your cluster, and then rebalance the database.

Follow the procedure given in the Administration Guide, Adding Nodes to a Database.

Removing Nodes From a Running AWS Cluster

Use these procedures to remove instances/nodes from an AWS cluster.

In This Section

- Preparing to Remove a Node
- Removing Hosts from the Database
- Removing Nodes from the Cluster
- Stopping the AWS instance

Preparing to Remove a Node

Back up the Database.

Vertica recommends that you back up the database before performing this significant operation because it entails creating new projections, deleting old projections, and reloading data.

Removing Hosts From the Database

Before performing the procedure in this section, you must have completed the tasks referenced in Preparing to Remove a Node. The following procedure assumes that you have both backed up your database and lowered the k-safety.

**Note:** Do not stop the database.
Perform the following to remove a host from the database.

1. While logged on as dbadmin, launch Administration Tools.

   $ /opt/vertica/bin/admintools

   **Note:** Do not remove the host that is attached to your EIP.

2. From the Main Menu, select Advanced Tools Menu.

3. From Advanced Menu, select Cluster Management. Select OK.

4. From Cluster Management, select Remove Host(s). Select OK.

5. From Select Database, choose the database from which you plan to remove hosts. Select OK.

6. Select the host(s) to remove. Select OK.

7. Click Yes to confirm removal of the hosts.

   **Note:** Enter a password if necessary. Leave blank if there is no password.

8. Select OK. The system displays a message letting you know that the hosts have been removed. Automatic re-balancing also occurs.

9. Select OK to confirm. Administration Tools brings you back to the Cluster Management menu.

**Removing Nodes From the Cluster**

To remove nodes from a cluster:

run the `install_vertica` script and specify:

- The option `--remove-hosts` followed by the IP addresses of the nodes you are removing
- The option `--ssh-identity` followed by the location and name of your *pem file. (The following example removes only one node from the cluster.)
- The option `--dba-user-password-disabled`

The following example removes 1 node from the cluster:
Stopping the AWS Instances (Optional)

Once you have removed one or more nodes from your cluster, to save costs associated with running instances, you can choose to stop or terminate the AWS instances that were previously part of your cluster. This step is optional because, once you have removed the node from your Vertica cluster, Vertica no longer sees the instance/node as part of the cluster even though it is still running within AWS.

To stop an instance in AWS:

1. On AWS, navigate to your Instances page.
2. Right-click on the instance, and choose Stop.

Upgrading and Migrating Vertica on AWS

The topics in this section explain how you upgrade your version of Vertica and migrate data between clusters on AWS.

Upgrading to the latest Version of Vertica on AWS

Use these procedures for upgrading to the latest version of Vertica on AWS. The procedures assume that you have a 7.1 or later cluster successfully configured and running on AWS. If you are setting up a Vertica cluster on AWS for the first time, follow the detailed procedure for installing and running Vertica on AWS.

Note: Both install_vertica and update_vertica use the same parameters.

In This Section

- Preparing to Upgrade Your Cluster
- Upgrading Vertica on AWS
Preparing to Upgrade Your Cluster

Prepare for the upgrade to the latest Vertica version by performing the following:

1. Back up your existing database.

2. Download the Vertica install package. See Download and Install the Vertica Install Package in the Installation Guide for more information.

Upgrading Vertica Running on AWS

Vertica supports upgrades of Vertica Server running on AWS instances created from the Vertica AMI. To upgrade Vertica, follow the instructions provided in the Vertica upgrade documentation.

Add the following arguments to the upgrade script:

- --dba-user-password-disabled
- --point-to-point

Migrating to Vertica 7.0 or later on AWS

Note: If you had a Vertica installation running on AWS prior to Release 6.1.x, you can migrate to Vertica 9.1.x or later using a new preconfigured AMI.

For more information, see the Solutions tab of the myVertica portal.

Migrating Data Between AWS Clusters

This section provides guidance for copying (importing) data from another AWS cluster, or exporting data between AWS clusters.

There are common issues that occur when exporting or copying on AWS clusters. The issues are listed below. Except for these specific issues as they relate to AWS, copying and exporting data works as documented in the Administrator's Guide section, Copying and Exporting Data.
1. **Ensure that all nodes in source and destination clusters have their own elastic IPs (or public IPs) assigned.**

   If your destination cluster is located within the same VPC as your source cluster, proceed to step 3. Each node in one cluster must be able to communicate with each node in the other cluster. Thus, each source and destination node needs an elastic IP (or public IP) assigned.

2. **Set the parameter `DontCheckNetworkAddress` to true.**

   On AWS, when creating a network interface, you receive an error if you attempt to assign the elastic IP to an AWS node (example uses a sample elastic IP address):
   ```sql
dbadmin=> CREATE NETWORK INTERFACE eipinterface ON v_tpch_node0001 with '107.23.151.10';
   ERROR 4125: No valid address found for [107.23.151.10] on this node
   This error occurs because the elastic IP is the public IP and not the private IP of the target node. To resolve this issue, first set the parameter `DontCheckNetworkAddress` to true:
   ```sql
   select set_config_parameter('DontCheckNetworkAddress','1');
   ```
   You can find information on the **CREATE NETWORK INTERFACE** statement and **SET_CONFIG_PARAMETER** in the SQL Reference Manual.

3. **Ensure your security group allows the AWS clusters to communicate.**

   Check your security groups for both your source and destination AWS clusters. Ensure that ports 5433 and 5434 are open. If one of your AWS clusters is on a separate VPC, ensure that your network access control list (ACL) allows communication on port 5434.

   **Note:** This communication method exports and copies (imports) data through the internet. You can alternatively use non-public IPs and gateways, or VPN to connect the source and destination clusters.

4. **If there is one or more ELB between the clusters, ensure that Port 5433 is opened between the ELBs and clusters.**

5. **If you use the Vertica client to connect to one or more ELBs, the ELBs only distribute incoming connections. The data transmission path occurs between clusters.**
Moving from Hourly License to BYOL (Bring Your Own License)

Vertica offers both Bring Your Own License (BYOL) and Vertica by the Hour deployments of Vertica through the Amazon Web Services Marketplace.

Vertica Bring Your Own License (BYOL) deployments use long-term licenses, which you obtain through an online licensing portal. These deployments also work with a free Community Edition license, which Vertica automatically implements if you do not install a license you purchased. (For more about Vertica licenses, see Managing Licenses and Understanding Vertica Licenses.)

Vertica by the Hour deployments are pay-as-you-go environments. The Hourly License deployment offers an alternative to purchasing a long-term license. This option might work better for you if you want to crunch large volumes of data within a short period of time.

After implementing an Hourly License, you may later decide to use a long-term BYOL license for your database. To purchase a BYOL license, you will go through a step-by-step process in the licensing portal, detailed in Obtaining a License Key File.

After receiving your new long-term license, you must shut down your database in the Hourly environment, then revive or restore it in a BYOL environment.

Depending on your database mode and environment, the procedure differs.

- **Eon Mode databases**: Use either the command line or Management Console to switch licenses, shut down the database, and revive it in a new environment.

- **Enterprise Mode databases**: Use the command line to switch licenses, back up the database, shut down, and restore it in a new environment.

Move to BYOL from Hourly License with Revive in the Command Line

In an Eon Mode database, follow the procedure below to move to BYOL and revive your database using the command line.

1. Obtain a long-term BYOL license from the online licensing portal, following the steps detailed in Obtaining a License Key File
2. In Vertica, view the licenses table using the function below. Take note of the name of the Hourly License listed in the name column, in order to check if it is still present during Step 4:
   `=> SELECT * FROM licenses;`

3. After you have purchased a license from Vertica, install the key in the database in your Hourly License environment, as follows:
   `=> SELECT install_license('<BYOL license path>');`

4. View the licenses table using the function below. If only the new BYOL license displays, skip to Step 6. If the Hourly License whose name you noted during Step 2 still displays, copy the name and proceed to Step 5:
   `=> SELECT * FROM licenses;`

5. If the Hourly License was still present in Step 4, drop it from the database as follows:
   `=> SELECT drop_license('<License name>');</`

6. Shut down the database as follows:
   `=> SELECT SHUTDOWN('true');</`

7. From the Amazon Web Services Marketplace, from a Vertica BYOL product page, deploy your new BYOL environment.

8. When you revive the database, the BYOL gets selected. For instructions on reviving a database go to Shutting Down and Reviving An Eon Mode Database.

9. After reviving the database on your new environment, terminate the instances for your Hourly license environment. To do so, on the AWS CloudFormation Stacks page, select the Hourly environment's stack (its collection of AWS resources) and click Actions > Delete Stack.

10. From the Amazon Web Services Marketplace, from a Vertica BYOL product page, deploy new instances for your BYOL Vertica environment.

   a. Restore the database on your new instances. See Backing Up and Restoring the Database. When you restore the database, BYOL gets selected.

**Move to BYOL from Hourly License with Revive in Management Console (MC)**

In an Eon Mode database monitored by MC, follow the procedure below to move to BYOL and revive your database using MC:
1. Purchase a long-term BYOL license from the online licensing portal, following the steps detailed in Obtaining a License Key File

2. After you have purchased a license from Vertica, install the license key file in the database in your Hourly License environment using MC:
   a. Log into MC and click your database to see its Overview page.
   b. Click the License tab.
   c. Take note of the name in the License Name column, in order to check if it is still present during Step 3.
   d. Click the Install New License button at the top of the page. The Settings: License page opens.
   e. Upload your new license key file on the Settings: License page, then click the Apply button on the top right of the page.

3. Return to the License tab and view the Installed Licenses table. If only the new BYOL license displays, skip to Step 5. If the Hourly License also displays, take note of its name in the License column and proceed to Step 4.

4. If the Hourly License was still present in Step 3, drop it from the database as follows:
   a. Click the Query Execution tab.
   b. Execute the following function, replacing 'License name' with the name of the Hourly license:
      ```sql
      => SELECT drop_license('<License name>');
      ```

5. Stop the database. From the MC home page, click View Your Infrastructure. Select your database, and in the dialog that appears, click Stop.

6. From the Amazon Web Services Marketplace, from a Vertica BYOL product page, deploy a new Vertica Management Console.

7. From the new MC, revive the database. See Reviving an Eon Mode Database in MC for the Management Console revive process.

8. After reviveing the database on your new environment, terminate the instances for your Hourly license environment. To do so, on the AWS CloudFormation Stacks page, select the Hourly environment’s stack (its collection of AWS resources) and click Actions > Delete Stack.
Move to BYOL from Hourly License with Backup and Restore

In an Enterprise Mode database, follow the procedure below to move to BYOL, then back up and restore your database:

1. Obtain a long-term BYOL license from the online licensing portal, following the steps detailed in Obtaining a License Key File

2. In Vertica, view the licenses table using the function below. Take note of the name of the Hourly License listed in the name column, in order to check if it is still present during Step 4:
   
   => SELECT * FROM licenses;

3. After you have purchased a long-term license from Vertica, install the license key in the database in your Hourly license environment, as follows:
   
   => SELECT install_license('<BYOL license path>');</n
4. View the licenses table using the function below. If only the new BYOL license displays, skip to Step 6. If the hourly license also displays, take note of its name in the name column and proceed to Step 5:
   
   => SELECT * FROM licenses;

5. If the hourly license was still present in Step 4, drop it from the database as follows:
   
   => SELECT drop_license('<License name>');

6. Back up the database. See Backing Up and Restoring the Database.

7. From the Amazon Web Services Marketplace, from a Vertica BYOL product page, deploy new instances for your BYOL Vertica environment.

8. Restore the database on your new instances. See Backing Up and Restoring the Database. When you restore the database, BYOL gets selected.

9. After restoring the database on your new environment, terminate the instances for your Hourly license environment. To do so, on the AWS CloudFormation Stacks page, select the Hourly environment's stack (its collection of AWS resources) and click Actions > Delete Stack.

   After completing one of the procedures above, see Viewing Your License Status to confirm the license drop and install were successful.
Vertica on Microsoft Azure

Welcome to the Vertica on Microsoft Azure guide. This section explains how you can create Vertica clusters on the Microsoft Azure Cloud Platform.

Overview of Vertica on Microsoft Azure

Vertica clusters on Microsoft Azure operate on virtual machines (VMs) within a virtual network. The instructions in this document apply to VMs in Azure that are built with Vertica.

For more information about Azure VMs, see the Azure documentation.

Recommended VM Types

Vertica supports a range of Microsoft Azure virtual machine (VM) types, each optimized for different purposes. Choose the VM type that best matches your performance and price needs as a user.

For the best performance in most common scenarios, use one of the following VMs:

<table>
<thead>
<tr>
<th>Optimization</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory optimized</td>
<td>DS13_v2</td>
</tr>
<tr>
<td></td>
<td>DS14_v2</td>
</tr>
<tr>
<td></td>
<td>DS15_v2</td>
</tr>
<tr>
<td></td>
<td>D8s_v3</td>
</tr>
<tr>
<td></td>
<td>D16s_v3</td>
</tr>
<tr>
<td></td>
<td>D32s_v3</td>
</tr>
<tr>
<td>High memory and I/O throughput</td>
<td>GS3</td>
</tr>
<tr>
<td></td>
<td>GS4</td>
</tr>
<tr>
<td></td>
<td>GS5</td>
</tr>
</tbody>
</table>
Note: The GS VMs are not available in all regions. Nor are they available on the Azure Marketplace, but you can use them by following the manual deployment steps described in Deploy Vertica on Azure: Manual Steps.

Note: Data stored on the drives of a VM exists only while that VM is powered on. After powering off a VM, data on temporary drives is lost.

Supported Azure Operating Systems

For best performance, use one of the following operating systems when deploying Vertica on Azure:

- Red Hat 7.3
- CentOS 7.3. The Azure Marketplace solution as of this writing (June 2017) is based on CentOS 7.3.1611.

For more information, see Vertica Supported Platforms.

Deploy Vertica from the Microsoft Azure Marketplace

For customers looking to quickly deploy a Vertica cluster in the Microsoft Azure Cloud, this section describes an automated deployment solution that can be accessed from the Azure Marketplace at Vertica Analytics Platform.

To deploy Vertica on Microsoft Azure, you need to upgrade from the Free Trial, which limits you to a 4-core quota, to Microsoft Azure’s Pay-As-You-Go subscription. The Pay-As-You-Go subscription requires a minimum quota of 12 cores which is what is needed for the Vertica Marketplace solution for Azure.
Check with Microsoft about the benefits and credits that you can carry over from the Free Trial to the Pay-As-You-Go subscription. For more information about upgrading a free Microsoft Azure trial account to Pay-As-You-Go, see Azure pricing.

When you’re ready, click Get It Now on Vertica Analytics Platform. The following sections describe the steps you need to take after you click that button.

Basic Information that Azure Needs

On the first plane (window) of the installer for your Vertica-Azure solution, enter the following information:

- **DBADMIN username**: The primary username for the virtual machines being created. This name is also used as the Vertica DBADMIN account.

- **Authentication Type**: VMs in Azure support either password or SSH public key authentication.

- **Password or SSH public key**: Enter either a password or a public key to be associated with the DBADMIN user.

- **Subscription**: Select an Azure subscription for the resources to be billed against.

- **Resource group**: Create a new resource group or select an existing resource group as the location to save all the Azure resources for your Vertica cluster.

- **Location**: Select an Azure data center to deploy the Vertica cluster. Make sure that you have enough quota assigned to that location.

Infrastructure Settings

In the second plane of the installer, make choices relating to the VMs. You need to choose two types of VMs, one to be used for the Vertica Management Console, and one to be used for the Vertica cluster nodes.

- **Management Console VM size**: Each Vertica deployment from the Azure marketplace includes a Vertica Management Console VM. This console is the jumping-off point to your cluster. During installation, the cluster configuration is automatically imported into the MC.
- **Number of Vertica cluster nodes**: This drop-down field allows you to choose the number of nodes for Azure to deploy for the cluster. The Marketplace solution allows you to create between 1 and 16 nodes. After the nodes have been created, the installer automatically forms your Vertica cluster, configures it, and creates your database. The Community Edition license is automatically applied to the cluster, and is limited to 1 TB of RAW data, and up to 3 Vertica nodes. For deployments where more than 3 Vertica Cluster nodes are chosen, the initial database is created on the first 3 nodes. To take advantage of deployments greater than 3 nodes, customers need to obtain and apply an Enterprise license.

  **Important**: To maintain K-safety for your database, select at least three nodes.

- **Virtual machine size**: Vertica engineers have populated this selection with different VM types that are suitable for Vertica clusters. This list only includes VM types that are available in the selected location in the first plane. When you highlight this field, Azure displays those types and their specific characteristics.

- **Total RAW storage per node**: Each VM comes configured with a set of premium data disks for Vertica to use. This set is configured and presented as a single storage location. The choices in this drop-down are 768 GB, 3 TB, 6 TB, or 12 TB.

### Network Options

The third installer plane contains the networking requirements for the Vertica cluster installation. These options are:

- **Virtual network**: The Azure Marketplace solution for Vertica allows you to create a new virtual network, or select an existing virtual network, in which to place the Vertica cluster. This control on the deployment provides a point-and-click navigation to do just that.

- **Subnets**: Based on the selection of the virtual network, the Subnets entry allows you to select or create the subnet you want to use within the virtual network.

- **Public IP address**: Each VM is configured with a publicly accessible IP address. This field allows you to specify the resource name for those IP addresses, and whether they are static or dynamic. When created, the first public IP address resource is created exactly as entered, and associated with the Vertica Management Console. Azure then appends a number from 1 to 16 to the resource name for each Vertica cluster node created. This number designates which VM that resource is associated with.
- **Domain name label:** Because each VM has a public IP address, each node is also required to have a DNS name. Enter a prefix for the name, such as `vertnode`. When created, the first DNS name is created exactly as entered and associated with the Vertica Management Console. Azure then appends a number from 1 to 16 to the DNS name. That number designates which VM it is associated with. Azure adds the remaining part of the fully qualified domain name based on the location where you created the cluster.

**Validate Your Configuration**

Review the settings on the installer Summary plane. Azure uses this plane to validate the values you entered. In addition, Azure checks your settings against the existing quota to make sure that your solution deploys correctly.

After you are satisfied with your choices and Azure has notified you that the validation passed, click OK.

**Finalize the Purchase**

On the final plane of the installer, agree to the Microsoft Terms of Use, and acknowledge that you agree to pay for the resources being created.

In addition, on this plane, review the Vertica Terms of Use and the privacy policy. After you click Purchase, the deployment begins.

**Monitor the Deployment**

After the deployment begins, you receive a notification that the deployment is in progress. When you click the notification, the Azure portal opens the deployment status page, which displays the resources for the cluster being created.

**Access the Cluster After Deployment**

After the deployment successfully completes, you receive a notification in the Azure portal. When you click the notification, the Azure portal opens the resource group and displays information about all the resources created.
Finalize the Cluster Installation

Take the following steps to finalize the cluster installation:

1. Open the resource group and locate the public IP address resource for the Vertica Management Console. The public IP address resource for the Vertica Management Console is the only public IP resource without a trailing number.

2. Copy the DNS name displayed in the public IP address resource for the Vertica Management Console.

3. From a browser, enter

   \[\text{https://<DNS\_Name\_of\_VMC>:5450}\]

   where `<DNS_Name_of_VMC>` is the copied value of the DNS name in the public IP address of the Vertica Management Console.

4. The browser opens the login page for the Vertica Management Console for your cluster. Log on using the default username (`mcadmin`) and the default password (`password`).

5. Accept the End User License Agreement.

6. To open the initial database, click the database icon labeled `vdb` on the lower left-hand section of the Vertica Management Console.

For complete information about how to use the Vertica Management Console, see Using Management Console in the Vertica documentation.

Access the Cluster VMs after Deployment

To access the cluster VMs directly, take the following steps:

1. Open the resource group and locate the public IP address resource for any of the Vertica cluster VMs. The public IP address resource for the Vertica cluster VMs is the public IP resource with a trailing number after the resource name. The trailing number corresponds to the VM number. For example, `PublicIP1` maps to Vertica cluster node 1, and so on.

2. Copy the DNS name displayed in the public IP address resource for the Vertica cluster node.
3. Connect to the node using the dbadmin user you created. Log in with the authentication method you chose (public key or password) using an SSH connection tool.

At this point, your cluster is fully installed and you are ready to use your new database.

**Deploy Vertica on Azure: Manual Steps**

To start creating your Vertica cluster in Azure using manual steps, you first need to create a VM. During the VM creation process, you create and configure the other resources required for your cluster, which are then available for any additional VMs that you create.

Follow these procedures to deploy Vertica on Azure.

**Configuring and Launching a New Instance**

An Azure VM is similar to a traditional host. Just as with an on-premises cluster, you must prepare and configure the hardware settings for your cluster and network before you install Vertica.

The first steps are:

1. From the Azure marketplace, select an operating system that Vertica supports.
2. Select a VM type. See [Recommended VM Types](#)
3. Choose a deployment model. For best results, choose the resource manager deployment model.

**Configure Network Security Group**

Vertica has specific network security group requirements, as described in [Network Security Group Configurations](#).

Create and name your own network security group, following these guidelines.

You must configure SSH as:

- **Protocol**: TCP
- **Source port range**: Any
• Destination port range: 22
• Source: Any
• Destination: Any

You can make additional modifications, based on your specific requirements.

Add Disk Containers

Create an Azure storage account, which later contains your cluster storage disk containers. For optimal throughput, select Premium storage and align the storage to a GS or DSv2 VM. For more information about what a storage account is, and how to create one, refer to About Azure storage accounts.

Configure Credentials

Create a password or assign an SSH key pair to use with Vertica. For information about how to use key pairs in Azure, see How to create and use an SSH public and private key pair for Linux VMs in Azure.

Assign a Public IP Address

A public IP is an IP address that you can use to connect to your cluster externally. For best results, assign a single static public IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using the internal IP addresses that Azure generated when you specified your virtual network settings.

By default, a public IP address is dynamic; it changes every time you shut down the server. You can choose a static IP address, but doing so can add cost to your deployment.

During a VM installation, you cannot set a DNS name. If you use dynamic public IPs, set the DNS name in the public IP resource for each VM after deployment.

For information about public IP addresses, refer to IP address types and allocation methods in Azure.

Create Additional VMs

If needed, to create additional VMs, repeat the previous instructions in this document.
Connect to a Virtual Machine

Before you can connect to any of the VMs you created, you must first make your virtual network externally accessible. To do so, you must attach the public IP address you created during network configuration to one of your VMs.

Connect to Your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the public IP address you created in the configuration steps.

2. Authenticate using the credentials and authentication method you specified during the VM creation process.

Connect to Other VMs

Connect to other virtual machines in your virtual network by first using SSH to connect to your publicly connected VM. Then, use SSH again from that VM to connect through the private IP addresses of your other VMs.

If you are using private key authentication, you may need to move your key file to the root directory of your publicly connected VM. Then, use PuTTY or WinSCP to connect to other VMs in your virtual network.

Prepare the Virtual Machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica License and Private Key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. These steps assume that the initial user you configured is the DBADMIN user.
1. As the DBADMIN user, copy your private key file from where you saved it locally onto your primary node.

   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the install_vertica script fails with a message similar to the following:

   Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.

   If you receive a failure message, enter the following command to correct permissions on your private key file:

   $ chmod 600 /<name-of-key>.pem

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

Install Software Dependencies for Vertica on Azure

In addition to the Vertica standard Installing the Required Packages, as the root user, you must install the following packages before you install Vertica on Azure:

- pstack
- mcelog
- sysstat
- dialog (Required for Vertica 8.0.x)

Configure Storage

Use a dedicated Azure storage account for node storage.

Caution: Do not store your information on the root volume, especially your data and catalog directories. Storing information on the root volume may result in data loss.

When configuring your storage, make sure to use a supported file system. For details, see Filesystem Requirement.
Attach Disk Containers to Virtual Machines (VMs)

Using your previously created storage account, attach disk containers to your VMs that are appropriate to your needs.

For best performance, combine multiple storage volumes into RAID-0. For most RAID-0 implementations, attach 6 storage disk containers per VM.

Combine Disk Containers for Storage

If you are using RAID, follow these steps to create a RAID-0 drive on your VMs. The following example shows how you can create a RAID-0 volume named md10 from 6 individual volumes named:

- sdc
- sdd
- sde
- sdf
- sdg
- sdh

1. Form a RAID-0 volume using the mdadm utility:

   ```bash
   $ mdadm --create /dev/md10 --level 0 --raid-devices=6 /dev/sdc /dev/sdd /dev/sde /dev/sdf /dev/sdg /dev/sdh
   ```

2. Format the file system to be one that Vertica supports:

   ```bash
   $ mkfs.ext4 /dev/md10
   ```

3. Find the UUID on the newly formed RAID volume:

   ```bash
   ls -l /dev/disk/by-uuid
   ```

4. Copy the UUID and place it in the FSTAB file:

   ```bash
   $ sudo vi /etc/fstab
   UUID=<uuid here> /dev/md10 ext4 defaults , errors=remount-ro 0 1
   ```
5. Create folders for your Vertica data and catalog.

   ```
   $ mkdir /vertica
   $ mkdir /vertica/data
   ```

6. Mount the RAID volume to your data and catalog directories.

   ```
   $ mount /dev/md10 /home/dbadmin/vertica/data
   ```

Create a Swap File

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file to operate.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on Azure:

1. Install devnull and swapfile:

   ```
   $ install -o root -g root -m 0600 /dev/null /swapfile
   ```

2. Create the swap file:

   ```
   $ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
   ```

3. Prepare the swap file using mkswap:

   ```
   $ mkswap /swapfile
   ```

4. Use swapon to instruct Linux to swap on the swap file:

   ```
   $ swapon /swapfile
   ```

5. Persist the swapfile in FSTAB:

   ```
   $ echo "/swapfile swap swap auto 0 0" >> /etc/fstab
   ```

Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

- Prepare Disk Storage Locations

Download Vertica

To download the Vertica server appropriate for your operating system and license type, go to vertica.com/download/vertica.

Run the rpm to extract the files.

After you complete the download and extraction, the next section describes how to use the install_vertica script to form a cluster and install the Vertica database software.

Form a Cluster and Install Vertica

Use the install_vertica script to combine two or more individual VMs to form a cluster and install the Vertica database.

Before You Start

Before you run the install_vertica script:

- Check the Virtual Network page for a list of current VMs and their associated private IP addresses.

- Identify your storage location. The installer assumes that you have mounted your storage to /vertica/data. To specify another location, use the --data-dir argument.

- Identify your storage location. To create your database's data directory on mounted RAID drive, when you run the install_vertica script, provide /vertica/data as the value of the --data-dir option.

Caution: Do not store your data on the root drive.
Combine Virtual Machines (VMs)

The following example shows how to combine VMs using the `install_vertica` script.

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.

   ```
   $ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-private-key>.pem --license <license.file>
   ```

2. Substitute the IP addresses for your VMs and include your root key file name, if applicable.

3. Include the `--point-to-point` parameter to configure spread to use direct point-to-point communication between all Vertica nodes, as required for clusters on Azure when installing or updating Vertica.

4. If you are using Vertica Community Edition, which limits you to three nodes, specify `--L CE` with no license file.

5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the shred command:

   ```
   $ shred examplekey.pem
   ```

   **Important:** You need your key file to perform future Vertica updates.

6. Reboot your cluster to complete the cluster formation and Vertica installation.

For complete information on the `install_vertica` script and its parameters, see Installing Vertica with the Installation Script.

After Your Cluster is Up and Running

Now that your cluster is configured and running, and Vertica is running, take these steps:
1. **Creating a Database.** When you installed Vertica, a database administrator user was created: DBADMIN.

2. Use this account to create and start a database. For detailed information about the DBADMIN role, see [DBADMIN Role](#).

3. **Configuring the Database.** After the database is installed, it's important to configure its settings, schemas, and security.

---

**Using Management Console (MC) on Azure**

The Vertica solution in the Azure marketplace provides a Management Console (MC) virtual machine. The MC VM allows you to deploy a VM dedicated to running MC onto a Vertica cluster on Azure.

You can deploy an MC VM to your Vertica on Azure cluster at any time, as long as your cluster meets the following requirements:

- Your Azure cluster must be running Vertica version 8.0.x or later.
- Your MC version must be compatible with the Vertica version of your cluster.

---

**Deploy an MC VM**

To deploy MC onto your target Vertica cluster on Azure, perform these tasks:

1. Select the Vertica Management Console deployment from the Azure Marketplace.
2. Specify an admin username for your new MC VM.
3. Place your MC VM in the same location as your target cluster.
4. Place your MC VM in a resource group, separate from your target cluster.
5. Specify the virtual network and subnet of your target cluster.
6. Specify a DNS name and public IP address.
7. Configure the network security group for the MC VM.
The MC VM requires specific security group configurations in order to communicate with the Vertica cluster. Configure the security rules for the MC VM as described in Configuring and Launching a New Instance.

Log in to MC and Manage Your Cluster

After you have deployed your MC VM and configured your security group settings, enter the following into your browser navigation field. This command launches the Management Console:

```
https://[IP address or DNS name]:5450
```

Log in to Management Console using the public IP address that you specified during instance creation.

From there, you can manage your Vertica database on Azure using standard MC procedures.

Uninstalling MC

To uninstall MC on Azure, follow the procedures provided in Uninstalling Management Console before terminating the MC node.

Deploy the Vertica Test Drive for Azure

For users looking to experience Vertica in a “test drive” environment on Azure, we offer that capability at the Azure Marketplace at Vertica Analytics Platform.

When you click the Test Drive button, Azure creates a single Vertica node that is preloaded with clickstream and sales data. This Test Drive allows you to explore and analyze the data before and after conducting A/B testing.

After the deployment completes, you receive an email with instructions on how to access the Test Drive. You can also consult the Test Drive user manual: Vertica Test Drive for Clickstream Analytics.
Vertica on Google Cloud Platform

Welcome to the Vertica on Google Cloud Platform guide.

Vertica clusters on Google Cloud Platform (GCP) operate on top of virtual machines (VMs) as part of the Google Compute Engine interconnected using a virtual private cloud (VPC) network. The VMs are accessible using the Internet with standard SSH connections. To access the Vertica Management Console, use HTTPS on port 5450.

The following topics describe several deployment methods to run Vertica on Google Cloud Platform:

Overview of Vertica on Google Cloud Platform

Vertica clusters on Google Cloud Platform (GCP) operate on top of virtual machines (VMs) as part of the Google Compute Engine interconnected using a virtual private cloud (VPC) network. The VMs are accessible using the Internet with standard SSH connections. To access the Vertica Management Console, use HTTPS on port 5450.

The following topics describe several deployment methods to run Vertica on Google Cloud Platform:

- Deploy Vertica from the Google Cloud Launcher Marketplace
- Deploy Vertica on Google Cloud Platform: Manual Steps

Deploy Vertica from the Google Cloud Launcher Marketplace

Are you looking to quickly deploy a Vertica cluster in the Google Cloud Platform (GCP)? If so, this section describes a Vertica-developed automated solution that you can access from the Vertica Analytics Platform Google Cloud Launcher.

The Vertica Cloud Launcher solution allows you to create up a 16-node cluster. The solution includes the Vertica Management Console (MC) as the primary UI for you to get started.

Each deployment automatically creates an initial database called vdb using the Community Edition (CE) license. The CE license is limited to a maximum of 3 nodes. In cases where you...
want to use more than 3 nodes for deployment on GCP, the deployment creates the initial
database on the first 3 nodes in the cluster.

After the launcher creates the initial database (vdb), it preconfigures the MC to attach to that
database automatically.

Configure the Vertica Cloud Launcher Solution

To get started with a deployment of Vertica from the Google Cloud Launcher, go to Vertica
Analytics Platform Google Cloud Launcher.

Follow these steps:

1. From the listing page, to start the solution launcher, click LAUNCH ON COMPUTE ENGINE.

2. Enter the following information:

   - **Deployment name**—Each deployment must have a unique name. That name is used as
     the prefix for the names of all VMs created during the deployment. The deployment
     name can only contain lowercase characters, numbers, and dashes. The name must
     start with a lowercase letter and cannot end with a dash.

   - **Zone**—GCP breaks its cloud data centers into regions and zones. *Regions* are a
     collection of zones in the same geographical location. *Zones* are collections of compute
     resources, which vary from zone to zone.

     For best results, pick the zone in your designated region that supports the latest Intel
     CPUs. For a complete listing of regions and zones, including supported processors, see
     Regions and Zones.

   - **Machine type for Vertica Management Console**—The Vertica Analytics Platform in
     Cloud Launcher always deploys the Vertica Management Console (MC) as part of the
     solution.

     The default machine type for MC is the n1-standard-4. However, you can choose
     another machine type that better suits the needs requires by the MC node for
     additional purposes, such serving as a target node for backups, data transformation, or
     additional management tools.

   - **Node count for Vertica Cluster**—The total number of VMs you want to deploy in the
     Vertica Cluster. The default is 3.
Note: The Cloud Launcher automatically deploys the Vertica Community Edition license, which limits the database to 3 nodes and up to 1 TB in raw data. If you intend to use the CE license, deployment of 4 or more nodes will result in an overpopulated cluster where VM resources are deployed (and incur costs) without being used by the database.

- **Machine type for Vertica Cluster nodes**—The Cloud Launcher builds each node in the cluster using the same machine type. The default value is the n1-highmem-16 type. Modify the machine type for your nodes based on the needs and costs associated with your workloads.

- **Data disk type**—GCP offers two types of persistent disk storage: Standard and SSD. The costs associated with Standard are less, but the performance of SSD storage is much better. Vertica recommends you use SSD storage. For more information on Standard and SSD persistent disks, see Storage Options.

- **Disk size for the Data disk**—Disk performance is directly tied to the disk size in GCP. The default value of 2000 GBs (2 TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.

  If you select a smaller disk size, the throughput performance decreases. If you select a large disk size, the performance remains the same as the 2 TB option.

- **Network name**—VMs in GCP must exist on a virtual private cloud (VPC). When you created your GCP account, a default VPC was created. Create additional VPCs to isolate solutions or projects from one another. The Vertica Analytics Platform creates all the nodes in the same VPC.

- **Subnetwork name**—Just as a GCP account may have multiple VPCs, each VPC may also have multiple subnets. Use additional subnets to group or isolate solutions within the same VPC.

After you have entered all the required information, click Deploy to begin the deployment process.

**Monitor the Deployment**

After the deployment begins, Google Cloud Launcher automatically opens a page that displays the status of the resources being created. Items that are still being processed have a spinning circle to the left of them and the text is a light gray color. Items that have been created are dark gray in color, with an icon designating that resource type on the left.
After the deployment completes, a green check mark appears next to the deployment name in the upper left-hand section of the screen.

Accessing the Cluster After Deployment

After the deployment completes, the right-hand section of the screen displays the following information:

- **dbadmin password**—A randomly generated password for the dbadmin account on the nodes. For security reasons, change the dbadmin password when you first log in to one of the Vertica cluster nodes.

- **mcadmin password**—A randomly generated password for the mcadmin account for accessing the Management Console. For security reasons, change the mcadmin password after you first log in to the MC.

- **Vertica Node 1 IP address**—The external IP address for the first node in the Vertica cluster is exposed here so that you can connect to the VM using a standard SSH client. To access the MC, press the Access Vertica MC button in the Get Started section of the dialog box. Copy the mcadmin password and paste it when asked.

For more information on using the MC, click Using Management Console.

Access the Cluster Nodes

There are two ways to access the cluster nodes directly:

- **Use GCP’s integrated SSH shell** by selecting the SSH button in the Get Started section. This shell opens a pop-up in your browser that runs GCP’s web-based SSH client. You are automatically logged on as the user you authenticated as in the GCP environment.

  After you have access to the first Vertica cluster node, execute the `su dbadmin` command, and authenticate using the dbadmin password.

- **In addition**, use other standard SSH clients to connect directly to the first Vertica cluster node. Use the Vertica Node 1 IP address listed on the screen as the dbadmin user, and authenticate with the dbadmin password.

  Follow the on-screen directions to log in using the mcadmin account and accept the EULA. After you've been authenticated, access the initial database by clicking the vdb icon (looks like a green cylinder) in the Recent Databases section.
When the cluster is fully deployed, check out the Getting Started Guide of the Vertica documentation.

Deploy Vertica on Google Cloud Platform: Manual Steps

Before you create your Vertica cluster in Google Cloud Platform (GCP) using manual steps, you must create a virtual machine (VM) instance from the Compute Engine section of GCP.

Configure and Launch a New Instance

All VM instances that you create should be launched in the same virtual public cloud (VPC).

To configure and launch a new VM instance, follow these instructions:

1. From within the Compute Engine section of GCP, from the menu on the left-hand site of the screen, select VM Instances.

   GCP displays all the VM instances that you have created so far.

2. Select the CREATE INSTANCE link.

3. Enter a name for the new instance.

4. Select the zone where you plan to deploy the instance.

   GCP breaks its cloud data centers down by regions and zones. Regions are a collection of zones that are all in the same geographical location. Zones are collections of compute resources, which vary from zone to zone. Always pick the zone in your designated region that supports the latest Intel CPUs.

   For a complete listing of regions and zones, including supported processors, see Regions and Zones.

5. Select a machine type.

   GCE offers many different types of VM instances. For best results, only deploy Vertica on VM instances with 8 vCPUs or more and at least 30 GB of RAM.
6. Select the boot disk (image).

You create VM instances from a public or custom image. If you are starting with Vertica in GCP for the first time, select either the CentOS 7 or RHEL 7 public image. Those images have been tested thoroughly with Vertica.

For more information about deploying a VM instance, see Creating and Starting an Instance.

After you have configured the VM instance to be used as a Vertica cluster node, GCP allows you to convert that instance into a custom image. Doing so allows you to deploy multiple versions of that VM instance; each VM instance is identical except for the node name and IP address.

For more information about creating a custom image, see Creating, Deleting, and Deprecating Custom Images.

Connect to a Virtual Machine

Before you can connect to any of the VMs you created, you must first identify the external IP address. The VM instance section of GCP contains a list of all currently deployed VMs and their associated external IP addresses.

Connect to Your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the external IP address you created in the configuration steps.

2. Authenticate using the credentials and SSH key that you provided to your GCP account upon creation.

Connect to Other VMs

To connect to other virtual machines in your virtual network:
1. Use SSH to connect to your publicly connected VM.

2. Use SSH again from that VM to connect through the private IP addresses of your other VMs.

Because GCP forces the use of private key authentication, you may need to move your key file to the root directory of your publicly connected VM. Then, use SSH to connect to other VMs in your virtual network.

Prepare the Virtual Machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica License and Private Key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. The following steps assume that the initial user you configured is the DBADMIN user:

1. As the DBADMIN user, copy your private key file from where you saved it locally onto your primary node.

   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the install_vertica script fails with a message similar to the following:

   ```
   Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.
   ```

   If you see the previous failure message, enter the following command to correct permissions on your private key file:

   ```
   $ chmod 600 /<name-of-key>.pem
   ```

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.
Install Software Dependencies for Vertica on GCP

In addition to the Vertica standard package dependencies, as the root user, you must install the following packages before you install Vertica:

- pstack
- mcelog
- sysstat
- dialog (Required for Vertica 8.0.x and later)

Configure Storage

For best disk performance in GCP, Vertica recommends customers use SSD persistent storage, configured to at least 2TB (2000 GB) in size. Disk performance is directly tied to the disk size in GCP. 2000 GBs (2TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.

**Caution:** Do not store your information on the root volume, especially in your data and catalog directories. Storing information on the root volume may result in data loss.

When configuring your storage, make sure to use a supported file system.

Create a Swap File

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file for the setup script to complete.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on GCP:

1. Install the devnull and swapfile files:

   ```bash
   $ install -o root -g root -m 0600 /dev/null /swapfile
   ```

2. Create the swap file:
3. Prepare the swap file using `mkswap`:

   ```
   $ mkswap /swapfile
   ```

4. Use `swapon` to instruct Linux to swap on the swap file:

   ```
   $ swapon /swapfile
   ```

5. Persist the swapfile in FSTAB:

   ```
   $ echo "/swapfile swap swap auto 0 0" >> /etc/fstab
   ```

6. Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

---

**Download Vertica**

To download the Vertica server appropriate for your operating system and license type, go to [https://vertica.com/download/vertica](https://vertica.com/download/vertica).

Download the rpm and run the rpm to extract the files as described in Download and Install the Vertica Server Package in the Vertica documentation.

After you complete the download and extraction, use the `install_vertica` script to form a cluster and install the Vertica database software, as described in the next section.

---

**Form a Cluster and Install Vertica**

Use the `install_vertica` script to combine two or more individual VMs to form a cluster and install your Vertica database.

Before you run the `install_vertica` script, follow these steps:

1. Check the VM Instances page of the Compute Engine section on GCP to locate a list of current VMs and their associated internal IP addresses.
2. Identify your storage location on your VMs. The installer assumes that you have mounted your storage to /home/dbadmin. To specify another location, use the --data-dir argument.

**Caution: Do not store your data on the root drive.**

The following steps show how to combine virtual machines (VMs) into a cluster using the install_vertica script:

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.

   ```bash
   $ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-private-key>.pem --license <license.file>
   ```

2. Substitute the IP addresses for your VMs, and include your root key file name, if applicable.

3. Include the --point-to-point parameter to configure spread to use direct point-to-point communication among all Vertica nodes, as required for clusters on GCP when installing or updating Vertica.

4. If you are using Vertica Community Edition, which limits you to three nodes, specify -L CE with no license file.

5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the shred command:

   ```bash
   $ shred examplekey.pem
   ```

**Important: You need your key file to perform future Vertica updates.**

For complete information about the install_vertica script and its parameters, see Installing Vertica with the Installation Script.

**After Your Cluster is Up and Running**

Now that your cluster is configured and running, and Vertica is running, take these steps:
1. **Create a Database.**

   When you installed Vertica, a database administrator user was created: DBADMIN. Use this account to create and start a database.

   For detailed information about the DBADMIN role, see DBADMIN Role.

2. **Configure the Database.** After the database is installed, it's important to configure its settings, schemas, and security.
Integrating with Apache Hadoop

Apache™ Hadoop™, like Vertica, uses a cluster of nodes for distributed processing. The primary component of interest is HDFS, the Hadoop Distributed File System.

You can use Vertica with HDFS in several ways:

- You can import HDFS data into locally-stored ROS files.
- You can access HDFS data in place using external tables. You can define the tables yourself or get schema information from Hive, a Hadoop component.
- You can use HDFS as a storage location for ROS files.
- You can export data from Vertica to share with other Hadoop components using a Hadoop columnar format.

See Hadoop Interfaces for more information about these options.

Hadoop file paths are expressed as URLs in the hdfs or webhdfs URL scheme. For more about the hdfs scheme, see Using HDFS URLs.
Hadoop Distributions

Vertica can be used with Hadoop distributions from Hortonworks, Cloudera, and MapR. See Vertica Integrations for Hadoop for the specific versions that are supported.

If you are using Cloudera, you can manage your Vertica cluster using Cloudera Manager. See Integrating With Cloudera Manager.

If you are using MapR, see Integrating Vertica with the MapR Distribution of Hadoop.
Cluster Layout

Vertica supports two cluster architectures for Hadoop integration. Which architecture you use affects the decisions you make about integration with HDFS. These options might also be limited by license terms.

- You can co-locate Vertica on some or all of your Hadoop nodes. Vertica can then take advantage of data locality.
- You can build a Vertica cluster that is separate from your Hadoop cluster. In this configuration, Vertica can fully use each of its nodes; it does not share resources with Hadoop.

With either architecture, if you are using the hdfs scheme to read ORC or Parquet files, you must do some additional configuration. See Configuring the hdfs Scheme.

Co-Located Clusters

With co-located clusters, Vertica is installed on some or all of your Hadoop nodes. The Vertica nodes use a private network in addition to the public network used by all Hadoop nodes, as the following figure shows:

![Graph showing Vertica Private Network and HDFS File System](image)

You might choose to place Vertica on all of your Hadoop nodes or only on some of them. If you are using HDFS Storage Locations you should use at least three Vertica nodes, the minimum number for K-Safety.

Using more Vertica nodes can improve performance because the HDFS data needed by a query is more likely to be local to the node.
You can place Hadoop and Vertica clusters within a single rack, or you can span across many racks and nodes. If you do not co-locate Vertica on every node, you can improve performance by co-locating it on at least one node in each rack. See Configuring Rack Locality.

Normally, both Hadoop and Vertica use the entire node. Because this configuration uses shared nodes, you must address potential resource contention in your configuration on those nodes. See Configuring Hadoop for Co-Located Clusters for more information. No changes are needed on Hadoop-only nodes.

### Hardware Recommendations

Hadoop clusters frequently do not have identical provisioning requirements or hardware configurations. However, Vertica nodes should be equivalent in size and capability, per the best-practice standards recommended in General Hardware and OS Requirements and Recommendations in Installing Vertica.

Because Hadoop cluster specifications do not always meet these standards, Vertica recommends the following specifications for Vertica nodes in your Hadoop cluster.

<table>
<thead>
<tr>
<th>Specifications For...</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Processor</td>
<td>For best performance, run:</td>
</tr>
<tr>
<td></td>
<td>- Two-socket servers with 8–14 core CPUs, clocked at or above 2.6 GHz for clusters over 10 TB</td>
</tr>
<tr>
<td></td>
<td>- Single-socket servers with 8–12 cores clocked at or above 2.6 GHz for clusters under 10 TB</td>
</tr>
<tr>
<td>Memory</td>
<td>Distribute the memory appropriately across all memory channels in the server:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Minimum</strong>—8 GB of memory per physical CPU core in the server</td>
</tr>
<tr>
<td></td>
<td>- <strong>High-performance applications</strong>—12–16 GB of memory per physical core</td>
</tr>
<tr>
<td></td>
<td>- <strong>Type</strong>—at least DDR3-1600, preferably DDR3-1866</td>
</tr>
<tr>
<td>Storage</td>
<td><strong>Read/write:</strong></td>
</tr>
<tr>
<td></td>
<td>- <strong>Minimum</strong>—40 MB/s per physical core of the CPU</td>
</tr>
</tbody>
</table>
- **For best performance**—60–80 MB/s per physical core

**Storage post RAID:** Each node should have 1–9 TB. For a production setting, Vertica recommends RAID 10. In some cases, RAID 50 is acceptable.

Because Vertica performs heavy compression and encoding, SSDs are not required. In most cases, a RAID of more, less-expensive HDDs performs just as well as a RAID of fewer SSDs.

If you intend to use RAID 50 for your data partition, you should keep a spare node in every rack, allowing for manual failover of a Vertica node in the case of a drive failure. A Vertica node recovery is faster than a RAID 50 rebuild. Also, be sure to never put more than 10 TB compressed on any node, to keep node recovery times at an acceptable rate.

| Network       | 10 GB networking in almost every case. With the introduction of 10 GB over cat6a (Ethernet), the cost difference is minimal. |

### Configuring Hadoop for Co-Located Clusters

If you are co-locating Vertica on any HDFS nodes, there are some additional configuration requirements.

### Hadoop Configuration Parameters

For best performance, set the following parameters with the specified minimum values:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Minimum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDFS block size</td>
<td>512MB</td>
</tr>
<tr>
<td>Namenode Java Heap</td>
<td>1GB</td>
</tr>
<tr>
<td>Datanode Java Heap</td>
<td>2GB</td>
</tr>
</tbody>
</table>

### WebHDFS

Hadoop has two services that can provide web access to HDFS:
• WebHDFS

• httpFS

For Vertica, you must use the WebHDFS service.

YARN

The YARN service is available in newer releases of Hadoop. It performs resource management for Hadoop clusters. When co-locating Vertica on YARN-managed Hadoop nodes you must make some changes in YARN.

Vertica recommends reserving at least 16GB of memory for Vertica on shared nodes. Reserving more will improve performance. How you do this depends on your Hadoop distribution:

• If you are using Hortonworks, create a "Vertica" node label and assign this to the nodes that are running Vertica.

• If you are using Cloudera, enable and configure static service pools.

Consult the documentation for your Hadoop distribution for details. Alternatively, you can disable YARN on the shared nodes.

Hadoop Balancer

The Hadoop Balancer can redistribute data blocks across HDFS. For many Hadoop services, this feature is useful. However, for Vertica this can reduce performance under some conditions.

If you are using HDFS storage locations, the Hadoop load balancer can move data away from the Vertica nodes that are operating on it, degrading performance. This behavior can also occur when reading ORC or Parquet files if Vertica is not running on all Hadoop nodes. (If you are using separate Vertica and Hadoop clusters, all Hadoop access is over the network, and the performance cost is less noticeable.)

To prevent the undesired movement of data blocks across the HDFS cluster, consider excluding Vertica nodes from rebalancing. See the Hadoop documentation to learn how to do this.

Replication Factor

By default, HDFS stores three copies of each data block. Vertica is generally set up to store two copies of each data item through K-Safety. Thus, lowering the replication factor to 2 can save
space and still provide data protection.

To lower the number of copies HDFS stores, set HadoopFSReplication, as explained in Troubleshooting HDFS Storage Locations.

**Disk Space for Non-HDFS Use**

You also need to reserve some disk space for non-HDFS use. To reserve disk space using Ambari, set dfs.datanode.du.reserved to a value in the hdfs-site.xml configuration file.

Setting this parameter preserves space for non-HDFS files that Vertica requires.

**Configuring Rack Locality**

*Note: This feature is supported only for reading ORC and Parquet data on co-located clusters. It is only meaningful on Hadoop clusters that span multiple racks.*

When possible, when planning a query Vertica automatically uses database nodes that are co-located with the HDFS nodes that contain the data. Moving query execution closer to the data reduces network latency and can improve performance. This behavior, called node locality, requires no additional configuration.

When Vertica is co-located on only a subset of HDFS nodes, sometimes there is no database node that is co-located with the data. However, performance is usually better if a query uses a database node in the same rack. If configured with information about Hadoop rack structure, Vertica attempts to use a database node in the same rack as the data to be queried.

For example, the following diagram illustrates a Hadoop cluster with three racks each containing three data nodes. (Typical production systems have more data nodes per rack.) In each rack, Vertica is co-located on one node.
If you configure rack locality, Vertica uses db01 to query data on dn1, dn2, or dn3, and uses db02 and db03 for data on rack2 and rack3 respectively. Because HDFS replicates data, any given data block can exist in more than one rack. If a data block is replicated on dn2, dn3, and dn6, for example, Vertica uses either db01 or db02 to query it.

Hadoop components are rack-aware, so configuration files describing rack structure already exist in the Hadoop cluster. To use this information in Vertica, configure fault groups that describe this rack structure. Vertica uses fault groups in query planning.

**Configuring Fault Groups**

Vertica uses [Fault Groups](#) to describe physical cluster layout. Because your database nodes are co-located on HDFS nodes, Vertica can use the information about the physical layout of the HDFS cluster.
Tip: For best results, ensure that each Hadoop rack contains at least one co-located Vertica node.

Hadoop stores its cluster-layout data in a topology mapping file in HADOOP_CONF_DIR. On HortonWorks the file is typically named topology_mappings.data. On Cloudera it is typically named topology.map. Use the data in this file to create an input file for the fault-group script. For more information about the format of this file, see Creating a Fault Group Input File.

Following is an example topology mapping file for the cluster illustrated previously:

```
[network_topology]
dn1.example.com=/rack1
10.20.41.51=/rack1
dn2.example.com=/rack1
10.20.41.52=/rack1
dn3.example.com=/rack1
10.20.41.53=/rack1
dn4.example.com=/rack2
10.20.41.71=/rack2
dn5.example.com=/rack2
10.20.41.72=/rack2
dn6.example.com=/rack2
10.20.41.73=/rack2
dn7.example.com=/rack3
10.20.41.91=/rack3
dn8.example.com=/rack3
10.20.41.92=/rack3
dn9.example.com=/rack3
10.20.41.93=/rack3
```

From this data, you can create the following input file describing the Vertica subset of this cluster:

```
/rack1 /rack2 /rack3
/rack1 = db01
/rack2 = db02
/rack3 = db03
```

This input file tells Vertica that the database node "db01" is on rack1, "db02" is on rack2, and "db03" is on rack3. In creating this file, ignore Hadoop data nodes that are not also Vertica nodes.

After you create the input file, run the fault-group tool:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py dbName input_file > fault_group_ddl.sql
```

The output of this script is a SQL file that creates the fault groups. Execute it following the instructions in Creating Fault Groups Using the Fault Group Script.

You can review the new fault groups with the following statement:
```sql
=> SELECT member_name, node_address, parent_name FROM fault_groups
INNER JOIN nodes ON member_name=node_name ORDER BY parent_name;
```

<table>
<thead>
<tr>
<th>member_name</th>
<th>node_address</th>
<th>parent_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>db01</td>
<td>10.20.41.51</td>
<td>/rack1</td>
</tr>
<tr>
<td>db02</td>
<td>10.20.41.71</td>
<td>/rack2</td>
</tr>
<tr>
<td>db03</td>
<td>10.20.41.91</td>
<td>/rack3</td>
</tr>
</tbody>
</table>

(3 rows)

**Working With Multi-Level Racks**

A Hadoop cluster can use multi-level racks. For example, /west/rack-w1, /west/rack-2, and /west/rack-w3 might be served from one data center, while /east/rack-e1, /east/rack-e2, and /east/rack-e3 are served from another. Use the following format for entries in the input file for the fault-group script:

```
/west /east
/west = /rack-w1 /rack-w2 /rack-w3
/east = /rack-e1 /rack-e2 /rack-e3
/rack-w1 = db01
/rack-w2 = db02
/rack-w3 = db03
/rack-e1 = db04
/rack-e2 = db05
/rack-e3 = db06
```

Do not create entries using the full rack path, such as /west/rack-w1.

**Auditing Results**

To see how much data can be loaded with rack locality, use `EXPLAIN` with the query and look for statements like the following in the output:

```
100% of ORC data including co-located data can be loaded with rack locality.
```

**Separate Clusters**

With separate clusters, a Vertica cluster and a Hadoop cluster share no nodes. You should use a high-bandwidth network connection between the two clusters.

The following figure illustrates the configuration for separate clusters:
Network

The network is a key performance component of any well-configured cluster. When Vertica stores data to HDFS it writes and reads data across the network.

The layout shown in the figure calls for two networks, and there are benefits to adding a third:

- **Database Private Network**: Vertica uses a private network for command and control and moving data between nodes in support of its database functions. In some networks, the command and control and passing of data are split across two networks.

- **Database/Hadoop Shared Network**: Each Vertica node must be able to connect to each Hadoop data node and the Name Node. Hadoop best practices generally require a dedicated network for the Hadoop cluster. This is not a technical requirement, but a dedicated network improves Hadoop performance. Vertica and Hadoop should share the dedicated Hadoop network.
• Optional Client Network: Outside clients may access the clustered networks through a client network. This is not an absolute requirement, but the use of a third network that supports client connections to either Vertica or Hadoop can improve performance. If the configuration does not support a client network, then client connections should use the shared network.

Hadoop Configuration Parameters

For best performance, set the following parameters with the specified minimum values:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Minimum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDFS block size</td>
<td>512MB</td>
</tr>
<tr>
<td>Namenode Java Heap</td>
<td>1GB</td>
</tr>
<tr>
<td>Datanode Java Heap</td>
<td>2GB</td>
</tr>
</tbody>
</table>
Hadoop Interfaces

Vertica provides several ways to interact with data stored in HDFS, described below. Decisions about Cluster Layout can affect the decisions you make about which Hadoop interfaces to use.

Querying Data Stored in HDFS

Vertica can query data directly from HDFS without requiring you to copy data. Doing so allows you to explore a large data lake without copying data into Vertica for analysis (and keeping the copy up to date). Queries against data in columnar formats are optimized to reduce the amount of data that Vertica has to read.

To query data, you define an external table as for any other external data source. (This option does not make use of schema definitions from Hive.) See Working with External Data for more about creating external tables, and Reading ORC and Parquet Formats for more about optimizations specific to these native Hadoop file formats.

Vertica can query the data directly from the HDFS nodes, bypassing the WebHDFS service. To query data directly, Vertica needs access to HDFS configuration files. See Using HDFS URLs.

Querying Data Using the HCatalog Connector

The HCatalog Connector uses Hadoop services (Hive and HCatalog) to query data stored in HDFS. Using the HCatalog Connector, Vertica can use Hive's schema definitions. However, performance can be poor compared to defining your own external table and querying the data directly. The HCatalog Connector is also sensitive to changes in the Hadoop libraries on which it depends; upgrading your Hadoop cluster might affect your HCatalog connections.

See Using the HCatalog Connector.

Using ROS Data

Storing data in the Vertica native file format (ROS) delivers better query performance than reading externally-stored data. You can create storage locations on your HDFS cluster to hold ROS data. Even if your data is already stored in HDFS, you might choose to copy that data into
an HDFS storage location for better performance. If your Vertica cluster also uses local file storage, you can use HDFS storage locations for lower-priority data.

See Using HDFS Storage Locations for information about creating and managing HDFS storage locations, and Using HDFS URLs for information about copying data into them.

**Exporting Data**

You might want to export data from Vertica, either to share it with other Hadoop-based applications or to move lower-priority data from ROS to less-expensive storage. You can export a table, or part of one, in Hadoop columnar format. After export you can still query the data using an external table, as for any other data.

See Exporting Data.
Accessing Kerberized HDFS Data

If your Hortonworks or Cloudera Hadoop cluster uses Kerberos authentication to restrict access to HDFS, Vertica must be granted access. If you use Kerberos authentication for your Vertica database, and database users have HDFS access, then you can configure Vertica to use the same principals to authenticate. However, not all Hadoop administrators want to grant access to all database users, preferring to manage access in other ways. In addition, not all Vertica databases use Kerberos.

Vertica provides the following options for accessing Kerberized Hadoop clusters:

- Using Vertica Kerberos principals.
- Using Hadoop proxy users combined with Vertica users.
- Using a user-specified delegation token which grants access to HDFS. Delegation tokens are issued by the Hadoop cluster.

Proxy users and delegation tokens both use a session parameter to manage identities. Vertica need not be Kerberized when using either of these methods.

Vertica does not support Kerberos for MapR.

Using Kerberos with Vertica

If you use Kerberos for your Vertica cluster and your principals have access to HDFS, then you can configure Vertica to use the same credentials for HDFS.

Vertica authenticates with Hadoop in two ways that require different configurations:

- **User Authentication**—On behalf of the user, by passing along the user's existing Kerberos credentials. This method is also called user impersonation. Actions performed on behalf of particular users, like executing queries, generally use user authentication.

- **Vertica Authentication**—On behalf of system processes (such as the Tuple Mover), by using a special Kerberos credential stored in a keytab file.

Note: Vertica and Hadoop must use the same Kerberos server or servers (KDCs).

Vertica can interact with more than one Kerberos realm. To configure multiple realms, see Multi-realm Support in Security and Authentication.
Vertica attempts to automatically refresh Hadoop tokens before they expire. See Token Expiration.

User Authentication

To use Vertica with Kerberos and Hadoop, the client user first authenticates with one of the Kerberos servers (Key Distribution Center, or KDC) being used by the Hadoop cluster. A user might run kinit or sign in to Active Directory, for example.

A user who authenticates to a Kerberos server receives a Kerberos ticket. At the beginning of a client session, Vertica automatically retrieves this ticket. Vertica then uses this ticket to get a Hadoop token, which Hadoop uses to grant access. Vertica uses this token to access HDFS, such as when executing a query on behalf of the user. When the token expires, Vertica automatically renews it, also renewing the Kerberos ticket if necessary.

The user must have been granted permission to access the relevant files in HDFS. This permission is checked the first time Vertica reads HDFS data.

Vertica can use multiple KDCs serving multiple Kerberos realms, if proper cross-realm trust has been set up between realms.

Vertica Authentication

Automatic processes, such as the Tuple Mover, do not log in the way users do. Instead, Vertica uses a special identity (principal) stored in a keytab file on every database node. (This approach is also used for Vertica clusters that use Kerberos but do not use Hadoop.) After you configure the keytab file, Vertica uses the principal residing there to automatically obtain and maintain a Kerberos ticket, much as in the client scenario. In this case, the client does not interact with Kerberos.

Each Vertica node uses its own principal; it is common to incorporate the name of the node into the principal name. You can either create one keytab per node, containing only that node's principal, or you can create a single keytab containing all the principals and distribute the file to all nodes. Either way, the node uses its principal to get a Kerberos ticket and then uses that ticket to get a Hadoop token.

When creating HDFS storage locations Vertica uses the principal in the keytab file, not the principal of the user issuing the CREATE LOCATION statement. The HCatalog Connector sometimes uses the principal in the keytab file, depending on how Hive authenticates users.
Configuring Users and the Keytab File

If you have not already configured Kerberos authentication for Vertica, follow the instructions in Configure Vertica for Kerberos Authentication. Of particular importance for Hadoop integration:

1. Create one Kerberos principal per node.
2. Place the keytab files in the same location on each database node and set configuration parameter KerberosKeytabFile to that location.
3. Set KerberosServiceNameFile to the name of the principal. (See Inform Vertica About the Kerberos Principal.)

If you are using the HCatalog Connector, follow the additional steps in Configuring Security in the HCatalog Connector documentation.

If you are using HDFS storage locations, follow the additional steps in Configuring Kerberos in the HDFS Storage Locations documentation.

Proxy Users and Delegation Tokens

An alternative to granting HDFS access to individual Vertica users is to use delegation tokens, either directly or with a proxy user. In this configuration, Vertica accesses HDFS on behalf of some other (Hadoop) user. The Hadoop users need not be Vertica users at all.

In Vertica, you can either specify the name of the Hadoop user to act on behalf of (doAs), or you can directly use a Kerberos delegation token that you obtain from HDFS (Bring Your Own Delegation Token). In the doAs case, Vertica obtains a delegation token for that user, so both approaches ultimately use delegation tokens to access files in HDFS.

Use the HadoopImpersonationConfig session parameter to specify a user or delegation token to use for HDFS access. Each session can use a different user and can use either doAs or a delegation token. The value of HadoopImpersonationConfig is a set of JSON objects. See HadoopImpersonationConfig Format for details.

When using delegation tokens of either type (more specifically, when HadoopImpersonationConfig is set), Vertica falls back to WebHDFS to access data. This fallback is automatic; continue to use the hdfs URL scheme when using delegation tokens.
User Impersonation (doAs)

You can use user impersonation to access data in an HDFS cluster from Vertica. This approach is called "doAs" (for "do as") because Vertica uses a single proxy user on behalf of another (Hadoop) user. The impersonated Hadoop user does not need to also be a Vertica user.

In the following illustration, Alice and Bob are Hadoop users but not Vertica users. They connect to Vertica as the proxy user, vertica-etl, in separate sessions. In each session, Vertica obtains a delegation token (DT) on behalf of the doAs user (Alice or Bob), and uses that delegation token to access HDFS.

You can use doAs with or without Kerberos, so long as HDFS and Vertica match. If HDFS uses Kerberos then Vertica must too.

User Configuration

The Hadoop administrator must create a proxy user and allow it to access HDFS on behalf of other users. Set values in core-site.xml as in the following example:

```
<name>hadoop.proxyuser.vertica-etl.users</name>
[value>*</value>
<name>hadoop.proxyuser.vertica-etl.hosts</name>
[value>*</value>
```

In Vertica, create a corresponding user.

Session Configuration

To make requests on behalf of a Hadoop user, first set the HadoopImpersonationConfig session parameter to specify the user and HDFS cluster. Vertica will access HDFS as that user until the
session ends or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies an HDFS cluster and a Hadoop user. For the cluster, you can specify either a nameservice or an individual namenode. If you are using HA namenode, then you must either use a nameservice or specify all namenodes. HadoopImpersonationConfig Format describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "vertica-etl" is a Vertica user.

```
$ vsql -U vertica-etl

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[["nameservice":"hadoopNS", "doAs":"stephanie"]];
=> COPY nation FROM 'hdfs:///user/stephanie/nation.dat';

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[["nameservice":"hadoopNS", "doAs":"bob"],
   {"authority":"hadoop2:50070", "doAs":"rob"]];
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';
```

Vertica uses Hadoop delegation tokens, obtained from the namenode, to impersonate Hadoop users. In a long-running session, a token could expire. Vertica attempts to renew tokens automatically; see Token Expiration.

## Bring Your Own Delegation Token

Instead of creating a proxy user and giving it access to HDFS for use with doAs, you can give Vertica a Hadoop delegation token to use. You must obtain this delegation token from the Hadoop name node. In this model, security is handled entirely on the Hadoop side, with Vertica just passing along a token. Vertica may or may not be Kerberized.

A typical workflow is:

- In an ETL front end, a user submits a query.
- The ETL system uses authentication and authorization services to verify that the user has sufficient permission to run the query.
- The ETL system requests a delegation token for the user from the name node.
- The ETL system makes a client connection to Vertica, sets the delegation token for the session, and runs the query.

When using a delegation token, clients can connect as any Vertica user. No proxy user is required.
In the following illustration, Bob and Carol have Hadoop-issued delegation tokens. They connect to Vertica and Vertica uses those delegation tokens to access files in HDFS.

**Session Configuration**

Set the HadoopImpersonationConfig session parameter to specify the delegation token and HDFS cluster. Vertica will access HDFS using that delegation token until the session ends, the token expires, or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies a delegation token ("token") in webhdfs format and an HDFS nameservice or namenode. HadoopImpersonationConfig Format describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "dbuser1" is a Vertica user with no special privileges.

```sql
$ vsql -U dbuser1
=> ALTER SESSION SET HadoopImpersonationConfig = '[{"authority":"hadoop1:50070","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB9igFg-zKEfY4ga048mhS3YtX1qrhBHbbUn4VScNg5BHWQx3XR1U1R1bGvYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}];
=> COPY nation FROM 'hdfs:///user/stephanie/nation.dat';
=> ALTER SESSION SET HadoopImpersonationConfig = '[{"authority":"hadoop1:50070","token":"HgADdG9tA3RvbQCKAWDXJgAoigFg-zKEk14ga148mhRo0Upq_j9xVhZINSMnodAQnhUth3XR1U1R1bGvYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}];
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';
```

You can use the WebHDFS REST API to get delegation tokens:

```bash
$ curl -s --no-proxy "*" --negotiate -u: -X GET "http://hadoop1:50070/webhdfs/v1/?op=GETDELEGATIONTOKEN"
```
Vertica does not, and cannot, renew delegation tokens when they expire. You must either keep sessions shorter than token lifetime or implement a renewal scheme.

Delegation Tokens and the HCatalog Connector

HiveServer2 uses a different format for delegation tokens. To use the HCatalog Connector, therefore, you must set two delegation tokens, one as usual (authority) and one for HiveServer2 (schema). The HCatalog Connector uses the schema token to access metadata and the authority token to access data. The schema name is the same Hive schema you specified in CREATE HCATALOG SCHEMA. The following example shows how to use these two delegation tokens.

```
$ vsql -U dbuser1

-- set delegation token for user and HiveServer2
=> ALTER SESSION SET 
    HadoopImpersonationConfig=' ["nameservice":"hadoopNS","token":"3QAHcmVsZwFzQ0dy2x1XNjAIoBVJ3KrYSKAWF2VzGEjgmzj_ IUCIrI9bBqu6awFTKs5c-fHB8xsSVCcSEbGUyBkZxwIZ2F0an9uETFwLjIWjQyLjEwOT04MDIw"],

{"schema":"access","token":"UwAHcmVsZwFzQ0dy2x1XNjAIoBVJ3KrYSKAWF2VzGEjgmzj_ IUCIrI9bBqu6awFTKs5c-fHB8xsSVCcSEbGUyBkZxwIZ2F0an9uETFwLjIWjQyLjEwOT04MDIw"}];

-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';

-- uses both tokens
=> SELECT * FROM access.t1;

--uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;
```

HiveServer2 does not provide a REST API for delegation tokens like WebHDFS does. See Getting a HiveServer2 Delegation Token for some tips.

Getting a HiveServer2 Delegation Token

To access Hive metadata using HiveServer2, you need a special delegation token. (See Bring Your Own Delegation Token.) HiveServer2 does not provide an easy way to get this token, unlike the REST API that grants HDFS (data) delegation tokens.

The following utility code shows a way to get this token. You will need to modify this code for your own cluster; in particular, change the value of the connectURL static.

```
import java.io.FileWriter;
import java.io.PrintStream;
```
import java.io.PrintWriter;
import java.io.StringWriter;
import java.io.Writer;
import java.security.PrivilegedExceptionAction;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.hive.shims.Utils;
import org.apache.hadoop.security.UserGroupInformation;
import org.apache.hive.jdbc.HiveConnection;
import org.json.simple.JSONArray;
import org.json.simple.JSONObject;
public class JDBCTest {

        result.append(res.getString(1));
    }
    System.out.println("current_user: " + result.toString());
}

private static void writeDTJSON(String token) {
    JSONArray arr = new JSONArray();
    JSONObject obj = new JSONObject();
    obj.put("schema", schemaName);
    obj.put("token", token);
    arr.add(obj);
    try {
        FileWriter fileWriter = new FileWriter("hcat_delegation.json");
        fileWriter.write(arr.toJSONString());
    } finally {
        fileWriter.close();
    }
}
HadoopImpersonationConfig Format

The value of the HadoopImpersonationConfig session parameter is a set of one or more JSON objects. Each object describes one doAs user or delegation token for one Hadoop destination.

Syntax

```
[ { ("doAs" | "token"): value,
    ("nameservice" | "authority" | "schema"): value } [,..] ]
```

Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>doAs</td>
<td>The name of a Hadoop user to impersonate.</td>
</tr>
<tr>
<td>token</td>
<td>A delegation token to use for HDFS access.</td>
</tr>
<tr>
<td>nameservice</td>
<td>A Hadoop nameservice. All access to this nameservice uses the doAs user or delegation token. You must use the hdfs URL scheme (for example, hdfs://ns-value/path).</td>
</tr>
<tr>
<td>authority</td>
<td>A namenode authority. All access to this authority uses the doAs user or delegation token. If the namenode fails over to another namenode, the doAs user or delegation token does not automatically apply to the failover namenode. If you are using HA namenode, use nameservice instead of authority or include objects for every namenode.</td>
</tr>
<tr>
<td>schema</td>
<td>A Hive schema, for use with the HCatalog Connector. Vertica uses this object's doAs user or token to access Hive metadata only. For data access you must also specify a nameservice or authority object, just like for all other data access.</td>
</tr>
</tbody>
</table>
Examples

In the following example of doAs, Bob is a Hadoop user and vertica-etl is a Kerberized proxy user.

```bash
$ kinit vertica-etl -kt /home/dbadmin/vertica-etl.keytab
$ vsq1 -U vertica-etl
=> ALTER SESSION SET
    HadoopImpersonationConfig = '{"nameservice":"hadoopNS", "doAs":"Bob"}';
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';
```

In the following example, the current Vertica user (it doesn't matter who that is) uses a Hadoop delegation token. This token belongs to Alice, but you never specify the user name here. Instead, you use it to get the delegation token from Hadoop.

```bash
$ vsq1 -U dbuser1
=> ALTER SESSION SET
    HadoopImpersonationConfig = '{"nameservice":"hadoopNS","token":"JAAGZG1ldGwxBmRiZXRsMQckAwdX1JgB91gFg- kE7y4gaOBns3YX1Qwhb/hhb/Un4VScNg58hWqtx3XRU11REZ1GRL1bgVnYXRpb24RM1AuJAwMTAwLjU0OjgwMjA"}';
=> COPY nation FROM 'hdfs:///user/alice/nation.dat';
```

In the following example, "authority" specifies the (single) namenode on a Hadoop cluster that does not use high availability.

```bash
$ vsq1 -U dbuser1
=> ALTER SESSION SET
    HadoopImpersonationConfig = '{"authority":"hadoop1:50070", "doAs":"Stephanie"}';
=> COPY nation FROM 'webhdfs://hadoop1:50070/user/stephanie/nation.dat';
```

To access data in Hive you need to specify two delegation tokens. The first, for a nameservice or authority, is for data access as usual. The second is for the HiveServer2 metadata for the schema. HiveServer2 requires a delegation token in webhdfs format. The schema name is the Hive schema you specify with CREATE HCATALOG SCHEMA.

```bash
$ vsq1 -U dbuser1
-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
    HadoopImpersonationConfig='[{"nameservice":"hadoopNS","token":"JQAHcmVsZwFzQdyZwX1YXNlAIoBYVJkYyskaWF2VzGEjgmzj_IUCI19b8Q6u6awFtk5sC-fHB8sxSV0vCSERGuYUKxkzW122F0aw9uETEwLj1Wl-jDylJjEWTo4MDiw"},
{"schema":"access","token":"UwAhcmVsZwFzQdyZwX1YXNlI2hpmMUZwX5Lw5LTEwMC52ZXJ8oAnhY29ycC5jM21lA0yvSV E1DQUNPb1AuQ09N1gFhUkeyTo0ByZwXwNk4BjgETFkN2xPUnr19Yq9tF- 0nekoD517zVuh3VkJYFREMrUdBVE1PT19UT0tFThzoaX21c2VydSYMkNsaWVudFRva2Vu"}'];
```
-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';

-- uses both tokens
=> SELECT * FROM access.t1;

-- uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;

Each object in the HadoopImpersonationConfig collection specifies one connection to one Hadoop cluster. You can add as many connections as you like, including to more than one Hadoop cluster. The following example shows delegation tokens for two different Hadoop clusters. Vertica uses the correct token for each cluster when connecting.

$ vsql -U dbuser1
=> ALTER SESSION SET HadoopImpersonationConfig = [
    {"nameservice":"productionNS","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB9igFg-zKcFy4ga4BmhJS3jYtxiWqrstBbUn4V5ScNg5BHQXq3XRUJIEZTIGR1bGvnyXRPb24RMTAuMjAuMTAwLjU0QjgwMjA"},
    {"nameservice":"testNS", "token":"HQAHcmVsZWFzZQdyZWxlYXNlAIoBYVJKrYSKAWF2VzGEjgmzj_IUCIrI9bBQu6awFTHk5nC-fHB8xs5V0VCSERGuy8kZw1lZ2F9a8n9uETEwLjIwLjQyLyEwOTo4MDIw"'}];
=> COPY clicks FROM 'hdfs://productionNS/data/clickstream.dat';
=> COPY testclicks FROM 'hdfs://testNS/data/clickstream.dat';

Token Expiration

Vertica uses Hadoop tokens when using Kerberos tickets (Using Kerberos with Vertica) or doAs (User Impersonation (doAs)). Vertica attempts to automatically refresh Hadoop tokens before they expire, but you can also set a minimum refresh frequency if you prefer. Use the HadoopFSTokenRefreshFrequency configuration parameter to specify the frequency in seconds:

=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';

If the current age of the token is greater than the value specified in this parameter, Vertica refreshes the token before accessing data stored in HDFS.

Vertica does not refresh delegation tokens (Bring Your Own Delegation Token).
Verifying Kerberos Configuration

Use the KERBEROS_HDFS_CONFIG_CHECK metafunction to verify that Vertica can use Kerberos to access HDFS and HiveServer2. You can call it with no parameters to test all paths described in the Hadoop configuration files. Alternatively, you can specify hdfs and webhdfs servers to test individually.

```sql
=> SELECT KERBEROS_HDFS_CONFIG_CHECK();
=> SELECT KERBEROS_HDFS_CONFIG_CHECK('node1.example.com:9433', 'node2.example.com:10443');
```
Using HDFS URLs

Use the hdfs URL scheme when accessing files in HDFS. With this scheme, Vertica bypasses the slower, less-stable WebHDFS service when possible, and falls back to it when necessary. To use WebHDFS for all access, set the HDFSUseWebHDFS configuration parameter and continue to use hdfs URLs; you do not need to rewrite URLs to change connection methods. (See Apache Hadoop Parameters.)

You can use the hdfs scheme with COPY and with CREATE EXTERNAL TABLE AS COPY. When using the hdfs scheme with COPY, you do not need to specify ON ANY NODE.

Vertica requires access to certain configuration files from your HDFS cluster.

If the file you want to read resides on an HDFS cluster that uses Kerberos authentication, Vertica uses the current user's principal, session doAs user, or session delegation token. See Accessing Kerberized HDFS Data for more information about these options.

HDFS URL Format

You specify the location of a file in HDFS using a URL. In most cases, you use the hdfs:// URL prefix (three slashes), and then specify the file path. The hdfs scheme uses the Libhdfs++ library to read files and is more efficient than WebHDFS.

The following example loads data stored in HDFS.

```sql
=> COPY t FROM 'hdfs:///opt/data/file1.dat';
```

Vertica uses the fs.defaultFS Hadoop configuration parameter to find the Name Node, which it uses to access the data. You can instead specify a host and port explicitly using the following format: hdfs://host:port/. The specified host is the Name Node, not an individual data node. If you are using High Availability (HA) Name Nodes you should not use an explicit host because high availability is provided through nameservices instead.

Your HDFS cluster might use High Availability Name Nodes or define nameservices. If so, you should use the nameservice instead of the host and port, in the format hdfs://nameservice/. The nameservice you specify must be defined in hdfs-site.xml.

The following example shows how you can use a nameservice, hadoopNS, with the hdfs scheme.

```sql
=> CREATE EXTERNAL TABLE tt (a1 INT, a2 VARCHAR(20))
AS COPY FROM 'hdfs://hadoopNS/data/file.csv';
```
If you are using Vertica to access data from more than one HDFS cluster, always use explicit nameservices or hosts in the URL. Using hdfs:// could produce unexpected results because Vertica uses the first value of fs.defaultFS that it finds. To access multiple HDFS clusters, you must use host and service names that are globally unique. See Configuring the hdfs Scheme for more information.

**Note:** All characters in URLs that are not a–z, A–Z, 0–9, '-', '.', '_' or '~' must be converted to URL encoding (%NN where NN is a two-digit hexadecimal number). For example, use %20 for space.

### Configuring the hdfs Scheme

Vertica uses information from the Hadoop cluster configuration to support the hdfs scheme. Vertica nodes therefore must have access to certain Hadoop configuration files. To use a cluster with High Availability Name Node or to read from more than one Hadoop cluster, you must perform additional configuration.

For both co-located and separate clusters that use Kerberos authentication, configure Vertica for Kerberos as explained in Configure Vertica for Kerberos Authentication.

Using the hdfs scheme still requires access to the WebHDFS service. For some special cases, Vertica cannot use the hdfs scheme and falls back to webhdfs.

### Accessing Hadoop Configuration Files

To support the hdfs scheme, your Vertica nodes need access to certain Hadoop configuration files:

- If Vertica is co-located on HDFS nodes, then those configuration files are already present.

- If Vertica is running on a separate cluster, you must copy the required files to all database nodes. A simple way to do so is to configure your Vertica nodes as Hadoop edge nodes. Client applications run on edge nodes; from Hadoop’s perspective, Vertica is a client application. You can use Ambari or Cloudera Manager to configure edge nodes. For more information, see the documentation from your Hadoop vendor.

Verify that the value of the HadoopConfDir configuration parameter (see Apache Hadoop Parameters) includes a directory containing the files listed in the following table. If you do not set a value, Vertica looks for the files in /etc/hadoop/conf. You can use the VERIFY_HADOOP_CONF_DIR meta-function to verify that Vertica can find configuration files.
Vertica uses the following configuration files and properties. If a property is not defined, Vertica uses the defaults shown in the table. Your Hadoop configuration files must specify all properties that have no defaults.

<table>
<thead>
<tr>
<th>File</th>
<th>Properties</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>core-site.xml</td>
<td>fs.defaultFS</td>
<td>none</td>
</tr>
<tr>
<td></td>

<tr>
<td></td>
<td>ipc.client.connect.retry.interval</td>
<td>10 seconds</td>
</tr>
<tr>
<td></td>
<td>(For HA NN:) dfs.nameservices</td>
<td>none</td>
</tr>
</tbody>
</table>

Using a Cluster with High Availability Name Nodes

If your Hadoop cluster uses High Availability (HA) Name Nodes, verify that the dfs.nameservices parameter and the individual name nodes are defined in hdfs-site.xml.

Using More Than One Hadoop Cluster

In some cases, a Vertica cluster requires access to more than one HDFS cluster. For example, your business might use separate HDFS clusters for separate regions, or you might need data from both test and deployment clusters.

To support multiple clusters, perform the following steps:

1. Copy the configuration files from all HDFS clusters to your database nodes. You can place the copied files in any location readable by Vertica. However, as a best practice, you should place them all in the same directory tree, with one subdirectory per HDFS cluster. The locations must be the same on all database nodes.

2. Set the HadoopConfDir configuration parameter. The value is a colon-separated path containing the directories for all of your HDFS clusters.
3. Use an explicit name node or name service in the URL when creating an external table or copying data. Do not use hdfs:// because it could be ambiguous. For more information about URLs, see HDFS URL Format.

Vertica connects directly to a name node or name service; it does not otherwise distinguish among HDFS clusters. Therefore, names of HDFS name nodes and name services must be globally unique.

Updating Configuration Files

If you update the configuration files after starting Vertica, use the following statement to refresh them:

```sql
=> SELECT CLEAR_HDFS_CACHES();
```

The CLEAR_HDFS_CACHES function also flushes information about which Name Node is active in a High Availability (HA) Hadoop cluster. Therefore, the first hdfs request after calling this function is slow, because the initial connection to the Name Node can take more than 15 seconds.

Troubleshooting Reads from the hdfs Scheme

You might encounter the following issues when using the hdfs URL scheme to access data in HDFS.

WebHDFS Error When Using hdfs URLs

When creating an external table or loading data and using the hdfs scheme, you might see errors from WebHDFS failures. Such errors indicate that Vertica was not able to use the hdfs scheme and fell back to webhdfs, but that the WebHDFS configuration is incorrect. Verify that the HDFS configuration files in HadoopConfDir have the correct WebHDFS configuration for your Hadoop cluster. See Configuring the hdfs Scheme for information about use of these files. See your Hadoop documentation for information about WebHDFS configuration.
Queries Take a Long Time to Run When Using HA

The High Availability Name Node feature in HDFS allows a name node to fail over to a standby name node. The dfs.client.failover.max.attempts configuration parameter (in hdfs-site.xml) specifies how many attempts to make when failing over. Vertica uses a default value of 4 if this parameter is not set. After reaching the maximum number of failover attempts, Vertica concludes that the HDFS cluster is unavailable and aborts the operation. A second parameter, ipc.client.connect.retry.interval, specifies the time to wait between attempts, with typical values being 10 to 20 seconds.

Cloudera and Hortonworks both provide tools to automatically generate configuration files. These tools can set the maximum number of failover attempts to a much higher number (50 or 100). If the HDFS cluster is unavailable (all name nodes are unreachable), Vertica can appear to hang for an extended period (minutes to hours) while trying to connect.

Failover attempts are logged in the QUERYEVENTS system table. The following example shows how to query this table to find these events:

```sql
=> SELECT event_category, event_type, event_description, operator_name,
    event_details, count(event_type) AS count
FROM query_events
WHERE event_type ilike 'LibHDFS++ FAILOVER RETRY'
GROUP BY event_category, event_type, event_description, operator_name, event_details;
```

<table>
<thead>
<tr>
<th>event_category</th>
<th>event_type</th>
<th>event_description</th>
<th>operator_name</th>
<th>event_details</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXECUTION</td>
<td>LibHDFS++ FAILOVER RETRY</td>
<td>LibHDFS++ Namenode failover and retry.</td>
<td>LibHDFS++ FileSystem</td>
<td>Libhdfs++ request failed on ns</td>
<td>4</td>
</tr>
</tbody>
</table>

You can either wait for Vertica to complete or abort the connection, or set the dfs.client.failover.max.attempts parameter to a lower value.
Exporting Data

You might want to export data from Vertica, either to share it with other Hadoop-based applications or to move lower-priority data from ROS to less-expensive storage. You can use the EXPORT TO PARQUET statement to export a table (or part of one) as Parquet data.

You can export data to HDFS, S3, or the local file system. You can export ROS data or data that is readable through external tables. After exporting ROS data, you can drop affected ROS partitions to reclaim storage space. If you need to access the data in Vertica again, you can create external tables from the exported data.

After exporting data, you can define external tables to read that data in Vertica. See Working with External Data.

Syntax

Use the EXPORT TO PARQUET statement to export data specified by a SELECT statement, as in the following example:

```
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_data')
    AS SELECT * FROM public.sales;
Rows Exported
-------------------
  14336
(1 row)
```

The directory argument specifies where to write the files and is required. You must have permission to write to the output directory. The directory must not already exist. You can export to the local disk, HDFS, or S3. For additional considerations specific to S3, see Exporting to S3.

**Note:** You can only perform one export per output directory. If you perform more than one concurrent export to the same directory, only one will succeed.

You can use EXPORT TO PARQUET to write queries across multiple tables in Vertica and export the results. With this approach you can take advantage of powerful, fast query execution in Vertica while making the results available to other Hadoop clients:

```
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_by_region')
    AS SELECT sale.price, sale.date, store.region
    FROM public.sales sale
    JOIN public.vendor store ON sale.distribID = store.ID;
```
EXPORT TO PARQUET takes optional parameters to specify compression format and row-group size (in MB), as in the following example:

```sql
=> EXPORT TO PARQUET(directory='s3://DataLake/sales_data',
   compression = 'uncompressed', rowGroupSizeMB = 32)
   AS SELECT * FROM public.sales;
```

 Rows Exported
-----------------
 14336
 (1 row)

The default compression type is Snappy.

The row-group size affects memory consumption during export. An export thread consumes at least 64MB of RAM if the value is 64. The default value of 64 is a compromise between writing larger row groups and allowing enough free memory for other Vertica operations. If you perform exports when the database is not otherwise under heavy load, you can improve read performance on the exported data by increasing row-group size on export. However, row groups that span multiple blocks on HDFS decrease read performance by requiring more I/O, so do not set the row-group size to be larger than your HDFS block size.

You can limit the size of output files by using the optional fileSizeMB parameter. See the reference documentation.

When exporting data you can use an OVER() clause to partition and sort the data as described in Partitioning and Sorting Data. Partitioning and sorting can improve query performance.

### Partitioning and Sorting Data

When exporting, you can use the optional OVER clause in the SELECT statement to specify how to partition and/or sort the exported data. Partitioning reduces the sizes of the output data files and can improve performance when Vertica queries external tables containing this data. (See Using Partition Columns.) If you do not specify how to partition the data, Vertica optimizes the export for maximum parallelism.

To specify partition columns, use PARTITION BY in the OVER clause as in the following example:

```sql
=> EXPORT TO PARQUET(directory = 'hdfs:///data/export')
   OVER(PARTITION BY date) AS SELECT date, price FROM public.sales;
```

 Rows Exported
-----------------
 14336
 (1 row)
You can sort values within each partition for a further performance improvement. Sort table columns based on the likelihood of their occurrence in query predicates; columns that most frequently occur in comparison or range predicates should be sorted first. You can sort values within each partition using ORDER BY in the OVER clause:

```sql
=> EXPORT TO PARQUET(directory = 'hdfs:///data/export')
  OVER(PARTITION BY date ORDER BY price) AS SELECT date, price FROM public.sales;
Rows Exported
-------------------
  28337
(1 row)
```

You can use ORDER BY even without partitioning. Storing data in sorted order can improve data access and predicate evaluation performance.

Targets in the OVER clause must be column references; they cannot be expressions. For more information about OVER, see SQL Analytics.

If you are exporting data to a local file system, you might want to force a single node to write all of the files. To do so, use an empty OVER clause.

## Exporting to S3

The S3 file system has some differences from other file systems that affect data export. You must set some additional configuration parameters for authentication and region, and there are some restrictions on the output.

### Configuration Parameters

To access S3 you must create an IAM role and grant that role permission to access your S3 resources. For more information about IAM roles, see Amazon's Web Services documentation.

Vertica uses several configuration parameters related to AWS, which can be set for the database or for a session. See AWS Parameters for the complete list. These parameters include:

- **AWSRegion**: the region containing the output S3 bucket. This configuration parameter affects all S3 access from the database, including reads, so if you are using S3 in other ways, set this as a session parameter to avoid conflicts.
- **AWSAuth**: the value is an ID (AccessKeyId) and a secret key (SecretAccessKey), formatted 'id:secret'. Use a session parameter to avoid storing credentials in the database.

- **AWSSessionToken**, if you are using multi-factor authentication: the value is a token generated by AWS STS. You must use a session parameter; AWS session tokens expire.

### Output Restrictions

S3 limits buckets to 5TB. You might need to divide very large exports.

The S3 file system does not support renaming files in place; it implements a rename as a copy followed by a delete. On other file systems, EXPORT TO PARQUET supports atomicity by writing its output into a temporary directory and renaming it when complete. Such an approach is impractical for S3, so EXPORT TO PARQUET writes directly to the destination path. It is therefore possible to begin reading the exported data before the export has finished, which could lead to errors. Be careful to wait for the export to finish before using the data.

On other file systems, Vertica retries a failed query if the database is K-safe. When exporting to S3, Vertica does not retry the export and instead reports an error. For example, if a node goes down during export, Vertica returns Error 4142 (Node failure during execution).

If you cancel an export or an export fails, Vertica does not clean up the partial output. On S3, that partial output costs you money, so after a cancellation or failure, delete the files on S3. Further, because the output path must not exist, you would need to delete the partial output before retrying the export with the same destination.

Be careful to avoid concurrent exports to the same output destination. Doing so is an error on any file system, and on other file systems the result is that only one export can succeed. Doing so on S3 could produce incorrect results because of the way S3 propagates changes.

### Data Types

EXPORT TO PARQUET converts Vertica data types to Hive data types as shown in the following table.

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Hive Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER, BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>FLOAT, DECIMAL, SMALLINT, TINYINT, CHAR, BOOLEAN</td>
<td>Corresponding Hive type</td>
</tr>
</tbody>
</table>
### Vertica Data Type | Hive Data Type
---|---
VARCHAR, LONG VARCHAR | VARCHAR (max 64KB) or STRING (can be read as either)
BINARY, VARBINARY, LONG VARBINARY | BINARY
DATE | DATE if supported by your version of Hive, otherwise INT96 (can be read as TIMESTAMP)
TIMESTAMP, TIMESTAMPTZ | TIMESTAMP
TIME, TIMEZ, INTERVAL | Not supported

You cannot export columns with the TIME, TIMEZ, and INTERVAL data types. If your table includes columns of these types, exclude them by explicitly selecting the columns you can export:

```sql
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_data') 
   AS SELECT date, transactionID, price FROM public.sales;
Rows Exported
----------
14336
(1 row)
```
Using the HCatalog Connector

The Vertica HCatalog Connector lets you access data stored in Apache's Hive data warehouse software the same way you access it within a native Vertica table.

If your files are in the Optimized Columnar Row (ORC) or Parquet format and do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. See Reading ORC and Parquet Formats for more information about these readers.

The HCatalog Connector performs predicate pushdown to improve query performance. Instead of reading all data across the network to evaluate a query, the HCatalog Connector moves the evaluation of predicates closer to the data. Predicate pushdown applies to Hive partition pruning, ORC stripe pruning, and Parquet row-group pruning. The HCatalog Connector supports predicate pushdown for the following predicates: >, >=, =, <>, <=, <.

Overview

There are several Hadoop components that you need to understand to use the HCatalog connector:

- Apache Hive lets you query data stored in a Hadoop Distributed File System (HDFS) the same way you query data stored in a relational database. Behind the scenes, Hive uses a set of serializer and deserializer (SerDe) classes to extract data from files stored in HDFS and break it into columns and rows. Each SerDe handles data files in a specific format. For example, one SerDe extracts data from comma-separated data files while another interprets data stored in JSON format.

- Apache HCatalog is a component of the Hadoop ecosystem that makes Hive's metadata available to other Hadoop components (such as Pig).

- HiveServer2 makes HCatalog and Hive data available via JDBC. Through it, a client can make requests to retrieve data stored in Hive, as well as information about the Hive schema. HiveServer2 can use authorization services (Sentry or Ranger). HiverServer2 can use Hive LLAP (Live Long And Process).

The Vertica HCatalog Connector lets you transparently access data that is available through HiveServer2. You use the connector to define a schema in Vertica that corresponds to a Hive database or schema. When you query data within this schema, the HCatalog Connector
transparently extracts and formats the data from Hadoop into tabular data. Vertica supports authorization services and Hive LLAP.

Note: You can use the WebHCat service instead of HiveServer2, but performance is usually better with HiveServer2. Support for WebHCat is deprecated. To use WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0. See Apache Hadoop Parameters. WebHCat does not support authorization services.

HCatalog Connection Features

The HCatalog Connector lets you query data stored in Hive using the Vertica native SQL syntax. Some of its main features are:

- The HCatalog Connector always reflects the current state of data stored in Hive.
- The HCatalog Connector uses the parallel nature of both Vertica and Hadoop to process Hive data. The result is that querying data through the HCatalog Connector is often faster than querying the data directly through Hive.
- Because Vertica performs the extraction and parsing of data, the HCatalog Connector does not significantly increase the load on your Hadoop cluster.
- The data you query through the HCatalog Connector can be used as if it were native Vertica data. For example, you can execute a query that joins data from a table in an HCatalog schema with a native table.

HCatalog Connector Considerations

There are a few things to keep in mind when using the HCatalog Connector:

- Hive's data is stored in flat files in a distributed filesystem, requiring it to be read and deserialized each time it is queried. This deserialization causes Hive performance to be much slower than that of Vertica. The HCatalog Connector has to perform the same process as Hive to read the data. Therefore, querying data stored in Hive using the HCatalog Connector is much slower than querying a native Vertica table. If you need to perform extensive analysis on data stored in Hive, you should consider loading it into Vertica. Vertica optimization often makes querying data through the HCatalog Connector faster than directly querying it through Hive.
• If Hive uses Kerberos security, the HCatalog Connector uses the querying user’s credentials in queries by default. If Hive uses Sentry or Ranger to enforce security, then you must either disable this behavior in Vertica by setting EnableHCatImpersonation to 0 or grant users access to the underlying data in HDFS. (Sentry supports ACL synchronization to automatically grant access.) Alternatively, you can specify delegation tokens for data and metadata access. See Configuring Security.

• Hive supports complex data types such as lists, maps, and structs that Vertica does not support. Columns containing these data types are converted to a JSON representation of the data type and stored as a VARCHAR. See Data Type Conversions from Hive to Vertica.

Note: The HCatalog Connector is read-only. It cannot insert data into Hive.

How the HCatalog Connector Works

When planning a query that accesses data from a Hive table, the Vertica HCatalog Connector on the initiator node contacts HiveServer2 (or WebHCat) in your Hadoop cluster to determine if the table exists. If it does, the connector retrieves the table’s metadata from the metastore database so the query planning can continue. When the query executes, all nodes in the Vertica cluster directly retrieve the data necessary for completing the query from HDFS. They then use the Hive SerDe classes to extract the data so the query can execute. When accessing data in ORC or Parquet format, the HCatalog Connector uses Vertica's internal readers for these formats instead of the Hive SerDe classes.
This approach takes advantage of the parallel nature of both Vertica and Hadoop. In addition, by performing the retrieval and extraction of data directly, the HCatalog Connector reduces the impact of the query on the Hadoop cluster.

For files in the Optimized Columnar Row (ORC) or Parquet format that do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. You can direct these readers to access custom Hive partition locations if Hive used them when writing the data. By default these extra checks are turned off to improve performance.

**HCatalog Connector Requirements**

Before you can use the HCatalog Connector, both your Vertica and Hadoop installations must meet the following requirements.

**Vertica Requirements**

All of the nodes in your cluster must have a Java Virtual Machine (JVM) installed. You must use the same Java version that the Hadoop cluster uses. See [Installing the Java Runtime on Your Vertica Cluster](#).

You must also add certain libraries distributed with Hadoop and Hive to your Vertica installation directory. See [Configuring Vertica for HCatalog](#).
Hadoop Requirements

Your Hadoop cluster must meet several requirements to operate correctly with the Vertica Connector for HCatalog:

- It must have Hive, HiveServer2, and HCatalog installed and running. See Apache's HCatalog page for more information.

- The HiveServer2 server and all of the HDFS nodes that store HCatalog data must be directly accessible from all of the hosts in your Vertica database. Verify that any firewall separating the Hadoop cluster and the Vertica cluster will pass HiveServer2, metastore database, and HDFS traffic.

- The data that you want to query must be in an internal or external Hive table.

- If a table you want to query uses a non-standard SerDe, you must install the SerDe's classes on your Vertica cluster before you can query the data. See Using Nonstandard SerDes.

Installing the Java Runtime on Your Vertica Cluster

The HCatalog Connector requires a 64-bit Java Virtual Machine (JVM). The JVM must support Java 6 or later, and must be the same version as the one installed on your Hadoop nodes.

Note: If your Vertica cluster is configured to execute User Defined Extensions (UDxs) written in Java, it already has a correctly-configured JVM installed. See Developing User-Defined Extensions (UDxs) in Extending Vertica for more information.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.

2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.
Installing a Java Runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or OpenJDK. You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the Java Standard Edition (SE) Download Page. You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the java command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

Note: Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

Setting the JavaBinaryForUDx Configuration Parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example /usr/bin/java). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```
If the java command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in /usr/java/default (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is /usr/java/default/bin/java.

You set the configuration parameter by executing the following statement as a database superuser:

```sql
=> ALTER DATABASE mydb SET JavaBinaryForUDx = '/usr/bin/java';
```

See ALTER DATABASE for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the CONFIGURATION_PARAMETERS system table:

```sql
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>parameter_name</th>
<th>current_value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>JavaBinaryForUDx</td>
<td>/usr/bin/java</td>
<td>Path to the java binary for executing UDx written in Java</td>
</tr>
</tbody>
</table>

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

Note: Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

### Configuring Vertica for HCatalog

Before you can use the HCatalog Connector, you must add certain Hadoop and Hive libraries to your Vertica installation. You must also copy the Hadoop configuration files that specify various connection properties. Vertica uses the values in those configuration files to make its own connections to Hadoop.

You need only make these changes on one node in your cluster. After you do this you can install the HCatalog connector.
Copy Hadoop Libraries and Configuration Files

Vertica provides a tool, hcatUtil, to collect the required files from Hadoop. This tool copies selected libraries and XML configuration files from your Hadoop cluster to your Vertica cluster. This tool might also need access to additional libraries:

- If you plan to use Hive to query files that use Snappy compression, you need access to the Snappy native libraries, libhadoop*.so and libsnappy*.so.

- If you plan to use Hive to query files that use LZO compression, you need access to the hadoop-lzo-* .jar and libgplcompression.so* libraries. In core-site.xml you must also edit the io.compression.codecs property to include com.hadoop.compression.lzo.LzopCodec.

- If you plan to use a JSON SerDe with a Hive table, you need access to its library. This is the same library that you used to configure Hive; for example:

  ```
  hive> add jar /home/release/json-serde-1.3-jar-with-dependencies.jar;
  
  hive> create external table nationjson (id int,name string,rank int,text string)
  
  ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
  LOCATION '/user/release/vt/nationjson';
  ```

- If you are using any other libraries that are not standard across all supported Hadoop versions, you need access to those libraries.

If any of these cases applies to you, do one of the following:

- Include the path(s) in the path you specify as the value of --hcatLibPath, or

- Copy the file(s) to a directory already on that path.

If Vertica is not co-located on a Hadoop node, you should do the following:

1. Copy /opt/vertica/packages/hcat/tools/hcatUtil to a Hadoop node and run it there, specifying a temporary output directory. Your Hadoop, HIVE, and HCatalog lib paths might be different. In newer versions of Hadoop the HCatalog directory is usually a subdirectory under the HIVE directory, and Cloudera creates a new directory for each revision of the configuration files. Use the values from your environment in the following command:
If you are using Hive LLAP, specify the hive2 directories.

2. Verify that all necessary files were copied:

   hcatUtil --verifyJars --hcatLibPath=/tmp/hadoop-files

3. Copy that output directory (/tmp/hadoop-files, in this example) to /opt/vertica/packages/hcat/lib on the Vertica node you will connect to when installing the HCatalog connector. If you are updating a Vertica cluster to use a new Hadoop cluster (or a new version of Hadoop), first remove all JAR files in /opt/vertica/packages/hcat/lib except vertica-hcatalogudl.jar.

4. Verify that all necessary files were copied:

   hcatUtil --verifyJars --hcatLibPath=/opt/vertica/packages/hcat

If Vertica is co-located on some or all Hadoop nodes, you can do this in one step on a shared node. Your Hadoop, HIVE, and HCatalog lib paths might be different; use the values from your environment in the following command:

   hcatUtil --copyJars
   --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
   --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
   --hcatLibPath="/opt/vertica/packages/hcat/lib"

The hcatUtil script has the following arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c, --copyJars</td>
<td>Copy the required JAR files from hadoopHiveHome and configuration files from hadoopHiveConfPath.</td>
</tr>
<tr>
<td>-v, --verifyJars</td>
<td>Verify that the required files are present in hcatLibPath. Check the output of hcatUtil for error and warning messages.</td>
</tr>
<tr>
<td>--hadoopHiveHome</td>
<td>Paths to the Hadoop, Hive, and HCatalog home directories. Separate directories by semicolons (;). Enclose paths in double quotes.</td>
</tr>
</tbody>
</table>

Note: Always place $HADOOP_HOME on the path before $HIVE_HOME. In some Hadoop distributions, these two directories contain different versions of the same library.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--hadoopHiveConfPath=&quot;value1;value2;...&quot;</code></td>
<td>Paths of the following configuration files:</td>
</tr>
<tr>
<td></td>
<td>• hive-site.xml</td>
</tr>
<tr>
<td></td>
<td>• core-site.xml</td>
</tr>
<tr>
<td></td>
<td>• yarn-site.xml</td>
</tr>
<tr>
<td></td>
<td>• webhcat-site.xml (optional with the default configuration; required if you use WebHCat instead of HiveServer2)</td>
</tr>
<tr>
<td></td>
<td>• hdfs-site.xml</td>
</tr>
<tr>
<td></td>
<td>Separate directories by semicolons (;). Enclose paths in double quotes.</td>
</tr>
<tr>
<td></td>
<td>In previous releases of Vertica this parameter was optional under some conditions. It is now required.</td>
</tr>
<tr>
<td><code>--hcatLibPath=&quot;value&quot;</code></td>
<td>Output path for the libraries and configuration files. On a Vertica node, use <code>/opt/vertica/packages/hcat/lib</code>. If you have previously run hcatUtil with a different version of Hadoop, first remove the old JAR files from the output directory (all except vertica-hcatalogudl.jar).</td>
</tr>
</tbody>
</table>

After you have copied the files and verified them, install the HCatalog connector.

**Install the HCatalog Connector**

On the same node where you copied the files from hcatUtil, install the HCatalog connector by running the `install.sql` script. This script resides in the `ddl/` folder under your HCatalog connector installation path. This script creates the library and `VHCatSource` and `VHCatParser`.

**Note:** The data that was copied using hcatUtil is now stored in the database. If you change any of those values in Hadoop, you need to rerun hcatUtil and `install.sql`. The following statement returns the names of the libraries and configuration files currently being used:

```sql
=> SELECT dependencies FROM user_libraries WHERE lib_name='VHCatalogLib';
```

Now you can create HCatalog schema parameters, which point to your existing Hadoop services, as described in Defining a Schema Using the HCatalog Connector.
Upgrading to a New Version of Vertica

After upgrading to a new version of Vertica, perform the following steps:

1. Uninstall the HCatalog Connector using the uninstall.sql script. This script resides in the ddl/ folder under your HCatalog connector installation path.

2. Delete the contents of the hcatLibPath directory except for vertica-hcatalogudl.jar.

3. Rerun hcatUtil.

4. Reinstall the HCatalog Connector using the install.sql script.

For more information about upgrading Vertica, see Upgrade Vertica.

Additional Options for Hadoop Columnar File Formats

When reading Hadoop columnar file formats (ORC or Parquet), the HCatalog Connector attempts to use the built-in readers. When doing so, it uses the hdfs scheme by default. In order to use the hdfs scheme, you must perform the configuration described in Configuring the hdfs Scheme.

To have the HCatalog Connector use the webhdfs scheme instead, use ALTER DATABASE to set HDFSUseWebHDFS to 1. This setting applies to all HDFS access, not just the HCatalog Connector.

Configuring Security

You can use any of the security options described in Accessing Kerberized HDFS Data to access Hive data. This topic describes additional steps needed specifically for using the HCatalog Connector.

If you use Kerberos from Vertica, the HCatalog Connector can use an authorization service (Sentry or Ranger). If you use delegation tokens, you must manage authorization yourself.
Kerberos

You can use Kerberos from Vertica as described in Using Kerberos with Vertica.

How you configure the HCatalog Connector depends on how Hive manages authorization.

- If Hive uses Sentry to manage authorization, and if Sentry uses ACL synchronization, then the HCatalog Connector must access HDFS as the current user. Verify that the EnableHCatImpersonation configuration parameter is set to 1 (the default). ACL synchronization automatically provides authorized users with read access to the underlying HDFS files.

- If Hive uses Sentry without ACL synchronization, then the HCatalog Connector must access HDFS data as the Vertica principal. (The user still authenticates and accesses metadata normally.) Set the EnableHCatImpersonation configuration parameter to 0. The Vertica principal must have read access to the underlying HDFS files.

- If Hive uses Ranger to manage authorization, and the Vertica users have read access to the underlying HDFS files, then you can use user impersonation. Verify that the EnableHCatImpersonation configuration parameter is set to 1 (the default). You can, instead, disable user impersonation and give the Vertica principal read access to the HDFS files.

- If Hive uses either Sentry or Ranger, the HCatalog Connector must use HiveServer2 (the default). WebHCat does not support authorization services.

- If Hive does not use an authorization service, or if you are connecting to Hive using WebHCat instead of HiveServer2, then the HCatalog Connector accesses Hive as the current user. Verify that EnableHCatImpersonation is set to 1. All users must have read access to the underlying HDFS files.

In addition, in your Hadoop configuration files (core-site.xml in most distributions), make sure that you enable all Hadoop components to impersonate the Vertica user. The easiest way to do so is to set the proxyuser property using wildcards for all users on all hosts and in all groups. Consult your Hadoop documentation for instructions. Make sure you set this property before running hcatUtil (see Configuring Vertica for HCatalog).
Delegation Tokens

You can use delegation tokens for a session as described in Bring Your Own Delegation Token. When using the HCatalog Connector you specify two delegation tokens, one for the data and one for the metadata. The metadata token is tied to a Hive schema. See HadoopImpersonationConfig Format for information about how to specify these two delegation tokens.

Defining a Schema Using the HCatalog Connector

After you set up the HCatalog Connector, you can use it to define a schema in your Vertica database to access the tables in a Hive database. You define the schema using the CREATE HCATALOG SCHEMA statement.

When creating the schema, you must supply the name of the schema to define in Vertica. Other parameters are optional. If you do not supply a value, Vertica uses default values. Vertica reads some default values from the HDFS configuration files; see Configuration Parameters.

To create the schema, you must have read access to all Hive data. Verify that the user creating the schema has been granted access, either directly or through an authorization service such as Sentry or Ranger. The dbadmin user has no automatic special privileges.

After you create the schema, you can change many parameters using the ALTER HCATALOG SCHEMA statement.

After you define the schema, you can query the data in the Hive data warehouse in the same way you query a native Vertica table. The following example demonstrates creating an HCatalog schema and then querying several system tables to examine the contents of the new schema. See Viewing Hive Schema and Table Metadata for more information about these tables.

```sql
CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin';
CREATE SCHEMA
=> \x
Expanded display is on.

SELECT * FROM v_catalog.hcatalog_schemata; 
- [ RECORD 1 ]-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```
Configuration Parameters

The HCatalog Connector uses the following values from the Hadoop configuration files if you do not override them when creating the schema.

<table>
<thead>
<tr>
<th>File</th>
<th>Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>hive-site.xml</td>
<td>hive.server2.thrift.bind.host (used for HIVESERVER2_HOSTNAME)</td>
</tr>
</tbody>
</table>
### Using Partitioned Data

Hive supports partitioning data, as in the following example:

```sql
hive> create table users (name varchar(64), address string, city varchar(64))
    partitioned by (state varchar(64)) stored as orc;
```

Vertica takes advantage of partitioning information for formats that provide it in metadata (ORC and Parquet). Queries can skip irrelevant partitions entirely (partition pruning), and Vertica does not need to materialize partition columns. For more about use of partitions, see [Improving Query Performance for Data Stored in HDFS](#) and [Using Partition Columns](#).

By default Hive stores partition information under the path for the table definition, which might be local to Hive. However, a Hive user can choose to store partition information elsewhere, such as in a shared location like S3, as in the following example:

```sql
hive> alter table users add partition (state='MA')
    location 's3a://DataLake/partitions/users/state=MA';
```
During query execution, therefore, Vertica must query Hive for the location of a table's partition information.

Because the additional Hive queries can be expensive, Vertica defaults to looking for partition information only in Hive's default location. If your Hive table specified a custom location, use the CUSTOM_PARTITIONS parameter:

```plaintext
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
   HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
   SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin'
   CUSTOM_PARTITIONS='yes';
```

Vertica can access partition locations in the S3 and S3a schemes, and does not support the S3n scheme.

The HIVE_CUSTOM_PARTITIONS_ACCESS system table records all custom partition locations that have been used in queries.

Using the HCatalog Connector with WebHCat

By default the HCatalog Connector uses HiveServer2 to access Hive data. If you are instead using WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0 before creating the schema as in the following example.

```plaintext
=> ALTER DATABASE mydb SET HCatalogConnectorUseHiveServer2 = 0;
=> CREATE HCATALOG SCHEMA hcat WITH WEBSERVICE_HOSTNAME='webhcat.example.com';
```

If you have previously used WebHCat, you can switch to using HiveServer2 by setting the configuration parameter to 1 and using ALTER HCATALOG SCHEMA to set HIVESERVER2_HOSTNAME. You do not need to remove the WebHCat values; the HCatalog Connector uses the value of HCatalogConnectorUseHiveServer2 to determine which parameters to use.

**Querying Hive Tables Using HCatalog Connector**

Once you have defined the HCatalog schema, you can query data from the Hive database by using the schema name in your query.

```plaintext
=> SELECT * from hcat.messages limit 10;
```

<table>
<thead>
<tr>
<th>messageid</th>
<th>userid</th>
<th>time</th>
<th>message</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Since the tables you access through the HCatalog Connector act like Vertica tables, you can perform operations that use both Hive data and native Vertica data, such as a join:

```sql
=> SELECT u.FirstName, u.LastName, d.time, d.Message from UserData u
JOIN hcat.messages d ON u.UserID = d.UserID LIMIT 10;
```

<table>
<thead>
<tr>
<th>FirstName</th>
<th>LastName</th>
<th>time</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Whitney</td>
<td>Kerr</td>
<td>2013-10-29</td>
<td>hymenaeos cursus lorem Suspendis</td>
</tr>
<tr>
<td>Troy</td>
<td>Oneal</td>
<td>2013-10-29</td>
<td>Fusce ad sem vehicula morbi</td>
</tr>
<tr>
<td>Renee</td>
<td>Coleman</td>
<td>2013-10-29</td>
<td>porta Vivamus condimentum</td>
</tr>

<td>Eaton</td>
<td>2013-10-29</td>
<td>turpis vehicula tortor</td>
</tr>
<tr>
<td>Cade</td>
<td>Barr</td>
<td>2013-10-29</td>
<td>sapien adipiscing eget Aliquam tor</td>
</tr>
<tr>
<td>Oprah</td>
<td>Mcmillan</td>
<td>2013-10-29</td>
<td>varius Cum iaculis metus</td>
</tr>
<tr>
<td>Astra</td>
<td>Sherman</td>
<td>2013-10-29</td>
<td>dignissim odio Pellentesque primis</td>
</tr>
<tr>
<td>Chelsea</td>
<td>Malone</td>
<td>2013-10-29</td>
<td>pede tempor dignissim Sed luctus</td>
</tr>
</tbody>
</table>

(10 rows)

### Viewing Hive Schema and Table Metadata

When using Hive, you access metadata about schemas and tables by executing statements written in HiveQL (Hive's version of SQL) such as `SHOW TABLES`. When using the HCatalog Connector, you can get metadata about the tables in the Hive database through several Vertica system tables.

There are four system tables that contain metadata about the tables accessible through the HCatalog Connector:

- **HCATALOG_SCHEMATA** lists all of the schemas that have been defined using the HCatalog Connector.

- **HCATALOG_TABLE_LIST** contains an overview of all of the tables available from all schemas defined using the HCatalog Connector. This table only shows the tables that the user querying the table can access. The information in this table is retrieved using a single call to
HiveServer2 for each schema defined using the HCatalog Connector, which means there is a little overhead when querying this table.

- **HCATALOG_TABLES** contains more in-depth information than HCATALOG_TABLE_LIST.

- **HCATALOG_COLUMNS** lists metadata about all of the columns in all of the tables available through the HCatalog Connector. As for HCATALOG_TABLES, querying this table results in one call to HiveServer2 per table, and therefore can take a while to complete.

The following example demonstrates querying the system tables containing metadata for the tables available through the HCatalog Connector.

```sql
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost'
-> HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT * FROM HCATALOG_SCHEMA;
-[- RECORD 1 ]---------------------------

Vertica Documentation
Integrating with Apache Hadoop
Synchronizing an HCatalog Schema or Table With a Local Schema or Table

Querying data from an HCatalog schema can be slow due to Hive performance issues. This slow performance can be especially annoying when you want to examine the structure of the tables in the Hive database. Getting this information from Hive requires you to query the HCatalog schema's metadata using the HCatalog Connector.

To avoid this performance problem you can use the `SYNC_WITH_HCATALOG_SCHEMA` function to create a snapshot of the HCatalog schema's metadata within a Vertica schema. You supply this function with the name of a pre-existing Vertica schema, typically the one created through `CREATE HCATALOG SCHEMA`, and a Hive schema available through the HCatalog Connector. You must have permission both in Vertica to write the data and in Hive and HDFS to read it.

Note: To synchronize a schema, you must have read permission for the underlying files in HDFS. If Hive uses Sentry to manage authorization, then you can use ACL synchronization to manage HDFS access. Otherwise, the user of this function must have read access in HDFS.

The function creates a set of external tables within the Vertica schema that you can then use to examine the structure of the tables in the Hive database. Because the metadata in the Vertica schema is local, query planning is much faster. You can also use standard Vertica statements and system-table queries to examine the structure of Hive tables in the HCatalog schema.

Caution: The `SYNC_WITH_HCATALOG_SCHEMA` function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

When `SYNC_WITH_HCATALOG_SCHEMA` creates tables in Vertica, it matches Hive's STRING and BINARY types to Vertica's VARCHAR(65000) and VARBINARY(65000) types. You might want to change these lengths, using `ALTER TABLE` SET DATA TYPE, in two cases:

- If the value in Hive is larger than 65000 bytes, increase the size and use LONG VARCHAR or LONG VARBINARY to avoid data truncation. If a Hive string uses multi-byte encodings, you must increase the size in Vertica to avoid data truncation. This step is needed because Hive counts string length in characters while Vertica counts it in bytes.

- If the value in Hive is much smaller than 65000 bytes, reduce the size to conserve memory in Vertica.
The Vertica schema is just a snapshot of the HCatalog schema's metadata. Vertica does not synchronize later changes to the HCatalog schema with the local schema after you call SYNC_WITH_HCATALOG_SCHEMA. You can call the function again to re-synchronize the local schema to the HCatalog schema. If you altered column data types, you will need to repeat those changes because the function creates new external tables.

By default, SYNC_WITH_HCATALOG_SCHEMA does not drop tables that appear in the local schema that do not appear in the HCatalog schema. Thus, after the function call the local schema does not reflect tables that have been dropped in the Hive database since the previous call. You can change this behavior by supplying the optional third Boolean argument that tells the function to drop any table in the local schema that does not correspond to a table in the HCatalog schema.

Instead of synchronizing the entire schema, you can synchronize individual tables by using SYNC_WITH_HCATALOG_SCHEMA_TABLE. If the table already exists in Vertica the function overwrites it. If the table is not found in the HCatalog schema, this function returns an error. In all other respects this function behaves in the same way as SYNC_WITH_HCATALOG_SCHEMA.

If you change the settings of any HCatalog Connector configuration parameters (Apache Hadoop Parameters), you must call this function again.

Examples

The following example demonstrates calling SYNC_WITH_HCATALOG_SCHEMA to synchronize the HCatalog schema in Vertica with the metadata in Hive. Because it synchronizes the HCatalog schema directly, instead of synchronizing another schema with the HCatalog schema, both arguments are the same.

```
=> CREATE HCATALOG_SCHEMA hcat WITH hostname='hcathost' HCATALOG_SCHEMA='default'
    HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema
-----------------------------
Schema hcat synchronized with hcat
    tables in hcat = 56
    tables altered in hcat = 0
    tables created in hcat = 56
    stale tables in hcat = 0
    table changes errored in hcat = 0
    (1 row)
=> -- Use vsql's \d command to describe a table in the synced schema

=> \d hcat.messages
List of Fields by Tables
  Schema | Table | Column | Type   | Size | Default | Not Null | Primary Key | Foreign
Key
```
This example shows synchronizing with a schema created using `CREATE HCATALOG SCHEMA`. Synchronizing with a schema created using `CREATE SCHEMA` is also supported.

You can query tables in the local schema that you synchronized with an HCatalog schema. However, querying tables in a synchronized schema isn't much faster than directly querying the HCatalog schema, because `SYNC_WITH_HCATALOG_SCHEMA` only duplicates the HCatalog schema's metadata. The data in the table is still retrieved using the HCatalog Connector,

## Data Type Conversions from Hive to Vertica

The data types recognized by Hive differ from the data types recognized by Vertica. The following table lists how the HCatalog Connector converts Hive data types into data types compatible with Vertica.

<table>
<thead>
<tr>
<th>Hive Data Type</th>
<th>Vertica Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT (1-byte)</td>
<td>TINYINT (8-bytes)</td>
</tr>
<tr>
<td>SMALLINT (2-bytes)</td>
<td>SMALLINT (8-bytes)</td>
</tr>
<tr>
<td>INT (4-bytes)</td>
<td>INT (8-bytes)</td>
</tr>
<tr>
<td>BIGINT (8-bytes)</td>
<td>BIGINT (8-bytes)</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>BOOLEAN</td>
</tr>
<tr>
<td>FLOAT (4-bytes)</td>
<td>FLOAT (8-bytes)</td>
</tr>
<tr>
<td>DECIMAL (precision, scale)</td>
<td>DECIMAL (precision, scale)</td>
</tr>
<tr>
<td>DOUBLE (8-bytes)</td>
<td>DOUBLE PRECISION (8-bytes)</td>
</tr>
<tr>
<td>CHAR (length in characters)</td>
<td>CHAR (length in bytes)</td>
</tr>
<tr>
<td>VARCHAR (length in characters)</td>
<td>VARCHAR (length in bytes), if length &lt;= 65000</td>
</tr>
<tr>
<td></td>
<td>LONG VARCHAR (length in bytes), if length &gt; 65000</td>
</tr>
</tbody>
</table>
### Data-Width Handling Differences Between Hive and Vertica

The HCatalog Connector relies on Hive SerDe classes to extract data from files on HDFS. Therefore, the data read from these files are subject to Hive's data width restrictions. For example, suppose the SerDe parses a value for an INT column into a value that is greater than \(2^{32}-1\) (the maximum value for a 32-bit integer). In this case, the value is rejected even if it would fit into a Vertica's 64-bit INTEGER column because it cannot fit into Hive's 32-bit INT.

Hive measures CHAR and VARCHAR length in characters and Vertica measures them in bytes. Therefore, if multi-byte encodings are being used (like Unicode), text might be truncated in Vertica.

Once the value has been parsed and converted to a Vertica data type, it is treated as native data. This treatment can result in some confusion when comparing the results of an identical query run in Hive and in Vertica. For example, if your query adds two INT values that result in a value that is larger than \(2^{32}-1\), the value overflows its 32-bit INT data type, causing Hive to return an error. When running the same query with the same data in Vertica using the HCatalog Connector, the value will probably still fit within Vertica's 64-int value. Thus the addition is successful and returns a value.

<table>
<thead>
<tr>
<th>Hive Data Type</th>
<th>Vertica Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRING (2 GB max)</td>
<td>VARCHAR (65000)</td>
</tr>
<tr>
<td>BINARY (2 GB max)</td>
<td>VARBINARY (65000)</td>
</tr>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td>LIST/ARRAY</td>
<td>VARCHAR (65000) containing a JSON-format representation of the list.</td>
</tr>
<tr>
<td>MAP</td>
<td>VARCHAR (65000) containing a JSON-format representation of the map.</td>
</tr>
<tr>
<td>STRUCT</td>
<td>VARCHAR (65000) containing a JSON-format representation of the struct.</td>
</tr>
</tbody>
</table>
Using Nonstandard SerDes

Hive stores its data in unstructured flat files located in the Hadoop Distributed File System (HDFS). When you execute a Hive query, it uses a set of serializer and deserializer (SerDe) classes to extract data from these flat files and organize it into a relational database table. For Hive to be able to extract data from a file, it must have a SerDe that can parse the data the file contains. When you create a table in Hive, you can select the SerDe to be used for the table's data.

Hive has a set of standard SerDes that handle data in several formats such as delimited data and data extracted using regular expressions. You can also use third-party or custom-defined SerDes that allow Hive to process data stored in other file formats. For example, some commonly-used third-party SerDes handle data stored in JSON format.

The HCatalog Connector directly fetches file segments from HDFS and uses Hive's SerDes classes to extract data from them. The Connector includes all Hive's standard SerDes classes, so it can process data stored in any file that Hive natively supports. If you want to query data from a Hive table that uses a custom SerDe, you must first install the SerDe classes on the Vertica cluster.

Determining Which SerDe You Need

If you have access to the Hive command line, you can determine which SerDe a table uses by using Hive's SHOW CREATE TABLE statement. This statement shows the HiveQL statement needed to recreate the table. For example:

```sql
hive> SHOW CREATE TABLE msgjson;
OK
CREATE EXTERNAL TABLE msgjson(
  messageid int COMMENT 'from deserializer',
  userid string COMMENT 'from deserializer',
  time string COMMENT 'from deserializer',
  message string COMMENT 'from deserializer')
ROW FORMAT SERDE
  'org.apache.hadoop.hive.contrib.serde2.JsonSerde'
STORED AS INPUTFORMAT
  'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
  'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
  'hdfs://hivehost.example.com:8020/user/exampleuser/msgjson'
TBLPROPERTIES
  ('transient_lastDdlTime'='1384194521')
Time taken: 0.167 seconds
```
In the example, ROW FORMAT SERDE indicates that a special SerDe is used to parse the data files. The next row shows that the class for the SerDe is named org.apache.hadoop.hive.contrib.serde2.JsonSerde. You must provide the HCatalog Connector with a copy of this SerDe class so that it can read the data from this table.

You can also find out which SerDe class you need by querying the table that uses the custom SerDe. The query will fail with an error message that contains the class name of the SerDe needed to parse the data in the table. In the following example, the portion of the error message that names the missing SerDe class is in bold.

```sql
=> SELECT * FROM hcat.jsontable;
ERROR 3399: Failure in U Dx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [org.apache.hcatalog.common.HCatException: 2004 : HCatOutputFormat not initialized, setOutput has to be called. Cause : java.io.IOException: java.lang.RuntimeException: MetaException (message:org.apache.hadoop.hive.serde2.SerDeException SerDe com.cloudera.hive.serde.JSONSerDe does not exist) ] HINT If error message is not descriptive or local, may be we cannot read metadata from hive metastore service thrift://hcathost:9083 or HDFS namenode (check U DxLogs/U DxFencedProcessesJava.log in the catalog directory for more information)
at com.vertica.hcatalogudl.HCatalogSplitsNoOpSourceFactory .plan(HCatalogSplitsNoOpSourceFactory.java:98)
at com.vertica.udxfence.U DxExecContext.planUDSource(U DxExecContext.java:898)
...
```

### Installing the SerDe on the Vertica Cluster

You usually have two options to getting the SerDe class file the HCatalog Connector needs:

- **Find the installation files for the SerDe, then copy those over to your Vertica cluster.** For example, there are several third-party JSON SerDes available from sites like Google Code and GitHub. You may find the one that matches the file installed on your Hive cluster. If so, then download the package and copy it to your Vertica cluster.

- **Directly copy the JAR files from a Hive server onto your Vertica cluster.** The location for the SerDe JAR files depends on your Hive installation. On some systems, they may be located in /usr/lib/hive/lib.

Wherever you get the files, copy them into the /opt/vertica/packages/hcat/lib directory on every node in your Vertica cluster.

**Important:** If you add a new host to your Vertica cluster, remember to copy every custom SerDe JAR file to it.
Troubleshooting HCatalog Connector Problems

You may encounter the following issues when using the HCatalog Connector.

Connection Errors

The HCatalog Connector can encounter errors both when you define a schema and when you query it. The types of errors you get depend on which CREATE HCATALOG SCHEMA parameters are incorrect. Suppose you have incorrect parameters for the metastore database, but correct parameters for HiveServer2. In this case, HCatalog-related system table queries succeed, while queries on the HCatalog schema fail. The following example demonstrates creating an HCatalog schema with the correct default HiveServer2 information. However, the port number for the metastore database is incorrect.

```sql
=> CREATE HCATALOG SCHEMA hcat2 WITH hostname='hcathost'
  HCATALOG_SCHEMA='default' HCATALOG_USER='hive' PORT=1234;
=> CREATE SCHEMA
=> SELECT * FROM HCATALOG_TABLE_LIST;
- RECORD 1 ]------------------------
table_schema_id | 45035996273864536
    table_schema | hcat2
    hcatalog_schema | default
    table_name | test
    hcatalog_user_name | hive

=> SELECT * FROM hcat2.test;
ERROR 3399: Failure in Udx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [
  org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not initialized, setOutput has to be called. Cause : java.io.IOException: MetaException(Could not connect to meta store using any of the URIs provided. Most recent failure: org.apache.thrift.transport.TTransportException: java.net.ConnectException: Connection refused
    at org.apache.thrift.transport.TSocket.open(TSocket.java:185)
    at org.apache.hadoop.hive.metastore.HiveMetaStoreClient.open(HiveMetaStoreClient.java:277)
...
```

To resolve these issues, you must drop and recreate the schema or alter the schema to correct the parameters. If you still have issues, determine whether there are connectivity issues between your Vertica cluster and your Hadoop cluster. Such issues can include a firewall that...
prevents one or more Vertica hosts from contacting the HiveServer2, metastore, or HDFS hosts.

**UDx Failure When Querying Data: Error 3399**

You might see an error message when querying data (as opposed to metadata like schema information). This might be accompanied by a ClassNotFoundException in the log. This can happen for the following reasons:

- You are not using the same version of Java on your Hadoop and Vertica nodes. In this case you need to change one of them to match the other.

- You have not used hcatUtil to copy all Hadoop and Hive libraries and configuration files to Vertica, or you ran hcatutil and then changed your version of Hadoop or Hive.

- You upgraded Vertica to a new version and did not rerun hcatutil and reinstall the HCatalog Connector.

- The version of Hadoop you are using relies on a third-party library that you must copy manually.

- You are reading files with LZO compression and have not copied the libraries or set the `io.compression.codecs` property in `core-site.xml`.

- You are reading Parquet data from Hive, and columns were added to the table after some data was already present in the table. Adding columns does not update existing data, and the ParquetSerDe provided by Hive and used by the HCatalog Connector does not handle this case. This error is due to a limitation in Hive and there is no workaround.

- The query is taking too long and is timing out. If this is a frequent problem, you can increase the value of the UDxFencedBlockTimeout configuration parameter. See General Parameters.

If you did not copy the libraries or configure LZO compression, follow the instructions in Configuring Vertica for HCatalog.

If the Hive jars that you copied from Hadoop are out of date, you might see an error message like the following:

```plaintext
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource], error code: 0 Error message is [ Found interface org.apache.hadoop.mapreduce.JobContext, but class was expected ] HINT hive metastore service is thrift://localhost:13433 (check UDxLogs/UDxFencedProcessesJava.log in the catalog directory for more information)
```
This error usually signals a problem with hive-hcatalog-core.jar. Make sure you have an up-to-date copy of this file. Remember that if you rerun hcatUtil you also need to re-create the HCatalog schema.

You might also see a different form of this error:

```
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource], error code: 0 Error message is [ javax/servlet/Filter ]
```

This error can be reported even if hcatUtil reports that your libraries are up to date. The javax.servlet.Filter class is in a library that some versions of Hadoop use but that is not usually part of the Hadoop installation directly. If you see an error mentioning this class, locate servlet-api-*.jar on a Hadoop node and copy it to the hcat/lib directory on all database nodes. If you cannot locate it on a Hadoop node, locate and download it from the Internet. (This case is rare.) The library version must be 2.3 or higher.

After you have copied the jar to the hcat/lib directory, reinstall the HCatalog connector as explained in Configuring Vertica for HCatalog.

**Authentication Error When Querying Data**

You might have successfully created a schema using CREATE HCATALOG SCHEMA but get errors at query time such as the following:

```
=> SELECT * FROM hcat.clickdata;
ERROR 6776: Failed to glob [hdfs:///user/hive/warehouse/click-*.parquet] because of error: hdfs:///user/hive/warehouse/click-12214.parquet: statAll failed;
error: AuthenticationFailed
```

You might see this error if Hive uses an authorization service. If the permissions on the underlying files in HDFS match those in the authorization service, then Vertica must use user impersonation when accessing that data. To enable user impersonation, set the EnableHCatImpersonation configuration parameter to 1.

Vertica uses the database principal to access HDFS. Therefore, if EnableHCatImpersonation is 0, the Vertica database principal must have access to the data inside the hive warehouse on HDFS. If it does not, you might see the following error:

```
=> SELECT * FROM hcat.salesdata;
ERROR 6776: Failed to glob [vertica_hdfs:///hive/warehouse/sales/*/*]
because of error: vertica_hdfs:///hive/warehouse/sales/: listStat failed;
error: Permission denied: user=vertica, access=EXECUTE, inode="/hive/warehouse/sales":hdfs:hdfs:d----
```

The URL scheme in this error message has been changed from hdfs to vertica_hdfs. This is an internal scheme and is not valid in URLs outside of Vertica. You cannot use this scheme when specifying paths in HDFS.
Differing Results Between Hive and Vertica Queries

Sometimes, running the same query on Hive and on Vertica through the HCatalog Connector can return different results. There are a few common causes of this problem.

This discrepancy is often caused by the differences between the data types supported by Hive and Vertica. See Data Type Conversions from Hive to Vertica for more information about supported data types.

If Hive string values are being truncated in Vertica, this might be caused by multi-byte character encodings in Hive. Hive reports string length in characters, while Vertica records it in bytes. For a two-byte encoding such as Unicode, you need to double the column size in Vertica to avoid truncation.

Discrepancies can also occur if the Hive table uses partition columns of types other than string.

If the Hive table stores partition data in custom locations instead of the default, you will see different query results if you do not specify the CUSTOM_PARTITIONS parameter when creating the Vertica schema. See Using Partitioned Data. Further, even when using custom partitions, there are differences between Vertica and Hive:

- If a custom partition is unavailable at query time, Hive ignores it and returns the rest of the results. Vertica reports an error.

- If a partition is altered in Hive to use a custom location after table creation, Hive reads data from only the new location while Vertica reads data from both the default and the new locations.

- If a partition value and its corresponding directory name disagree, Hive uses the value in its metadata while Vertica uses the value in the directory name.

The following example illustrates these differences. A table in Hive, partitioned on the state column, starts with the following data:

```
hive> select * from inventory;
+------------+-----------+-------------+
<table>
<thead>
<tr>
<th>inventory_ID</th>
<th>inventory_quant</th>
<th>inventory_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>300</td>
<td>CA</td>
</tr>
<tr>
<td>4</td>
<td>400</td>
<td>CA</td>
</tr>
<tr>
<td>5</td>
<td>500</td>
<td>DC</td>
</tr>
<tr>
<td>1</td>
<td>100</td>
<td>PA</td>
</tr>
<tr>
<td>2</td>
<td>200</td>
<td>PA</td>
</tr>
</tbody>
</table>
+------------+---------------+---------------+```
The partition for one state, CA, is then moved. This directory contains some data already. Note that the query now returns different results for the CA partitions.

```
hive> ALTER TABLE inventory PARTITION (state='CA') SET LOCATION 'hdfs:///partitions/inventory/state=MD';
hive> select * from inventory;

+-------------------------------+-------------+--------+
| inventory.ID | inventory.quant | inventory.state |
+-------------------------------+-------------+--------+
|      20       |        30000  |       CA |
|      40       |        40000  |       CA |
|       5       |          500  |      DC |
|       1       |           100  |      PA |
|       2       |           200  |      PA |
+-------------------------------+-------------+--------+
5 rows selected (0.399 seconds)
```

The CA partitions were moved to a directory named state=MD. Vertica reports the state for the first two rows, the ones in the new partition location, as MD because of the directory name. It also reports the CA values from the original location in addition to the new one:

```
=> SELECT * FROM hcat.inventory;

ID | quant | state
---+-------+-------
20 | 30000 | MD
40 | 40000 | MD
 2 |   300 | CA
 4 |   400 | CA
 1 |   100 | PA
 2 |   200 | PA
 5 |   500 | DC
(7 rows)
```

HCatalog Connector Installation Fails on MapR

If you mount a MapR file system as an NFS mount point and then install the HCatalog Connector, it could fail with a message like the following:

```
ROLLBACK 2929: Couldn't create new UDx side process, failed to get UDx side process info from zygote: Broken pipe
```

This might be accompanied by an error like the following in dbLog:

```
java.io.IOException: Couldn't get lock for /home/dbadmin/node02_catalog/UDxLogs/UDxFencedProcessesJava.log
at java.util.logging.FileHandler.openFiles(FileHandler.java:389)
at java.util.logging.FileHandler.<init>(FileHandler.java:287)
at com.vertica.udxfence.UDxLogger.setup(UDxLogger.java:78)
at com.vertica.udxfence.UDxSideProcess.go(UDxSideProcess.java:75)
...
```
This error occurs if you locked your NFS mount point when creating it. Locking is the default. If you use the HCatalog Connector with MapR mounted as an NFS mount point, you must create the mount point with the -o noLock option. For example:

```
sudo mount -o noLock -t nfs MaprCLDBserviceHostname:/mapr/ClusterName/vertica/${(hostname -f)}/vertica
```

You can use the HCatalog Connector with MapR without mounting the MapR file system. If you mount the MapR file system, you must do so without a lock.

### Excessive Query Delays

Network issues or high system loads on the HiveServer2 server can cause long delays while querying a Hive database using the HCatalog Connector. While Vertica cannot resolve these issues, you can set parameters that limit how long Vertica waits before canceling a query on an HCatalog schema. You can set these parameters globally using Vertica configuration parameters. You can also set them for specific HCatalog schemas in the `CREATE HCATALOG SCHEMA` statement. These specific settings override the settings in the configuration parameters.

The HCatConnectionTimeout configuration parameter and the `CREATE HCATALOG SCHEMA` statement’s `HCATALOG_CONNECTION_TIMEOUT` parameter control how many seconds the HCatalog Connector waits for a connection to the HiveServer2 server. A value of 0 (the default setting for the configuration parameter) means to wait indefinitely. If the server does not respond by the time this timeout elapses, the HCatalog Connector breaks the connection and cancels the query. If you find that some queries on an HCatalog schema pause excessively, try setting this parameter to a timeout value, so the query does not hang indefinitely.

The HCatSlowTransferTime configuration parameter and the `CREATE HCATALOG SCHEMA` statement’s `HCATALOG_SLOW TRANSFER_TIME` parameter specify how long the HCatalog Connector waits for data after making a successful connection to the server. After the specified time has elapsed, the HCatalog Connector determines whether the data transfer rate from the server is at least the value set in the HCatSlowTransferLimit configuration parameter (or by the `CREATE HCATALOG SCHEMA` statement’s `HCATALOG_SLOW TRANSFER_LIMIT` parameter). If it is not, then the HCatalog Connector terminates the connection and cancels the query.

You can set these parameters to cancel queries that run very slowly but do eventually complete. However, query delays are usually caused by a slow connection rather than a problem establishing the connection. Therefore, try adjusting the slow transfer rate settings first. If you find the cause of the issue is connections that never complete, you can alternately adjust the Linux TCP socket timeouts to a suitable value instead of relying solely on the HCatConnectionTimeout parameter.
SerDe Errors

Errors can occur if you attempt to query a Hive table that uses a nonstandard SerDe. If you have not installed the SerDe JAR files on your Vertica cluster, you receive an error similar to the one in the following example:

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not initialized, setOutput has to be called. Cause : java.io.IOException: java.lang.RuntimeException: MetaException(message:org.apache.hadoop.hive.serde2.SerDeException SerDe com.cloudera.hive.serde.JSONSerDe does not exist) ] HINT If error message is not descriptive or local, may be we cannot read metadata from hive metastore service thrift://hcathost:9083 or HDFS namenode (check UDxLogs/UDxFencedProcessesJava.log in the catalog directory for more information) at com.vertica.hcatalogudl.HCatalogSplitsNoOpSourceFactory.plan(HCatalogSplitsNoOpSourceFactory.java:98)
at com.vertica.udxfence.UDxExecContext.planUDSource(UDxExecContext.java:898)
...
```

In the error message, you can see that the root cause is a missing SerDe class (shown in bold). To resolve this issue, install the SerDe class on your Vertica cluster. See Using Nonstandard SerDes for more information.

This error may occur intermittently if just one or a few hosts in your cluster do not have the SerDe class.
Using HDFS Storage Locations

Vertica stores data in its native format, ROS, in storage locations. You can place storage locations on the local Linux file system or in HDFS. If you are using Premium Edition, you typically use HDFS storage locations for lower-priority data. Doing so frees space on your Vertica cluster for higher-priority data. If you are using Vertica for SQL on Apache Hadoop, you typically place ROS data only on HDFS.

If you use any HDFS storage locations, the HDFS data must be available at the time you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you have moved data files, or if they have become corrupted, or if your HDFS cluster is not responsive, Vertica cannot start.

Requirements for HDFS Storage Locations

Caution:
If you use any HDFS storage locations, the HDFS data must be available at the time you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you have moved data files, or if they have become corrupted, or if your HDFS cluster is not responsive, Vertica cannot start.

To store Vertica's data on HDFS, verify that:

- Your Hadoop cluster has WebHDFS enabled.
- All of the nodes in your Vertica cluster can connect to all of the nodes in your Hadoop cluster. Any firewall between the two clusters must allow connections on the ports used by HDFS.
- If your HDFS cluster is unsecured, you have a Hadoop user whose username matches the name of the Vertica database superuser (usually named dbadmin). This Hadoop user must have read and write access to the HDFS directory where you want Vertica to store its data.
- If your HDFS cluster uses Kerberos authentication, you have a Kerberos principal for Vertica, and it has read and write access to the HDFS directory that will be used for the storage location. See Configuring Kerberos. The Kerberos KDC must also be running.
• Your HDFS cluster has enough storage available for Vertica data. See HDFS Space Requirements below for details.

• The data you store in an HDFS-backed storage location does not expand your database’s size beyond any data allowance in your Vertica license. Vertica counts data stored in an HDFS-backed storage location as part of any data allowance set by your license. See Managing Licenses in the Administrator’s Guide for more information.

HDFS Space Requirements

If your Vertica database is K-safe, HDFS-based storage locations contain two copies of the data you store in them. One copy is the primary projection, and the other is the buddy projection. If you have enabled HDFS’s data-redundancy feature, Hadoop stores both projections multiple times. This duplication might seem excessive. However, it is similar to how a RAID level 1 or higher stores redundant copies of both the primary and buddy projections. The redundant copies also help the performance of HDFS by enabling multiple nodes to process a request for a file.

Verify that your HDFS installation has sufficient space available for redundant storage of both the primary and buddy projections of your K-safe data. You can adjust the number of duplicates stored by HDFS by setting the HadoopFSReplication configuration parameter. See Troubleshooting HDFS Storage Locations for details.

Additional Requirements for Backing Up Data Stored on HDFS

To back up your data stored in HDFS storage locations, your Hadoop cluster must have snapshotting enabled for the directories to be used for backups. The easiest way to do this is to give the database administrator’s account superuser privileges in Hadoop, so that snapshotting can be set automatically. Alternatively, use Hadoop to enable snapshotting for each directory before using it for backups.

In addition, your Vertica database must:

• Have enough Hadoop components and libraries installed to run the Hadoop distcp command as the Vertica database-administrator user (usually dbadmin).

• Have the JavaBinaryForUDx and HadoopHome configuration parameters set correctly.
Caution: After you have created an HDFS storage location, full database backups will fail with the error message:

```
ERROR 5127: Unable to create snapshot
No such file /usr/bin/hadoop:
check the HadoopHome configuration parameter
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back these locations. After you configure Vertica and Hadoop, you can once again perform full database backups.

See Backing Up HDFS Storage Locations for details on configuring your Vertica and Hadoop clusters to enable HDFS storage location backup.

**Best Practices for SQL on Apache Hadoop**

If you are using the Vertica for SQL on Apache Hadoop product, Vertica recommends the following best practices for storage locations:

- Place only data type storage locations on HDFS storage.

- Place temp space directly on the local Linux file system, not in HDFS.

- For the best performance, place the Vertica catalog directly on the local Linux file system.

- Create the database first on a local Linux file system. Then, you can extend the database to HDFS storage locations and set storage policies that exclusively place data blocks on the HDFS storage location.

- For better performance, if you are running Vertica only on a subset of the HDFS nodes, do not run the HDFS balancer on them. The HDFS balancer can move data blocks farther away, causing Vertica to read non-local data during query execution. Queries run faster if they do not require network I/O.

Generally, HDFS requires approximately 2 GB of memory for each node in the cluster. To support this requirement in your Vertica configuration:

1. Create a 2-GB resource pool.

2. Do not assign any Vertica execution resources to this pool. This approach reserves the space for use by HDFS.

Alternatively, use Ambari or Cloudera Manager to find the maximum heap size required by HDFS and set the size of the resource pool to that value.
For more about how to configure resource pools, see Managing Workloads.

**Configuring Kerberos**

To use a storage location in HDFS with Kerberos, take the following steps:

1. Create a Kerberos principal for each Vertica node as explained in Using Kerberos with Vertica.

2. Give all node principals read and write permission to the HDFS directory you will use as a storage location.

If you plan to back up your HDFS storage locations, take the following additional steps:

1. Grant Hadoop superuser privileges to the new principals.

2. Configure backups, including setting the HadoopConfigDir configuration parameter, following the instructions in Configuring Hadoop and Vertica to Enable Backup of HDFS Storage.

3. Configure user impersonation to be able to restore from backups following the instructions in "Setting Kerberos Parameters" in Configuring Vertica to Restore HDFS Storage Locations.

Because the keytab file supplies the principal used to create the location, you must have it in place before creating the storage location. After you deploy keytab files to all database nodes, use the CREATE LOCATION statement to create the storage location as usual.

**How the HDFS Storage Location Stores Data**

Vertica stores data in storage locations on HDFS similarly to the way it stores data in the Linux file system. See Managing Storage Locations in the Administrator's Guide for more information about storage locations. When you create a storage location on HDFS, Vertica stores the ROS containers holding its data on HDFS. You can choose which data uses the HDFS storage location: from the data for just a single table or partition to all of the database's data.

When Vertica reads data from or writes data to an HDFS storage location, the node storing or retrieving the data contacts the Hadoop cluster directly to transfer the data. If a single ROS container file is split among several HDFS nodes, the Vertica node connects to each of them. The Vertica node retrieves the pieces and reassembles the file. Because each node fetches its own data directly from the source, data transfers are parallel, increasing their
efficiency. Having the Vertica nodes directly retrieve the file splits also reduces the impact on the Hadoop cluster.

**What You Can Store in HDFS**

Use HDFS storage locations to store only data. You cannot store catalog information in an HDFS storage location.

---

**Caution:** While it is possible to use an HDFS storage location for temporary data storage, you must never do so. Using HDFS for temporary storage causes severe performance issues.

---

**What HDFS Storage Locations Cannot Do**

Because Vertica uses storage locations to store ROS containers in a proprietary format, MapReduce and other Hadoop components cannot access your Vertica ROS data stored in HDFS. Never allow another program that has access to HDFS to write to the ROS files. Any outside modification of these files can lead to data corruption and loss. Applications must use the Vertica client libraries to access Vertica data. If you want to share ROS data with other Hadoop components, you can export it (see Exporting Data).

The storage location stores and reads only ROS containers. It cannot read data stored in native formats in HDFS. See Hadoop Interfaces for other ways to read data stored in HDFS.

**Creating an HDFS Storage Location**

Use the `CREATE LOCATION` statement to create an HDFS storage location. Make the following changes from creating local storage locations:

- For the path, use the `hdfs://` URL for the HDFS directory where you want Vertica to store the location’s data. See HDFS URL Format for information about the URL format.

- Include the ALL NODES SHARED keywords, as all HDFS storage locations are shared storage. This is required even if you have only one HDFS node in your cluster.

---

**Caution:**
If you use any HDFS storage locations, the HDFS data must be available at the time you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If
you have moved data files, or if they have become corrupted, or if your HDFS cluster is not responsive, Vertica cannot start.

Creating the Storage Location

To create an HDFS storage location, first create the location on all nodes and then set its storage policy to HDFS. To create the location in HDFS on all nodes:

```sql
CREATE LOCATION 'hdfs:///user/dbadmin' ALL NODES SHARED
USAGE 'data' LABEL 'coldstorage';
```

Next, set the storage policy for your database objects to use this location:

```sql
SELECT SET_OBJECT_STORAGE_POLICY('SchemaName','coldstorage');
```

This causes all data in the named schema to be written to the HDFS storage location (coldstorage) instead of the local disk. You can set storage policies for a schema, a table, a partition, or the entire database.

For more information, see Managing Storage Locations.

Adding HDFS Storage Locations to New Nodes

If you add nodes to your Vertica cluster, they do not automatically have access to existing HDFS storage locations. You must manually create the storage location for the new node using the CREATE LOCATION statement. Do not use the ALL NODES keyword in this statement. Instead, use the NODE keyword with the name of the new node to tell Vertica that just that node needs to add the shared location.

Caution: You must manually create the storage location. Otherwise, the new node uses the default storage policy (usually, storage on the local Linux filesystem) to store data that the other the nodes store in HDFS. As a result, the node can run out of disk space.

The following example shows how to add the storage location from the preceding example to a new node named `v_vmart_node0004`:

```sql
CREATE LOCATION 'hdfs:///user/dbadmin' NODE 'v_vmart_node0004'
SHARED USAGE 'data' LABEL 'coldstorage';
```

Any active standby nodes in your cluster when you create an HDFS-based storage location automatically create their own instances of the location. When the standby node takes over for a down node, it uses its own instance of the location to store data for objects using the HDFS-
based storage policy. Treat standby nodes added after you create the storage location as any other new node. You must manually define the HDFS storage location.

Creating a Storage Policy for HDFS Storage Locations

After you create an HDFS storage location, you assign database objects to the location by setting storage policies. Based on these storage policies, database objects such as partition ranges, individual tables, whole schemas, or even the entire database store their data in the HDFS storage location. Use the `SET_OBJECT_STORAGE_POLICY` function to assign objects to an HDFS storage location. In the function call, supply the label you assigned to the HDFS storage location as the location label argument. You do so using the CREATE LOCATION statement's LABEL keyword.

The following example demonstrates using `SET_OBJECT_STORAGE_POLICY` to store a table in an HDFS storage location. The example statement sets the policy for an existing table, named messages, to store its data in an HDFS storage location, named coldstorage.

```sql
=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'coldstorage');
```

This table's data is moved to the HDFS storage location with the next merge-out. Alternatively, you can have Vertica move the data immediately by using the `enforce-storage-move` parameter.

You can query the `STORAGE_CONTAINERS` system table and examine the location_label column to verify that Vertica has moved the data:

```sql
=> SELECT node_name, projection_name, location_label, total_row_count FROM V_MONITOR.STORAGE_CONTAINERS
   WHERE projection_name ILIKE 'messages%';
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>projection_name</th>
<th>location_label</th>
<th>total_row_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>messages_b0</td>
<td>coldstorage</td>
<td>366057</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>messages_b1</td>
<td>coldstorage</td>
<td>366511</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>messages_b0</td>
<td>coldstorage</td>
<td>367432</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>messages_b1</td>
<td>coldstorage</td>
<td>366057</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>messages_b0</td>
<td>coldstorage</td>
<td>366511</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>messages_b1</td>
<td>coldstorage</td>
<td>367432</td>
</tr>
</tbody>
</table>
(6 rows)

See Creating Storage Policies in the Administrator's Guide for more information about assigning storage policies to objects.
Back Up HDFS Storage Locations

Vertica recommends that you regularly back up the data in your Vertica database. This recommendation includes data stored in your HDFS storage locations. The Vertica backup script (vbr) can back up HDFS storage locations. However, you must perform several configuration steps before it can back up these locations.

**Caution:** After you have created an HDFS storage location, full database backups will fail with the error message:

```
ERROR 5127: Unable to create snapshot No such file /usr/bin/hadoop:
check the HadoopHome configuration parameter
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back these locations. After you configure Vertica and Hadoop, you can once again perform full database backups.

There are several considerations for backing up HDFS storage locations in your database:

- HDFS storage locations do not support object-level backups. You must perform a full database backup to back up the data in your HDFS storage locations.

- Data in an HDFS storage location is backed up to HDFS. This backup guards against accidental deletion or corruption of data. It does not prevent data loss in the case of a catastrophic failure of the entire Hadoop cluster. To prevent data loss, you must have a backup and disaster recovery plan for your Hadoop cluster.

  Data stored on the Linux native filesystem is still backed up to the location you specify in the backup configuration file. It and the data in HDFS storage locations are handled separately by the vbr backup script.

- You must configure your Vertica cluster to restore database backups containing an HDFS storage location. See Configuring Vertica to Restore HDFS Storage Locations for the configuration steps you must take.

- The HDFS directory for the storage location must have snapshotting enabled. You can either directly configure this yourself or enable the database administrator’s Hadoop account to do it for you automatically. See Configuring Hadoop and Vertica to Enable Backup of HDFS Storage for more information.
The topics in this section explain the configuration steps you must take to enable the backup of HDFS storage locations.

**Configuring Hadoop and Vertica to Enable Backup of HDFS Storage**

The Vertica backup script uses HDFS's snapshotting feature to create a backup of HDFS storage locations. A directory must allow snapshotting before HDFS can take a snapshot. Only a Hadoop superuser can enable snapshotting on a directory. Vertica can enable snapshotting automatically if the database administrator is also a Hadoop superuser.

If HDFS is unsecured, the following instructions apply to the database administrator account, usually dbadmin. If HDFS uses Kerberos security, the following instructions apply to the principal stored in the Vertica keytab file, usually vertica. The instructions below use the term "database account" to refer to this user.

We recommend that you make the database administrator or principal a Hadoop superuser. If you are not able to do so, you must enable snapshotting on the directory before configuring it for use by Vertica.

The steps you need to take to make the Vertica database administrator account a superuser depend on the distribution of Hadoop you are using. Consult your Hadoop distribution's documentation for details.

**Manually Enabling Snapshotting for a Directory**

If you cannot grant superuser status to the database account, you can instead enable snapshotting of each directory manually. Use the following command:

```
hdfs dfsadmin -allowSnapshot path
```

Issue this command for each directory on each node. Remember to do this each time you add a new node to your HDFS cluster.

Nested snapshottable directories are not allowed, so you cannot enable snapshotting for a parent directory to automatically enable it for child directories. You must enable it for each individual directory.
Additional Requirements for Kerberos

If HDFS uses Kerberos, then in addition to granting the keytab principal access, you must set a Vertica configuration parameter. In Vertica, set the HadoopConfDir parameter to the location of the directory containing the core-site.xml, hdfs-site.xml, and yarn-site.xml configuration files:

```
=> ALTER DATABASE exampledb SET HadoopConfDir = '/etc/hadoop/conf';
```

All three configuration files must be present in this directory.

If your Vertica nodes are not co-located on HDFS nodes, then you must copy these files from an HDFS node to each Vertica node. Use the same path on every database node, because HadoopConfDir is a global value.

Testing the Database Account's Ability to Make HDFS Directories Snapshottable

After making the database account a Hadoop superuser, verify that the account can set directories snapshottable:

1. Log into the Hadoop cluster as the database account (dbadmin by default).

2. Determine a location in HDFS where the database administrator can create a directory. The /tmp directory is usually available. Create a test HDFS directory using the command:

```
$ hdfs dfs -mkdir /path/testdir
```

3. Make the test directory snapshottable using the command:

```
$ hdfs dfsadmin -allowSnapshot /path/testdir
```

The following example demonstrates creating an HDFS directory and making it snapshottable:

```
$ hdfs dfs -mkdir /tmp/snaptest
$ hdfs dfsadmin -allowSnapshot /tmp/snaptest
Allowing snapshot on /tmp/snaptest succeeded
```
Configuring Vertica to Restore HDFS Storage Locations

Your Vertica cluster must be able to run the Hadoop distcp command to restore a backup of an HDFS storage location. The easiest way to enable your cluster to run this command is to install several Hadoop packages on each node. These packages must be from the same distribution and version of Hadoop that is running on your Hadoop cluster.

The steps you need to take depend on:

- The distribution and version of Hadoop running on the Hadoop cluster containing your HDFS storage location.
- The distribution of Linux running on your Vertica cluster.

Note: Installing the Hadoop packages necessary to run distcp does not turn your Vertica database into a Hadoop cluster. This process installs just enough of the Hadoop support files on your cluster to run the distcp command. There is no additional overhead placed on the Vertica cluster, aside from a small amount of additional disk space consumed by the Hadoop support files.

Configuration Overview

The steps for configuring your Vertica cluster to restore backups for HDFS storage location are:

1. If necessary, install and configure a Java runtime on the hosts in the Vertica cluster.
2. Find the location of your Hadoop distribution's package repository.
3. Add the Hadoop distribution's package repository to the Linux package manager on all hosts in your cluster.
4. Install the necessary Hadoop packages on your Vertica hosts.
5. Set two configuration parameters in your Vertica database related to Java and Hadoop.
6. If your HDFS storage location uses Kerberos, set additional configuration parameters to allow Vertica user credentials to be proxied.
7. Confirm that the Hadoop distcp command runs on your Vertica hosts.

The following sections describe these steps in greater detail.
Installing a Java Runtime

You Vertica cluster must have a Java Virtual Machine (JVM) installed to run the Hadoop distcp command. It already has a JVM installed if you have configured it to:

- Execute User-Defined Extensions developed in Java. See Developing User-Defined Extensions (UDxs) for more information.
- Access Hadoop data using the HCatalog Connector. See Using the HCatalog Connector for more information.

If your Vertica database has a JVM installed, verify that your Hadoop distribution supports it. See your Hadoop distribution's documentation to determine which JVMs it supports.

If the JVM installed on your Vertica cluster is not supported by your Hadoop distribution you must uninstall it. Then you must install a JVM that is supported by both Vertica and your Hadoop distribution. See Vertica SDKs in Supported Platforms for a list of the JVMs compatible with Vertica.

If your Vertica cluster does not have a JVM (or its existing JVM is incompatible with your Hadoop distribution), follow the instructions in Installing the Java Runtime on Your Vertica Cluster.

Finding Your Hadoop Distribution's Package Repository

Many Hadoop distributions have their own installation system, such as Cloudera's Manager or Hortonwork's Ambari. However, they also support manual installation using native Linux packages such as RPM and .deb files. These package files are maintained in a repository. You can configure your Vertica hosts to access this repository to download and install Hadoop packages.

Consult your Hadoop distribution's documentation to find the location of its Linux package repository. This information is often located in the portion of the documentation covering manual installation techniques:

Each Hadoop distribution maintains separate repositories for each of the major Linux package management systems. Find the specific repository for the Linux distribution running on your Vertica cluster. Be sure that the package repository that you select matches the version of Hadoop distribution installed on your Hadoop cluster.
Configuring Vertica Nodes to Access the Hadoop Distribution’s Package Repository

Configure the nodes in your Vertica cluster so they can access your Hadoop distribution's package repository. Your Hadoop distribution’s documentation should explain how to add the repositories to your Linux platform. If the documentation does not explain how to add the repository to your packaging system, refer to your Linux distribution's documentation.

The steps you need to take depend on the package management system your Linux platform uses. Usually, the process involves:

- Downloading a configuration file.
- Adding the configuration file to the package management system's configuration directory.
- For Debian-based Linux distributions, adding the Hadoop repository encryption key to the root account keyring.
- Updating the package management system's index to have it discover new packages.

You must add the Hadoop repository to all hosts in your Vertica cluster.

Installing the Required Hadoop Packages

After configuring the repository, you are ready to install the Hadoop packages. The packages you need to install are:

- hadoop
- hadoop-hdfs
- hadoop-client

The names of the packages are usually the same across all Hadoop and Linux distributions. These packages often have additional dependencies. Always accept any additional packages that the Linux package manager asks to install.

To install these packages, use the package manager command for your Linux distribution. The package manager command you need to use depends on your Linux distribution:
On Red Hat and CentOS, the package manager command is yum.

On Debian and Ubuntu, the package manager command is apt-get.

On SUSE the package manager command is zypper.

Consult your Linux distribution's documentation for instructions on installing packages.

### Setting Configuration Parameters

You must set two configuration parameters to enable Vertica to restore HDFS data:

- **JavaBinaryForUDx** is the path to the Java executable. You may have already set this value to use Java UDxs or the HCatalog Connector. You can find the path for the default Java executable from the Bash command line using the command:

  ```bash
  which java
  ```

- **HadoopHome** is the path where Hadoop is installed on the Vertica hosts. This is the directory that contains `bin/hadoop` (the `bin` directory containing the Hadoop executable file). The default value for this parameter is `/usr`. The default value is correct if your Hadoop executable is located at `/usr/bin/hadoop`.

The following example demonstrates setting and then reviewing the values of these parameters.

```sql
=> ALTER DATABASE mydb SET JavaBinaryForUDx = '/usr/bin/java';
=> SELECT get_config_parameter('JavaBinaryForUDx');
get_config_parameter
-------------
/usr/bin/java
(1 row)
=> ALTER DATABASE mydb SET HadoopHome = '/usr';
=> SELECT get_config_parameter('HadoopHome');
get_config_parameter
-------------
/usr
(1 row)
```

There are additional parameters you may, optionally, set:

- **HadoopFSReadRetryTimeout** and **HadoopFSWriteRetryTimeout** specify how long to wait before failing. The default value for each is 180 seconds. If you are confident that your file system will fail more quickly, you can potentially improve performance by lowering these...
values.

- HadoopFSReplication is the number of replicas HDFS makes. By default the Hadoop client chooses this; Vertica uses the same value for all nodes. We recommend against changing this unless directed to.

- HadoopFSBlockSizeBytes is the block size to write to HDFS; larger files are divided into blocks of this size. The default is 64MB.

Setting Kerberos Parameters

If your Vertica nodes are co-located on HDFS nodes and you are using Kerberos, you must change some Hadoop configuration parameters. These changes are needed in order for restoring from backups to work. In yarn-site.xml on every Vertica node, set the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>yarn.resourcemanager.proxy-user-privileges.enabled</td>
<td>true</td>
</tr>
<tr>
<td>yarn.resourcemanager.proxyusers.*.groups</td>
<td>*</td>
</tr>
<tr>
<td>yarn.resourcemanager.proxyusers.*.hosts</td>
<td>*</td>
</tr>
<tr>
<td>yarn.resourcemanager.proxyusers.*.users</td>
<td>*</td>
</tr>
<tr>
<td>yarn.timeline-service.http-authentication.proxyusers.*.groups</td>
<td>*</td>
</tr>
<tr>
<td>yarn.timeline-service.http-authentication.proxyusers.*.hosts</td>
<td>*</td>
</tr>
<tr>
<td>yarn.timeline-service.http-authentication.proxyusers.*.users</td>
<td>*</td>
</tr>
</tbody>
</table>

No changes are needed on HDFS nodes that are not also Vertica nodes.

Confirming that distcp Runs

After the packages are installed on all hosts in your cluster, your database should be able to run the Hadoop distcp command. To test it:

1. Log into any host in your cluster as the database superuser.

2. At the Bash shell, enter the command:
3. The command should print a message similar to the following:

```plaintext
$ hadoop distcp

usage: distcp OPTIONS [source_path...] [target_path]

OPTIONS
-async          Should distcp execution be blocking
-atomic         Commit all changes or none
-bandwidth <arg> Specify bandwidth per map in MB
-delete         Delete from target, files missing in source
-f <arg>        List of files that need to be copied
-filelimit <arg> (Deprecated!) Limit number of files copied to <= n
-i              Ignore failures during copy
-log <arg>      Folder on DFS where distcp execution logs are saved
-m <arg>        Max number of concurrent maps to use for copy
-mapredSslConf <arg> Configuration for ssl config file, to use with https://
-overwrite      Choose to overwrite target files unconditionally, even if they exist.
-p <arg>        preserve status (rbugpc)(replication, block-size, user, group, permission, checksum-type)
-sizeLimit <arg> (Deprecated!) Limit number of files copied to <= n bytes
-skipcrccheck   Whether to skip CRC checks between source and target paths.
-strategy <arg> Copy strategy to use. Default is dividing work based on file sizes
-tmp <arg>      Intermediate work path to be used for atomic commit
-update         Update target, copying only missing files or directories
```

4. Repeat these steps on the other hosts in your database to verify that all of the hosts can run distcp.

**Troubleshooting**

If you cannot run the distcp command, try the following steps:

- If Bash cannot find the hadoop command, you may need to manually add Hadoop’s bin directory to the system search path. An alternative is to create a symbolic link in an existing directory in the search path (such as /usr/bin) to the hadoop binary.

- Ensure the version of Java installed on your Vertica cluster is compatible with your Hadoop distribution.
• Review the Linux package installation tool's logs for errors. In some cases, packages may not be fully installed, or may not have been downloaded due to network issues.

• Ensure that the database administrator account has permission to execute the hadoop command. You may need to add the account to a specific group in order to allow it to run the necessary commands.

Performing Backups Containing HDFS Storage Locations

After you configure Hadoop and Vertica, HDFS storage locations are automatically backed up when you perform a full database backup. If you already have a backup configuration file for a full database backup, you do not need to make any changes to it. You just run the vbr backup script as usual to perform the full database backup. See Creating Full Backups in the Administrator's Guide for instructions on running the vbr backup script.

If you do not have a backup configuration file for a full database backup, you must create one to back up the data in your HDFS storage locations. See Creating vbr Configuration Files in the Administrator's Guide for more information.

Removing HDFS Storage Locations

The steps to remove an HDFS storage location are similar to standard storage locations:

1. Remove any existing data from the HDFS storage location by using SET_OBJECT_STORAGE_POLICY to change each object's storage location. Alternatively, you can use CLEAR_OBJECT_STORAGE_POLICY. Because the Tuple Mover runs infrequently, set the enforce-storage-move parameter to true to make the change immediately.

2. Retire the location on each host that has the storage location defined by using RETIRE_LOCATION. Set enforce-storage-move to true.

3. Drop the location on each host that has the storage location defined by using DROP_LOCATION.

4. Optionally remove the snapshots and files from the HDFS directory for the storage location.

For more information about changing storage policies, changing usage, retiring locations, and dropping locations, see Managing Storage Locations in the Administrator's Guide.
Important: If you have backed up the data in the HDFS storage location you are removing, you must perform a full database backup after you remove the location. If you do not and restore the database to a backup made before you removed the location, the location's data is restored.

Removing Storage Location Files from HDFS

Dropping an HDFS storage location does not automatically clean the HDFS directory that stored the location's files. Any snapshots of the data files created when backing up the location are also not deleted. These files consume disk space on HDFS and also prevent the directory from being reused as an HDFS storage location. Vertica refuses to create a storage location in a directory that contains existing files or subdirectories. You must log into the Hadoop cluster to delete the files from HDFS. An alternative is to use some other HDFS file management tool.

Removing Backup Snapshots

HDFS returns an error if you attempt to remove a directory that has snapshots:

```
$ hdfs dfs -rm -r -f -skipTrash /user/dbadmin/v_vmart_node0001
rm: The directory /user/dbadmin/v_vmart_node0001 cannot be deleted since /user/dbadmin/v_vmart_node0001 is snapshottable and already has snapshots
```

The Vertica backup script creates snapshots of HDFS storage locations as part of the backup process. See Backing Up HDFS Storage Locations for more information. If you made backups of your HDFS storage location, you must delete the snapshots before removing the directories.

HDFS stores snapshots in a subdirectory named `.snapshot`. You list the snapshots in the directory using the standard HDFS ls command. The following example demonstrates listing the snapshots defined for node0001.

```
$ hdfs dfs -ls /user/dbadmin/v_vmart_node0001/.snapshot
Found 1 items
drwxrwxr-x - dbadmin supergroup 0 2014-09-02 10:13 /user/dbadmin/v_vmart_node0001/.snapshot/s20140902-101358.629
```

To remove snapshots, use the command:

```
hdfs dfs -removeSnapshot directory snapshotname
```

The following example demonstrates the command to delete the snapshot shown in the previous example:

```
$ hdfs dfs -deleteSnapshot /user/dbadmin/v_vmart_node0001 s20140902-101358.629
```
You must delete each snapshot from the directory for each host in the cluster. After you have deleted the snapshots, you can delete the directories in the storage location.

Important: Each snapshot's name is based on a timestamp down to the millisecond. Nodes independently create their own snapshot. They do not synchronize snapshot creation, so their snapshot names differ. You must list each node's snapshot directory to learn the names of the snapshots it contains.

See Apache's HDFS Snapshot documentation for more information about managing and removing snapshots.

Removing the Storage Location Directories

You can remove the directories that held the storage location's data by either of the following methods:

- Use an HDFS file manager to delete directories. See your Hadoop distribution's documentation to determine if it provides a file manager.

- Log into the Hadoop NameNode using the database administrator’s account and use HDFS's \texttt{rmr} command to delete the directories. See Apache's File System Shell Guide for more information.

The following example uses the HDFS \texttt{rmr} command from the Linux command line to delete the directories left behind in the HDFS storage location directory \texttt{/user/dbadmin}. It uses the \texttt{-skipTrash} flag to force the immediate deletion of the files.

```
$ hdfsp dfs -ls /user/dbadmin
Found 3 items
drwxrwx--- - dbadmin supergroup 0 2014-08-29 15:11 /user/dbadmin/v_mart_node0001
drwxrwx--- - dbadmin supergroup 0 2014-08-29 15:11 /user/dbadmin/v_mart_node0002
drwxrwx--- - dbadmin supergroup 0 2014-08-29 15:11 /user/dbadmin/v_mart_node0003

$ hdfsp dfs -rmr -skipTrash /user/dbadmin/*
Deleted /user/dbadmin/v_mart_node0001
Deleted /user/dbadmin/v_mart_node0002
Deleted /user/dbadmin/v_mart_node0003
```

Troubleshooting HDFS Storage Locations

This topic explains some common issues with HDFS storage locations.
HDFS Storage Disk Consumption

By default, HDFS makes three copies of each file it stores. This replication helps prevent data loss due to disk or system failure. It also helps increase performance by allowing several nodes to handle a request for a file.

A Vertica database with a K-Safety value of 1 or greater also stores its data redundantly using buddy projections.

When a K-Safe Vertica database stores data in an HDFS storage location, its data redundancy is compounded by HDFS's redundancy. HDFS stores three copies of the primary projection's data, plus three copies of the buddy projection for a total of six copies of the data.

If you want to reduce the amount of disk storage used by HDFS locations, you can alter the number of copies of data that HDFS stores. The Vertica configuration parameter named HadoopFSReplication controls the number of copies of data HDFS stores.

You can determine the current HDFS disk usage by logging into the Hadoop NameNode and issuing the command:

```
hdfs dfsadmin -report
```

This command prints the usage for the entire HDFS storage, followed by details for each node in the Hadoop cluster. The following example shows the beginning of the output from this command, with the total disk space highlighted:

```
$ hdfs dfsadmin -report
Configured Capacity: 51495516981 (47.96 GB)
Present Capacity: 32087212032 (29.88 GB)
DFS Remaining: 31565144064 (29.40 GB)
DFS Used: 522067968 (497.88 MB)
DFS Used%: 1.63%
Under replicated blocks: 0
Blocks with corrupt replicas: 0
Missing blocks: 0
```

After loading a simple million-row table into a table stored in an HDFS storage location, the report shows greater disk usage:

```
Configured Capacity: 51495516981 (47.96 GB)
Present Capacity: 32085299338 (29.88 GB)
DFS Remaining: 31373565952 (29.22 GB)
DFS Used: 711733386 (678.76 MB)
DFS Used%: 2.22%
Under replicated blocks: 0
Blocks with corrupt replicas: 0
Missing blocks: 0
```

The following Vertica example demonstrates:
1. Dropping the table in Vertica.

2. Setting the HadoopFSReplication configuration option to 1. This tells HDFS to store a single copy of an HDFS storage location's data.

3. Recreating the table and reloading its data.

```sql
=> DROP TABLE messages; 
DROP TABLE 
=> ALTER DATABASE mydb SET HadoopFSReplication = 1; 
=> CREATE TABLE messages (id INTEGER, text VARCHAR); 
CREATE TABLE 
=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'hdfs'); 
  SET_OBJECT_STORAGE_POLICY 
-------------------------- 
Object storage policy set.  
(1 row) 
=> COPY messages FROM '/home/dbadmin/messages.txt' DIRECT; 
  Rows Loaded 
-------------------------- 
 1000000
```

Running the HDFS report on Hadoop now shows less disk space use:

```
$ hdfs dfsadmin -report  
Configured Capacity: 51495516981 (47.96 GB)  
Present Capacity: 32086278190 (29.88 GB)  
DFS Remaining: 31500988416 (29.34 GB)  
DFS Used: 585289774 (558.18 MB)  
DFS Used%: 1.82%  
Under replicated blocks: 0  
Blocks with corrupt replicas: 0  
Missing blocks: 0  
... 
```

**Caution:** Reducing the number of copies of data stored by HDFS increases the risk of data loss. It can also negatively impact the performance of HDFS by reducing the number of nodes that can provide access to a file. This slower performance can impact the performance of Vertica queries that involve data stored in an HDFS storage location.

**ERROR 6966: StorageBundleWriter**

You might encounter Error 6966 when loading data into a storage location on a small Hadoop cluster (5 or fewer data nodes). This error is caused by the way HDFS manages the write pipeline and replication. You can mitigate this problem by reducing the number of replicas as
explained in **HDFS Storage Disk Consumption**. For configuration changes you can make in the Hadoop cluster instead, see this blog post from Hortonworks.

**Kerberos Authentication When Creating a Storage Location**

If HDFS uses Kerberos authentication, then the CREATE LOCATION statement authenticates using the Vertica keytab principal, not the principal of the user performing the action. If the creation fails with an authentication error, verify that you have followed the steps described in **Configuring Kerberos** to configure this principal.

When creating an HDFS storage location on a Hadoop cluster using Kerberos, CREATE LOCATION reports the principal being used as in the following example:

```bash
=> CREATE LOCATION 'hdfs:///user/dbadmin' ALL NODES SHARED
    USAGE 'data' LABEL 'coldstorage';
NOTICE 0: Performing HDFS operations using kerberos principal [vertica/hadoop.example.com]
CREATE LOCATION
```

**Backup or Restore Fails When Using Kerberos**

When backing up an HDFS storage location that uses Kerberos, you might see an error such as:

```bash
createSnapshot: Failed on local exception: java.io.IOException: 
java.lang.IllegalArgumentException: Server has invalid Kerberos principal: 
hdfs/test.example.com@EXAMPLE.COM;
```

When restoring an HDFS storage location that uses Kerberos, you might see an error such as:

```bash
Error msg: Initialization thread logged exception:
    Distcp failure!
```

Either of these failures means that Vertica could not find the required configuration files in the HadoopConfDir directory. Usually this is because you have set the parameter but not copied the files from an HDFS node to your Vertica node. See "Additional Requirements for Kerberos" in **Configuring Hadoop and Vertica to Enable Backup of HDFS Storage**.
Integrating With Cloudera Manager

The Cloudera distribution of Hadoop includes Cloudera Manager, a web-based tool for managing a Hadoop cluster. Cloudera Manager can manage any service for which a service description is available, including Vertica.

You can use Cloudera Manager to start, stop, and monitor individual database nodes or the entire database. You can manage both co-located and separate Vertica clusters—Cloudera can manage services on nodes that are not part of the Hadoop cluster.

You must install and configure your Vertica database before proceeding; you cannot use Cloudera Manager to create the database.

Installing the Service

Note: Because the service has to send the database password over the network, you should enable encryption on your Hadoop cluster before proceeding.

A Cloudera Service Description (CSD) file describes a service that Cloudera can manage. The Vertica CSD is in /opt/vertica/share/CSD on a database node.

To install the Vertica CSD, follow these steps:

1. On a Vertica node, follow the instructions in VerticaAPIKey to generate an API key. You need this key to finish the installation of the CSD.

2. On the Hadoop node that hosts Cloudera Manager, copy the CSD file into /opt/cloudera/csd.

3. Restart Cloudera Manager:

   $ service cloudera-scm-server restart

4. In a web browser, go to Cloudera Manager and restart the Cloudera Management Service.

5. If your Vertica cluster is separate from your Hadoop cluster (not co-located on it): Use Cloudera Manager to add the hosts for your database nodes. If your cluster is co-located, skip this step.

6. Use Cloudera Manager to add the Vertica service.
7. On the "Role Assignment" page, select the hosts that are database nodes.

8. On the "Configuration" page, specify values for the following fields:
   - database name
   - agent port (accept the default if you're not sure)
   - API key
   - database user to run as (usually dbadmin) and password

**About the Agent**

When you manage Vertica through Cloudera Manager, you are actually interacting with the Vertica Agent, not the database directly. The Agent runs on all database nodes and interacts with the database on your behalf. Management Console uses the same agent. Most of the time this extra indirection is transparent to you.

A Cloudera-managed service contains one or more roles. In this case the service is "Vertica" and the single role is "Vertica Node".

**Available Operations**

Cloudera Manager shows two groups of operations. Service-level operations apply to the service on all nodes, while role-level operations apply only to a single node.

You can perform the following service-level operations on all nodes:

- **Start**: Starts the agent and, if it is not already running, the database.
- **Stop**: Stops the database and agent.
- **Restart**: Calls Stop and then Start.
- **Add Role Instances**: Adds new database nodes to Cloudera Manager. The nodes must already be part of the Vertica cluster, and the hosts must already be known to Cloudera Manager.
- **Enter Maintenance Mode**: Suppresses health alerts generated by Cloudera Manager.
- **Exit Maintenance Mode**: Resumes normal reporting.
• Update Memory Pool Size: Applies memory-pool settings from the Static Service Pools configuration page.

You can perform all of these operations except Add Role Instances on individual nodes as role-level operations.

Managing Memory Pools

Cloudera Manager allows you to change resource allocations, such as memory and CPU, for the nodes it manages. If you are using co-located clusters, centrally managing resources can simplify your cluster management. If you are using separate Hadoop and Vertica clusters, you might prefer to manage Vertica separately as described in Managing the Database in the Administrator's Guide.

Use the Cloudera Manager "Static Service Pools" configuration page to configure resource allocations. The "Vertica Memory Pool" value, specified in GB, is the maximum amount of memory to allocate to the database on each node. If the configuration page includes "Cgroup Memory Hard Limit", set it to the same value as "Vertica Memory Pool".

After you have set these values, you can use the "Update Memory Pool Size" operation to apply the value to the managed nodes. This operation is equivalent to ALTER RESOURCE POOL GENERAL MAXMEMORYSIZE. Configuration changes in "Static Service Pools" do not take effect in Vertica until you perform this operation.

Uninstalling the Service

To uninstall the Vertica CSD, follow these steps:

1. Stop the Vertica service and then remove it from Cloudera Manager.
2. Remove the CSD file from /opt/cloudera/csd.
3. From the command line, restart the Cloudera Manager server.
4. In Cloudera Manager, restart the Cloudera Management Service.
Integrating Vertica with the MapR Distribution of Hadoop

MapR is a distribution of Apache Hadoop produced by MapR Technologies that extends the standard Hadoop components with its own features. Vertica can integrate with MapR in the following ways:

- You can read data from MapR through an NFS mount point. After you mount the MapR file system as an NFS mount point, you can use CREATE EXTERNAL TABLE AS COPY or COPY to access the data as if it were on the local file system. For ORC or Parquet data, see also Reading ORC and Parquet Formats. This option provides the best performance for reading data.

- You can use the HCatalog Connector to read Hive data. Do not use the HCatalog Connector with ORC or Parquet data in MapR for performance reasons. Instead, mount the MapR file system as an NFS mount point and create external tables without using the Hive schema. For more about reading Hive data, see Using the HCatalog Connector.

- You can create a storage location to store data in MapR using the native Vertica format (ROS). Mount the MapR file system as an NFS mount point and then use CREATE LOCATION...ALL NODES SHARED to create a storage location. (CREATE LOCATION does not support NFS mount points in general, but does support them for MapR.)

Note: If you create a Vertica database and place its initial storage location on MapR, Vertica designates the storage location for both DATA and TEMP usage. Vertica does not support TEMP storage locations on MapR, so after you create the location, you must alter it to store only DATA files. See Altering Location Use. Ensure that you have a TEMP location on the Linux file system.

Other Vertica integrations for Hadoop are not available for MapR.

For information on mounting the MapR file system as an NFS mount point, see Accessing Data with NFS and Configuring Vertica Analytics Platform with MapR on the MapR website. In particular, you must configure MapR to add Vertica as a MapR service.

Examples

In the following examples, the MapR file system has been mounted as /mapr.
The following statement creates an external table from ORC data:

```sql
CREATE EXTERNAL TABLE t (a1 INT, a2 VARCHAR(20))
AS COPY FROM '/mapr/data/file.orc' ORC;
```

The following statement creates an external table from Parquet data and takes advantage of partition pruning (see Using Partition Columns):

```sql
CREATE EXTERNAL TABLE t2 (id int, name varchar(50), created date, region varchar(50))
AS COPY FROM '/mapr/*/*/*' PARQUET(hive_partition_cols='created,region');
```

The following statement loads ORC data from MapR into Vertica:

```sql
COPY t FROM '/mapr/data/*.orc' ON ANY NODE ORC;
```

The following statements create a storage location to hold ROS data in the MapR file system:

```sql
CREATE LOCATION '/mapr/my.cluster.com/data' SHARED USAGE 'DATA' LABEL 'maprfs';
SELECT ALTER_LOCATION_USE('/mapr/my.cluster.com/data', '', 'DATA');
```
Integrating with Apache Kafka

Welcome to the Vertica Data Streaming Integration Guide.
Audience

This book is intended for anyone who wants to load data from an existing data streaming message bus into a Vertica database.
Prerequisites

This document assumes that you have installed and configured Vertica as described in *Installing Vertica* and the Configuring the Database section of the Administrator's Guide. In addition, you must have Java 7.0 or later installed on your Vertica node. Refer to the Vertica product documentation to learn more.

In addition, this guide assumes you have installed and configured your data streaming platform. For details on installing and using third party applications, please refer to the documentation for that application.
How Vertica and Data Streaming Work Together

Vertica provides a high-performance mechanism for streaming data both to and from third party message buses. Data streaming provides high volumes of data with low latency.

This feature lets you:

- Store and analyze data that is generated by any application that writes to the message bus. With a message bus, you do not need to worry about individually configuring each application to connect to Vertica.

- Send Vertica data to any application that can read from the message bus. There are two types of data you can send to a data bus:
  - Vertica tables and results of queries. This feature lets you export the results of Vertica analytics to any other application connected to the message bus.
  - Data from Vertica’s Data Collector tables. You can use this data to monitor your Vertica database’s performance and health via third-party monitoring tools.

Because Vertica can both receive and send data to a streaming message bus, you can use it as part of an automated analytics workflow. Vertica can retrieve data from the message bus, perform analytics on it, and then send the results back to the message bus for consumption by other applications.

Common Uses of Data Streaming with Vertica

There are many cases where you could use Vertica to process data from a streaming data source. This document will use the following two cases as examples:

- Retrieving and processing data from an e-commerce site. This includes raw access logs from a web server farm, clickstream data generated by a JavaScript-based Web 2.0 interface, and even back-end fulfillment processing.

- An Internet of Things (IOT) network where device sensor data is sent from many individual devices to the message bus via web API calls.
Data Streaming Integration Terms

Vertica uses the following terms to describe its streaming feature. These are general terms, which may differ from each specific streaming platform's terminology.

### Terminology

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>A data streaming server.</td>
</tr>
<tr>
<td>Source</td>
<td>A feed of messages in a common category which streams into the same Vertica target tables. In Apache Kafka, a source is known as a topic.</td>
</tr>
<tr>
<td>Partition</td>
<td>Unit of parallelism within data streaming. Data streaming splits a source into multiple partitions, which can each be served in parallel to consumers such as a Vertica database. Within a partition, messages are usually ordered chronologically.</td>
</tr>
<tr>
<td>Offset</td>
<td>An index into a partition. This index is the position within an ordered queue of messages, not an index into an opaque byte stream.</td>
</tr>
<tr>
<td>Message</td>
<td>A unit of data within data streaming. The data is typically in JSON or Avro format. Messages are loaded as rows into Vertica tables, and are uniquely identified by their source, partition, and offset.</td>
</tr>
</tbody>
</table>

### Data Loader Terminology

<table>
<thead>
<tr>
<th>Data Loader Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheduler</td>
<td>An external tool that schedules data loads from a streaming data source into Vertica.</td>
</tr>
</tbody>
</table>
| Microbatch       | A microbatch represents a single segment of a data load from a
<table>
<thead>
<tr>
<th>Data Loader Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>streaming data source. It encompasses all of the information the scheduler needs to perform a load from a streaming data source into Vertica.</td>
<td></td>
</tr>
<tr>
<td>Frame</td>
<td>The window of time during which a Scheduler executes microbatches to load data. This window controls the duration of each COPY statement the scheduler runs as a part of the microbatch. The during the frame, the scheduler gives an active microbatch from each source an opportunity to load data. It gives priority to microbatches that need more time to load data based on the history of previous microbatches.</td>
</tr>
<tr>
<td>Stream</td>
<td>A feed of messages that is identified by a source and partition. The offset uniquely identifies the position within a particular source-partition stream.</td>
</tr>
<tr>
<td>Lane</td>
<td>A thread within a job scheduler instance that issues microbatches to perform the load. The number of lanes available is based on the PlannedConcurrency of the job scheduler's resource pool. Multiple lanes allow the scheduler to run microbatches for different sources in parallel during a frame.</td>
</tr>
</tbody>
</table>
Vertica and Apache Kafka

Currently, the only data streaming platform that Vertica supports is Apache Kafka. Kafka is an open-source distributed real-time streaming platform. See Apache's main Kafka page for more information. By integrating Kafka and Vertica, you can load data from any application that produces Kafka messages.

The integration features between Vertica and Kafka consist of:

- A UDx library containing functions that load and parse data from Kafka topics into Vertica.
- A job scheduler that uses the UDL library to continuously consume data from your message bus with exactly-once semantics
- Push-based Monitoring Vertica Using Notifiers that send data collector messages from Vertica to Kafka
- A KafkaExport function that sends Vertica data to Kafka.

Consuming Data from Kafka

There are two ways to load data from Kafka:
Manually, by directly executing a COPY statement. You use this method to load a finite amount of data. Some reasons you may want to manually load data:

- Managing a streaming data load with greater control than using a scheduler. Schedulers can manage data loads in many cases. However, you may find you need greater control over the data load than is available through the scheduler.

- Loading specific chunks of data you want to analyze, rather than constantly streaming data. For example, you may want to load web server logs from a specific time period to perform in-depth analytics.

- Manually testing your Kafka and Vertica configuration before creating a streaming data load. See Manually Copying Data From Kafka for more information.

Automatically via job schedulers. The schedulers constantly load data from Kafka and ensure each Kafka message is loaded exactly once. See Automatically Copying Data From Kafka for more information.

Producing Data for Kafka

Vertica can send data to Kafka for processing by other consumers of Kafka's data streams. There are two ways you can send data to Kafka:

- You use notifiers to send Vertica health and performance data stored in the Data Collector tables. This feature is useful to stream data to third-party monitoring tools.

- You use the KafkaExport function to export Vertica data to Kafka. See Producing Data Using KafkaExport for more information.
Configuring Vertica and Kafka

Both Vertica and Kafka have settings you can use to optimize your streaming data loads. The topics in this section explain these settings.

Kafka and Vertica Configuration Settings

The following sections lists settings for Vertica and Kafka that you can set to optimize performance.

Vertica Producer Settings

These settings change how Vertica acts as a Kafka producer when using either the KafkaExport function or through notifiers. How you change these settings depends on the method you are using to export data (KafkaExport or Notifiers).

<table>
<thead>
<tr>
<th>Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>queue.buffering.max.messages</td>
<td>Specifies the size of the Vertica producer queue. If Vertica generates too many messages too quickly, the queue can fill, resulting in dropped messages. Increasing this value consumes more memory, but reduces the chance of lost messages.</td>
</tr>
<tr>
<td>queue.buffering.max.ms</td>
<td>Specifies the frequency with which Vertica flushes the producer message queue. Lower values decrease latency at the cost of throughput. Higher values increase throughput, but can cause the producer queue (set by queue.buffering.max.messages) to fill more frequently, resulting in dropped messages.</td>
</tr>
<tr>
<td>message.max.bytes</td>
<td>Specifies the maximum size of a Kafka protocol request message batch. This values should be the same on your sources, brokers, and producers.</td>
</tr>
<tr>
<td>message.send.max.retries</td>
<td>Specifies the number of attempts the producer makes to deliver the message to a broker. Higher values increase the chance of success.</td>
</tr>
</tbody>
</table>
### Kafka Broker Settings

Kafka brokers receive messages from producers and distribute them among Kafka consumers. Configure these settings on the brokers themselves. These settings function independently of your producer and consumer settings. For detailed information on Apache Kafka broker settings, refer to the [Apache Kafka documentation](https://kafka.apache.org/documentation/).

<table>
<thead>
<tr>
<th>Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>retry.backoff.ms</td>
<td>Specifies the interval Vertica waits before resending a failed message.</td>
</tr>
<tr>
<td>request.required.acks</td>
<td>Specifies how many broker replica acknowledgments Kafka requires before it considers message delivery successful. Requiring acknowledgments increases latency. Removing acknowledgments increases the risk of message loss.</td>
</tr>
<tr>
<td>request.timeout.ms</td>
<td>Specifies the interval that the producer waits for a response from the broker. Broker response time is affected by server load and the number of message acknowledgments you require. Higher values increase latency.</td>
</tr>
<tr>
<td>message.max.bytes</td>
<td>Specifies the maximum size of a Kafka protocol request message batch. This values should be the same on your sources, brokers, and producers.</td>
</tr>
<tr>
<td>num.io.threads</td>
<td>Specifies the number of network threads the broker uses to receive and process requests. More threads can increase your concurrency.</td>
</tr>
<tr>
<td>num.network.threads</td>
<td>Specifies the number of network threads the broker uses to accept network requests. More threads can increase your concurrency.</td>
</tr>
</tbody>
</table>
Vertica Consumer Settings

The following settings changes how Vertica acts when it consumes data from Kafka. You can set this value using the kafka_conf parameter on the KafkaSource UDL when directly executing a COPY statement. For schedulers, use the --message_max_bytes settings in the scheduler tool.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>message.max.bytes</td>
<td>Specifies the maximum size of a Kafka protocol request message batch. Set this value to a high enough value to prevent the overhead of fetching batches of messages interfering with loading data. Defaults to 24MB for newly-created load specs.</td>
</tr>
</tbody>
</table>

**Important:** The meaning of this setting changed between Kafka version 0.10 and 0.11. If you have a scheduler you created using Vertica version 9.1.0 or earlier, see Changes to the message.max.bytes Setting in Kafka Version 0.11 and Later for settings you may need to change.

Directly Setting Kafka Library Options

Vertica relies on the open source rdkafka library to communicate with Apache Kafka. This library contains many options for controlling how Vertica and Kafka interact. You set the most common rdkafka library options through the settings in the vkconfig utility and the Kafka integration functions such as KafkaSource.

There are some rdkafka settings that cannot be directly set from within the Vertica. Under normal circumstances, you do not need to change them. However, if you find that you need to set a specific rdkafka setting that is not directly available from Vertica, you can directly pass options to the rdkafka library through the kafka_conf options.

The kafka_conf argument is supported when using a scheduler to load data from Kafka. You can set the values in the following ways (listed in order of lower to higher precedence):
- The Linux environment variable `VERTICA_RDKAFKA_CONF` set on the host where you run the `vkconfig` utility.

- The Linux environment variable `VERTICA_RDKAFKA_CONF_KAFKA_CLUSTER` set on the host where you run the `vkconfig` utility. The `KAFKA_CLUSTER` portion of the variable name is the name of a Kafka cluster you have defined using `vkconfig`'s `cluster utility`. The settings in this environment variable only affect the specific Kafka cluster you name in `KAFKA_CLUSTER`.

- The `--kafka_conf` option of the `vkconfig` utility. This option can be set in the `cluster`, `source`, `launch`, and `sync` tools. Note that the setting only applies to each `vkconfig` utility call—it does not carry over to other `vkconfig` utility calls. For example, if you need to supply an option to the cluster and source tool, you must supply the `kafka_conf` option to both of them.

  **Note:** Using an environment variable to set your rdkafka options helps to keep your settings consistent. It is easy to forget to set the `--kafka_conf` option for each call to the `vkconfig` script.

All of these options cascade, so setting an option using the `--kafka_conf` argument to the cluster tool overrides the same option that was set in the environment variables.

You can also directly set rdkafka options when directly calling KafkaExport, KafkaSource, and several other Kafka integration functions. These functions accept a parameter named `kafka_conf`.

### The `kafka_conf` Option Settings

The format for the `kafka_conf` setting is an option name, an equal sign, and a value. You can supply multiple options by separating them with a semicolon. For example, the `--kafka_conf` option to the `vkconfig` utility looks like this:

```
--kafka_conf 'option1=value1;option2=value2'
```

See the [rdkafka project on github](https://github.com/edenhill/librdkafka) for a list of the configuration options supported by the rdkafka library.

**Important:** Arbitrarily setting options via `kafka_conf` can result in errors or unpredictable behavior. If you encounter a problem loading messages after setting an rdkafka option using the `kafka_conf` option, roll back your change to see if that was the source of the problem. To prevent confusion, never set options via the `kafka_conf` parameter that can be set
directly through scheduler options. For example, do not use the \texttt{kafka\_conf} option to set Kafka's \texttt{message.max.bytes} setting. Instead, use the load-spec tool's \texttt{--message-max-bytes} option.

\section*{Example}

The following example demonstrates disabling \texttt{rdkafka}'s \texttt{api.version.request} option when manually loading messages using KafkaSource. You should always disable this option when accessing Kafka cluster running version 0.9 or earlier. See Configuring Vertica for Apache Kafka Version 0.9 and Earlier for more information.

\begin{verbatim}
=> CREATE FLEX TABLE iot_data();
CREATE TABLE
=> COPY public.iot_data SOURCE KafkaSource(stream='iot\_json|0|-2',
brokers='kafka-01.example.com:9092',
stop_on_eof=True,
kafka_conf='api.version.request=false')
PARSER KafkaJSONParser();
Rows Loaded
-------------
  5000
(1 row)
\end{verbatim}

This example demonstrates setting two options when calling the cluster tool. It disables the \texttt{api.version.request} option and enables CRC checks of messages from Kafka using the \texttt{check.crcs} option:

\begin{verbatim}
$ vkconfig cluster --create --cluster StreamCluster1 \ 
  --hosts kafka01.example.com:9092,kafka02.example.com:9092 \ 
  --conf myscheduler.config \ 
  --kafka_conf 'api.version.request=false;check.crcs=true'
\end{verbatim}

The following example demonstrates setting the same options using an environment variable:

\begin{verbatim}
$ export VERTICA_RDKAFKA_CONF=api.version.request=false;check.crcs=true
$ vkconfig cluster --create --cluster StreamCluster1 \ 
  --hosts kafka01.example.com:9092,kafka02.example.com:9092 \ 
  --conf myscheduler.config
\end{verbatim}

Setting the \texttt{check.crc} option is just used an example here. Vertica does not suggest you enable the CRC check in your schedulers under normal circumstances. It adds additional overhead and can result in slower performance.
Configuring Vertica for Apache Kafka Version 0.9 and Earlier

Apache Kafka version 0.10 introduced a new feature that allows consumers to determine which version of the Kafka API the Kafka brokers support. Consumers that support this feature send an initial API version query to the Kafka broker to determine the API version to use when communicating with them. Kafka brokers running version 0.9.0 or earlier cannot respond to the API query. If the consumer does not receive a reply from the Kafka broker within a timeout period (set to 10 seconds by default) the consumer can assume the Kafka broker is running Kafka version 0.9.0 or earlier.

The Vertica integration with Kafka supports this API query feature starting in version 9.1.1. This API check can cause problems if you are connecting Vertica to a Kafka cluster running 0.9.0 or earlier. You may notice poorer performance loading messages from Kafka and may experience errors as the 10 second API request timeout can cause parts of the Kafka integration feature to time out and report errors.

For example, if you run the vkconfig source utility to configure a source on a Kafka 0.9 cluster, you may get the following error:

```
$ vkconfig source --create --conf weblog.conf --cluster kafka_weblog --source web_hits
Exception in thread "main" com.vertica.solutions.kafka.exception.ConfigurationException:

```
Disabling the API Version Request When Using the Streaming Job Scheduler

To avoid these problems, you must disable the API version request feature in the rdkafka library that Vertica uses to communicate with Kafka. The easiest way to disable this setting when using the scheduler is to set a Linux environment variable on the host on which you run the vkconfig script. Using the environment variable ensures that each call to vkconfig includes the setting to disable the API version request. The vkconfig script checks two variables:

- `VERTICA_RDKAFKA_CONF` applies to all Kafka clusters that the scheduler running on the host communicates with.

- `VERTICA_RDKAFKA_CONF_CLUSTER_NAME` applies to just the Kafka cluster named `CLUSTER_NAME`. Use this variable if your scheduler communicates with several Kafka clusters, some of which are not running version 0.9 or earlier.

If you set both variables, the cluster-specific one takes precedence. This feature is useful if most of the clusters your scheduler connects to are running Kafka 0.9 or earlier, but a few run 0.10 or later. This case, you can disable the API version check for most clusters using the `VERTICA_RDKAFKA_CONF` variable and re-enable the check for specific clusters using `VERTICA_RDKAFKA_CONF_CLUSTER_NAME`.

If just a few of your Kafka clusters run version 0.9 or earlier, you can just set the cluster-specific variables for them, and leave the default values in place for the majority of your clusters.

The content of the environment variable is the setting to tell the rdkafka library to not to query the Kafka cluster for the API version it supports:

```
api.version.request=false
```

To set the environment variable in BASH, use the export command:

```
$ export VERTICA_RDKAFKA_CONF=api.version.request=false
```

If you wanted the setting to just affect a cluster named kafka_weblog, the command is:

```
$ export VERTICA_RDKAFKA_CONF_kafka_weblog=api.version.request=false
```

You can add the command to any of the common user environment configuration files such as ~/.bash_profile or the system-wide files such as /etc/profile. You must ensure that the same setting is used for all users who may run the vkconfig script, including any calls made by daemon processes such as init. You can also directly include this command in any script you use to set configure or start your scheduler.
Disabling the API Version Request When Directly Loading Messages

You can disable the API request when you directly call KafkaSource to load messages by using the kafka_conf parameter:

```sql
=> CREATE FLEX TABLE iot_data();
CREATE TABLE => COPY public.iot_data SOURCE KafkaSource(stream='iot_json\0|\-2',
brokers='kafka-01.example.com:9092',
stop_on_eof=True,
kafka_conf='api.version.request=false')
PARSER KafkaJSONParser();
Rows Loaded
-------------
5000
(1 row)
```

Changes to the message.max.bytes Setting in Kafka Version 0.11 and Later

In Kafka version 0.10 and earlier, the message.max.bytes setting configured the maximum allowable size for an individual message. Starting in version 0.11, Kafka began grouping messages into batches. This version changed the meaning of this setting to be the largest allowable size of a message batch.

This change can have a significant impact on how fast your Vertica database loads messages from Kafka 0.11 and later. If you created your streaming job scheduler using Vertica version
9.1.0 or earlier, you may find that its load spec's message.max.bytes value is set too low. Upgrading your scheduler does not automatically adjust this setting.

To prevent slow throughput when using Vertica with Kafka 0.11 and later, manually adjust the message.max.bytes setting in scheduler's load spec. Testing by Vertica suggests the best value for this setting is 25165824 (24 × 1024 × 1024) bytes.

The following example demonstrates updating the message.max.bytes setting in the load spec named weblog_load of an existing scheduler that is defined using the configuration file named weblog.conf:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update \  --load-spec weblog_load --conf weblog.conf --message-max-bytes 25165824
```
Manually Copying Data From Kafka

You can manually stream data from Kafka into Vertica using a COPY statement. This technique is similar to copying data from other sources, such as the local file system, a client system, or from Apache Hadoop. See Bulk-Loading Data and the COPY statement reference for more information about using the COPY statement.

Manually copying data from Kafka is useful when you have a specific set of messages that you want to analyze. It is also useful when you want to explore the data in a Kafka stream before setting up a scheduler to continuously stream the data into Vertica.

Manually copying data from Kafka also gives you more control over the data load than using a scheduler. For example, suppose you want to perform business logic or custom rejection handling during the data load from Kafka. The scheduler does not support performing additional processing during its transactions. Instead, you may choose to periodically run a transaction that executes a COPY statement to load data from Kafka and then perform additional processing.

Unlike other copy methods, copying from Kafka usually implies your COPY statement loads data for a set period of time, rather than loading all of the data from a file or other source. For example, you can choose to COPY all of the messages sent to a Kafka topic for one minute. Vertica copies just the data streamed during that one minute period. After the duration is up, the COPY statement ends and Vertica does not load any further data.

**Important:** The durations you set for your data load is not exact. The duration actually controls how long the KafkaSource process runs. The actual COPY statement may run for a shorter period of time.

If you start a long-duration COPY statement from Kafka and need to stop it, you can call one of the functions that closes its session, such as `CLOSE_ALL_SESSIONS`.

You can also choose specific ranges of messages to load from a topic using offsets. Kafka stores a backlog of messages for topics. How long it stores these messages is configured by the Kafka administrator. Copying using offsets lets you load this previously sent data. You can even choose to load all of the messages that Kafka has stored for a topic and also load the messages sent over a period of time.

When copying data from Kafka, the source of your COPY statement is always `KafkaSource`. Your COPY statement usually uses one of three parsers: `KafkaParser`, `KafkaJSONParser`, or `KafkaAvroParser`. The other parsers (such as the Flex FCSVPARSER) are not directly compatible with the output of KafkaSource. You must alter KafkaSource's output using filters before other parsers can process the data. See Parsing Custom Formats for more information.

This example demonstrates copying data from Kafka into a Vertica table:
=> COPY public.from_kafka
    SOURCE KafkaSource(stream='iot_data|0|-2,iot_data|1|-2',
                        brokers='kafka01.example.com:9092',
                        duration=interval '10000 milliseconds')
    PARSER KafkaAvroParser(schema_registry_url='http://localhost:8081/subjects/iot_data-value/versions/1')
    REJECTED DATA AS TABLE public.rejections
    DIRECT NO COMMIT;

In the previous example:

- The data is copied into a table named from_kafka in the public schema.
- The KafkaSource streams data from partitions 0 and 1 of the topic named iot_data.
- The streaming starts from the earliest available message in the stream set by the -2 in the stream offset parameter. This is a special offset value indicating that the load should start from the earliest possible message.
- KafkaSource reads the data from the Kafka broker running on the host named kafka01.example.com on port 9092.
- COPY loads data for 10000 milliseconds (10 seconds). If it loads all of the existing data in the topic in this time, it waits for any streaming data to arrive until the 10 seconds has elapsed.
- The stream is parsed as Avro data.
- The schema that the Avro parser uses to parse the data is retrieved from a schema registry running on the local system.
- Rejected data is saved in a table named public.rejections.

For more information, see the KafkaSource reference topic.

When you use COPY TRICKLE, Vertica recommends enabling the ReflexiveMoveout configuration parameter to trigger a Tuple Mover moveout task every time a commit occurs:

=> ALTER DATABASE dbname SET ReflexiveMoveout=1;

Note: If you are copying data containing default values into a flex table, you must identify the default value column as __raw__. For more information, refer to "Handling Default Values During Loading" in Bulk Loading Data into Flex Tables.
Manually Loading Kafka Data Example

This example demonstrates loading JSON-encoded data from a Kafka topic named web_hits that streams server logs of requests from a web site. The messages in the topic look like this:

```json
{"url": "list.jsp", "ip": "144.177.38.106", "date": "2017/05/02 20:56:00", "user-agent": "Mozilla/5.0 (compatible; MSIE 6.0; Windows NT 6.0; Trident/5.1)"}
{"url": "search/wp-content.html", "ip": "215.141.172.28", "date": "2017/05/02 20:56:01", "user-agent": "Opera/9.53.(Windows NT 5.2; sl-SI) Presto/2.9.161 Version/10.00"}
```

In order to load this data, you first need a table to receive it. At first glance, the data seems rather uniform, so you could load it into a standard Vertica table. However, as this is JSON data, some messages may have added values that aren't apparent from a small sample. It is safer in this case to load the data into flex table. Flex tables can dynamically accept additional fields that appear in the data. For more information about flex tables, see Using Flex Tables.

The following example creates a flex table named web_hits to hold the Kafka data:

```sql
=> CREATE FLEX TABLE web_hits();
```

Before you load data from Kafka, you must determine the values for your call to the KafkaSource UDL based on your Kafka cluster and the topic you are loading:

- What are the host names (or IP addresses) and port numbers of the brokers in your Kafka cluster? The Kafka brokers are the service Vertica accesses in order to retrieve the Kafka data. In this example, the Kafka cluster has a single broker named kafka01.example.com, running on port 6667. This value is set in the brokers parameter.

- What topic will you be loading from, and from what partitions in that topic? Kafka topics are split their messages into different partitions to get scalable throughput. As mentioned earlier, this example will load data from a topic named web_hits. There is a single partition in web_hits, so this example will just specify 0 for the partition. This value is set in the stream parameter.

- What offset within the topic do you want to start loading data? Kafka keeps a backlog of messages. The Kafka administrator sets the length of this backlog. You can choose to load some or all of the messages in the backlog, or just load the currently streamed messages. You can also choose to end loading at a specific offset. This example will start loading data at the earliest possible message. The offset value to load the entire backlog is -2. This value is also set in the stream parameter.
• When should the COPY statement stop loading data? Copying data from Kafka is unlike most other sources (such as files), because streamed data is constantly arriving. You can choose to:
  ■ copy as much data as possible during a set amount of time.
  ■ have the COPY statement load data until no new data arrives within a timeout period.
  ■ load all of the data that is available, and not wait for any further data to arrive.
  ■ load a specific set of data from a starting offset to an ending offset

In this example, the COPY will run for 10000 milliseconds (10 seconds) to get a sample of the data. If the COPY statement is able to load the entire backlog of data in under 10 seconds, it will spend the remaining time loading streaming data as it arrives. This values is set in the duration parameter.

• How many threads will Vertica use to load the data from Kafka? Usually, you want to use 1 thread per partition being loaded from the Kafka topic. You can choose to not specify a value and let Vertica determine the number of threads to use based on the number of partitions and the resources available in the resource pool. This value is set in the KafkaSource's executionparallelism parameter. In this example, there is only one partition, so there's no need for additional threads to load data.

  Note: The EXECUTIONPARALLELISM setting on the resource pool assigned to your COPY statement sets the upper limit on the number of threads it can use. Setting the executionparallelism parameter on the KafkaSource function call to a value that is higher than that of the resource pool's EXECUTIONPARALLELISM setting will not increase the number of threads Vertica uses beyond the limits of the resource pool.

• What parser do you need to parse the data? Kafka does not enforce any sort of formatting on the messages it sends. They are often in Avro or JSON format. However, they could be in any format. In this example, the data in the web_hits is encoded in JSON format, so it will use the KafkaJSONParser. This value is set in the COPY statement's PARSER clause.

• Where should rejected data be sent? Vertica saves raw Kafka messages that the parser cannot parse to a rejects table along with information on why it was rejected. This table is created by the COPY statement. This example will use the table named web_hits_rejections. This value is set in the COPY statement's REJECTED DATA AS TABLE clause.

The following statement loads the data using these options:
A few things to note in the example statement:

- The stream parameter combines the name of the topic, the topic partition to load from, and the offset into a list delimited by a pipe character (|). To load from additional partitions in the same topic, or even additional topics, supply a comma separated list of topic name, partition number, and offset values delimited by pipe characters. For example, to load from partitions 0 through 2, your stream argument would be:

  stream=\'web\_hits\|0\|2,web\_hits\|1\|2,web\_hits\|2\|2\'
flex table, which can accommodate almost any data you want to load.

- The KafkaJSONParser accepts parameters that let you control how JSON data is transformed. See KafkaJSONParser for more information.
Automatically Copying Data From Kafka

Vertica offers a scheduler that loads streamed messages from one or more Kafka topics. Automatically loading streaming data has a number of advantages over manually using COPY:

- The streamed data automatically appears in your database. The frequency with which new data appears in your database is governed by the scheduler's frame duration.

- The scheduler provides an exactly-once consumption process. The schedulers manage offsets for you so that each message sent by Kafka is consumed once.

- You can configure backup schedulers to provide high-availability. Should the primary scheduler fail for some reason, the backup scheduler automatically takes over loading data.

- The scheduler manages resources for the data load. You control its resource usage through the settings on the resource pool you assign to it. When loading manually, you must take into account the resources your load consumes.

There are a few drawbacks to using a scheduler which may make it unsuitable for your needs. You may find that schedulers do not offer the flexibility you need for your load process. For example, schedulers cannot perform business logic during the load transaction. If you need to perform this sort of processing, you are better off creating your own load process. This process would periodically run COPY statements to load data from Kafka. Then it would perform the business logic processing you need before committing the transaction.

For information on job scheduler requirements, refer to Vertica Integration for Apache Kafka.

What the Job Scheduler Does

The scheduler is responsible for scheduling loads of data from Kafka. The scheduler's basic unit of processing is a frame, which is a period of time. Within each frame, the scheduler assigns a slice of time for each active microbatch to run. Each microbatch is responsible for loading data from a single source. Once the frame ends, the scheduler starts the next frame. The scheduler continues this process until you stop it.
The Anatomy of a Scheduler

Each scheduler has several groups of settings, each of which control an aspect of the data load. These groups are:

- The scheduler itself, which defines the configuration schema, frame duration, and resource pool.
- Clusters, which define the hosts in the Kafka cluster that the scheduler contacts to load data. Each scheduler can contain multiple clusters, allowing you to load data from multiple Kafka clusters with a single scheduler.
- Sources, which define the Kafka topics and partitions in those topics to read data from.
- Targets, which define the tables in Vertica that will receive the data. These tables can be traditional Vertica database tables, or they can be flex tables.
- Load specs, which define setting Vertica uses while loading the data. These settings include the parsers and filters Vertica needs to use to load the data. For example, if you are reading a Kafka topic that is in Avro format, your load spec needs to specify the Avro parser.
- Microbatches, which represent an individual segment of a data load from a Kafka stream. They combine the definitions for your cluster, source, target, and load spec that you create using the other vkconfig tools. The scheduler uses all of the information in the microbatch to execute COPY statements using the KafkaSource UDL function to transfer data from Kafka to Vertica. The statistics on each microbatch's load is stored in the stream_microbatch_history table.

The vkconfig Script

You use a Linux command-line script named vkconfig to create, configure, and run schedulers. This script is installed on your Vertica hosts along with the Vertica server in the following path:

```
/opt/vertica/packages/kafka/bin/vkconfig
```

Note: You can install and use the vkconfig utility on a non-Vertica host. You may want to do this if:
You do not want the scheduler to use Vertica host resources.

You want users who do not have shell accounts on the Vertica hosts to be able to set up and alter schedulers.

The easiest way to install vkconfig on a host is to install the Vertica server RPM. You must use the RPM that matches the version of Vertica installed on your database cluster. Do not create a database after installing the RPM. The vkconfig utility and its associated files will be in the /opt/vertica/packages/kafka/bin directory on the host.

The vkconfig script contains multiple tools. The first argument to the vkconfig script is always the tool you want to use. Each tool performs one function, such as changing one group of settings (such as clusters or sources) or starting and stopping the scheduler. For example, to create or configure a scheduler, you use the command:

$ /opt/vertica/packages/kafka/bin/vkconfig scheduler other options...

What Happens When You Create a Scheduler

When you create a new scheduler, the vkconfig script takes the following steps:

- Creates a new Vertica schema using the name you specified for the scheduler. You use this name to identify the scheduler during configuration.

- Creates the tables needed to manage the Kafka data load in the newly-created schema. See Data Streaming Schema Tables for more information.

- Sets the LOCKTIMEOUT session configuration parameter to 0 for the session running the microbatches. When LOCKTIMEOUT is 0, data loads continuously because the scheduler does not have to wait for a lock to be released. If a table is already locked, Vertica cancels the frame and records an error in the events table.

- Creates the kafka_default_pool resource pool if it does not already exist. Schedulers use this resource pool if you do not assign them a pool of their own. Vertica recommends that you always create a resource pool for the exclusive use of your scheduler. See Create a Resource Pool for Your Scheduler for more information.
Validating Schedulers

When you create or configure a scheduler, it validates the following settings:

- Confirms that all brokers in the specified cluster exist.
- Connects to the specified host or hosts and retrieves the list of all brokers in the Kafka cluster. Getting this list always ensures that the scheduler has an up-to-date list of all the brokers. If the host is part of a cluster that has already been defined, the scheduler cancels the configuration.
- Confirms that the specified source exists.
- Retrieves the number of partitions in the source. If no number of partitions is specified, Vertica sets the value to the number of partitions the source has in the cluster.

You can disable validation using the --validation-type option in the vkconfig script's scheduler tool. See Scheduler Tool Options for more information.

Synchronizing Schedulers

By default, the scheduler automatically synchronizes its configuration and source information with Kafka host clusters. You can configure the synchronization interval using the --config-refresh scheduler utility option. Each interval, the scheduler:

- Checks for updates to the scheduler's configuration by querying its settings in its Vertica configuration schema.
- Performs all of the checks listed in Validating Schedulers.

You can configure synchronization settings using the --auto-sync option using the vkconfig script's scheduler tool. Scheduler Tool Options for details.

Launching a Scheduler

You use the vkconfig script's launch tool to launch a scheduler.
When you launch a scheduler, it collects data from your sources, starting at the specified offset. You can view the stream_microbatch_history table to see what the scheduler is doing at any given time.

To learn how to create, configure, and launch a scheduler, see Setting up a Scheduler in this guide.

You can also choose to bypass the scheduler. For example, you might want to do a single load with a specific range of offsets. For more information, see Manually Copying Data From Kafka in this guide.

Managing a Running Scheduler

When you launch a scheduler from the command line, it runs in the foreground. It will run until you kill it (or the host shuts down). Usually, you want to start the scheduler as a daemon process that starts it when the host operating system starts, or after the Vertica database has started.

You shut down a running scheduler using the vkconfig script's shutdown tool. See Shutdown Tool Options for details.

You can change most of a scheduler's settings (adding or altering clusters, sources, targets, and microbatches for example) while it is running. The scheduler automatically acts on the configuration updates.

Launching Multiple Job Schedulers for High Availability

For high availability, you can launch two or more identical schedulers that target the same configuration schema. You differentiate the schedulers using the launch tool's --instance-name option (see Launch Tool Options). The scheduler not in use remains in stand-by mode until the active scheduler fails or is disabled. If the active scheduler fails, the backup scheduler takes over loading data from Kafka where the primary left off.
Viewing Schedulers from the MC

You can view the status of Kafka jobs from the MC. For more information, refer to Viewing Load History.

Setting up a Scheduler

You set up a scheduler using the Linux command line. Usually you perform the configuration on the host where you want your scheduler to run. It can be one of your Vertica hosts, or a separate host where you have installed the vkconfig utility (see The vkconfig Script for more information).

Follow these steps to set up and start a scheduler to stream data from Kafka to Vertica:

1. Create a Config File (Optional)
2. Add the vkconfig Directory to Your Path (Optional)
3. Create a Resource Pool for Your Scheduler
4. Create the Scheduler
5. Create a Cluster
6. Create a Data Table
7. Create a Source
8. Create a Target
9. Create a Load-Spec
10. Create a Microbatch
11. Launch the Scheduler

These steps are explained in the following sections. These sections will use the example of loading web log data (hits on a web site) from Kafka into a Vertica table.
Create a Config File (Optional)

Many of the arguments you supply to the vkconfig script while creating a scheduler do not change. For example, you often need to pass a username and password to Vertica to authorize the changes to be made in the database. Adding the username and password to each call to vkconfig is tedious and error-prone.

Instead, you can pass the vkconfig utility a configuration file using the `--conf` option that specifies these arguments for you. It can save you a lot of typing and frustration.

The config file is a text file with a `keyword=value` pair on each line. Each keyword is a vkconfig command-line option, such as the ones listed in Common vkconfig Script Options

The following example shows a config file named `weblog.conf` that will be used to define a scheduler named `weblog_sched`. This config file is used throughout the rest of this example.

```plaintext
# The configuration options for the weblog_sched scheduler.
username=dbadmin
password=mypassword
dbhost=vertica01.example.com
dbport=5433
config-schema=weblog_sched
```

Add the vkconfig Directory to Your Path (Optional)

The vkconfig script is located in the `/opt/vertica/packages/kafka/bin` directory. Typing this path for each call to vkconfig is tedious. You can add vkconfig to your search path for your current Linux session using the following command:

```bash
$ export PATH=/opt/vertica/packages/kafka/bin:$PATH
```

For the rest of your session, you are able to call vkconfig without specifying its entire path:

```bash
$ vkconfig
Invalid tool
Valid options are scheduler, cluster, source, target, load-spec, microbatch, sync, launch, shutdown, help
```

If you want to make this setting permanent, add the export statement to your `~/.profile` file. The rest of this example assumes that you have added this directory to your shell's search path.
Create a Resource Pool for Your Scheduler

Vertica recommends you always create a resource pool specifically for your scheduler. Schedulers assume they have exclusive use of the resource pool they are assigned. Using a separate pool for a scheduler lets you fine-tune its impact on your Vertica cluster's performance. You create resource pools within Vertica using the CREATE RESOURCE POOL statement.

```sql
=> CREATE RESOURCE POOL weblog_pool MEMORIESIZE '10%' PLANNEDCONCURRENCY 1 QUEUETIMEOUT 0;
```

One key setting in the resource pool for a scheduler is PLANNEDCONCURRENCY. This value tells Vertica how many simultaneous tasks (such as loads) will be using the resource pool. This value allows the scheduler to load from each topic simultaneously. This setting controls the number of simultaneous COPY statements the scheduler runs during each microbatch. Set this value to at least the number of topics the scheduler is reading data from. Setting it slightly higher than the number of topics is a good practice. The higher PLANNEDCONCURRENCY allocates resources for the scheduler's own internal processes, preventing them from impacting the data load.

Another important setting is the pool's EXECUTIONPARALLELISM which controls the number of threads that Vertica uses to load data from the topic. Ideally, you set this value to reflect the number of partitions within the topic. Often, a topic has too many partitions to assign a thread to each one. In these cases, you should set the EXECUTIONPARALLELISM to a value so the threads have an equal number of partitions to read from. For example, suppose the topic your scheduler is reading from has 100 partitions. Then you could set EXECUTIONPARALLELISM to 10, so that each thread will be reading from 10 partitions.

Finally, set the QUEUETIMEOUT parameter to 0. A value of 0 allows data to load continuously. If the scheduler has to wait for resources, it cannot progress, compromising scheduling configurations. By exclusively allocating a resource pool for your scheduler, you do not have to worry about it oversubscribing and causing queuing.

Leave reflexive moveout enabled. This option is on automatically when you create a scheduler.
With reflexive moveout turned on, the Tuple Mover automatically performs a moveout operation when data is committed so that your WOS always has space to load data. For large volumes of data (>100 MB) use a load method of DIRECT.
Not allocating enough resources to your schedulers can result in errors. For example, you may get OVERSHOT DEADLINE FOR FRAME errors if the scheduler is not able to load data from all of the topics it is supposed to in a data frame.

If you do not create and assign a resource pool for your scheduler, it will use the default resource pool named kafka_default_pool.
See Resource Pool Architecture for more information about resource pools.

Create the Scheduler

Vertica includes a default scheduler named stream_config. You can use this scheduler or create a new scheduler using the vkconfig script's scheduler tool with the --create and --config-schema options:

```
$ vkconfig scheduler --create --config-schema scheduler_name --conf conf_file
```

The --create and --config-schema options are the only ones required to add a scheduler with default options. This command creates a new schema in Vertica that holds the scheduler's configuration. See What Happens When You Create a Scheduler for details on the creation of the scheduler's schema.

You can use additional configuration parameters to further customize your scheduler. See Scheduler Tool Options for more information.

The following example:

- Creates a scheduler named weblog_sched using the --config-schema option.
- Grants privileges to configure and run the scheduler to the Vertica user named kafka_user with the --operator option. The dbadmin user must specify additional privileges separately.
- Specifies a frame duration of thirty seconds with the --frame-duration option.
- Sets the resource pool that the scheduler uses to the weblog_pool created earlier:

```
$ vkconfig scheduler --create --config-schema weblog_sched --operator kafka_user
   --frame-duration '00:00:30' --resource-pool weblog_pool --conf weblog.conf
```

Note: Technically, the previous example doesn't need to supply the --config-schema argument because it is set in the weblog.conf file. It appears in this example for clarity. There's no harm in supplying it on the command line as well as in the configuration file, as long as the values match. If they do not match, the value given on the command line takes priority.
Create a Cluster

You must associate at least one Kafka cluster with your scheduler. Schedulers can access more than one Kafka cluster. To create a cluster, you supply a name for the cluster and host names and ports the Kafka cluster's brokers.

When validating your settings, the scheduler connects to the cluster and automatically retrieves the list of all brokers in the cluster. Therefore, you do not have to list every single broker in the --hosts parameter.

The following example creates a cluster named kafka_weblog, with two Kafka broker hosts: kafka01 and kafka03 in the example.com domain. The Kafka brokers are running on port 9092.

```bash
$ vkconfig cluster --create --cluster kafka_weblog 
    --hosts kafka01.example.com:9092,kafka03.example.com:9092 --conf weblog.conf
```

See Cluster Tool Options for more information.

Create a Source

Next, create at least one source for your scheduler to read. The source defines the Kafka topic the scheduler loads data from as well as the number of partitions the topic contains.

To create and associate a source with a configured scheduler, use the source tool. When you create a source, Vertica connects to the Kafka cluster to verify that the topic exists. So, before you create the source, make sure that the topic already exists in your Kafka cluster. Because Vertica verifies the existence of the topic, you must supply the previously-defined cluster name using the --cluster option.

The following example creates a source for the Kafka topic named web_hits on the cluster created in the previous step. This topic has a single partition.

```bash
$ vkconfig source --create --cluster kafka_weblog --source web_hits --partitions 1 --conf weblog.conf
```

Note: The --partitions parameter is the number of partitions to load, not a list of individual partitions. For example, if you set this parameter to 3, the scheduler will load data from partitions 0, 1, 2, and 3.

See Source Tool Options for more information.
Create a Data Table

Before you can create a target for your scheduler, you must create a target table in your Vertica database. This is the table Vertica uses to store the data the scheduler loads from Kafka. You must decide which type of table to create for your target:

- A standard Vertica database table, which you create using the `CREATE TABLE` statement. This type of table stores data efficiently. However, you must ensure that its columns match the data format of the messages in Kafka topic you are loading. You cannot load complex types of data into a standard Vertica table.

- A flex table, which you create using `CREATE FLEX TABLE`. A flex table is less efficient than a standard Vertica database table. However, it is flexible enough to deal with data whose schema varies and changes. It also can load most complex data types that (such as maps and lists) that standard Vertica tables cannot.

Important: Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before it is loaded by the scheduler.

The data in this example is in a set format, so the best table to use is a standard Vertica table. The following example creates a table named `web_hits` to hold four columns of data. This table is located in the public schema.

```sql
=> CREATE TABLE web_hits (ip VARCHAR(16), url VARCHAR(256), date DATETIME, user_agent VARCHAR(1024));
```

Note: You do not need to create a rejection table to store rejected messages. The scheduler creates the rejection table automatically.

Create a Target

Once you have created your target table, you can create your scheduler's target. The target tells your scheduler where to store the data it retrieves from Kafka. This table must exist when you create your target. You use the `vkconfig` script's `target` tool with the `--target-schema` and `--target_table` options to specify the Vertica target table's schema and name. The following example adds a target for the table created in the previous step.

```bash
$ vkconfig target --create --target-schema public --target-table web_hits --conf weblog.conf
```
Create a Load Spec

The scheduler's load spec provides parameters that Vertica uses when parsing the data loaded from Kafka. The most important option is --parser which sets the parser that Vertica uses to parse the data. You have three parser options:

- **KafkaAvroParser** for data in Avro format.
- **KafkaJSONParser** for data in JSON format.
- **KafkaParser** to load each message into a single VARCHAR field. See Parsing Custom Formats for more information.

In this example, the data being loaded from Kafka is in JSON format. The following command creates a load spec named weblog_load and sets the parser to KafkaJSONParser.

```bash
$ vkconfig load-spec --create --parser KafkaJSONParser --load-spec weblog_load --conf weblog.conf
```

See Load Spec Tool Options for more information.

Create a Microbatch

The microbatch combines all of the settings added to the scheduler so far to define the individual COPY statements that the scheduler uses to load data from Kafka.

The following example uses all of the settings created in the previous examples to create a microbatch called weblog.

```bash
$ vkconfig microbatch --create --microbatch weblog --target-schema public --target-table web_hits \
  --add-source web_hits --add-source-cluster kafka_weblog --load-spec weblog_load \
  --conf weblog.conf
```

See Microbatch Tool Options for more information.

Launch the Scheduler

Once you've created at least one microbatch, you can run your scheduler. You start your scheduler using the launch tool, passing it the name of the scheduler's schema. The scheduler begins scheduling microbatch loads for every enabled microbatch defined in its schema.

The following example launches the weblog scheduler defined in the previous steps.

```bash
$ vkconfig launch --schema weblog
```
$ vkconfig launch --conf weblog.conf &

Important: Vertica does not recommend specifying a password on the command line. Passwords on the command line can be exposed by the system's list of processes, which shows the command line for each process. Instead, put the password in a configuration file. Make sure the configuration file's permissions only allow it to be read by the user.

See Launch Tool Options for more information.

Checking that the Scheduler is Running

Once you have launched your scheduler, you can verify that it is running by querying the stream_microbatch_history table in the scheduler's schema. This table lists the results of each microbatch the scheduler has run.

For example, this query lists the microbatch name, the start and end times of the microbatch, the start and end offset of the batch, and why the batch ended. The results are ordered to start from when the scheduler was launched:

```
=> SELECT microbatch, batch_start, batch_end, start_offset, end_offset, end_reason
    FROM weblog_sched.stream_microbatch_history
    ORDER BY batch_start DESC LIMIT 10;
```

Limiting Loads Using Offsets

Kafka maintains a user-configurable backlog of messages. By default, a newly-created scheduler reads all of the messages in a Kafka topic, including all of the messages in the backlog, not just the messages that are streamed out after the scheduler starts. Often, this is what you want.

In some cases, however, you may want to stream just a section of a source into a table. For example, suppose you want to analyze the web traffic of your e-commerce site starting at specific date and time. However, your Kafka topic contains web access records from much further back in time than you want to analyze. In this case, you can use an offset to stream just the data you want into Vertica for analysis.

Another common use case is when you have already loaded data some from Kafka manually (see Manually Copying Data From Kafka). Now you want to stream all of the newly-arriving data. By default, your scheduler ill reload all of the previously loaded data (assuming it is still available from Kafka). You can use an offset to tell your scheduler to start automatically loading data at the point where your manual data load left off.

Configuring a Scheduler to Start Streaming From an Offset

The vkconfig script's microbatch tool has an --offset option that lets you specify the index of the message in the source where you want the scheduler to begin loading. This option accepts a comma-separated list of index values. You must supply one index value for each partition in the source unless you use the --partition option. This option lets you choose the partitions the offsets apply to. The scheduler cannot be running when you set an offset in the microbatch.

If your microbatch defines more than one cluster, use the --cluster option to select which one the offset option applies to. Similarly, if your microbatch has more than one source, you must select one using the --source option.

For example, suppose you want to load just the last 1000 messages from a source named web_hits. To make things easy, suppose the source contains just a single partition, and the microbatch defines just a single cluster and single topic.

Your first task is to determine the current offset of the end of the stream. You can do this on one of the Kafka nodes by calling the GetOffsetShell class with the time parameter set to -1 (the end of the topic):
\$ \textit{path to kafka/bin/kafka-run-class.sh kafka.tools.GetOffsetShell} \ \
\hspace{1cm} \textit{--broker-list kafka01:9092,kafka03:9092 --time -1} \ \
\hspace{1cm} \textit{--topic web\_hits}

\{metadata.broker.list=kafka01:9092,kafka03:9092, request.timeout.ms=1000, \ 
\hspace{1cm} \textit{client.id=GetOffsetShell, security.protocol=PLAINTEXT}\}

\textit{web\_hits:0:8932}

You can also use \texttt{GetOffsetShell} to find the offset in the stream that occurs before a timestamp.

In the above example, the \textit{web\_hits} topic's single partition has an ending offset of 8932. If we want to load the last 1000 messages from the source, we need to set the microbatch's offset to 8932 - 1001 or 7931.

\textbf{Note:} The start of an offset is inclusive in the Vertica COPY statement. Kafka's native starting offset is exclusive. Therefore, you must add one to the offset to get the correct number of messages.

With the offset calculated, you are ready to set it in the microbatch's configuration. The following example:

- Shuts down the scheduler whose configuration information stored in the \texttt{weblog.conf} file.
- Sets the starting offset using the microbatch utility.
- Restarts the scheduler.

\$ \texttt{vkconfig shutdown --conf weblog.conf} \\
\$ \texttt{vkconfig microbatch --microbatch weblog --update --conf weblog.conf --offset 7931} \\
\$ \texttt{vkconfig launch --conf weblog.conf &}

If the target table was empty or truncated before the scheduler started, it will have 1000 rows in the table in it (until more messages are streamed through the source):

\texttt{=> select count(*) from web\_hits;}
\texttt{count}
\texttt{-------}
\texttt{1000}
\texttt{(1 row)}

\textbf{Note:} The last example assumes that the offset values for the last 1000 messages in the Kafka topic were assigned consecutively. This assumption is not always be true. A Kafka topic can have gaps in its offset numbering for a variety of reasons. Offsets refer to the key value assigned to a message by Kafka, not its position in the topic.
Ending a COPY From Kafka at an Offset

When you manually copy data from a Kafka source into Vertica, the COPY statement defaults to loading all of the messages in the topic. You can specify a maximum offset the COPY should load to by supplying an end offset value in addition to the starting offset in the KafaSource's source parameter.

Updating Schedulers After Vertica Upgrades

A scheduler is only compatible with the version of Vertica that created it. Between Vertica versions, the scheduler's configuration schema or the UDx function the scheduler calls may change. After you upgrade Vertica, you must update your schedulers to account for these changes.

When you upgrade Vertica to a new major version or service pack, use the vkconfig scheduler tool's --upgrade option to update your scheduler. If you do not update a scheduler, you receive an error message if you try to launch it. For example:

```bash
$ vkconfig launch --conf weblog.conf
com.vertica.solutions.kafka.exception.FatalException: Configured scheduler schema and current scheduler configuration schema version do not match. Upgrade configuration by running:
vkconfig scheduler --upgrade
    at com.vertica.solutions.kafka.scheduler.StreamCoordinator.assertVersion(StreamCoordinator.java:54)
    at com.vertica.solutions.kafka.scheduler.StreamCoordinator.run(StreamCoordinator.java:125)
    at com.vertica.solutions.kafka.Launcher.run(Launcher.java:205)
    at com.vertica.solutions.kafka.Launcher.main(Launcher.java:258)
$ vkconfig scheduler --upgrade --conf weblog.conf
Checking if UPGRADE necessary...
UPGRADE required, running UPGRADE...
UPGRADE completed successfully, now the scheduler configuration schema version is v8.1.1
$ vkconfig launch --conf weblog.conf
```

Vertica Eon Mode and Kafka

You can use the Vertica integration with Apache Kafka when the Vertica customer is running in Eon Mode. See Using Eon Mode for more information about Eon Mode.

There are differences between Vertica running in Eon Mode verses Enterprise Mode you must take into account when streaming data from Kafka to Vertica:

- In Eon Mode, Vertica does not have a WOS to temporarily store the data it is loading. Not having a WOS means that using the COPY statement to load data from KafkaSource always uses DIRECT mode, even if you specify a TRICKLE load. Similarly, telling the scheduler to use TRICKLE loads (which is its default behavior) has no effect. It always loads data using DIRECT mode.

- Consider using a larger frame duration for your schedulers in Eon Mode clusters. Cloud infrastructures lead to larger latencies overall, especially when storage layers are separated from compute layers. If you leave the scheduler's frame size at the default 10 seconds, you will experience a lower data throughput, as more of the frame's time is lost to overhead caused by the cloud environment. Using a longer frame length can also help prevent Vertica from creating many small ROS containers when loading data from Kafka. The tradeoff when you use a larger frame length is that your data load experiences more latency.
Monitoring Vertica Message Consumption with Consumer Groups

Apache Kafka has a feature named consumer groups that helps distribute message consumption loads across sets of consumers. When using consumer groups, Kafka evenly divides up messages based on the number of consumers in the group. Consumers report back to the Kafka broker which messages it read successfully. This reporting helps Kafka to manage message offsets in the topic's partitions, so that no consumer in the group is sent the same message twice.

Vertica does not rely on Kafka's consumer groups to manage load distribution or preventing duplicate loads of messages. The streaming job scheduler manages topic partition offsets on its own.

Even though Vertica does not need consumer groups to manage offsets, it does report back to the Kafka brokers which messages it consumed. This feature lets you use third-party tools to monitor the Vertica cluster's progress as it loads messages. By default, Vertica reports its progress to a consumer group named vertica-databaseName, where databaseName is the name of the Vertica database. You can change the name of the consumer group that Vertica reports its progress to when defining a scheduler or during manual loads of data. Third party tools can query the Kafka brokers to monitor the Vertica cluster's progress when loading data.

For example, you can use Kafka's kafka-consumer-groups.sh script (located in the bin directory of your Kafka installation) to view the status of the Vertica consumer group. The following example demonstrates listing the consumer groups available defined in the Kafka cluster and showing the details of the Vertica consumer group:

```
$ cd /opt/kafka/bin
$ ./kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

vertica-vmart
$ ./kafka-consumer-groups.sh --describe --group vertica-vmart
   --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-vmart' has no active members.

<table>
<thead>
<tr>
<th>TOPIC</th>
<th>PARTITION HOST</th>
<th>CURRENT-OFFSET</th>
<th>LOG-END-OFFSET CLIENT-ID</th>
<th>LAG</th>
<th>CONSUMER-ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>web_hits</td>
<td>0</td>
<td>24500</td>
<td>30000</td>
<td>5500</td>
<td>-</td>
</tr>
</tbody>
</table>
```

From the output, you can see that Vertica reports its consumption of messages back to the vertica-vmart consumer group. This group is the default consumer group when Vertica has the example VMart database loaded. The second command lists the topics being consumed by the
vertica-vmart consumer group. You can see that the Vertica cluster has read 24500 of the 30000 messages in the topic's only partition. Later, running the same command will show the Vertica cluster's progress:

```
$ cd /opt/kafka/bin
$ /kafka-consumer-groups.sh --describe --group vertica-vmart \   --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-vmart' has no active members.

<table>
<thead>
<tr>
<th>TOPIC</th>
<th>PARTITION</th>
<th>CURRENT-OFFSET</th>
<th>LOG-END-OFFSET</th>
<th>LAG</th>
<th>CONSUMER-ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>web_hits</td>
<td></td>
<td>30000</td>
<td>30000</td>
<td>0</td>
<td>-</td>
</tr>
</tbody>
</table>
```

### Changing the Consumer Group Where Vertica Reports its Progress

You can change the consumer group to which Vertica reports its progress when consuming messages. When using a scheduler, you set the consumer group by setting the `--consumer-group-id` argument to the `vkconfig` script's `scheduler` or `microbatch` utilities. For example, suppose you want the example scheduler shown in Setting up a Scheduler to report its consumption to the consumer group name vertica-database. Then you could use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --update \   --conf weblog.conf --microbatch weblog --consumer-group-id vertica-database
```

When the scheduler begins loading data, it will start updating the new consumer group. You can see this on a Kafka node using `kafka-consumer-groups.sh`:

```
$ /opt/kafka/bin/kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

vertica-database
vertica-vmart
$ /opt/kafka/bin/kafka-consumer-groups.sh --describe --group vertica-database \   --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-database' has no active members.

<table>
<thead>
<tr>
<th>TOPIC</th>
<th>PARTITION</th>
<th>CURRENT-OFFSET</th>
<th>LOG-END-OFFSET</th>
<th>LAG</th>
<th>CONSUMER-ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>web_hits</td>
<td></td>
<td>30300</td>
<td>30300</td>
<td>0</td>
<td>-</td>
</tr>
</tbody>
</table>
To change the consumer group when manually loading data, use the group_id parameter of KafkaSource function:

```sql
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
    brokers='kafka01.example.com:9092',
    stop_on_eof=True,
    group_id='vertica_database')

Rows Loaded
---------
50000
(1 row)
```

## Using Consumer Group Offsets When Loading Messages

You can choose to have your scheduler, manual load, or custom loading script start loading messages from the consumer group's offset. You tell the scheduler or KafkaSource function to load messages from the last offset stored in the consumer group using the special -3 offset value.

This example demonstrates loading messages from the web_hits topic based on the saved offset in a consumer group named vertica_manual. This consumer group is created by the first COPY statement, as it did not exist in Kafka previously. So, this initial COPY statement is identical to using the special -2 offset to load all of the messages currently in the Topic's partition because there was no previously-saved offset. The second COPY statement is run almost immediately after the first, before any more messages have arrived, so it does not load any messages. The third COPY statement is run some time after that, after new messages have arrived:

```sql
=> TRUNCATE TABLE web_hits;

=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-3',
    brokers='kafka01.example.com:9092',
    stop_on_eof=True,
    group_id='vertica_manual')

Rows Loaded
---------
50000
(1 row)
```

```sql
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-3',
    brokers='kafka01.example.com:9092',
    stop_on_eof=True,
    group_id='vertica_manual')

PARSER KafkaJsonParser();
```
Rows Loaded  
-------------
 0
(1 row)

=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-3',
   brokers='kafka01.example.com:9092',
   stop_on_eof=True,
   group_id='vertica_manual')

Rows Loaded  
-------------
 2400
(1 row)

You can have your scheduler start loading messages from the consumer group's saved offset. Use the `--offset` argument of the vkconfig script's microbatch tool to set the offset to -3 from all topic partitions your scheduler reads from. Once it starts its initial load, the scheduler still manages its offsets on its own.

### Disabling Consumer Group Reporting

Vertica reports the offsets of the messages it consumes to Kafka by default. If you do not specifically configure a consumer group for Vertica, it still reports its offsets to a consumer group named `vertica_database-name` (where `database-name` is the name of the database Vertica is currently running).

If you want to completely disable having Vertica report its consumption back to Kafka, you can set the consumer group to an empty string or NULL. For example:

```sql
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
   brokers='kafka01.example.com:9092',
   stop_on_eof=True,
   group_id=NULL)

Rows Loaded  
-------------
 60000
(1 row)
```
Parsing Custom Formats

Vertica supports the use of user-defined filters to manipulate data arriving from your streaming message bus. You can apply these filters to data before you parse it. By default, data that flows from the source does not contain message boundaries. The default Kafka parsers can locate the message boundaries on their own. However, other user-defined and Vertica parsers are not designed to recognize the message boundaries. Two Kafka-specific filters let you insert message boundary information to the data stream (such as delimiters) so that parsers are able to extract and parse individual messages.

Filters for Use with Kafka Data

Vertica includes the following filters:

- **KafkaInsertDelimiters** — Transforms the Kafka data stream by inserting a user-specified delimiter between each message. The delimiter can contain any characters and be of any length. This parser uses the following syntax:

  \[
  \text{KafkaInsertDelimiters}(\text{delimiter} = \text{'delimiter'})
  \]

- **KafkaInsertLengths** — Transforms the Kafka data stream by inserting the length of the following record in bytes at the beginning of the record. Vertica writes lengths as 4-byte uint32 values in Big Endian network byte order. For example, a 100-byte record would be preceded by 0x00000064.

  \[
  \text{KafkaInsertLengths()}
  \]

**Note:** The Vertica provided filters are mutually exclusive. You cannot use both to process a Kafka data stream in the same COPY statement.

Vertica also supports the use of additional Vertica and user-defined filters. If you are using a Vertica filter, it must appear first in the filter list. Use a comma to delimit multiple filters. If you are using a non-Kafka parser, you must use at least one filter to prepare your content for that parser. If you do not provide a filter, the parser fails with the message:

```
Input is not from Kafka source.
```
Example

The following example demonstrates loading comma-separated values from two partitions in a topic named iot-data. The load processes all of the messages in the two partitions, and exits when it reaches the end of the messages currently in Kafka. The example uses the KafkaInsertDelimiters filter to insert newlines between Kafka messages, turning them into traditional rows of data. It relies on the standard COPY parser to parse the CSV values by telling it to use a comma as the column delimiter.

```sql
=> COPY kafka_iot SOURCE KafkaSource(stream='iot-data|0|2,iot-data|1|2',
   brokers='kafka01:9092',
   stop_on_eof=True)
   FILTER KafkaInsertDelimiters(delimiter = E'\n')
   DELIMITER ',';

Rows Loaded
----------
3430
(1 row)
```
Using a Schema Registry with Kafka

Vertica supports the use of a Confluent schema registry for Avro schemas with the KafkaAvroParser. By using a schema registry, you enable the Avro parser to parse and decode messages written by the registry and to retrieve schemas stored in the registry. In addition, a schema registry enables Vertica to process streamed data without sending a copy of the schema with each record. Vertica can access a schema registry in the following ways:

- schema ID
- subject and version

Note: If you use the compatibility config resource in your schema registry, you should specify a value of at least BACKWARD. You may also choose to use a stricter compatibility setting. For more information on installing and configuring a schema registry, refer to the Confluent documentation.

Schema ID Loading

In schema ID based loading, the Avro parser checks the schema ID associated with each message to identify the correct schema to use. A single COPY statement can reference multiple schemas. Because each message is not validated, Vertica recommends that you use a flex table as the target table for schema ID based loading.

The following example shows a COPY statement that refers to a schema registry located on the same host.

```sql
=> COPY logs source kafkasource(stream='simple|0|0', stop_on_eof=true, duration=interval '10 seconds') parser KafkaAvroParser(schema_registry_url='http://localhost:8081/');
```

Subject and Version Loading

In subject and version loading, you specify a subject and version in addition to the schema registry URL. The addition of the subject and version identifies a single schema to use for all messages in the COPY. If any message in the statement is incompatible with the schema, the COPY fails. Because all messages are validated prior to loading, Vertica recommends that you use a standard Vertica table as the target for subject and version loading.
The following example shows a COPY statement that identifies a schema subject and schema version as well as a schema registry.

```sql
=> COPY t source kafkasource(stream='simpleEvolution|0|0',
stop_on_eof=true, duration=interval '10 seconds') parser
KafkaAvroParser(schema_registry_url='http://repository:8081/schema-repo/',
schema_registry_subject='simpleEvolution-value',schema_registry_version='1')
REJECTED DATA AS TABLE "t_rejects";
```
Using Vertica to Produce Data for Kafka

In addition to consuming data from Kafka, Vertica can produce data for Kafka. There are two ways you can have Vertica stream data to Kafka:

- Using the KafkaExport function to send Vertica data to a Kafka topic. Use this feature to export arbitrary data to Kafka for consumption by any other application that is a Kafka consumer.

- Using notifiers to send Vertica diagnostic data from the data collector tables. You use this method primarily to let third-party monitoring applications view the status of your Vertica cluster. See Monitoring Vertica Using Notifiers.

The topics in this section explain how to use these methods in greater detail.

Producing Data Using KafkaExport

The KafkaExport function lets you stream data from Vertica to Kafka. You pass this function three arguments and two or three parameters:

```sql
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
    USING PARAMETERS brokers='host[:port][,host...]',
    topic='topicname'
    [,kafka_conf='kafka_configuration_setting']
OVER (partition_clause) FROM table;
```

The `partitionColumn` and `keyColumn` arguments set the Kafka topic's partition and key value, respectively. You can set either or both of these values to NULL. If you set the partition to NULL, Kafka uses its default partitioning scheme (either randomly assigning partitions if the key value is NULL, or based on the key value if it is not).

The `valueColumn` argument is a LONG VARCHAR containing message data that you want to send to Kafka. Kafka does not impose structure on the message content. Your only restriction on the message format is what the consumers of the data are able to parse.

You are free to convert your data into a string in any way you like. For simple messages (such as a comma-separated list), you can use functions such as CONCAT to assemble your values into a message. If you need a more complex data format, such as JSON, consider writing a UDx function that accepts columns of data and outputs a LONG VARCHAR containing the data in the format you require. See Developing User-Defined Extensions (UDxs) for more information.

The data exported from Vertica using KafkaExport is sent to Kafka in JSON format. See KafkaExport for detailed information about KafkaExport's syntax.
Export Example

This example shows you how to perform a simple export of several columns of a table. Suppose you have the following table containing a simple set of Internet of things (IOT) data:

```
=> SELECT * FROM iot_report LIMIT 10;
server | date       | location | id
--------+------------+----------+----
1       | 2016-10-11 | -14.86058, 112.75848 | 70982027
1       | 2017-07-02 | -21.42197, -127.17672 | 49494918
1       | 2017-10-19 | -71.72156, -36.27381 | 94328189
1       | 2018-07-11 | -9.41315, 102.36866 | 48366610
1       | 2018-08-30 | 83.97962, 162.83848 | 967212
2       | 2017-01-20 | 37.17372, 136.14026 | 36670100
2       | 2017-07-29 | -38.99517, 171.72671 | 52049116
2       | 2018-04-19 | 69.28989, 133.98275 | 36059026
2       | 2018-08-28 | -59.71784, -144.97142 | 77310139
2       | 2018-09-14 | 58.07275, 111.07354 | 4198109
```

You want to send the data in this table to a Kafka topic named iot_results for consumption by other applications. Looking at the data and the structure of the iot_report, you may decide the following:

- The server column is a good match for the partitions in iot_report. There are three partitions in the Kafka topic, and the values in server column are between 1 and 3. Suppose the partition column had a larger range of values (for example, between 1 and 100). Then you could use the modulo operator (%) to coerce the values into the same range as the number of partitions (server % 3).
  
  A complication with these values is that the values in the server are 1-based (the lowest value in the column is 1). Kafka's partition numbering scheme is zero-based. So, you must adjust the values in the server column by subtracting 1 from them.

- The id column can act as the key. This column has a data type of INTEGER. The KafkaExport function expects the key value to be a VARCHAR. Vertica does not automatically cast INTEGER values to VARCHAR, so you must explicitly cast the value in your function call.
The consumers of the `iot_report` topic expect values in comma-separated format. You can combine the values from the date and location columns into a single VARCHAR using nested calls to the CONCAT function.

The final piece of information you need to know is the host names and port numbers of the brokers in your Kafka cluster. In this example, there are two brokers named `kafka01` and `kafka03`, running on port 6667 (the port that Hortonworks clusters use). Once you have all of this information, you are ready to export your data.

The following example shows how you might export the contents of `iot_report`:

```sql
=> SELECT KafkaExport(server - 1, id::VARCHAR,
    CONCAT(CONCAT(date, ' ', location))
    USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
    topic='iot_results') OVER (PARTITION BEST) FROM iot_report;

 partition | key | message | failure_reason
-------------------------

(0 rows)
```

KafkaExport returned 0 rows which means Vertica was able to send all of your data to Kafka without any errors.

Other things to note about the example:

- The CONCAT function automatically converts the date column's DATETIME value to a VARCHAR for you, so you do not need to explicitly cast it.

- Two nested CONCAT functions are necessary to concatenate the date field with a comma, and the resulting string with the location field.

- Adding a third column to the message field would require **two** additional CONCAT function calls (one to concatenate a comma after the location column, and one to concatenate the additional column's value). Using CONCAT becomes messy after just a few column's worth of data.

On the Kafka side, you will see whatever you sent as the valueColumn (third) argument of the KafkaExport function. In the above example, this is a CSV list. If you started a console consumer for `iot_results` topic before running the example query, you would see the following output when the query runs:

```bash
$ /opt/kafka/bin/kafka-console-consumer.sh --topic iot_results --zookeeper localhost
2017-10-10 12:08:33, 78.84883, -137.56584
2017-12-06 16:50:57, -25.33024, -157.91389
2018-08-19 00:02:18, 13.00436, 85.44815
2016-10-11 04:09:28, -14.86058, 112.75848
2017-10-19 14:04:33, -71.72156, -36.27381
```
KafkaExport's Return Value

KafkaExport outputs any rows that Kafka rejected. For example, suppose you forgot to adjust the partition column to be zero-based in the previous example. Then some of the rows exported to Kafka would specify a partition that does not exist. In this case, Kafka rejects these rows, and KafkaExport reports them in table format:

```sql
=> SELECT KafkaExport(server, id::VARCHAR,
    CONCAT(CONCAT(date, ', '), location)
    USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
    topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
```

<table>
<thead>
<tr>
<th>partition</th>
<th>key</th>
<th>message</th>
<th>failure_reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>48492866</td>
<td>2017-10-10 12:08:33, 78.84883, -137.56584</td>
<td>Local: Unknown partition</td>
</tr>
<tr>
<td>3</td>
<td>73846006</td>
<td>2017-12-06 16:50:57, -25.33024, -157.91389</td>
<td>Local: Unknown partition</td>
</tr>
<tr>
<td>3</td>
<td>27462612</td>
<td>2018-09-19 00:02:18, 13.00436, 85.44815</td>
<td>Local: Unknown partition</td>
</tr>
</tbody>
</table>

(4 rows)

**Note:** Another common reason for Kafka rejecting a row is that its message value is longer than Kafka's message.max.bytes setting.

You can capture this output by creating a table to hold the rejects. Then use an INSERT statement to insert KafkaExport's results:

```sql
=> CREATE TABLE export_rejects (partition INTEGER, key VARCHAR, message LONG VARCHAR, failure_reason VARCHAR);
CREATE TABLE
=> INSERT INTO export_rejects SELECT KafkaExport(server, id::VARCHAR,
    CONCAT(CONCAT(date, ', '), location)
    USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
    topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
```

<table>
<thead>
<tr>
<th>partition</th>
<th>key</th>
<th>message</th>
<th>failure_reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>27462612</td>
<td>2018-09-19 00:02:18, 13.00436, 85.44815</td>
<td>Local: Unknown partition</td>
</tr>
<tr>
<td>3</td>
<td>48492866</td>
<td>2017-10-10 12:08:33, 78.84883, -137.56584</td>
<td>Local: Unknown partition</td>
</tr>
<tr>
<td>3</td>
<td>73846006</td>
<td>2017-12-06 16:50:57, -25.33024, -157.91389</td>
<td>Local: Unknown partition</td>
</tr>
</tbody>
</table>
Producing Kafka Messages Using Notifiers

You can use notifiers to help you monitor your Vertica database using third-party Kafka-aware tools. Notifiers let you directly publish messages to a Kafka topic. You can directly publish messages (for example, from a SQL script to indicate a long-running query has finished). Notifiers can also automatically send messages when a component in the data collector tables is updated.

Creating a Notifier

You must create a notifier before you can use it. At a minimum, a notifier defines:

- A unique name.
- A message protocol. This is kafka:// when sending messages to Kafka.
- The server to communicate with. For Kafka, this is the address and port number of a Kafka broker.
- The maximum message buffer size. If the queue of messages to be sent via the notifier exceed this limit, messages are dropped.

You create the notifier using the CREATE NOTIFIER statement. This example creates a notifier named load_progress_notifier that sends messages via the Kafka broker running on kafka01.example.com on port 9092:

```
=> CREATE NOTIFIER load_progress_notifier
    ACTION 'kafka://kafka01.example.com:9092'
    MAXMEMORYSIZE '10M';
```

Sending Individual Messages Via a Notifier

You can send an individual message via a notifier using the NOTIFY function. This feature is useful for reporting the progress of SQL scripts such as ETL tasks to third-party reporting tools.

You pass this function three string values:
The message to send.

The name of the notifier to send the message.

The Kafka topic to receive the message.

For example, suppose you want to send the message "Daily load finished" to the vertica_notifications topic of the Kafka cluster defined in the load_progress_notifier notifier created earlier. Then you could execute the following statement:

```sql
=> SELECT NOTIFY('Daily load finished.',
    'load_progress_notifier',
    'vertica_notifications');

NOTIFY
--------
OK
(1 row)
```

The message the notifier sends to Kafka is in JSON format. You can see the resulting message by using the console consumer on a Kafka node. For example:

```bash
$ /opt/kafka/bin/kafka-console-consumer.sh --bootstrap-server localhost:9092 \
    --from-beginning \ 
    --topic vertica_notifications \ 
    --max-messages 1

{"_db":"vmart","_schema":"v_internal","_table":"dc_notifications","channel":"vertica_notifications","message":"Daily load finished.","node_name":"v_vmart_node0001","notifier":"load_progress_notifier","request_id":2,"session_id":"v_vmart_node0001-463079:0x4ba6f","statement_id":-1,"time":"2018-06-19 09:48:42.314181-04","transaction_id":45035996275565458,"user_id":45035996273704962,"user_name":"dbadmin"}

Processed a total of 1 messages
```

Automatically Sending Notifications of DC Table Changes

The VerticaData Collector (DC) tables monitor many different database functions. You can have a notifier automatically send a message when a DC component updates. You can query the DATA_COLLECTOR table to get a list of the DC components.

You configure the notifier to send DC component updates to Kafka using the function SET_DATA_COLLECTOR_NOTIFY_POLICY.

The following example demonstrates creating a notifier, then sends it notifications each time the LoginFailures component updates. This component updates every time there is a failed attempt to log into the Vertica database.
Vertica Documentation
Integrating with Apache Kafka

=> CREATE NOTIFIER vertica_stats
ACTION 'kafka://kafka01.example.com:9092'
MAXMEMORYSIZE '10M';
CREATE NOTIFIER
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures',
'vertica_stats',
'vertica_notifications', True);
SET_DATA_COLLECTOR_NOTIFY_POLICY
---------------------------------SET
(1 row)

Like the messages sent via the NOTIFY function, the data sent to Kafka from the DC
components is in JSON format. The previous example results in messages like the following
being sent to the vertica_notifications Kafka topic:
{"_db":"vmart","_schema":"v_internal","_table":"dc_login_failures",
"authentication_method":"Reject","client_authentication_name":"",
"client_hostname":"::1","client_label":"","client_os_user_name":"dbadmin",
"client_pid":481535,"client_version":"","database_name":"alice",
"effective_protocol":"3.8","node_name":"v_vmart_node0001",
"reason":"INVALID USER","requested_protocol":"3.8","ssl_client_fingerprint":"",
"time":"2018-06-19 14:51:22.437035-04","user_name":"alice"}

Seeing Automatic Notification Policies for a DC Component
Use the GET_DATA_COLLECTOR_NOTIFY_POLICY function to list the policies set for a
DC component.
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
GET_DATA_COLLECTOR_NOTIFY_POLICY
---------------------------------------------------------------------Notifiable; Notifier: vertica_stats; Channel: vertica_notifications
(1 row)

Disabling a Notification Policy
Call the SET_DATA_COLLECTOR_NOTIFY_POLICY function with its fourth argument set to
FALSE to disable a notification policy.
The following example disables the notify policy for the LoginFailures component created in an
earlier example:
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures',
'vertica_stats',
'vertica_notifications',
False);

Vertica Analytic Database (9.1.x)

Page 5183 of 6174


```
SET_DATA_COLLECTOR_NOTIFY_POLICY
-------------------------------------
SET
(1 row)
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
GET_DATA_COLLECTOR_NOTIFY_POLICY
-------------------------------------
Not notifiable;
(1 row)
```
Using SSL with Kafka

Vertica supports the use of SSL authentication between Kafka, Vertica, and the Kafka Scheduler. For information on SSL authentication with Vertica, refer to TLS/SSL Server Authentication.
Scheduler/Vertica Communication

The scheduler uses keystore information on a per-session basis to communicate with Vertica. It passes information through a JDBC SSL connection to Vertica. The Scheduler connects to Vertica through a JVM. As a result, your SSL keys must be within the JVM keystore and the CA must be within the JVM truststore. When connecting between Vertica and Kafka, the Scheduler uses its keys to authenticate Kafka.

Vertica/Kafka Communication

In a typical configuration, each Kafka broker contains its own key store and trust store. Vertica and Kafka authenticate against your certifying authority. Kafka authenticates by means of the librdkafka library.

Adding SSL to Vertica/Kafka Integration

To add SSL authentication to your Vertica/Kafka integration, you must configure SSL support on various components in Vertica, Kafka, and Java.

1. Configure Vertica for SSL.
2. Configure Kafka for SSL.
3. Configure your scheduler for SSL.
4. Configure Java on your scheduler for SSL.

Configuring Kafka for SSL

A typical Kafka/Vertica configuration consists of the following steps:

1. Create a certifying authority certificate.
2. Create a trust store and key store on your Kafka brokers using your certificate.
3. Configure the server.properties file on each Kafka broker to use your key store.

Create a Certifying Authority Certificate

If you do not already have one, create a certifying authority certificate, as shown in the following example.

```bash
openssl req -new -x509 -keyout ca-key -out ca-cert -days 365
```

For more information on generating a certificate, refer to the OpenSSL documentation.

Create a Trust Store and Key Store on your Kafka Brokers

You must create a trust store and key store on each of your Kafka brokers.

1. Create a trust store on your Kafka broker by importing your certificate. The following example shows a typical trust store command.

```bash
keytool -keystore kafka.truststore.jks -alias caroot -import -file ca-cert
```

2. Create a key store on your Kafka broker, as shown in the following example. The following example shows a typical series of key store commands.

```bash
keytool -keystore brokername.keystore.jks -alias brokername -validity 365 -keyalg RSA -genkey
keytool -keystore brokername.keystore.jks -alias brokername -certreq -file cert-file
openssl x509 -req -CA ca-cert -CAkey ca-key -in cert-file -out cert-signed -days 365 -CAcreateserial
keytool -keystore brokername -alias caroot -import -file ca-cert
keytool -keystore brokername.keystore.jks -alias broker$i -import -file cert-signed
```

3. Repeat the key store and trust store configuration process for each Kafka broker, specifying the correct alias and key store name for that broker.

Configure the server.properties File on Each Kafka Broker to Use Your Key Store

You can pass SSL configuration information from your Kafka broker to Vertica by including user defined session parameters in your server.properties file. For more information on configuring your server.properties file, refer to the Apache Kafka documentation.
Vertica Documentation
Integrating with Apache Kafka

Configuring Your Scheduler for SSL

Your scheduler requires a trust store, key store and launch parameters to use SSL.

Create a Trust Store and and Key Store on Your Scheduler

You must create a trust store and key store on your scheduler.

1. Create a trust store on your scheduler by importing your certificate. The following example shows a typical trust store command.

   ```
   keytool -keystore schedulername.truststore.jks -alias caroot -import -file ca-cert
   ```

2. Create a key store on your scheduler, as shown in the following example. The following example shows a typical series of key store commands.

   ```
   keytool -keystore schedulername.keystore.jks -alias vsched -validity 365 -keyalg RSA -genkey
   keytool -keystore schedulername.keystore.jks -alias vsched -certreq -file cert-file
   openssl x509 -req -CA ca-cert -CAkey ca-key -in cert-file -out cert-signed -days 365
   keytool -keystore schedulername.keystore.jks -alias caroot -import -file ca-cert
   keytool -keystore schedulername.keystore.jks -alias vsched -import -file cert-signed
   ```

Launch Your Scheduler with SSL Enabled

When you launch your scheduler, you must include SSL parameters to enable SSL support. For more information on scheduler utility parameters, refer to Scheduler Tool Options.

The following example shows a launch command including all the required SSL parameters.

```bash
/opt/vertica/packages/kafka/bin/vkconfig launch --enable-SSL true --ssl-ca-alias authenticicert --ssl-key-alias ourkey --ssl-key-password secret
```
Configuring the Scheduler Java to Use SSL

The scheduler uses JDBC to communicate with your Vertica session. If your Vertica database uses SSL, authentication you must configure your scheduler JVM and JDBC settings for SSL. For information on configuring your JVM and JDBC, refer to the Java documentation.

Configure Your Scheduler JVM

To use SSL authentication with Kafka, you must configure your scheduler JVM to use the key store and trust store you created. Vertica recommends that you use a configuration file to provide this information. Include the following options in your configuration file:

```
-Djavax.net.ssl.trustStore=/path/to/truststore
-Djavax.net.ssl.keyStore=/path/to/keystore
-Djavax.net.ssl.keyStorePassword=password1234
```

Configure Your Scheduler JDBC to use SSL

Add the following to your scheduler's configuration:

```
--jdbc-opt ssl=true
```

This option add the ssl=true argument to the scheduler's JDBC connection string.

Using SSL Without a Scheduler

You can also configure Vertica to interact with Kafka without using a scheduler. In this case, Kafka integration requires user-defined extensions (UDXs) that do not have access to global Vertica configuration parameters. As a result, you must load your SSL Certificates as session parameters.

1. Configure your `MaxSessionUDParameterSize` to a value larger than the length of your certificate chain.

```
ALTER SESSION SET MaxSessionUDParameterSize=100000
```
2. **Provide certificate, key, and password information to your session.** Vertica does not log parameters that end in _secret. For more information on these parameters, refer to [Kafka User-Defined Session Parameters](#).

```sql
=> ALTER SESSION SET UDPARAMETER kafka_SSL_Certificate='<client.crt contents>';  
ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKey_secret='<client.key contents>';  
ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKeyPassword_secret='<password, if applicable>';  
ALTER SESSION SET UDPARAMETER kafka_SSL_CA='<ca.crt contents>';  
```

3. **Enable SSL authentication for your session.**

```sql
=> ALTER SESSION SET UDPARAMETER kafka_Enable_SSL=1;  
```

You can now run COPY commands with SSL authentication.
Troubleshooting Kafka Integration Issues

The following topics can help you troubleshoot issues integrating Vertica with Apache Kafka.

Using kafkacat to Troubleshoot Kafka Integration Issues

Kafkacat is a third-party open-source utility that lets you connect to Kafka from the Linux command line. It uses the same underlying library that the Vertica integration for Apache Kafka uses to connect to Kafka. This shared library makes kafkacat a useful tool for testing and debugging your Vertica integration with Kafka.

You may find kafkacat useful for:

- Testing connectivity between your Vertica and Kafka clusters.
- Examining Kafka data for anomalies that may prevent some of it from loading into Vertica.
- Producing data for test loads into Vertica.
- Listing details about a Kafka topic.

For more information about kafkacat, see its project page at Github.

Running kafkacat on Vertica Nodes

The kafkacat utility is bundled in the Vertica install package, so it is available on all nodes of your Vertica cluster in the /opt/vertica/packages/kafka/bin directory. This is the same directory containing the vkconfig utility, so if you have added it to your path, you can use the kafkacat utility without specifying its full path. Otherwise, you can add this path to your shell's environment variable using the command:

```
set PATH=/opt/vertica/packages/kafka/bin:$PATH
```
Note: On Debian and Ubuntu systems, you must tell kafkacat to use Vertica's own copy of the SSL libraries by setting the LD_LIBRARY_PATH environment variable:

$ export LD_LIBRARY_PATH=/opt/vertica/lib

If you do not set this environment variable, the kafkacat utility exits with the error:

kafkacat: error while loading shared libraries: libcrypto.so.10:
  cannot open shared object file: No such file or directory

Executing kafkacat without any arguments gives you a basic help message:

$ kafkacat
Error: -b <broker,..> missing

Usage: kafkacat <options> [file1 file2 .. | topic1 topic2 ..]]
kafkacat - Apache Kafka producer and consumer tool
https://github.com/edenhill/kafkacat
Copyright (c) 2014-2015, Magnus Edenhill
Version releases/VER_8_1_RELEASE_BUILD_1_555_20170615-
4931-g3fb918 (librdkafka releases/VER_8_1_RELEASE_BUILD_1_555_20170615-
4931-g3fb918)

General options:
-C | -P | -L Mode: Consume, Produce or metadata List
-G <group-id> Mode: High-level KafkaConsumer (Kafka 0.9 balanced consumer groups)
  Expects a list of topics to subscribe to
-t <topic> Topic to consume from, produce to, or list
-p <partition> Partition
-b <brokers,..> Bootstrap broker(s) (host[:port])
-D <delim> Message delimiter character:
  a-z.. | \r | \n | \t | \xNN
  Default: \n
-K <delim> Key delimiter (same format as -D)
-c <cnt> Limit message count
-X list List available librdkafka configuration properties
-X prop=val Set librdkafka configuration property.
  Properties prefixed with "topic." are applied as topic properties.
-X dump Dump configuration and exit.
-d <dbg1,...> Enable librdkafka debugging:
  all,generic,broker,topic,metadata,queue,msg,protocol,cgrp,security,fetch,feature
-q Be quiet (verbosity set to 0)
-v Increase verbosity
-V Print version

Producer options:
-z snappy|gzip Message compression. Default: none
-p -1 Use random partitioner
-D <delim> Delimiter to split input into messages
-K <delim> Delimiter to split input key and message
-l Send messages from a file separated by delimiter, as with stdin.
  (only one file allowed)
-T Output sent messages to stdout, acting like tee.
-c <cnt> Exit after producing this number of messages
-Z Send empty messages as NULL messages
file1 file2.. Read messages from files.
  With -l, only one file permitted.
Otherwise, the entire file contents will be sent as one single message.

Consumer options:
- o <offset> Offset to start consuming from:
  beginning | end | stored |
  <value> (absolute offset) |
  - <value> (relative offset from end)
- e Exit successfully when last message received
- f <fmt..> Output formatting string, see below.
  Takes precedence over -D and -K.
- D <delim> Delimiter to separate messages on output
- K <delim> Print message keys prefixing the message
  with specified delimiter.
- 0 Print message offset using -K delimiter
- c <cnt> Exit after consuming this number of messages
- Z Print NULL messages and keys as "NULL" (instead of empty)
- u Unbuffered output

Metadata options:
- t <topic> Topic to query (optional)

Format string tokens:
% s Message payload
% S Message payload length (or -1 for NULL)
% R Message payload length (or -1 for NULL) serialized
  as a binary big endian 32-bit signed integer
% k Message key
% K Message key length (or -1 for NULL)
% t Topic
% p Partition
% o Message offset
\n \r \t Newlines, tab
\XX \xNNN Any ASCII character

Example:
- f 'Topic %t [%p] at offset %o: key %k: %s
'

Consumer mode (writes messages to stdout):
  kafkacat -b <broker> -t <topic> -p <partition>
or:
  kafkacat -C -b ...

High-level KafkaConsumer mode:
  kafkacat -b <broker> -G <group-id> topic1 top2 ^aregex\d+

Producer mode (reads messages from stdin):
  ... | kafkacat -b <broker> -t <topic> -p <partition>
or:
  kafkacat -P -b ...

Metadata listing:
  kafkacat -L -b <broker> [-t <topic>]
Testing Connectivity to a Kafka Cluster and Getting Metadata

One basic troubleshooting step you often need to perform is verifying that Vertica nodes can connect to the Kafka cluster. Successfully executing just about any kafkacat command will prove the Vertica node you are logged into is able to reach the Kafka cluster. One simple command you can execute to verify connectivity is to get the metadata for all of the topics the Kafka cluster has defined. The following example demonstrates using kafkacat's metadata listing command to connect to the broker named kafka01 running on port 6667 (the Kafka broker port used by Hortonworks Hadoop clusters).

$ kafkacat -L -b kafka01:6667
Metadata for all topics (from broker -1: kafka01:6667/bootstrap):
  2 brokers:
    broker 1001 at kafka03.example.com:6667
    broker 1002 at kafka01.example.com:6667
  4 topics:
    topic "iot-data" with 3 partitions:
      partition 2, leader 1002, replicas: 1002, isrs: 1002
      partition 1, leader 1001, replicas: 1001, isrs: 1001
      partition 0, leader 1002, replicas: 1002, isrs: 1002
    topic "_consumer_offsets" with 50 partitions:
      partition 23, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 41, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 32, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 8, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 17, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 44, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 35, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 26, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 11, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 29, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 38, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 47, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 20, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 2, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 5, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 14, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 46, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 49, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 48, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 4, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 13, leader 1001, replicas: 1002,1001, isrs: 1001,1002
      partition 22, leader 1002, replicas: 1002,1001, isrs: 1001,1002
      partition 31, leader 1001, replicas: 1002,1001, isrs: 1001,1002

topic "ambari_kafka_service_check" with 1 partitions:
partition 0, leader 1002, replicas: 1002, isrs: 1002

You can also use this output to verify the topics defined by your Kafka cluster, as well as the
number of partitions each topic defines. You need this information when copying data
between Kafka and Vertica.

Retrieving Messages from a Kafka Topic
When you are troubleshooting issues with streaming messages from Kafka in Vertica, you often
want to look at the raw data that Kafka sent. For example, you may want to verify that the
messages are in the format that your expect. Or, you may want to review specific messages to
see if some of them weren't in the right format for Vertica to parse. You can use kafkacat to
read messages from a topic using its consume command (-C). At the very least, you must pass
kafkacat the brokers (-b argument) and the topic you want to read from (-t). You can also
choose to read messages from a specific offset (-o) and partition (-p). You will usually also
want kafkacat to exit after completing the data read (-e) instead continuing to wait for more
messages.
This example gets the last message in the topic named web_hits. The offset argument uses a
negative value, which tells kafkacat to read from the end of the topic.
$ kafkacat -C -b kafka01:6667 -t web_hits -o -1 -e
{"url": "wp-content/list/search.php", "ip": "132.74.240.52",
"date": "2018/03/28 14:12:34",
"user_agent": "Mozilla/5.0 (iPod; U; CPU iPhone OS 4_2 like

Vertica Analytic Database (9.1.x)

Page 5195 of 6174


You can also read a specific range of messages by specifying an offset and a limit (-c argument). For example, you may want to look at a specific range of data to determine why Vertica could not load it. The following example reads 10 messages from the topic iot-data starting at offset 3280:

```
$ kafkacat -C -b kafka01:6667 -t iot-data -o 3280 -c 10 -e
63680, 19, 24.439323, 26.0128725
43510, 71, 162.319857, -74.735731
88508, 14, -85.821967, -7.236280
20419, 31, -129.583988, 13.995481
79365, 79, 153.184594, -74.8593245
26283, 25, -168.911020, 35.331027
56808, 17, 19.603286, -0.7698495
91113, 53, 139.764857, -74.735731
8118, 73, 97.365445, -74.8593245
```

**Generating Data for a Kafka Topic**

If you are preparing to stream data from a Kafka topic that is not yet active, you may want a way to stream test messages. You can then verify that the topic's messages load into Vertica without worrying that you will miss actual data.

To send data to Kafka, use kafkacat's produce command (-P). The easiest way to supply it with messages is to pipe them in via STDIN, one message per line. You can choose a specific partition for the data, or have kafkacat randomly assign each message to a random partition by setting the partition number to -1. For example, suppose you have a file named iot-data.csv that you wanted to produce to random partitions of a Kafka topic named iot-data. Then you could use the following command:

```
$ cat iot_data.csv | kafkacat -P -p -1 -b kafka01:6667 -t iot-data
```

**Troubleshooting Slow Load Speeds**

Here are some potential issues that could cause messages to load slowly from Kafka.
Verify You Have Disabled the API Version Check When Communicating with Kafka 0.9 or Earlier

If your Kafka cluster is running 0.9 or earlier, be sure you have disable the rdkafka library's `api.version.request` option. If you do not, every Vertica connection to Kafka will pause for 10 seconds until the API version request times out. Depending on the frame size of your load or other timeout settings, this delay can either reduce the throughput of your data loads. It can even totally prevent messages from being loaded. See Configuring Vertica for Apache Kafka Version 0.9 and Earlier

Update the message-max-bytes Setting of Schedulers Created Before Vertica Version 9.1.1

If you find that a scheduler is loading data slowly after upgrading to Vertica Version 9.1.1 or later, consider updating its load spec's message-max-bytes parameter. The meaning of this setting changed in Kafka 0.11. See Changes to the message.max.bytes Setting in Kafka Version 0.11 and Later for more information.

Eon Mode and Cloud Latency

Eon Mode separates compute from storage in a Vertica cluster, which can cause a small amount of latency when Vertica loads and saves data. Cloud computing infrastructure can also cause latency. This latency can eat into the frame duration for your schedulers, causing them to load less data in each frame. For this reason, you should consider increasing frame durations when loading data from Kafka in an Eon Mode database. See Vertica Eon Mode and Kafka for more information.
**vkconfig Script Options**

Vertica includes the vkconfig script that lets you configure your schedulers. This script contains multiple tools that set groups of options in the scheduler, as well as starting and shutting it down. You supply the tool you want to use as the first argument in your call to the vkconfig script.

The topics in this section explain each of the tools available in the vkconfig script as well as their options. You can use the options in the Common vkconfig Script Options topic with any of the utilities. Utility-specific options appear in their respective tables.

### Common vkconfig Script Options

These options are available across the different tools available in the vkconfig script.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--config-schema <strong>schema_name</strong></td>
<td>The name of the scheduler's Vertica schema. This value is the same as the name of the scheduler. You use this name to identify the scheduler during configuration.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> stream_config</td>
</tr>
<tr>
<td>--help</td>
<td>Prints out a help menu listing available options with a description.</td>
</tr>
<tr>
<td>--version</td>
<td>Displays the version number of the scheduler.</td>
</tr>
<tr>
<td>--dbhost <strong>host_name</strong></td>
<td>The host name or IP address of the Vertica node acting as the initiator node for the scheduler.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> localhost</td>
</tr>
<tr>
<td>--dbport <strong>port_number</strong></td>
<td>The port to use to connect to a Vertica node</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>database. Default Value: 5433</td>
<td>The Vertica database user used to alter the configuration of the scheduler. This use must have create privileges on the scheduler's schema. Default Value: Current user</td>
</tr>
<tr>
<td>--username <strong>username</strong></td>
<td>The Vertica database user used to alter the configuration of the scheduler. This use must have create privileges on the scheduler's schema. Default Value: Current user</td>
</tr>
<tr>
<td>--password <strong>password</strong></td>
<td>Password for the database user.</td>
</tr>
<tr>
<td>--jdbc-url <strong>url</strong></td>
<td>A complete JDBC URL that vkconfig uses instead of standard JDBC URL string to connect to Vertica. Cannot be combined with --jdbc-url.</td>
</tr>
<tr>
<td>--jdbc-opt <strong>option=value</strong></td>
<td>One or more options to add to the standard JDBC URL that vkconfig uses to connect to Vertica. Cannot be combined with --jdbc-url.</td>
</tr>
<tr>
<td>[&amp;option2=value2...]</td>
<td></td>
</tr>
<tr>
<td>--conf <strong>filename</strong></td>
<td>A text file containing configuration options for the vkconfig script. See Configuration File Format below.</td>
</tr>
<tr>
<td>--create</td>
<td>Creates a new instance of the supplied type.</td>
</tr>
<tr>
<td>--update</td>
<td>Updates an existing instance of the supplied type.</td>
</tr>
<tr>
<td>--delete</td>
<td>Delete an instance of the supplied type.</td>
</tr>
<tr>
<td>--enable-ssl</td>
<td>Enables the vkconfig script to use SSL to connect to Vertica or between Vertica and Kafka. See Configuring Your Scheduler for SSL for more information.</td>
</tr>
<tr>
<td>--ssl-ca-alias <strong>alias_name</strong></td>
<td>The alias of the root certificate authority in the trust store. Must be set</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>when Vertica uses SSL to connect to Kafka.</td>
</tr>
<tr>
<td>--ssl-key-alias alias_name</td>
<td>The alias of the key and certificate pairs within the key store. Must be set when Vertica uses SSL to connect to Kafka.</td>
</tr>
<tr>
<td>--ssl-key-password password</td>
<td>The password for the SSL key. Must be set when Vertica uses SSL to connect to Kafka.</td>
</tr>
<tr>
<td></td>
<td>Caution: Specifying this option on the command line can expose it to other users logged into the host. Always use a configuration file to set this option.</td>
</tr>
</tbody>
</table>

### Configuration File Format

You can use a configuration file to store common parameters you use in your calls to the `vkconfig` utility. The configuration file is a text file containing one option setting per line in the format:

```
option=value
```

You can also include comments in the option file by prefixing them with a hash mark (`#`).

```bash
#config.properties:
username=myuser
password=mypassword
dbhost=localhost
dbport=5433
```

You tell `vkconfig` to use the configuration file using the `--conf` option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --conf config.properties
```

You can override any stored parameter from the command line:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --conf config.properties --dbhost otherVerticaHost
```
Examples

These examples show how you can use the shared utility options.

Display help for the scheduler utility:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --help
```

This command configures a Scheduler, which can run and load data from configured sources and clusters into Vertica tables. It provides options for changing the 'frame duration' (time given per set of batches to resolve), as well as the dedicated Vertica resource pool the Scheduler will use while running.

Available Options:

<table>
<thead>
<tr>
<th>PARAMETER</th>
<th>REQUIRED</th>
<th>#ARGS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>conf</td>
<td>no</td>
<td>1</td>
<td>Allow the use of a properties file to associate parameter keys and values. This file enables command string reuse and cleaner command strings.</td>
</tr>
<tr>
<td>help</td>
<td>no</td>
<td>0</td>
<td>Outputs a help context for the given subutility.</td>
</tr>
<tr>
<td>version</td>
<td>no</td>
<td>0</td>
<td>Outputs the current Version of the scheduler.</td>
</tr>
<tr>
<td>skip-validation</td>
<td>no</td>
<td>0</td>
<td>[Depricated] Use --validation-type. Determine what happens when there are configuration errors. Accepts: ERROR - errors out, WARN - prints out a message and continues, SKIP - skip running validations</td>
</tr>
<tr>
<td>validation-type</td>
<td>no</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>dbhost</td>
<td>no</td>
<td>1</td>
<td>The Vertica database hostname that contains metadata and configuration information. The default value is 'localhost'.</td>
</tr>
<tr>
<td>dbport</td>
<td>no</td>
<td>1</td>
<td>The port at the hostname to connect to the Vertica database. The default value is '5433'.</td>
</tr>
<tr>
<td>username</td>
<td>no</td>
<td>1</td>
<td>The user to connect to Vertica. The default value is the current system user.</td>
</tr>
<tr>
<td>password</td>
<td>no</td>
<td>1</td>
<td>The password for the user connecting to Vertica. The default value is empty.</td>
</tr>
<tr>
<td>jdbc-url</td>
<td>no</td>
<td>1</td>
<td>A JDBC URL that can override Vertica connection parameters and provide additional JDBC options.</td>
</tr>
<tr>
<td>jdbc-opt</td>
<td>no</td>
<td>1</td>
<td>Options to add to the JDBC URL used to connect to Vertica ('&amp;'-separated key=value list). Used with generated URL (i.e. not with '--jdbc-url' set).</td>
</tr>
<tr>
<td>enable-ssl</td>
<td>no</td>
<td>1</td>
<td>Enable SSL between JDBC and Vertica and/or Vertica and Kafka.</td>
</tr>
<tr>
<td>ssl-ca.alias</td>
<td>no</td>
<td>1</td>
<td>The alias of the root CA within the provided trust store used when connecting between Vertica and Kafka.</td>
</tr>
<tr>
<td>ssl-key.alias</td>
<td>no</td>
<td>1</td>
<td>The alias of the key and certificate pair within the provided key store used when connecting between Vertica and Kafka.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>--------------------</td>
<td>---------</td>
<td>------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>ssl-key-password</td>
<td>no 1</td>
<td>The password for the key used when connecting between Vertica and Kafka. Should be hidden with file access (see --conf).</td>
<td></td>
</tr>
<tr>
<td>config-schema</td>
<td>no 1</td>
<td>The schema containing the configuration details to be used, created or edited. This parameter defines the scheduler. The default value is 'stream_config'.</td>
<td></td>
</tr>
<tr>
<td>create</td>
<td>no 0</td>
<td>Create a new instance of the supplied type.</td>
<td></td>
</tr>
<tr>
<td>update</td>
<td>no 0</td>
<td>Update an instance of the supplied type.</td>
<td></td>
</tr>
<tr>
<td>delete</td>
<td>no 0</td>
<td>Delete an instance of the supplied type.</td>
<td></td>
</tr>
<tr>
<td>drop</td>
<td>no 0</td>
<td>Drops the specified configuration schema. CAUTION: this command will completely delete and remove all configuration and monitoring data for the specified scheduler.</td>
<td></td>
</tr>
<tr>
<td>operator</td>
<td>no 1</td>
<td>Specifies a user designated as an operator for the created configuration. Used with --create.</td>
<td></td>
</tr>
<tr>
<td>add-operator</td>
<td>no 1</td>
<td>Add a user designated as an operator for the specified configuration. Used with --update.</td>
<td></td>
</tr>
<tr>
<td>remove-operator</td>
<td>no 1</td>
<td>Removes a user designated as an operator for the specified configuration. Used with --update.</td>
<td></td>
</tr>
<tr>
<td>upgrade</td>
<td>no 0</td>
<td>Upgrade the current scheduler configuration schema to the current version of this scheduler. WARNING: if upgrading between EXCAVATOR and FRONTLOADER be aware that the Scheduler is not backwards compatible. The upgrade procedure will translate your kafka model into the new stream model.</td>
<td></td>
</tr>
<tr>
<td>upgrade-to-schema</td>
<td>no 1</td>
<td>Used with upgrade: will upgrade the configuration to a new given schema instead of upgrading within the same schema.</td>
<td></td>
</tr>
<tr>
<td>fix-config</td>
<td>no 0</td>
<td>Attempts to fix the configuration (ex: dropped tables) before doing any other updates. Used with --update.</td>
<td></td>
</tr>
<tr>
<td>frame-duration</td>
<td>no 1</td>
<td>The duration of the Scheduler's frame, in which every configured Microbatch runs. Default is 10 seconds: '00:00:10'</td>
<td></td>
</tr>
<tr>
<td>resource-pool</td>
<td>no 1</td>
<td>The Vertica resource pool to run the Scheduler on. Default is 'kafka_default_pool'.</td>
<td></td>
</tr>
<tr>
<td>config-refresh</td>
<td>no 1</td>
<td>The interval of time between Scheduler configuration refreshes. Default is 5 minutes: '00:05'</td>
<td></td>
</tr>
<tr>
<td>new-source-policy</td>
<td>no 1</td>
<td>The policy for new Sources to be scheduled during a frame. Options are: START, END, and FAIR. Default is 'FAIR'.</td>
<td></td>
</tr>
<tr>
<td>eof-timeout-ms</td>
<td>no 1</td>
<td>The duration in milliseconds that any Microbatch waits for additional data before considering itself at end of stream.</td>
<td></td>

</tbody>
</table>
Scheduler Tool Options

The vkconfig script's scheduler tool lets you configure schedulers that continuously loads data from Kafka into Vertica. Use the scheduler tool to create, update, or delete a scheduler, defined by `config-schema`. If you do not specify a scheduler, commands apply to the default `stream_config` scheduler. It accepts the following arguments in addition to the Common `vkconfig` Script Options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--operator username</code></td>
<td>Allows the dbadmin to grant privileges to a previously created Vertica user or role. This option gives the specified user all privileges on the scheduler instance and EXECUTE privileges on the <code>libkafka</code> library and all its UDxs. Granting operator privileges gives the user the right to read data off any source in any cluster that can be reached from the Vertica node. The dbadmin must grant the user separate permission for them to have write privileges on the target tables. Requires the <code>--create</code> shared utility option. Use the <code>--add-operator</code> option to grant operate privileges after the scheduler has been created. To revoke privileges, use the <code>--remove</code> option with the <code>--operator</code> option.</td>
</tr>
<tr>
<td><code>--drop schema_name</code></td>
<td>Drops the specified scheduler's schema. Dropping its schema deletes the scheduler. After you drop the scheduler's schema, you cannot recover it.</td>
</tr>
<tr>
<td><code>--add-operator user_name</code></td>
<td>Grants a Vertica user account or role access to use and alter the scheduler. Requires the <code>--update</code> shared utility option.</td>
</tr>
<tr>
<td><code>--remove-operator user_name</code></td>
<td>Removes access to the scheduler from a Vertica user account. Requires the <code>--update</code> shared utility option.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>--upgrade</strong></td>
<td>Upgrades the existing scheduler and configuration schema to the current Vertica version. The upgraded version of the scheduler is not backwards compatible with earlier versions. To upgrade a scheduler to an alternate schema, use the <code>upgrade-to-scheme</code> parameter. See <a href="#">Updating Schedulers After Vertica Upgrades</a> for more information.</td>
</tr>
<tr>
<td><strong>--upgrade-to-scheme</strong></td>
<td>Copies the scheduler's schema to a new schema specified by <code>schema name</code> and then upgrades it to be compatible with the current version of Vertica. Vertica does not alter the old schema. Requires the <code>--upgrade</code> scheduler utility option.</td>
</tr>
</tbody>
</table>
| **--frame-duration**          | The interval of time that all individual frames last with this scheduler. Vertica must have enough time to complete COPY tasks within this duration. You can approximate the average available time per COPY using the following equation:  

\[
TimePerCopy = (FrameDuration \times Parallellism) / Microbatches
\]

This is just a rough estimate as there are many factors that impact the amount of time that each COPY statement will be able to run.  

Vertica requires at least 100 milliseconds per COPY to function. You can increase the available time per COPY by increasing your frame duration.  

**Default Value:** 00:00:10 |
| **--config-refresh**          | The interval of time that the scheduler runs before synchronizing its settings and updating its cached metadata (such as changes made by using the `--update` option).  

**Default Value:** 00:05:00 |
| **--resource-pool**           | The resource pool to be used by all queries executed by this scheduler. You must create this pool in advance if you are not using the default pool.  

**Default Value:**  |
### Option Description

<table>

<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stream_default_pool</td>
<td><strong>stream_default_pool</strong></td>
</tr>
</tbody>
</table>
| --new-source-policy {FAIR|START|END} | Determines how Vertica allocates resources to the newly added source.  
**Valid Values:**  
- **FAIR**: Takes the average length of time from the previous batches and schedules itself appropriately.  
- **START**: All new sources start at the beginning of the frame. The batch receives the minimal amount of time to run.  
- **END**: All new sources start at the end of the frame. The batch receives the maximum amount of time to run.  
**Default Value:**  
FAIR |
| --eof-timeout-ms number_ofMilliseconds | If a COPY command does not receive any messages within the eof-timeout-ms interval, Vertica responds by ending that COPY statement.  
**Default Value:**  
1 second  
See [Manually Copying Data From Kafka](#) for more information. |
| --message_max_bytes max_message_size | Specifies the maximum size, in bytes, of a Kafka protocol batch message.  
**Default Value:**  
25165824 |

**Important**: You may need to manually update this value if you created a scheduler using Vertica 9.1.0 or earlier. The meaning of Kafka's max.message.bytes setting changed between version 0.10 and 0.11. See [Changes to the message.max.bytes Setting in Kafka Version 0.11 and Later](#) for more information.
<table>
<thead>
<tr>

<tr>
<td></td>
<td>For more information on synchronization, refer to Automatically Copying Data From Kafka.</td>
</tr>
<tr>
<td>--consumer-group-id id_name</td>
<td>The name of the Kafka consumer group to which Vertica reports its progress consuming messages. By default, Vertica reports its progress to a group named vertica_&lt;database-name&gt;. See Monitoring Vertica Message Consumption with Consumer Groups for more information.</td>
</tr>
<tr>
<td></td>
<td>Set this value to an empty string (&quot;&quot;) to disable progress reports to a Kafka consumer group.</td>
</tr>
</tbody>
</table>
Examples

These examples show how you can use the scheduler utility options.

Give a user, Jim, privileges on the StreamConfig scheduler. Specify that you are making edits to the stream_config scheduler with the --config-schema option:

```sh
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --update --config-schema stream_config --add-operator Jim
```

Edit the default stream_config scheduler so that every microbatch waits for data for one second before ending:

```sh
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --update --eof-timeout-ms 1000
```

Upgrade the scheduler named iot_scheduler_8.1 to a new scheduler named iot_scheduler_9.0 that is compatible with the current version of Vertica:

```sh
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --upgrade --config-schema iot_scheduler_8.1 --upgrade-to-schema iot_scheduler_9.0
```

Drop the schema scheduler219a:

```sh
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --drop --config-schema scheduler219a --username dbadmin
```

Cluster Tool Options

The vkconfig script's cluster tool lets you define the streaming hosts your scheduler connects to. It accepts the following arguments in addition to the Common vkconfig Script Options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--cluster</strong> <em>cluster_name</em></td>
<td>A unique, case insensitive name for the cluster.</td>
</tr>
<tr>
<td><strong>--new-cluster</strong> <em>cluster_name</em></td>
<td>The updated name for the cluster. Requires the --update shared utility option.</td>
</tr>
<tr>
<td><strong>--hosts</strong> b1:port[,b2:port...</td>
<td>Identifies the broker hosts that you want to add, edit, or remove from a</td>

</tr>
<tr>
<td>--kafka_conf 'option=value [;option2=value2...]'</td>
<td>A semicolon-delimited list of option=value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly Setting Kafka Library Options for details.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows how you can create the cluster, StreamCluster1, and assign two hosts:

```
$ /opt/vertica/packages/kafka/bin/vkconfig cluster --create --cluster StreamCluster1 \ 
  --hosts 10.10.10.10:9092,10.10.10.11:9092 \ 
  --conf myscheduler.config
```

**Source Tool Options**

Use the vkconfig script's source tool to create, update, or delete a source. It accepts the following arguments in addition to the Common vkconfig Script Options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--source source_name</td>
<td>The name for the source to add to, remove from, or edit in the scheduler configuration. You can use any name you like for a new source. Most people use the name of the Kafka topic the scheduler loads its data from.</td>
</tr>
<tr>
<td>--new-source source_name</td>
<td>Updates the name of an existing source to the name specified by this parameter. Requires: --update shared utility option</td>
</tr>
<tr>
<td>--partitions</td>
<td>Sets the number of partitions in the source.</td>
</tr>
</tbody>
</table>
Option | Description
--- | ---
**count** | Default Value: 1
**Requires:** --create and --source options
You must keep this consistent with the number of partitions in the source.
Renamed from --num-partitions.

--cluster **cluster_name** | Identifies the cluster containing the source that you want to create or edit.
You must have already defined this cluster in the scheduler.

--new-cluster **cluster_name** | Changes the cluster this source belongs to.
All sources referencing the old cluster source now target this cluster.
**Requires:** --update and --source options

--enabled TRUE|FALSE | When TRUE, the source is available for use.

**Examples**

The following examples show how you can create or update SourceFeed.

Create the source SourceFeed and assign it to the cluster, StreamCluster1 in the scheduler defined by the myscheduler.conf config file:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --create --source SourceFeed \
   --cluster StreamCluster1 --partitions 3 \
   --conf myscheduler.conf
```

Update the existing source SourceFeed to use the existing cluster, StreamCluster2 in the scheduler defined by the myscheduler.conf config file:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --source SourceFeed \
   --new-cluster StreamCluster2 \
   --conf myscheduler.conf
```
Target Tool Options

Use the target tool to configure a Vertica table to receive data from your streaming data application. It accepts the following arguments in addition to the Common vkconfig Script Options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--target-schema <em>schema.table_name</em></td>
<td>The existing Vertica target schema associated with this target.</td>
</tr>
<tr>
<td>--new-target-schema <em>schema_name</em></td>
<td>Changes the Vertica schema associated with this schema to a new, already created schema. Requires: --update option.</td>
</tr>
<tr>
<td>--target-table <em>table_name</em></td>
<td>The name of a Vertica table corresponding to the target.</td>
</tr>
<tr>
<td>--new-target-table <em>schema_name</em></td>
<td>Changes the Vertica target table associated with this schema to a new, already created table. Requires: --update option.</td>
</tr>
</tbody>
</table>

Important: Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before is it loaded by the scheduler.

Examples

This example shows how you can create a target for the scheduler defined in the myscheduler.conf configuration file from public.streamtarget table:

```
$ /opt/vertica/packages/kafka/bin/vkconfig target --create --target-table streamtarget --conf myscheduler.conf
```
## Load Spec Tool Options

The `vkconfig` script's load spec tool lets you provide parameters for the COPY statement that loads streaming data. It accepts the following arguments in addition to the Common `vkconfig` Script Options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--load-spec spec_name</code></td>
<td>A unique name for this copy load spec.</td>
</tr>
<tr>
<td><code>--filters &quot;filter_name&quot;</code></td>
<td>A Vertica FILTER chain containing all UDFilters for the COPY statement. For more information on filters, refer to Parsing Custom Formats.</td>
</tr>
<tr>
<td><code>--message-max-bytes max_message_size</code></td>
<td>Specifies the maximum size, in bytes, of a Kafka protocol batch message. Default Value: 25165824</td>
</tr>
<tr>
<td><code>--parser parser name</code></td>
<td>Identifies a Vertica UDFParser to use with a specified target. This parser is used within the COPY statement that the scheduler runs to load data. If you are using a Vertica native parser, the values supplied to the <code>--parser-parameters</code> option are passed through to the COPY statement. Default Value: KafkaParser</td>
</tr>
<tr>
<td><code>--parser-parameters &quot;key=value,&quot;</code></td>
<td>A list of parameters to provide to the parser</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>key=value&quot;</code></td>
<td>specified in the <code>--parser</code> parameter. When you use a Vertica native parser, the scheduler passes these parameters to the COPY statement where they are in turn passed to the parser.</td>
</tr>
<tr>
<td><code>--new-load-spec new_name</code></td>
<td>A new, unique name for an existing load spec. Requires the <code>--update</code> parameter.</td>
</tr>
<tr>
<td><code>--uds-kv-parameters key=value, key=value</code></td>
<td>A comma separated list of key value pairs for the user-defined source.</td>
</tr>
<tr>
<td>`--load-method AUTO</td>
<td>TRICKLE</td>
</tr>
</tbody>
</table>

**Examples**

These examples show how you can use the Load Spec utility options.

Create the load spec, Streamspec1:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --create --load-spec Streamspec1 --conf myscheduler.conf
```

Update the load spec, Streamspec1, to the name Streamspec2, and also update the load method to Direct:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update --load-spec Streamspec1 \
   --new-load-spec Streamspec2 --load-method direct \
   --conf myscheduler.conf
```

Update the load spec, Filterspec, to use the KafkaInsertLengths filter and a custom decryption filter:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update --load-spec Filterspec \(parameter=Key)" \ 
   --filters "KafkaInsertLengths() DecryptFilter \ 
   --conf myscheduler.conf
```
Microbatch Tool Options

The `vkconfig` script's microbatch tool lets you configure a scheduler's microbatches. It accepts the following arguments in addition to the Common `vkconfig` Script Options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--microbatch name</code></td>
<td>A unique, case insensitive name for the microbatch.</td>
</tr>
<tr>
<td><code>--new-microbatch updated_name</code></td>
<td>The updated name for the microbatch. Requires the <code>--update</code> shared utility option.</td>
</tr>
<tr>
<td><code>--load-spec loadspec_name</code></td>
<td>The load spec to use while processing this microbatch.</td>
</tr>
<tr>
<td><code>--target-schema schema_name</code></td>
<td>The existing Vertica target schema associated with this microbatch.</td>
</tr>
<tr>
<td><code>--rejection-schema schema_name</code></td>
<td>The existing Vertica schema that contains a table for storing rejected messages.</td>
</tr>
<tr>
<td>`--target-columns column_name, ...</td>
<td>column expression`</td>
</tr>
<tr>
<td><code>--rejection-table table_name</code></td>
<td>The existing Vertica table that stores rejected messages.</td>
</tr>
<tr>
<td>`--enabled TRUE</td>
<td>FALSE`</td>
</tr>
<tr>
<td><code>--target-table table_name</code></td>
<td>The name of a Vertica table corresponding to the target. This table must belong to the target schema.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>--add-source</strong> <code>source_name</code></td>
<td>The name of a source to assign to this microbatch. You can use this parameter once per command. You can also use it with <strong>--update</strong> to add sources to a microbatch. Requires <strong>--add-source-cluster</strong>.</td>
</tr>
<tr>
<td><strong>--add-source-cluster</strong> <code>cluster_name</code></td>
<td>The name of a cluster to assign to this microbatch. You can use this parameter once per command. You can also use it with <strong>--update</strong> to add sources to a microbatch. You can only add sources from the same cluster to a single microbatch. Requires <strong>--add-source</strong>.</td>
</tr>
<tr>
<td><strong>--remove-source</strong> <code>source_name</code></td>
<td>The name of a source to remove from this microbatch. You can use this parameter once per command. You can also use it with <strong>--update</strong> to remove multiple sources from a microbatch. Requires <strong>--remove-source-cluster</strong>.</td>
</tr>
<tr>
<td><strong>--remove-source-cluster</strong> <code>cluster_name</code></td>
<td>The name of a cluster to remove from this microbatch. You can use this parameter once per command. Requires <strong>--remove-source</strong>.</td>
</tr>
<tr>
<td><strong>--offset</strong> <code>partition_1 offset [,partition_2_offset,...]</code></td>
<td>The offset of the message in the source where the microbatch starts its load. If you use this parameter, you must supply an offset value for each partition in the source or each partition you list in the <strong>--partition</strong> option. You can use this option to skip some messages in the source or reload previously read messages.</td>
</tr>
<tr>
<td><strong>--partition</strong> <code>partition_1 [,partition_2,...]</code></td>
<td>One or more partitions to which the offsets given in the <strong>--offset</strong> option apply. If you supply this option, then the offset values given in the <strong>--offset</strong> option applies to the partitions you specify. Requires the <strong>--offset</strong> option.</td>
</tr>
<tr>
<td><strong>--source</strong> <code>source_name</code></td>
<td>The name of the source to which the offset in the <strong>--offset</strong> option applies. Required when the microbatch defines more than one source or the <strong>--cluster</strong> parameter is given. Requires the <strong>--offset</strong> option.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>--cluster</strong>&lt;br&gt;<code>cluster_name</code></td>
<td>The name of the cluster to which the <code>--offset</code> option applies. Only required if the microbatch defines more than one cluster or the <code>--source</code> parameter is supplied. Requires the <code>--offset</code> option.</td>
</tr>
<tr>
<td><strong>--consumer-group-id</strong>&lt;br&gt;<code>id_name</code></td>
<td>The name of the Kafka consumer group to which Vertica reports its progress consuming messages. By default, Vertica reports its progress to a group named <code>vertica_database-name</code>. See <a href="#">Monitoring Vertica Message Consumption with Consumer Groups</a> for more information. Set this value to an empty string (&quot;&quot;`) to disable progress reports to a Kafka consumer group.</td>
</tr>
</tbody>
</table>

### Special Starting Offset Values

The `start_offset` portion of the `stream` parameter lets you start loading messages from a specific point in the topic's partition. It also accepts one of two special offset values:

- `-2` tells the scheduler to start loading at the earliest available message in the topic's partition. This value is useful when you want to load as many messages as you can from the Kafka topic's partition.

- `-3` tells the scheduler to start loading from the consumer group's saved offset. If the consumer group does not have a saved offset, it starts loading from the earliest available message in the topic partition. See [Monitoring Vertica Message Consumption with Consumer Groups](#) for more information.

### Examples

This example shows how you can create the microbatch, `mbatch1`. This microbatch identifies the schema, target table, load spec, and source for the microbatch:

```
/opt/vertica/packages/kafka/bin/vkconfig microbatch --create --microbatch mbatch1
  --target-schema public
  --target-table BatchTarget
  --load-spec Filterspec
  --add-source SourceFeed
  --add-source-cluster StreamCluster1
  --conf myscheduler.conf
```
# Launch Tool Options

Use the `vkconfig` script's launch tool to assign a name to a scheduler instance. It accepts the following arguments in addition to the Common `vkconfig` Script Options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`--enable-ssl {true</td>
<td>false}`</td>
</tr>
<tr>
<td><code>--ssl-ca-alias alias</code></td>
<td>The user-defined alias of the root certifying authority you are using to authenticate communication between Vertica and Kafka. This parameter is used only when SSL is enabled.</td>
</tr>
<tr>
<td><code>--ssl-key-alias alias</code></td>
<td>The user-defined alias of the key/certificate pair you are using to authenticate communication between Vertica and Kafka. This parameter is used only when SSL is enabled.</td>
</tr>
<tr>
<td><code>--ssl-key-password password</code></td>
<td>The password used to create your SSL key. This parameter is used only when SSL is enabled.</td>
</tr>
<tr>
<td><code>--instance-name name</code></td>
<td>(Optional) Allows you to name the process running the scheduler.</td>
</tr>
</tbody>
</table>
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can use this command when viewing the scheduler_history table, to find which instance is currently running.</td>
<td></td>
</tr>
<tr>
<td><strong>--kafka_conf 'option=value[;option2=value2...]'</strong></td>
<td>A semicolon-delimited list of option=value pairs to pass directly to the rdafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See <a href="#">Directly Setting Kafka Library Options</a> for details.</td>
</tr>
</tbody>
</table>

### Examples

This example shows how you can launch the scheduler defined in the myscheduler.conf config file and give it the instance name PrimaryScheduler:

```bash
$ /opt/vertica/packages/kafka/bin/vkconfig launch --instance-name PrimaryScheduler --conf myscheduler.conf
```

This example shows how you can launch an instance named SecureScheduler with SSL enabled:

```bash
$ /opt/vertica/packages/kafka/bin/vkconfig launch --instance-name SecureScheduler --enable-SSL true \ --ssl-ca-alias authenticcert --ssl-key-alias ourkey \ --ssl-key-password secret \ --conf myscheduler.conf
```
Shutdown Tool Options

Use the vkconfig script's shutdown tool to terminate all Vertica schedulers running on a host. Always run this command before restarting a scheduler to ensure the scheduler has shutdown correctly.

**Note:** Launching a scheduler without terminating any existing instances of it can produce unexpected behavior.

Examples

This example shows how you can terminate all Vertica Kafka schedulers:

```
$ /opt/vertica/packages/kafka/bin/vkconfig shutdown --conf myscheduler.conf
```

Sync Tool Options

The sync utility immediately updates all source definitions by querying the Kafka cluster's brokers defined by the source. By default, it updates all of the sources defined in the target schema. To update just specific sources, use the `--source` and `--cluster` options to specify which sources to update.

It accepts the following arguments in addition to the Common vkconfig Script Options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--source</code></td>
<td>The name of the source sync. This source must already exist in the target</td>
</tr>
<tr>
<td><code>source_name</code></td>
<td>schema.</td>
</tr>
<tr>
<td><code>--cluster</code></td>
<td>Identifies the cluster containing the source that you want to sync. You must</td>
</tr>
<tr>
<td><code>cluster_name</code></td>
<td>have already defined this cluster in the scheduler.</td>
</tr>
<tr>
<td><code>--kafka_conf</code></td>
<td>A semicolon-delimited list of <code>option=value</code> pairs to pass directly to the</td>
</tr>
<tr>
<td><code>conf</code></td>
<td>rdkafka library. This is the library Vertica uses to communicate with Kafka.</td>
</tr>
<tr>
<td></td>
<td>You can use this parameter to directly set configuration options that are not</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>option =value</code> [; <code>option2 =value2 ...</code>]'</td>
<td>available through the Vertica integration with Kafka. See <a href="#">Directly Setting Kafka Library Options</a> for details.</td>
</tr>
</tbody>
</table>
Kafka Function Reference

This section lists the functions that make up Vertica's Kafka integration feature.

KafkaAvroParser

The KafkaAvroParser parses Avro-formatted Kafka messages and loads them into a regular Vertica table or a Vertica flex table.

```
KafkaAvroParser(
    [enforce_length=Boolean]
    [, reject_on_materialized_type_error=Boolean]
    [, flatten_maps=Boolean]
    [, flatten_arrays=Boolean]
    [, flatten_records=Boolean]
    [, external_schema=JSON_string]
    [, codec='default'|'snappy'|'null']
    [, with_metadata=Boolean]
    [, schema-registry-url='url']
    [, schema-registry-subject='subject_name']
    [, schema-registry-version='version_number']
    [, key_separator='separator']
)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enforce_length</td>
<td>When set to TRUE, rejects the row if any value is too wide to fit into its column. When using the default setting (FALSE), the parser truncates any value that is too wide to fit within the column's maximum width.</td>
</tr>
<tr>
<td>reject_on_materialized_type_error</td>
<td>When set to TRUE, rejects the row if it contains a materialized column value that cannot be mapped into the materialized column's data type.</td>
</tr>
<tr>
<td>flatten_maps</td>
<td>If set to TRUE, flattens all Avro maps.</td>
</tr>
<tr>
<td>flatten_arrays</td>
<td>If set to TRUE, flattens Avro arrays.</td>
</tr>
<tr>
<td>flatten_records</td>
<td>If set to TRUE, flattens all Avro records.</td>
</tr>
<tr>
<td>external_schema</td>
<td>Specifies the schema of the Avro file as a JSON string. If this parameter is not specified, the parser assumes that each message has the schema on it. If you are using a schema registry, do not use this parameter.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>codec</td>
<td>Specifies the codec in which the Avro file was written. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>* 'default' - Avro’s default</td>
</tr>
<tr>
<td></td>
<td>* 'snappy' - snappy compression</td>
</tr>
<tr>
<td></td>
<td>* 'null' - data is not compressed and codec is not needed</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is mainly provided for backwards compatibility. You usually have Kafka compress data at the message level, and have KafkaSource decompress the message for you.</td>
</tr>
<tr>
<td>with_metadata</td>
<td>If set to TRUE, messages include Avro datum, schema, and object metadata. By default, the KafkaAvroParser parses messages without including schema and metadata. If you enable this parameter, write your messages using the Avro API and confirm they contain only Avro datum. The default value is FALSE.</td>
</tr>
<tr>
<td>schema_registry_url</td>
<td>Specifies the URL of the Confluent schema registry. This parameter is required to load data based on a schema registry version. If you are using an external schema, do not use this parameter. For more information, refer to <strong>Using a Schema Registry with Kafka</strong>.</td>
</tr>
<tr>
<td>schema_registry_subject</td>
<td>In the schema registry, the subject of the schema to use for data loading.</td>
</tr>
<tr>
<td>schema_registry_version</td>
<td>In the schema registry, the version of the schema to use for data loading.</td>
</tr>
<tr>
<td>key_separator</td>
<td>Sets the character to use as the separator between keys.</td>
</tr>
</tbody>
</table>

See **Loading Avro Data** for more information.

The following example demonstrates loading data from Kafka in an Avro format. The statement:
- Loads data into an existing flex table named weather_logs.
- Copies data from the default Kafka broker (running on the local system on port 9092).
- The source is named temperature.
- The source has a single partition.
- The load starts from offset 0.
- The load ends either after 10 seconds or the load reaches the end of the source, whichever occurs first.
- The KafkaAvroParser does not flatten any arrays, maps, or records it finds in the source.
- The schema for the data is provided in the statement as a JSON string. It defines a record type named Weather that contains fields for a station name, a time, and a temperature.
- Rejected rows of data are saved to a table named t_rejects1.

```sql
=> COPY weather_logs
    SOURCE KafkaSource(stream='temperature|0|0', stop_on_eof=true, duration=interval '10 seconds')
    PARSER KafkaAvroParser(flatten_arrays=False, flatten_maps=False, flatten_records=False, external_schema=E'{"type":"record","name":"Weather","fields":
    [{'"name":"station","type":"string"},
    {'"name":"time","type":"long"},
    {'"name":"temp","type":"int"}]')
    REJECTED DATA AS TABLE "t_rejects1";
```

KafkaCheckBrokers

Retrieves information about the brokers in a Kafka cluster. This function is intended mainly for internal use—it used by the streaming job scheduler to get the list of brokers in the Kafka cluster. You can call the function to determine which brokers Vertica knows about.

Syntax

```
KafkaCheckBrokers(USING PARAMETERS brokers='hostname:port[,hostname2:port...]'
                  [, kafka_conf='option=value[;option2=value2...]']
                  [, timeout=timeout_sec])
```
### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>brokers</td>
<td>The host name and port number of a broker in the Kafka cluster used to retrieve the list of brokers. You can supply more than one broker as a comma-separated list. If the list includes brokers from more than one Kafka cluster, the cluster containing the last host in the list is queried.</td>
</tr>
<tr>
<td>kafka_conf</td>
<td>A semicolon-delimited list of <code>option=value</code> pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See <a href="#">Directly Setting Kafka Library Options</a> for details.</td>
</tr>
<tr>
<td>timeout</td>
<td>Integer number of seconds to wait for a response from the Kafka cluster.</td>
</tr>
</tbody>
</table>

### Example

```sql
=> SELECT KafkaCheckBrokers(USING PARAMETERS brokers='kafka01.example.com:9092') OVER ();

broker_id | hostname     | port |
----------|--------------|------|
    2      | kafka03.example.com | 9092 |
    1      | kafka02.example.com | 9092 |
    3      | kafka04.example.com | 9092 |
    0      | kafka01.example.com | 9092 |
(4 rows)
```

### KafkaExport

Sends Vertica data to Kafka.

If Vertica successfully exports all of the rows of data to Kafka, this function returns zero rows. You can use the output of this function to copy failed messages to a secondary table for evaluation and reprocessing.
Syntax

```sql
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
    USING PARAMETERS brokers='host[:port][,host...]',
    topic='topicname'
    [,kafka_conf='kafka_configuration_setting']
) OVER (partition_clause) FROM table;
```

Parameters

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>partitionColumn</code></td>
<td>The target partition for the export. If you set this value to NULL, Vertica uses the default partitioning scheme. You can use the partition argument to send messages to partitions that map to Vertica segments.</td>
</tr>
<tr>
<td><code>keyColumn</code></td>
<td>The user defined key value associated with the <code>valueColumn</code>. Use NULL to skip this argument.</td>
</tr>
<tr>
<td><code>valueColumn</code></td>
<td>The message itself. The column is a LONG VARCHAR, allowing you to send up to 32MB of data to Kafka. However, Kafka may impose its own limits on message size.</td>
</tr>
<tr>
<td><code>brokers</code></td>
<td>A string containing a comma-separated list of one or more host names or IP addresses (with optional port number) of brokers in the Kafka cluster.</td>
</tr>
<tr>
<td><code>topic</code></td>
<td>The Kafka topic to which you are exporting.</td>
</tr>
<tr>
<td><code>kafka_conf</code></td>
<td>A semicolon-delimited list of <code>option=value</code> pairs to pass directly to the rdafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly Setting Kafka Library Options for details.</td>
</tr>
</tbody>
</table>
### Examples

```sql
=> SELECT KafkaExport(partition, messageId, message
  USING PARAMETERS brokers='kafka01.example.com:9092',
  source='failure_test',
  kafka_conf='message.max.bytes=64000')
OVER (PARTITION BEST)
FROM failure_test;
```

<table>
<thead>
<tr>
<th>partition</th>
<th>key</th>
<th>substr</th>
<th>failure_reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>-123</td>
<td>key1</td>
<td>negative partition not allowed</td>
<td>Local: Unknown partition</td>
</tr>
<tr>
<td>54321</td>
<td>key1</td>
<td>nonexistent partition</td>
<td>Local: Unknown partition</td>
</tr>
<tr>
<td>0</td>
<td>normal key1</td>
<td>normal value1</td>
<td>Broker: Message size too</td>
</tr>
<tr>
<td>large</td>
<td>0</td>
<td>aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa</td>
<td>Broker: Message size too</td>
</tr>
<tr>
<td>large</td>
<td>0</td>
<td>normal key2</td>
<td>Broker: Message size too</td>
</tr>
<tr>
<td>large</td>
<td>0</td>
<td>normal value2</td>
<td>Broker: Message size too</td>
</tr>
</tbody>
</table>

### See Also

*Producing Data Using KafkaExport*

### KafkaJSONParser

The KafkaJSONParser parses JSON-formatted Kafka messages and loads them into a regular Vertica table or a Vertica flex table.

### Syntax

```sql
KafkaJSONParser(
  [enforce_length=Boolean]
  [, flatten_maps=Boolean]
  [, flatten_arrays=Boolean]
  [, start_point=string]
  [, start_point_occurrence=integer]
  [, omit_empty_keys=Boolean]
  [, reject_on_duplicate=Boolean]
  [, reject_on_materialized_type_error=Boolean]
  [, reject_on_empty_key=Boolean]
  [, key_separator=char]
  [, suppress_nonalphanumeric_key_chars=Boolean]
)
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enforce_length</td>
<td>If set to TRUE, rejects the row if data being loaded is too wide to fit into its column. Defaults to FALSE, which truncates any data that is too wide to fit into its column.</td>
</tr>
<tr>
<td>flatten_maps</td>
<td>If set to TRUE, flattens all JSON maps.</td>
</tr>
<tr>
<td>flatten_arrays</td>
<td>If set to TRUE, flattens JSON arrays.</td>
</tr>
<tr>
<td>start_point</td>
<td>Specifies the key in the JSON data that the parser should parse. The parser only extracts data that is within the value associated with the start_point key. It parses the values of all instances of the start_point key within the data.</td>
</tr>
<tr>
<td>start_point_occurrence</td>
<td>Integer value indicating which occurrence of the key specified by the start_point parameter where the parser should begin parsing. For example, if you set this value to 4, the parser will only begin loading data from the fifth occurrence of the start_point key. Only has an effect if you also supply the start_point parameter.</td>
</tr>
<tr>
<td>omit_empty_keys</td>
<td>If set to TRUE, omits any key from the load data that does not have a value set.</td>
</tr>
<tr>
<td>reject_on_duplicate</td>
<td>If set to TRUE, rejects the row that contains duplicate key names. Key names are case-insensitive, so the keys &quot;mykey&quot; and &quot;MyKey&quot; are considered duplicates.</td>
</tr>
<tr>
<td>reject_on_materialized_type_error</td>
<td>If set to TRUE, rejects the row if the data includes keys matching an existing materialized column and has a key that cannot be mapped into the materialized column's data type.</td>
</tr>
<tr>
<td>reject_on_empty_key</td>
<td>If set to TRUE, rejects any row containing a key without a value.</td>
</tr>
<tr>
<td>key_separator</td>
<td>A single character to use as the separator between key values instead of the default period (.) character.</td>
</tr>
<tr>
<td>suppress_nonalphanumeric_key_chars</td>
<td>If set to TRUE, replaces all non-alphanumeric characters in JSON key values with an underscore (_) character.</td>
</tr>
</tbody>
</table>

See [Loading JSON Data](#) for more information.
The following example demonstrates loading JSON data from Kafka. The parameters in the statement define to the load to:

- Load data into the pre-existing table named logs.
- The KafkaSource streams the data from a single partition in the source called server_log.
- The Kafka broker for the data load is running on the host named kafka01 on port 9092.
- KafkaSource stops loading data after either 10 seconds or on reaching the end of the stream, whichever happens first.
- The KafkaJSONParser flattens any arrays or maps in the JSON data.

```sql
=> COPY logs SOURCE KafkaSource(stream='server_log|0|0',
     stop_on_eof=true,
     duration=interval '10 seconds',
     brokers='kafka01:9092')
     PARSER KafkaJSONParser(flatten_arrays=True, flatten_maps=True);
```

### KafkaListManyTopics

Retrieves information about all topics from a Kafka broker. This function lists all of the topics defined in the Kafka cluster as well the number of partitions it contains and which brokers serve the topic.

#### Syntax

```
KafkaListManyTopics('broker:port[;...]'
  [USING PARAMETERS
    [kafka_conf='option=value[;option2=value2...]'
    [, timeout=timeout_sec]])
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>broker</td>
<td>The hostname (or ip address) of a broker in the Kafka cluster</td>
</tr>
<tr>
<td>port</td>
<td>The port number on which the broker is running.</td>
</tr>
<tr>
<td>kafka_conf</td>
<td>A semicolon-delimited list of <code>option=value</code> pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See [Directly Setting](Vertica Documentation)</td>
</tr>
</tbody>
</table>
Kafka Library Options for details.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeout</td>
<td>Integer number of seconds to wait for a response from the Kafka cluster.</td>
</tr>
</tbody>
</table>

Example

```
=> \x
Expanded display is on.
=> SELECT KafkaListManyTopics('kafka01.example.com:9092')
               OVER (PARTITION AUTO);
- [ RECORD 1 ]-============================================================================
  brokers | kafka01.example.com:9092,kafka02.example.com:9092
  topic   | _consumer_offsets
  num_partitions | 50
- [ RECORD 2 ]-============================================================================
  brokers | kafka01.example.com:9092,kafka02.example.com:9092
  topic   | iot_data
  num_partitions | 1
- [ RECORD 3 ]-============================================================================
  brokers | kafka01.example.com:9092,kafka02.example.com:9092
  topic   | test
  num_partitions | 1
```

KafkaListTopics

Gets the list of topics available from a Kafka broker.

Syntax

```
KafkaListTopics(USING PARAMETERS brokers='hostname:port[,hostname2:port2...]'
               [, kafka_conf='option=value[,option2=value2...]']
               [, timeout=timeout_sec])
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>brokers</td>
<td>The host name and port number of the broker to query for a topic list. You can supply more than one broker as a comma-separated list. However, the returned list will only contains the topics served by the last broker in the list.</td>
</tr>
<tr>
<td>kafka_conf</td>
<td>A semicolon-delimited list of option=value pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See Directly Setting</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td><strong>Kafka Library Options</strong> for details.</td>
</tr>
<tr>
<td>timeout</td>
<td>Integer number of seconds to wait for a response from the Kafka cluster.</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT KafkaListTopics(USING PARAMETERS brokers='kafka1-01.example.com:9092')
    OVER ();
```

<table>
<thead>
<tr>
<th>topic</th>
<th>num_partitions</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>1</td>
</tr>
<tr>
<td>iot_data</td>
<td>1</td>
</tr>
<tr>
<td>__consumer_offsets</td>
<td>50</td>
</tr>
<tr>
<td>vertica_notifications</td>
<td>1</td>
</tr>
<tr>
<td>web_hits</td>
<td>1</td>
</tr>
</tbody>
</table>

**KafkaOffsets**

The KafkaOffsets user-defined transform function returns load operation statistics generated by the most recent invocation of KafkaSource. Query KafkaOffsets to see the metadata produced by your most recent load operation. You can query KafkaOffsets after each KafkaSource invocation to view information about that load. If you are using the scheduler, you can also view historical load information in the stream_microbatch_history table.

For each load operation, KafkaOffsets returns the following:

- source kafka topic
- source kafka partition
- starting offset
- ending offset
- number of messages loaded
- number of bytes read
- duration of the load operation
- end message
- end reason

The following example demonstrates calling KafkaOffsets to show partition information on the table named web_test that was loaded using KafkaSource.

```sql
def select kpartition, start_offset, end_offset, msg_count, ending
FROM (select KafkaOffsets() over()
FROM web_test) AS stats
ORDER BY kpartition;
```

<table>
<thead>
<tr>
<th>kpartition</th>
<th>start_offset</th>
<th>end_offset</th>
<th>msg_count</th>
<th>ending</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-2</td>
<td>9999</td>
<td>1068</td>
<td>END_OFFSET</td>
</tr>
</tbody>
</table>

The output shows that KafkaSource loaded 1068 messages (rows) from Kafka in a single partition. The KafkaSource ended the data load because it reached the ending offset.

**Note:** The values shown in the start_offset column are exclusive (the message with the shown offset was not loaded) and the values in the end_offset column are inclusive (the message with the shown offset was loaded). This is the opposite of the values specified in the KafkaSource's stream parameter. The difference between the inclusiveness of KafkaSource's and KafkaOffset's start and end offsets are based on the needs of the job scheduler. KafkaOffset is primarily intended for the job scheduler's use, so the start and end offset values are defined so the scheduler can easily start streaming from where left off.

**KafkaParser**

The KafkaParser does not parse data loaded from Kafka. Instead, it passes the messages through as LONG VARCHAR values. Use this parser when you want to load raw Kafka messages into Vertica for further processing. You can use this parser as a catch-all for unsupported formats.

KafkaParser does not take any parameters.

**Example**

The following example loads raw messages from a Kafka topic named iot-data into a table named raw_iot.

```sql
def create table raw_iot(message long varchar);
create table
```
KafkaSource

The KafkaSource UDL accesses data from a Kafka cluster. All Kafka parsers must use KafkaSource. Messages processed by KafkaSource must be at least one byte in length. KafkaSource writes an error message to vertica.log for zero length messages.

The output of KafkaSource does not work directly with any of the non-Kafka parsers in Vertica (such as the FCSVParser). The KafkaParser produces additional metadata about the stream that parsers need to use in order to correctly parse the data. You must use filters such as KafkaInsertDelimiters to transform the data into a format that can be processed by other parsers. See Parsing Custom Formats for more an example.

You can cancel a running KafkaSource data load by using a close session function such as CLOSE_ALL_SESSIONS.

Syntax

KafkaSource(stream='topic_name|partition|start_offset[|end_offset][,...]',
            [., brokers='host:port[,...]']
            [., duration=interval]
            [., executionparallelism='value']
            [., stop_on_eof=Boolean]
            [., eof_timeout=timeout]
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| stream | Required. Defines the data to be loaded as a comma-separated list of one or more partitions. Each partition is defined by three required values and one optional value separated by pipe characters (|):
  - **topic_name**: the name of the Kafka topic to load data from. You can read from different Kafka topics in the same stream parameter, with some limitations. See [Loading from Multiple Topics in the Same Stream Parameter](#) below for more information.
  - **partition**: the partition in the Kafka topic to copy.
  - **start_offset**: the offset in the Kafka topic where the load will begin. This offset is inclusive (the message with the offset **start_offset** is loaded). See [Special Starting Offset Values](#) below for additional options.
  - **end_offset**: the optional offset where the load should end. This offset is exclusive (the message with the offset **end_offset** will not be loaded). To end a load using **end_offset**, you must supply an ending offset value for all partitions in the stream parameter. Attempting to set an ending offset for some partitions and not set offset values for others results in an error.
    - If you do not specify an ending offset, you must supply at least one other ending condition using **stop_on_eof** or **duration**. |
| brokers | A comma-separated list of host:port pairs of the brokers in the Kafka cluster. Vertica recommends running Kafka on a different machine than Vertica.  
**Default Value**: localhost:9092 |
| duration | An INTERVAL that specifies the duration of the frame. After this specified amount of time, KafkaSource terminates the COPY statements. If this parameter is not set, you must set at
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>least one other</td>
<td>least one other ending condition by using stop_on_eof or specify an ending offset instead. See Duration Note below for more information.</td>
</tr>
<tr>
<td>executionparallelism</td>
<td>The number of threads to use when loading data. Normally, you set this to an integer value between 1 and the number of partitions the node is loading from. Setting this parameter to a reduced value limits the number of threads used to process any COPY statement. It also increases the throughput of short queries issued in the pool, especially if the queries are executed concurrently. If you do not specify this parameter, Vertica automatically creates a thread for every partition, up to the limit allowed by the resource pool. If the value you specify for the KafkaSource is lower than the value specified for the scheduler resource pool, the KafkaSource value applies. This value cannot exceed the value specified for the scheduler's resource pool.</td>
</tr>
<tr>
<td>stop_on_eof</td>
<td>Determines whether KafkaSource should terminate the COPY statement after it reaches the end of a file. If this value is not set, you must set at least one other ending condition using duration or by supplying ending offsets instead. Default Value: FALSE</td>
</tr>
<tr>
<td>eof_timeout</td>
<td>A timeslice of type INTERVAL. If a COPY command does not receive any Kafka messages within the eof_timeout interval, Vertica responds by ending that COPY statement. This parameter applies only if stop_on_eof is TRUE. Deprecated: This parameter has been deprecated and will be removed in a future version of the product. It is no longer necessary because newer versions of the library that Vertica uses to communicate with Kafka now indicate when the stream has ended.</td>
</tr>
<tr>
<td>group_id</td>
<td>The name of the Kafka consumer group to which Vertica reports its progress consuming messages. By default, Vertica reports its progress to a group named vertica_database-</td>
</tr>
</tbody>
</table>
### Special Starting Offset Values

The `start_offset` portion of the `stream` parameter lets you start loading messages from a specific point in the topic's partition. It also accepts one of two special offset values:

- `-2` tells KafkaSource to start loading at the earliest available message in the topic's partition. This value is useful when you want to load as many messages as you can from the Kafka topic's partition.

- `-3` tells KafkaSource to start loading from the consumer group's saved offset. If the consumer group does not have a saved offset, it starts loading from the earliest available message in the topic partition. See Monitoring Vertica Message Consumption with Consumer Groups for more information.

### Loading from Multiple Topics in the Same Stream Parameter

You can load from multiple Kafka topics in a single stream parameter as long as you follow these guidelines:

- The data for the topics must be in the same format because you pass the data from KafkaSource to a single parser. For example, you cannot load data from one topic that is in Avro format and another in JSON format.
• Similarly, you need to be careful if you are loading Avro data and specifying an external schema from a registry. The Avro parser accepts a single schema per data load. If the data from the separate topics have different schemas, then all of the data from one of the topics will be rejected.

• The data in the different topics should have the same (or very similar) schemas, especially if you are loading data into a traditional Vertica table. While you can load data with different schemas into a flex table, there are only a few scenarios where it makes sense to combine dissimilar data into a single table.

Duration Note

The duration parameter applies to the length of time that Vertica allows the KafkaSource function to run. It usually reflects the amount of time the overall load statement takes. However, if KafkaSource is loading a large volume of data or the data needs extensive processing and parsing, the overall runtime of the query can exceed the amount of time specified in duration.

Example

The following example demonstrates calling KafkaSource to load data from Kafka into an existing flex table named web_test with the following options:

• The stream is named web_hits which has a single partition.

• The load starts at the earliest message in the stream (identified by passing -2 as the start offset).

• The load ends when it reaches the message with offset 10000.

• The Kafka cluster's brokers are kafka01 and kafka03 in the example.com domain.

• The brokers are listening on port 6667. (This is port number that the Hortonworks Hadoop distribution assigns to its Kafka brokers.)

• The load ends if it reaches the end of the stream before reaching the message with offset 10000. If you do not supply this option, the connector waits until Kafka sends a message with offset 10000.

• The loaded data is sent to the KafkaJSONParser for processing.
=> COPY web_test
    SOURCE KafkaSource(stream='web_hits|0|-2|10000',
                        brokers='kafka01.example.com:6667,kafka03.example.com:6667',
                        stop_on_eof=true)
    PARSER KafkaJSONParser();

Data Streaming Schema Tables

Every time you create a scheduler (--create), Vertica creates a schema for that scheduler with the name you specify or the default stream_config. Each schema has the following tables:

- stream_clusters
- stream_events
- stream_load_specs
- stream_microbatch_history
- stream_microbatch_source_map
- stream_microbatches
- stream_scheduler
- stream_scheduler_history
- stream_sources
- stream_targets

Caution: Vertica recommends that you do not alter these tables except in consultation with support.

stream_clusters

This table lists clusters and hosts. You change settings in this table using the vkconfig cluster tool. See Cluster Tool Options for more information.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>INTEGER</td>
<td>The identification number assigned to the cluster.</td>
</tr>
<tr>
<td>cluster</td>
<td>VARCHAR</td>
<td>The name of the cluster.</td>
</tr>
<tr>
<td>hosts</td>
<td>VARCHAR</td>
<td>A comma-separated list of hosts associated with the cluster.</td>
</tr>
</tbody>
</table>
Examples

This example shows a cluster and its associated hosts.

```
=> SELECT * FROM stream_config.stream_clusters;

<table>
<thead>
<tr>
<th>id</th>
<th>cluster</th>
<th>hosts</th>
</tr>
</thead>
<tbody>
<tr>
<td>2250001</td>
<td>streamcluster1</td>
<td>10.10.10.10:9092,10.10.11:9092</td>
</tr>
</tbody>
</table>

(1 rows)
```

stream_events

This table logs microbatches and other important events from the scheduler in an internal log table.

This table was renamed from kafka_config.kafka_events.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event_time</td>
<td>TIMESTAMP</td>
<td>The time the event was logged.</td>
</tr>
<tr>
<td>log_level</td>
<td>VARCHAR</td>
<td>The type of event that was logged.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Valid Values:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- TRACE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DEBUG</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- FATAL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ERROR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- WARN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- INFO</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Default value:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>INFO</td>
</tr>
<tr>
<td>frame_start</td>
<td>TIMESTAMP</td>
<td>The time when the frame executed.</td>
</tr>
<tr>
<td>frame_end</td>
<td>TIMESTAMP</td>
<td>The time when the frame completed.</td>
</tr>
<tr>
<td>Column</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>microbatch</td>
<td>INTEGER</td>
<td>The identification number of the associated microbatch.</td>
</tr>
<tr>
<td>message</td>
<td>VARCHAR</td>
<td>A description of the event.</td>
</tr>
</tbody>
</table>
| exception | VARCHAR   | If this log is in the form of a stack trace, this column lists the exception.

**Examples**

This example shows typical rows from the stream_events table.

```sql
=> SELECT * FROM stream_config.stream_events;

-[ RECORD 1 ]-+-------------+
| event_time | 2016-07-17 13:28:35.548-04 |
| log_level  | INFO                     |
| frame_start|                          |
| frame_end  |                          |
| microbatch |                          |
| message    | New leader registered for schema stream_config. New ID: 0, new Host: 10.20.100.62 004:9092,eng-g9-005:9092), resource pool: kafka_default_pool |
| exception  |                          |

-[ RECORD 2 ]-+-------------+
| event_time | 2016-07-17 13:28:45.643-04 |
| log_level  | INFO                     |
| frame_start| 2015-07-17 12:28:45.633   |
| frame_end  | 2015-07-17 13:28:50.701-04|
| microbatch |                          |
| message    | Generated tuples: test3|2|-2,test3|1|-2,test3|0|-2 |
| exception  |                          |

-[ RECORD 3 ]-+-------------+
| event_time | 2016-07-17 14:28:50.701-04 |
| log_level  | INFO                     |
| frame_start| 2016-07-17 13:28:45.633   |
| frame_end  | 2016-07-17 14:28:50.701-04|
| microbatch |                          |
| message    | Total rows inserted: 0   |
| exception  |                          |
```

**stream_load_specs**

This table describes user-created load specs. You change the entries in this table using the `vkconfig` utility's load spec tool.
### Column

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>INTEGER</td>
<td>The identification number assigned to the cluster.</td>
</tr>
<tr>
<td>load_spec</td>
<td>VARCHAR</td>
<td>The name of the load spec.</td>
</tr>
<tr>
<td>filters</td>
<td>VARCHAR</td>
<td>A comma-separated list of hosts associated with the cluster.</td>
</tr>
<tr>
<td>parser</td>
<td>VARCHAR</td>
<td>A VerticaUDParser to use with a specified target. If you are using a Vertica native parser, parser parameters serve as a COPY statement parameters.</td>
</tr>
<tr>
<td>parser_ parameters</td>
<td>VARCHAR</td>
<td>A list of parameters to provide to the parser.</td>
</tr>
<tr>
<td>load_method</td>
<td>VARCHAR</td>
<td>The COPY load method to use for all loads with this scheduler. See the COPY statement for more information.</td>
</tr>
<tr>
<td>message_max_bytes</td>
<td>INTEGER</td>
<td>The maximum size, in bytes, of a message.</td>
</tr>
<tr>
<td>uds_kv_parameters</td>
<td>VARCHAR</td>
<td>A list of parameters that are supplied to the KafkaSource statement. If the value in this column is in the format key=value, the scheduler it to the COPY statement's KafkaSource call.</td>
</tr>
</tbody>
</table>

### Examples

This example shows the load specs that you can use with a Vertica instance.

```sql
SELECT * FROM stream_config.stream_load_specs;
-| RECORD 1 |----------------|
  | id       | 1               |
  | load_spec| loadspec2       |
  | filters  |                |
  | parser   | KafkaParser     |
  | parser_parameters |          |
  | load_method| direct        |
  | message_max_bytes| 1048576     |
  | uds_kv_parameters |            |
-| RECORD 2 |----------------|
  | id       | 750001          |
  | load_spec| streamspec1     |
  | filters  |                |
  | parser   | KafkaParser     |
  | parser_parameters |          |
  | load_method| TRICKLE       |
```
stream_microbatch_history

This table contains a history of every microbatch executed within this scheduler configuration.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_name</td>
<td>VARCHAR</td>
<td>The name of the source.</td>
</tr>
<tr>
<td>source_cluster</td>
<td>VARCHAR</td>
<td>The name of the source cluster. The clusters are defined in stream_clusters.</td>
</tr>
<tr>
<td>source_partition</td>

stream_microbatch_source_map

This table maps microbatches to their associated sources.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>microbatch</td>
<td>INTEGER</td>
<td>The identification number of the microbatch.</td>
</tr>
<tr>
<td>source</td>
<td>INTEGER</td>
<td>The identification number of the associated source.</td>
</tr>
</tbody>
</table>

Examples

This example shows typical rows from the stream_microbatch table.

```
SELECT * FROM stream_config.stream_microbatch_source_map;
```

<table>
<thead>
<tr>
<th>microbatch</th>
<th>source</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>

(2 rows)

stream_microbatches

This table contains configuration data related to microbatches.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>INTEGER</td>
<td>The identification number of the microbatch.</td>
</tr>
<tr>
<td>microbatch</td>
<td>VARCHAR</td>
<td>The name of the microbatch.</td>
</tr>
<tr>
<td>target</td>
<td>INTEGER</td>
<td>The identification number of the target associated with the microbatch.</td>
</tr>
<tr>
<td>load_spec</td>
<td>INTEGER</td>
<td>The identification number of the load spec associated with the microbatch.</td>
</tr>
<tr>
<td>target_columns</td>
<td>VARCHAR</td>
<td>The table columns associated with the</td>
</tr>
<tr>
<td>Column</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>rejection_schema</td>
<td>VARCHAR</td>
<td>The schema that contains the rejection table.</td>
</tr>
<tr>
<td>rejection_table</td>
<td>VARCHAR</td>
<td>The table where Vertica stores messages that are rejected by the database.</td>
</tr>
<tr>
<td>enabled</td>
<td>BOOLEAN</td>
<td>When TRUE, the microbatch is enabled for use.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows a row from a typical stream_microbatches table.

```sql
SELECT * FROM stream_config.stream_microbatches;
```

```
 id     | 1
 microbatch | mbatch1
 target | 1
 load_spec  | 750001
 target_columns | rejected_messages
 rejection_schema | public
 rejection_table | t
```

**stream_scheduler**

This table contains metadata related to a single scheduler.

This table was renamed from kafka_config.kafka_scheduler.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>VARCHAR</td>
<td>The version of the scheduler.</td>
</tr>
<tr>
<td>frame_duration</td>
<td>INTERVAL</td>
<td>The length of time of the frame. The default is 00:00:10.</td>
</tr>
<tr>
<td>resource_pool</td>
<td>VARCHAR</td>
<td>The resource pool associated with this scheduler.</td>
</tr>
<tr>
<td>Column</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>config_refresh</td>
<td>INTERVAL</td>
<td>The interval of time that the scheduler runs before applying any changes to its metadata, such as, changes made using the --update option. For more information, refer to --config-refresh in Scheduler Tool Options.</td>
</tr>
</tbody>
</table>
| new_source_policy   | VARCHAR   | When during the frame that the source runs. Set this value with the --new-source-policy in Source Tool Options. Valid Values:  

- **FAIR**: Takes the average length of time from the previous batches and schedules itself appropriately.  
- **START**: Runs all new sources at the beginning of the frame. In this case, Vertica gives the minimal amount of time to run.  
- **END**: Runs all new sources starting at the end of the frame. In this case, Vertica gives the maximum amount of time to run.  

Default Value: FAIR |
| eof_timeout_ms      | INTEGER   | The maximum amount of time the scheduler waits for data from the source before ending the batch.  

Default Value: 1000 |
<p>| pushback_policy     | VARCHAR   | (Not currently used.) How Vertica handles delays for microbatches that continually fail.                                                  |</p>
<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pushback_max_count</td>
<td>INTEGER</td>
<td>(Currently not used.) The maximum number of times a microbatch can fail before Vertica terminates it.</td>
</tr>
<tr>
<td>auto_sync</td>
<td>BOOLEAN</td>
<td>When TRUE, the scheduler automatically synchronizes source information with host clusters. For more information, refer to Automatically Copying Data From Kafka. Default Value: TRUE</td>
</tr>
</tbody>
</table>

**Examples**

This example shows a typical row in the stream_scheduler table.

```
SELECT * FROM stream_config.stream_scheduler;
-[ RECORD 1 ]-------------------------
version       | v8.0.0
frame_duration| 00:00:10
resource_pool | kafka_default_pool
config_refresh| 00:05
new_source_policy | FAIR
eof_timeout_ms  | 10000
pushback_policy  | LINEAR
pushback_max_count | 5
auto_sync       | t
```
stream_scheduler_history

This table shows the history of launched scheduler instances.

This table was renamed from kafka_config.kafka_scheduler_history.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>elected_leader_time</td>
<td>TIMESTAMP</td>
<td>The time when this instance took began scheduling operations.</td>
</tr>
<tr>
<td>host</td>
<td>VARCHAR</td>
<td>The host name of the machine running the scheduler instance.</td>
</tr>
<tr>
<td>launcher</td>
<td>VARCHAR</td>
<td>The name of the currently active scheduler instance.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Default Value:</strong> NULL</td>
</tr>
<tr>
<td>scheduler_id</td>
<td>INTEGER</td>
<td>The identification number of the scheduler.</td>
</tr>
<tr>
<td>version</td>
<td>VARCHAR</td>
<td>The version of the scheduler.</td>
</tr>
</tbody>
</table>

Examples

This example shows typical rows from the stream_scheduler_history table.

```
SELECT * FROM stream_config.stream_scheduler_history;
```

```
<table>
<thead>
<tr>
<th>elected_leader_time</th>
<th>host</th>
<th>launcher</th>
<th>scheduler_id</th>
<th>version</th>
</tr>
</thead>
<tbody>
<tr>
<td>2016-07-26 13:19:42.692</td>

<td>0</td>
<td>v8.0.0</td>
</tr>
<tr>
<td>2016-07-26 13:54:37.715</td>
<td>10.20.100.62</td>
<td></td>
<td>1</td>
<td>v8.0.0</td>
</tr>
<tr>
<td>2016-07-26 13:56:06.785</td>
<td>10.20.100.62</td>
<td></td>
<td>2</td>
<td>v8.0.0</td>
</tr>
<tr>
<td>2016-07-26 13:56:56.033</td>
<td>10.20.100.62</td>
<td>SchedulerInstance</td>
<td>3</td>
<td>v8.0.0</td>
</tr>
<tr>
<td>2016-07-26 15:51:20.513</td>
<td>SchedulerInstance</td>
<td>4</td>
<td>v8.0.0</td>
<td></td>
</tr>
<tr>
<td>2016-07-26 15:51:35.111</td>
<td>SchedulerInstance</td>
<td>5</td>
<td>v8.0.0</td>
<td></td>
</tr>
</tbody>
</table>
```

(6 rows)

stream_sources

This table contains metadata related to data streaming sources.
This table was formerly named kafka_config.kafka_scheduler.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>INTEGER</td>
<td>The identification number of the source</td>
</tr>
<tr>
<td>source</td>
<td>VARCHAR</td>
<td>The name of the source.</td>
</tr>
<tr>
<td>cluster</td>
<td>INTEGER</td>
<td>The identification number of the cluster associated with the source.</td>
</tr>
<tr>
<td>partitions</td>
<td>INTEGER</td>
<td>The number of partitions in the source.</td>
</tr>
<tr>
<td>enabled</td>
<td>BOOLEAN</td>
<td>When TRUE, the source is enabled for use.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows a typical row from the stream_sources table.

```sql
select * from stream_config.stream_sources;
```

```
-[ RECORD 1 ]--------------------
id | 1
source | SourceFeed1
cluster | 1
partitions | 1
enabled | t
-[ RECORD 2 ]--------------------
id | 250001
source | SourceFeed2
cluster | 1
partitions | 1
enabled | t
```

**stream_targets**

This table contains the metadata for all Vertica target tables.

The table was formerly named kafka_config.kafka_targets.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>INTEGER</td>
<td>The identification number of the target table</td>
</tr>
<tr>
<td>Column</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------</td>
</tr>
<tr>
<td>target_schema</td>
<td>VARCHAR</td>
<td>The name of the schema for the target table.</td>
</tr>
<tr>
<td>target_table</td>
<td>VARCHAR</td>
<td>The name of the target table.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows typical rows from the stream_tables table.

```sql
=> SELECT * FROM stream_config.stream_targets;
-[ RECORD 1 ]-+-------------------------+
 id   | 1
 target_schema | public
 target_table | streamFlex1
-[ RECORD 2 ]-+-------------------------+
 id   | 2
 target_schema | public
 target_table | streamFlex2
```
Integrating with Apache Spark

Welcome to the Vertica Vertica Connector for Apache Spark Guide.

The Vertica Connector for Apache Spark is a fast parallel connector that transfers data between the Vertica Analytics Platform and Apache Spark. This feature lets you use Spark to pre-process data for Vertica and to use Vertica data in your Spark application.

Apache Spark is an open-source, general-purpose cluster-computing framework. It evolved as a faster, multi-stage, in-memory alternative to the two stage, disk-based Map Reduce framework offered by Hadoop. The Spark framework is based on Resilient Distributed Datasets (RDDs), which are logical collections of data partitioned across machines. Spark is typically used in upstream workloads to process data before loading it in Vertica for interactive analytics. It can also be used downstream of Vertica, where data pre-processed by Vertica is then moved into Spark for further transformation.

Using the Vertica Vertica Connector for Apache Spark, you can:

- Move large volumes of data from Spark DataFrames to Vertica tables; the connector allows you to write Spark DataFrames to Vertica tables.

- Move data from Vertica to Spark RDDs or DataFrames for use with Python, R, Scala and Java. The connector efficiently pushes down column selection and predicate filtering to Vertica before loading the data.
Audience

This book is intended for anyone who wants to transfer data between a Vertica database and an Apache Spark cluster.
Prerequisites and Compatibility

This document assumes that you have installed and configured Vertica as described in Installing Vertica and the Configuring the Database section of the Administrator's Guide. You must also have installed your Apache Spark clusters.

To save data from Spark to Vertica, you must have an HDFS cluster for an intermediate staging location. Your Vertica database must be configured to read data from this HDFS cluster. See Using HDFS URLs in Integrating with Apache Hadoop for more information.

For details on installing and using Apache Spark and Apache Hadoop, see the Apache Spark web site, the Apache Hadoop website, or your Hadoop vendor's installation documentation.

For supported versions of Apache Spark and Apache Hadoop see the following sections in the Supported Platforms guide:

- Vertica Integration for Apache Spark
- Vertica Integrations for Hadoop
Getting the Spark Connector

The Vertica Connector for Apache Spark is packaged as a JAR file. You install this file on your Spark cluster to enable Spark and Vertica to exchange data. In addition to the Connector JAR file, you also need the Vertica JDBC client library. The Connector uses this library to connect to the Vertica database.

Both of these libraries are installed with the Vertica server and are available on all nodes in the Vertica cluster in the following locations:

- The Spark Connector files are located in /opt/vertica/packages/SparkConnector/lib.
- The JDBC client library is /opt/vertica/java/vertica-jdbc.jar.

Choosing the Correct Connector Version

Vertica supplies multiple versions of the Spark Connector JAR files. Each file is compatible one or more versions of Apache Spark and a specific version of Scala. The Connector file you need depends on the version of Apache Spark and Scala you have installed. You can determine your Spark and Scala version by starting a Spark shell:

```
$ spark-shell
SPARK_MAJOR_VERSION is set to 2, using Spark2
Setting default log level to "WARN".
To adjust logging level use sc.setLogLevel(newLevel). For SparkR, use setLogLevel(newLevel).
Spark context Web UI available at http://node01:4040
Spark context available as 'sc' (master = local[*], app id = local-1488824765565).
Spark session available as 'spark'.
Welcome to

/\_/\  \_   _/  /
 /\ \  \_ \  /  '/\ /
 / _\ \_._.'\_  _//
/_\/_/\/_\_\_\_\_\_/

version 2.1.0.2.6.0.3-8

```

The startup messages contain the version numbers of both Spark and Scala (shown in bold in the previous example for clarity).

The list in Vertica Integration for Apache Spark tells you which version of the Spark Connector JAR file you need for each combination of Spark and Scala. Note that some versions of the
Spark Connector are compatible with multiple versions of Spark. For example, the connector for Spark 2.1 is also compatible with Spark 2.2.

**Note:** Prior to Vertica version 9.1, the Spark Connector was distributed on the myVertica portal. If you have a version of Vertica prior to 9.1, you must download the correct connector file from the portal.
Deploying the Vertica Connector for Apache Spark

Once you have the connector and JDBC library JAR files, you can deploy them to your Spark cluster in two ways:

- Include the connector and Vertica JDBC JAR files using the "--jars" option when invoking spark-submit or spark-shell.
- Deploy the connector to a Spark cluster so that all Spark applications have access across all nodes.

Copying the Connector for Use with Spark Submit or Spark Shell

1. Log on as the Spark user on any Spark machine.

2. Copy both the Vertica Spark Connector and Vertica JDBC Driver JAR files from the package to your local Spark directory.

3. Then, run the connector in any of the following ways (replace the version number in the jar names with your version number):

   - Run a Spark Application using spark-submit ([http://spark.apache.org/docs/latest/submitting-applications.html#launching-applications-with-spark-submit](http://spark.apache.org/docs/latest/submitting-applications.html#launching-applications-with-spark-submit)). You must run the command on the node with the Vertica JAR files:

     ```
     spark-submit --jars vertica-8.1.0_spark2.0_scala2.11.jar,vertica-jdbc-8.1.0-0.jar other options SparkApplication.jar
     ```

     **Note:** Do not include a space before or after the comma in the --jars argument.

   - Use the Interactive spark-shell ([http://spark.apache.org/docs/latest/programming-guide.html#using-the-shell](http://spark.apache.org/docs/latest/programming-guide.html#using-the-shell)). You must run the command on the node with the Vertica JAR files:
Deploying the Connector to a Spark Cluster

You can optionally deploy the JAR files to a Spark cluster. This approach gives all applications (such as shell and submit) access; it does not require specifying them on the command line.

To deploy to the Spark cluster:

1. Copy the files to a common path on all Spark machines.

2. Add the path for the connector and JDBC driver to your conf/spark-defaults.conf, and restart the Spark Master. For example, modify the spark.jars line by adding the connector and JDBC JARS as follows (replace paths and version numbers with your values):

   ```
   spark.jars /JAR_file_Path/vertica-8.1.0_spark2.0_scala2.11.jar,/JAR_file_Path/vertica-jdbc-8.1.0-0.jar
   ```

Note: The version numbers in the JAR file names will vary depending on your version of Vertica, Spark, and Scala.
Saving an Apache Spark DataFrame to a Vertica Table

The Vertica Connector for Apache Spark copies data partitions distributed across multiple Spark worker-nodes into a temporary location in HDFS. Vertica then reads the data from HDFS. These data transfers use parallel reads and writes, letting the connector efficiently load large volumes of data from Spark to Vertica.

Save Options

When writing Spark DataFrames to Vertica, you specify a Vertica target table. You also set how the data is saved using the DataFrame SaveMode. The valid values for the SaveMode are:

- **SaveMode.Overwrite** overwrites or create new table.
  
  Note: The existing table is dropped whether the save succeeds or not, except when the connector is asked to load a DataFrame that contains zero rows.

- **SaveMode.Append** appends data to an existing table or creates the table if it does not exist.

- **SaveMode.ErrorIfExists** creates a new table if the table does not exist, otherwise returns an error.

- **SaveMode.Ignore** creates a new table if the table does not exist, otherwise it does not save the data and does not return an error.

The `save()` operation never results in a partial or duplicate save. The connector either saves the DataFrame in its entirety to the target table successfully or it aborts the save. In case of failures, to avoid leaving the target table in an inconsistent state, the connector:

1. Saves the data to HDFS as an intermediate staging location

2. Safely copies it into the actual target table in Vertica
Rejected Rows

For bulk loads, the connector API provides user control to specify a tolerance for rejected rows. You can specify the user tolerance as a parameter (see Parameters in Saving Spark Data to Vertica Using the DefaultSource API). If the number of rejected rows falls within the tolerance level, the save completes successfully. Otherwise, the connector aborts the save and reports an error.

Job Status

The connector creates a Vertica table, S2V_JOB_STATUS_USER_\$USERNAME\$, to report the status of each job. When the save to Vertica starts, the connector writes the unique job_id to the Spark log. After the Spark job is started, users can consult this table for the job status based on the job_id. The S2V_JOB_STATUS_USER_\$USERNAME\$ has the following columns:

- target_table_schema
- target_table_name
- save_mode
- job_name
- start_time
- all_done
- success
- percent_failed_rows

The table indicates the start time, unique job name, date, percentage of rows that failed, and final outcome of the save job (success=T/F). The column all_done indicates the Spark job finished without errors and the column success indicates the data was saved to the Vertica table (rejected rows must fall within specified tolerance).
Saving Spark Data to Vertica Using the DefaultSource API

The Vertica Connector for Apache Spark provides the `com.vertica.spark.datasource.DefaultSource` API to simplify writing data from a Spark DataFrame to a Vertica table using the Spark `df.write.format()` method. The DefaultSource API provides generic key-value options for configuring the database connection and tuning parameters as well as other options.

Requirements

The following requirements apply to using the connector to save Spark data to Vertica.

- When you append to an existing Vertica table (using `SaveMode.Append`), your DataFrame must have the same column types, column order, and number of columns as the Vertica table.

- The specified Vertica username must have CREATE privileges on the Vertica schema. The connector defaults to "public" schema, but any schema name can be provided as an option by using the "dbschema" optional argument.

- A Spark `SaveMode` must to be specified (Append, Overwrite, Ignore, ErrorIfExists). See Saving an Apache Spark DataFrame to a Vertica Table and https://spark.apache.org/docs/1.6.2/api/java/org/apache/spark/sql/SaveMode.html.

Limitations

The following limitations apply to using the connector to save Spark data to Vertica.

- **Supported Data Types**—The Spark DataFrame cannot have complex types such as Maps, Structs, and Arrays. Vertica currently supports all other Spark data types. The connector cannot save a DataFrame that contains any of these types.

- **Target Table Limitations**—The Vertica target table specified cannot be a view or a temporary table.
Null Values in Spark and Vertica—Spark’s long type is converted to Vertica’s INTEGER type when data moves from Spark to Vertica. Vertica uses the value \(-2^{63}\) (-9223372036854775808) to represent a NULL value. Spark does not treat this value in any special way. If you save \(-2^{63}\) from Spark to Vertica then it is stored as NULL in Vertica.

SQL Strings—Length of Strings. Currently the connector converts all Spark SQL Strings to VARCHAR(strlen) for Vertica. The ‘strlen’ parameter is a user option that defaults to 1024. If strlen is set to a value greater than 65000, Spark SQL Strings are instead converted to LONG VARCHAR(strlen). Values in the range 1 to 32,000,000 are valid.

When using SaveMode.Append, the existing Vertica table should have the corresponding column types for Spark SQL Strings declared as either VARCHAR or LONG VARCHAR.

Spark SQL Strings longer than strlen are always truncated when saving to Vertica.

Float Values—Float Values Represented Differently. Because float values are approximations, the value of a float can be different when it is moved from Spark to Vertica. If you require more precision, then use a more precise data type in Spark, such as double or decimal.

Gregorian/Julian Calendar Issues—Inconsistent dates before the year 1583. The ORC file writer used to stage the data to in HDFS converts dates before 1583 from the Gregorian calendar to the Julian calendar. However Vertica does not perform this conversion. If your data in Spark contains dates before 1583, then the values in Spark and the corresponding values in Vertica can differ by up to 10 days. This difference applies to both DATE and TIMESTAMP values.

Wrong results for Decimal Type. If your version of Vertica is prior to 7.2 SP3, then decimal numbers are incorrectly loaded from Spark to Vertica. Upgrade to a newer version of Vertica to resolve this issue.

Different Jobs Writing to the Same Table in Overwrite Mode cause error:—ERROR: java.sql.SQLNonTransientException: [Vertica][VJDBC](3007) ERROR: DDL statement interfered with this statement. If you have different jobs writing to the same table and are using Overwrite mode then errors can occur. For example, Job 1 starts and begins writing to the Vertica table. Then Job 2 begins and is set to write to the same table. Because the mode is Overwrite, it drops the table to which Job 1 is writing, causing an error. Do not use different jobs to write to the same table when using overwrite mode.

Files not cleaned up if process interrupted.—The files written on by Spark to HDFS are normally cleaned up when the job completes. However, if something interrupts the process
(such as a network failure), then files may be left behind and you should manually cleanup the HDFS directory. The HDFS directory is the one provided in the hdfs_url path, and the specific subdirectory is $S2V_jobxyz$ as reported by the connector.

- **Error if the DataFrame has zero rows**—The connector returns an error message asking you to check whether the DataFrame is empty. This error occurs before the connector begins loading data into Vertica. The data in the targeted Vertica table is not altered, even if mode was set to SaveMode.Overwrite (which would normally delete the table).

### Parameters

To save your Spark DataFrame to Vertica, you must specify the following required parameters as options to sqlContext.createDataFrame(...).format("com.vertica.spark.datasource.DefaultSource").options(...):

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The name of the target Vertica table to save your Spark DataFrame.</td>
</tr>
<tr>
<td>db</td>
<td>The name of the Vertica Database</td>
</tr>
<tr>
<td>user</td>
<td>The name of the Vertica user. This user must have CREATE and INSERT privileges in the Vertica schema. The schema defaults to “public”, but may be changed using the “dbschema” optional tuning parameter.</td>
</tr>
<tr>
<td>password</td>
<td>The password for the Vertica user.</td>
</tr>
<tr>
<td>host</td>
<td>The hostname of a Vertica node. This value is used to make the initial connection to Vertica and look up all the other Vertica node IP addresses. You can provide a specific IP address or a resolvable name such as myhostname.com.</td>
</tr>
<tr>
<td>hdfs_url</td>
<td>The fully-qualified path to a directory in HDFS that will be used as a data staging area. For example, hdfs://myhost:8020/data/test.</td>
</tr>
</tbody>
</table>

The connector first saves the DataFrame in its entirety to this location before loading into Vertica. The data is saved in ORC format, and the files are saved in a directory specific to each job. This directory is then is deleted when the job completes.

Note that you need additional configuration changes for to use HDFS. You must first configure all nodes to use HDFS. See [Configuring the hdfs Scheme](#).
You can optionally use the webhdfs protocol instead. See [HDFS and WebHDFS](#).

**Note:** You must provide an HDFS URL even if you intend to use webhdfs. You can use a dummy URL.

In addition to the required parameters, you can optionally specify the following parameters as options to `sqlContext.createDataFrame(...)`.format("com.vertica.spark.datasource.DefaultSource").options(...).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbschema</td>
<td>The schema space for the Vertica table. Default Value: public</td>
</tr>
<tr>
<td>port</td>
<td>The Vertica Port. Default value: 5433</td>
</tr>
<tr>
<td>failed_rows_percent_tolerance</td>
<td>The tolerance level for failed rows, as a percentage. For example, to specify that the job fail if greater than 10% of the rows are rejected, specify this value as 0.10 for 10% tolerance. Default Value: 0.00</td>
</tr>
<tr>
<td>strlen</td>
<td>The string length. Use this option to increase (or decrease) the default length when saving Spark StringType to Vertica VARCHAR type. Default Value: 1024</td>
</tr>
<tr>
<td>web_hdfs_url</td>
<td>The fully-qualified path to a directory in HDFS that will be used by Vertica to retrieve the data. For example, <code>webhdfs://myserver:50070/data/test</code>. You must use this option (in addition to “hdfs_url”) if the Vertica nodes are not configured for HDFS access. See <a href="#">HDFS and WebHDFS</a>. below.</td>
</tr>
<tr>
<td>fileformat</td>
<td>The format for the intermediate data file written to HDFS. Supported values are:  &lt;br&gt;  - &quot;orc&quot; (default) &lt;br&gt;  - &quot;parquet&quot;  &lt;br&gt;  See <a href="#">Intermediate Data File Format Settings</a> below for more information.</td>
</tr>
</tbody>
</table>
HDFS and WebHDFS

The connector transfers data from Spark to an HDFS directory before moving it to Vertica. Vertica can access data in the HDFS directory either directly using the hdfs scheme, or through the web-based webhdfs scheme. For greater performance and reliability, Vertica should use direct HDFS access whenever possible.

You must configure your Vertica cluster before it can directly access data stored in HDFS. See Configuring the hdfs Scheme in the Integrating with Apache Hadoop.

By default, the connector uses the hdfs protocol when possible. It falls back to the webhdfs protocol in several cases:

- If you do not have your nodes configured for direct HDFS access.
- If the data stored in the HDFS directory is encrypted. The library that Vertica uses to read directly from HDFS cannot decrypt this data. The webhdfs scheme transparently decrypts the data for Vertica.

For Vertica to fall back to webhdfs, you must verify that webhdfs.enabled set to true on your HDFS cluster.

Intermediate Data File Format Settings

When Spark sends data to Vertica, it writes the data to intermediate files stored in HDFS. Vertica then reads these files off of HDFS. By default, Spark writes these data files in ORC format. You can choose to have it use Parquet format instead by setting the fileformat parameter to "parquet".

You usually do not directly access these files, so you normally do not care about their format. The Spark connector automatically deletes these files after Vertica is through with them.

Important: Testing shows that Spark writes ORC files faster than Parquet files. Writing of the data files makes up a large portion of the time it takes to transfer data from Spark to Vertica. Using the format that takes Spark the least amount of time to write results in faster transfers. For this reason, Vertica recommends you use the default ORC format for the intermediate files unless you are required to use Parquet format files.
Quick Start with Code Example

You can use the spark-shell and some brief Scala code to verify that the connector can write data from Spark to Vertica.

1. Start the spark-shell and include both the Vertica JDBC Driver and the Vertica Spark Connector JAR files in the jars argument. Then, specify any other Spark options you normally use:

   ```bash
   spark-shell --jars vertica-8.1.0_spark2.0 scala2.11.jar,vertica-jdbc-8.1.0-0.jar other options
   ```

2. The following code creates a DataFrame in Spark and saves it to a new Vertica table using the connector:

   a. Modify the host, db, user, password, and table settings in the following example to match your Vertica instance.

   b. Paste the following code into your Spark shell.

   ```scala
   // S2V_basic.scala
   import org.apache.spark.sql.types._
   import org.apache.spark.sql.{DataFrame, Row, SQLContext, SaveMode}
   import com.vertica.spark._

   // Create a sample DataFrame and save it to Vertica
   val rows = sc.parallelize(Array(
      Row(1, "hello", true),
      Row(2, "goodbye", false)
    ))

   val schema = StructType(Array(
      StructField("id", IntegerType, false),
      StructField("message", StringType, true),
      StructField("still_here", BooleanType, true)
    ))

   // Note: Spark's API changed between version 1.6 and 2.0. In version 1.6
   // you use sqlContext to create a DataFrame. In 2.0, you use the spark object.
   // val df = sqlContext.createDataFrame(rows, schema) // Spark 1.6
   val df = spark.createDataFrame(rows, schema) // Spark 2.0

   // View the sample data and schema
   df.show
   df.schema

   // Setup the user options, defaults are shown where applicable for optional values.
   // Replace the values in italics with the settings for your Vertica instance.
   val opts: Map[String, String] = Map(
     "table" -> "VerticaTableName",
   )
   ```
"db" -> "VerticaDatabaseName",
"user" -> "VerticaDatabaseUser",
"password" -> "VerticaDatabasePassword",
"host" -> "VerticaHostName",
"hdfs_url" -> "hdfs://HDFSNameNode:9000/user/hduser/someDirectory",
"web_hdfs_url" -> "webhdfs://HDFSNameNode:50070/user/hduser/someDirectory"
// "failed_rows_percent_tolerance"-> "0.00" // OPTIONAL (default val shown)
// "dbschema" -> "public" // OPTIONAL (default val shown)
// "port" -> "5433" // OPTIONAL (default val shown)
// "strlen" -> "1024" // OPTIONAL (default val shown)
// "fileformat" -> "orc" // OPTIONAL (default val shown)

// SaveMode can be either Overwrite, Append, ErrorIfExists, Ignore
val mode = SaveMode.Overwrite

// save the DataFrame via Spark's Datasource API
df.write.format("com.vertica.spark.datasource.DefaultSource").options(opts).mode(mode).save()
Loading Vertica Data into a Spark DataFrame or RDD

The Vertica Connector for Apache Spark includes APIs to simplify loading Vertica table data efficiently with an optimized parallel data-reader:

- `com.vertica.spark.datasource.DefaultSource` — The data source API, which is used for writing to Vertica and is also optimized for loading data into a DataFrame.

- RDD API `com.vertica.spark.rdd.VerticaRDD` — This API simplifies creating an RDD object based on a Vertica table or view.

Typically, Vertica tables are segmented across multiple nodes. Using the Spark connector, you invoke a parallel data reader to efficiently read data from Vertica by minimizing data movement between Vertica nodes. The DataFrame reader supports pushing column and row filtering to Vertica to avoid transferring large volumes of Vertica data into the Spark in-memory data structures.

**Important:** For the best possible performance, segment your Vertica table by hash on one or more attributes that return integer values. Micro Focus does not recommend segmenting by a custom expression, because doing so can result in lower performance than segmenting by hash. See Hash Segmentation Clause for more details. An example of creating a table segmented by hash:

```sql
create table example(a integer, b integer) segmented by hash(a) all nodes;
```

Loading Vertica Table Segments into the Spark DataFrames and RDD Partitions

All Spark RDDs and DataFrames require you to define the number of partitions. You can define an arbitrary number of partitions. The Vertica Spark connector library automatically generates the hash-intervals for each partition and intervals. When you segment the table by a proper hash expression on one or more of its columns, these intervals minimize cross-node data shuffling (w) inside Vertica and data skew.

No cross-node data shuffling occurs inside Vertica when both of the following conditions exist:
The Vertica cluster has \( N \) nodes.

The number of the Spark partitions is \( P \times N \) (\( P \) is an integer greater than 0).

Therefore, you can use the full network throughput for data transfer, achieving the best performance. The following figure shows 8 Spark partitions defined over 4 Vertica segmentations.

![Spark partitions over 4 Vertica segmentations](image1)

The next figure shows another example where the number of Spark partitions is smaller (two) than the number of Vertica segmentations (four).

![Spark partitions over 2 Vertica segmentations](image2)

According to Vertica benchmark tests, a setting of \( P=4 \) achieves the best loading performance. For example, when Vertica has 4 nodes, the number of Spark partitions recommended is 16 (\( P = 4, \text{Nodes} = 4, P \times N = 16 \text{ partitions} \)).

During Spark job execution, each Spark partition executes inside a task. Each task launches a JDBC connection to a Vertica node. This connection contacts the Vertica node that stores the segment containing the data of the Spark partition. The Spark task then issues a query to the Vertica node and fetches the query result into a VerticaRDD/DataFrame.

For an unsegmented Vertica table, the connector replicates the table onto multiple Vertica nodes. The Spark partition is defined as a range on the sorted columns of the table. Spark tasks send the queries to different replicas for load-balancing. The next figure shows Spark partitions defined over an unsegmented table.

![Spark partitions over an unsegmented table](image3)

The following figure illustrates the runtime behavior of the Vertica to Spark connector. Spark tasks containing VerticaRDD/DataFrame partitions fetch data from Vertica through JDBC connections. Those queries that are used to fetch data are based on the computed ranges of hash values.
Spark Numeric Value Limitation

Both Vertica and Spark support variable-precision NUMERIC values. Vertica's NUMERIC values support more digits of precision (up to 1024) than Spark does (38 digits). If you attempt to copy a Vertica table to Spark that has a NUMERIC column with more than 38 digits of precision, the VerticaDataSourceRDD class throws an error similar to the following:

```
java.lang.IllegalArgumentException: requirement failed: Decimal precision 41 exceeds max precision 38
  at scala.Predef$.require(Predef.scala:224)
  at org.apache.spark.sql.types.Decimal.set(Decimal.scala:113)
  at org.apache.spark.sql.types.Decimal$.apply(Decimal.scala:426)
  at com.vertica.spark.datasource.VerticaDataSourceRDD$$anon$1.getNext(VerticaRDD.scala:382)
  ...
```

Loading Vertica Data into a Spark DataFrame Using the Vertica Data Source API

The Vertica Connector for Apache Spark data source API supports both parallel write and read operations. The following code sample illustrates how you can create an in-memory DataFrame by invoking SQLContext.read function, using Vertica's com.vertica.spark.datasource.DefaultSource formatter.

Parameters

To connect to Vertica, you must specify the following parameters for the options in sqlContext.read.format("com.vertica.spark.datasource.DefaultSource").options(...).
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The name of the target Vertica table or view to save your Spark DataFrame. Note that the Vertica table must be segmented by hash or by an expression that returns non-negative integer values. Also, if the Vertica table is an external table, the underlying file(s) on which the external table is based must be accessible on all Vertica nodes.</td>
</tr>
<tr>
<td>db</td>
<td>The name of the Vertica Database</td>
</tr>
<tr>
<td>user</td>
<td>The name of the Vertica user. This user must have CREATE and INSERT privileges in the Vertica schema. The schema defaults to “public”, but may be changed using the dbschema optional parameter.</td>
</tr>
<tr>
<td>password</td>
<td>The password for the Vertica user.</td>
</tr>
<tr>
<td>host</td>
<td>The hostname of a Vertica node. This value is used to make the initial connection to Vertica and look up all the other Vertica node IPs. You can provide a specific IP address or resolvable name such as myhostname.com.</td>
</tr>
<tr>
<td>numPartitions</td>
<td>Optional. The number of Spark partitions for the load from the Vertica job, each partition creates a JDBC connection. Default Value: 16.</td>
</tr>
<tr>
<td>dbschema</td>
<td>Optional. The schema space for the Vertica table. Default value: public.</td>
</tr>
<tr>
<td>port</td>
<td>Optional. The Vertica Port. Default value: 5433</td>
</tr>
</tbody>
</table>

**Example: Load Data into a DataFrame**

The following example demonstrates reading the content of a Vertica table named test into a DataFrame.

```java
import org.apache.spark.SparkContext
import org.apache.spark.SparkContext._
import org.apache.spark.sql._
import org.apache.spark.SparkConf

// Note: the following is deprecated in Spark 2.0. It will warn you to use // SparkSession instead.
val sqlContext = new SQLContext(sc)

val table = "test"
val db = "myDB"
```
```scala
val user = "myUser"
val password = "myPassword"
val host = "myVerticaHost"
val part = "12";
val opt = Map("host" -> host, "table" -> table, "db" -> db, "numPartitions" -> part, "user" -> user, "password" -> password)
val df = sqlContext.read.format("com.vertica.spark.datasource.DefaultSource").options(opt).load()
```

## Column Selection and Filter Push Down

Column selections and row filters applied on the DataFrame are pushed down into Vertica. Refer to the Spark SQL API for more details about applying column selections and row filters. The following example illustrates how you can load a column containing filtered rows as a DataFrame:

```scala
val c = df.select("a").filter("a > 5").count
```

**Note:** When filtering it is important to specify the correct type. For example, single-quoted values are treated as strings, so if you wrote the above filter code as `filter("a > '5'")` then the filter is not pushed down, because the target column is an integer and the value '5' when single-quoted is treated as a string.

Additionally, when using other types such as dates, cast the value as a date type, such as:

```scala
filter("c1 >= cast('2010-1-2' as date) rather than filter("c1 >= '2010-1-2'"). The latter example does not push down.
```

Additional examples of valid filters:

- `df.filter("id<=3").groupBy("id").sum("id").show`  
- `df.filter($"c".like("str\%"))\show // has to be varchar type to be pushed down
- `df.filter($"c".rlike("str").show // has to be varchar type to be pushed down
- `df.filter($"id".isin(3,5)).show
```
Considerations When Using the Spark DataFrame Filter Method with Vertica

Be aware of the following considerations when using the DataFrame's filter method when loading data from Vertica:

- Vertica supports the case insensitive terms “inf” and “infinity” to refer to INFINITY in SQL queries. However, when filtering using Spark’s filter method you must instead use the term (case sensitive) “Infinity”.

- When filtering on Boolean values, do not use "is true/false" or "is not true/false" instead, cast the value as a Boolean, or use the equals operator, for example:
  - df.filter("c = 1").show
  - df.filter("c = True").show
  - df.filter("c = False").show

Example: Creating a DataFrame Using the Vertica Data Source

Use the following example to learn how to create a Spark DataFrame from a Vertica table:

1. Create a sample table in Vertica:

```sql
=> CREATE TABLE test (a int, b int, c int, d varchar);
=> INSERT INTO test VALUES (1, 3, 5, 'odds');
=> INSERT INTO test VALUES (10, 14, 8, 'evens');
=> INSERT INTO test VALUES (11, 13, 19, 'odds');
=> COMMIT;
```

2. Modify the database connection details (host, db, table, user, and password) in the code below with your Vertica connection details.

```python
import org.apache.spark.sql.SQLContext
import org.apache.spark.SparkConf
import org.apache.spark.SparkContext

val conf = new SparkConf().setAppName("vertica-spark-connector-testing").setMaster("local[1]")
val sc = new SparkContext(conf)
```
3. Run the example code in a Spark shell. Start the shell, then paste in your modified code.

### Loading Vertica Data into a Spark RDD Using the Vertica RDD API

Use the Vertica RDD API to load Vertica table data into a Spark RDD. You create a VerticaRDD object either by initiating it or by calling one of the multiple RDD.create methods available. The following example uses VerticaRDD.create to create an RDD from Vertica data. In this example, the parameters of create() are:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname</td>
<td>A Vertica node host name</td>
</tr>
<tr>
<td>port</td>
<td>Vertica port number. The default value is 5433.</td>
</tr>
<tr>
<td>prop</td>
<td>A property object that include user name and password</td>
</tr>
<tr>
<td>table</td>
<td>Vertica table name, including the schema name, such as, “schema_name.table_name”.</td>
</tr>
<tr>
<td>dbname</td>
<td>Vertica database name</td>
</tr>
<tr>
<td>col</td>
<td>The column names of the Vertica table that will be loaded into Spark. An empty col array means all columns.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>numPartitions</td>
<td>The number of Spark partitions for the resulting VerticaRDD</td>
</tr>
<tr>
<td>mapRow</td>
<td>A function used to convert one row of JDBC results into the element data type T of VerticaRDD. The generated VerticaRDD has the type VerticaRDD[T]. For example:</td>
</tr>
<tr>
<td></td>
<td>val extractValues = (r: ResultSet) =&gt; {</td>
</tr>
<tr>
<td></td>
<td>(r.getInt(1), r.getInt(2))</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>This function converts a tuple that contains two integers—for example, (101, 102), into an array of objects. Refer to the Spark JDBC RDD for more details about this parameter.</td>
</tr>
<tr>
<td></td>
<td>Note: This function must be serializeable by Spark.</td>
</tr>
</tbody>
</table>

**RDD Create Methods**

The com.vertica.spark.rdd.VerticaRDD API has three different create methods that you can use to create a VerticaRDD object:

- create(sc, connect, table, columns, numPartitions, mapRow)
- create(sc, connect, table, columns, numPartition, ipMap, mapRow)
- create(sc, host, port: Int = 5433, db, properties, table, columns, numPartitions, mapRow)

The parameters for the Create methods:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sc</td>
<td>Spark Context object.</td>
</tr>
<tr>
<td>connect</td>
<td>A connection object that contains a function that returns an open JDBC Connection.</td>
</tr>
<tr>
<td>table</td>
<td>A string value for the database table name</td>
</tr>
<tr>
<td>columns</td>
<td>An Array[String] that contains the columns of the database table</td>
</tr>
</tbody>
</table>
### Table

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>numPartitions</td>
<td>An integer value specifying the number of partitions for the VerticaRDD.</td>
</tr>
<tr>
<td>ipMap</td>
<td>A Map [String, String] containing the optional map from private IP addresses to public IP addresses for all Vertica nodes. This map is used only when Vertica is installed on private IP addresses but is listening on both private and public IP addresses. You can also update each Vertica node's EXPORT_ADDRESS instead of providing the ipMap parameter if Vertica is running on both private and public IP addresses. When a database is installed, the export_address and node_address in the system NODES table are set to the same value. If you installed Vertica on a private address, you must set the export_address to a public address for each node. See Identify the Database or Nodes Used for Import/Export in the Administrator's Guide.</td>
</tr>
<tr>
<td>mapRow</td>
<td>A function from a ResultSet to a single row of the upi result types you want. This function should call only getInt, getString, etc; the RDD takes care of calling next. The default maps a ResultSet to an array of Object.</td>
</tr>
<tr>
<td>host</td>
<td>A string containing the host name (or IP address) of a Vertica node, that can be used to connect to Vertica.</td>
</tr>
<tr>
<td>port</td>
<td>An integer value specifying the number for Vertica connection. Default Value: 5433</td>
</tr>
<tr>
<td>properties</td>
<td>Properties object for JDBC connection properties, such as user, password.</td>
</tr>
</tbody>
</table>

### Example: Loading Vertica Table Data into a VerticaRDD

This section contains complete example code used to create a VerticaRDD from a Vertica table, test whose definition is:

```java
create table test (a int, b int);
```
This program creates VerticaRDD[(Int, Int)] and calls count that returns the number of rows of table, test.

```scala
// V2S_rdd.scala
import com.vertica.spark.rdd.VerticaRDD
import java.util.Properties
import java.sql.ResultSet
import org.apache.spark.SparkConf
import org.apache.spark.SparkContext

val extractValues = (r: ResultSet) => {
  (r.getInt(1), r.getInt(2))
}

val conf = new SparkConf().setAppName("vertica-spark-connector-testing").setMaster("local[1]")
//val sc = new SparkContext(conf) // uncomment if not used in spark shell

val host = "VerticaHost"
val port = 5433
val db = "VerticaDB"
val prop = new Properties
prop.put("user", "VerticaUserName")
prop.put("password", "VerticaPassword")
val table = "test"
val cols = Array[String]()
val part = 12;
val data = VerticaRDD.create(sc, host, port, db, prop, table, cols, numPartitions = part, mapRow = extractValues)
val c = data.count
println("count:" + c)
```
Integrating with Voltage SecureData

Voltage SecureData is a suite of encryption technologies that let you integrate end-to-end data encryption into other applications. It uses Format-Preserving Encryption (FPE): the encrypted values have the same overall format as the unencrypted data. This feature means you do not have to change the data types of table columns that you want to encrypt. It also preserves reference integrity: the encrypted values have the same sort order as unencrypted data, and encrypted values can be cross-referenced between tables, as long as each instance of the value is encrypted with the same key.

See the Voltage web site for more about SecureData.

This section explains how you can integrate the SecureData encryption feature into Vertica.
How Vertica and SecureData Work Together

Vertica provides functions to encrypt and decrypt data using SecureData.

Voltage SecureData supplies a number of interfaces for applications to use its encryption: web-based APIs, command-line tools, and SDKs for C, C#, and Java. Vertica has developed a connector that calls the SecureData API that lets you:

- Encrypt sensitive data as it is being loaded into Vertica using SecureData's FPE feature. You can ensure data is stored in Vertica in its encrypted state (referred to as "encrypted at rest"). Authorized users can decrypt the data as needed. Unauthorized users only see the encrypted values. Decryption for authorized users can be automated using views or access policies. The data is transparently decrypted for them.

- Encrypt semi-sensitive data that is stored unencrypted in Vertica so unauthorized users only see a masked version of the data. You can also automate this on-the-fly encryption using access policies.

The encryption method you choose depends in the data you are processing. For example, regulations or contracts may require you to encrypt specific pieces of data. In these cases, use SecureData to encrypt your data as it is loaded, so it is never stored in an unencrypted format within Vertica.

In other cases, you may have semi-sensitive data that you can choose between the two options. In these cases, choose the method that requires the least number encryptions or decryptions (and therefore of calls to SecureData). If most of the queries on the data need to be masked from users who should not see the unencrypted values, then encrypt the data at rest. Alternatively, if the most of the queries will be from authorized users, with only occasional queries where the data should be masked, then store the data in an unencrypted format and use on-the-fly encryption to mask the data.
Requirements for Integrating with SecureData

Before you can use SecureData with Vertica, you must verify the following:

- You are using version 6.0 or later of SecureData. The Vertica integration functions use APIs introduced in version 6.0 of SecureData.

- All of the nodes in your Vertica cluster are able to communicate with all of your SecureData appliance hosts. Any firewalls between your Vertica cluster and your SecureData appliance must allow connections on the ports that SecureData uses for communications. See "Ensuring Access to SecureData Services" in the SecureData Appliance Installation Guide for a list of the ports that SecureData uses.

- Your Vertica database is not using Federal Information Processing Standard (FIPS) mode. FIPS is incompatible with the Voltage SecureData integration. When FIPS mode is active, the SecureData integration library is not installed by default. Do not manually install this library if you are using FIPS.
Verifying the Vertica Server's Access to the SecureData CA Certificate

Before you can use SecureData with Vertica, you must verify that the root certificate authority (CA) and any intermediate certificate authority used to sign the SecureData Appliance's certificate is in the Vertica server's trust store (/opt/vertica/packages/voltagesecure/trustStore/). Vertica supplies many standard root certificates in this directory. If your SecureData Appliance uses a certificate signed by a standard CA authority, it is likely already in the trust store.

If your SecureData Appliance is using a certificate signed by your own internal CA authority, you must add this CA Certificate to the Vertica trust store.

If you are unsure whether your CA Certificate is in the Vertica trust store, follow the steps under Troubleshooting Certificate Problems to test whether the Vertica already has the CA certificate. If you are able to retrieve the client policy XML file from the SecureData Appliance, then your Vertica cluster has the correct CA certificate to access SecureData.

Adding the CA Certificate to Vertica.

You must add the CA to Vertica trust store before using the SecureData Integration if you used:

- Your own CA certificate to sign your SecureData Appliance's certificate.
- A third-party CA that is not in the Vertica trust store.

To add the CA certificate to the Vertica trust store, you need:

- The certificate authority (CA) file used to sign the SecureData Appliance's certificate. This file must be in Privacy Enhanced Mail (.pem) format. The file name does not matter, as long as it has the .pem extension.
- Access to the dbadmin account on the Vertica nodes. This access is required in order to copy the certificate file to trust store directory in the Vertica installation.

To add the necessary CA file to Vertica:
1. Login to one of the Vertica nodes as the dbadmin user.

2. Copy the .pem file to the /opt/vertica/packages/voltagesecure/trustStore/ directory. You only need to copy this file to a single node. Vertica takes care of distributing the file to the rest of the nodes in the cluster.

3. On the Linux command line, execute the following command to reinstall the SecureData integration library:

   ```
   $ admintools -t install_package -d database_name -p 'password' --package voltagesecure --force-reinstall
   ```

When Vertica reinstalls the SecureData integration library, it copies the CA authority file to the all nodes in the cluster. After the file is distributed, all Vertica nodes can authenticate with the SecureData Appliance.

For example, suppose:

- Your certificate file is named my_ca.cert.pem, and you have copied it to the dbadmin home directory on node in your cluster.
- Your database is named VMart.

Then the process of installing the CA file would look like this:

```
$ cp my_ca.cert.pem /opt/vertica/packages/voltagesecure/trustStore/
$ admintools -t install_package -d VMart -p dbadminpassword --package voltagesecure --force-reinstall
Installing package voltagesecure...
...Success!
```

**Troubleshooting Certificate Problems**

You can test whether the Vertica trust store has the correct certificate by executing the following statement from the Linux command line:

```
$ curl --capath /vertica_catalog_directory/Libraries/\ $(vsql -A -t -c "SELECT sal_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';")\ https://SecureData_appliance_hostname/policy/clientPolicy.xml
```

Where:

- **vertica_catalog_directory** is the absolute path to the Vertica catalog directory. See [Understanding the Catalog Directory](...) for more information about the catalog directory.
SecureData_appliance_hostname is the host name of your Voltage SecureData Appliance.

For example, suppose you are connected to node0001 of the example VMart database. Also, your Voltage SecureData appliance's host name is voltage-pp-0000.example.com. Then you would use the following command to test your certificate installation.

```bash
$ curl --capath /home/dbadmin/VMart/v_vmart_node0001_catalog/Libraries/$(vsql -A -t -c "SELECT sal_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';") \ https://voltage-pp-0000.example.com/policy/clientPolicy.xml
```

The `<clientPolicy>`... output (which is the content of the `clientPolicy.xml` file) indicates that the Vertica node was able to use its CA certificate to connect to the SecureData Appliance.

Tip: If you are unsure which Format Preserving Encryption (FPE) formats are defined in your SecureData Appliance, examine the output of the curl command. Look for the tags with `formatName` attributes which describe each of the formats.

If the CA certificate you installed on Vertica does not match the certificate installed on the SecureData Appliance, you will see an error similar to the following:

```bash
$ curl --capath /home/dbadmin/VMart/v_vmart_node0001_catalog/Libraries/$(vsql -A -t -c "SELECT sal_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';")\ https://voltage-pp-0000.example.com/policy/clientPolicy.xml
```

curl: (60) Peer certificate cannot be authenticated with known CA certificates
More details here: http://curl.haxx.se/docs/sslcerts.html
In this case, verify that you have installed the correct CA certificate in Vertica, and that its file name has a .pem extension.

If you see other errors, such as "couldn't connect to host," verify that your firewall configuration allows your Vertica nodes to access your SecureData Appliance.
Configuring Access to SecureData

The Vertica integration functions require several pieces of information in order to connect to and authenticate with SecureData:

- **policy_url**: the URL of the SecureData policy file. This file provides the SecureData integration library with details of how the SecureData Appliance is configured. The library also uses this URL to determine the address of the SecureData Appliance.

- Your authentication credentials for SecureData. The exact information you need depends on your SecureData Appliance's configuration. There are four potential settings you can use:
  - **username**: a username that you use to identify yourself. Your username is either defined by LDAP (when using LDAP authentication) or by the SecureData appliance when using shared secret authentication.
  - **identity**: the SecureData identity to use. See the *SecureData Administrator Guide* for more information about identities in SecureData. The identity usually takes the form of an email address. When your SecureData Appliance uses LDAP authentication, your LDAP account must have access to this identity.
  - **shared_secret**: a password set in SecureData.
  - **password**: the LDAP password to use to authenticate with SecureData.

There are also two optional session variables you can set to alter how the SecureData integration operates:

- **allow_short_fpe**: When set to True, SecureData ignores the lower length limit for encoding FPE values. Usually, SecureData does not use FPE to encrypt data shorter than a lower limit (usually, 8 bits). See the *SecureData Architecture Guide*’s section on Data Length Restrictions for more information.

- **enable_file_cache**: When set to True, Vertica caches the SecureData policy file and encryption keys to disk, rather than just to memory. Defaults to false.

**Important**: The SecureData integration only supports one configuration for the SecureData Appliance at a time. All users that access the SecureData integration must use the same value for policy_url, allow_short_fpe, and enable_file_cache. Having users with different settings for these values making simultaneous queries can result in errors. Be sure all users know which values to use for these variables, or see the instructions below on how to create a shared configuration file.
You can supply both a username and identity, depending on the SecureData Appliance's configuration. Your SecureData Appliance can be configured to supply the identity based on your SecureData username.

However, you can only use a shared_secret or a password. If you set both parameters, the Vertica SecureData functions exit with an error.

You have two options for setting these configuration values: setting them in user-defined session parameters, or saving the values in a configuration file stored in the Vertica distributed file system.

### Setting User-Defined Session Parameters

Use the `ALTER SESSION` statement to set parameters for the voltagesecurelib library. This library contains all of the SecureData functions. The following example demonstrates configuring the session to access SecureData using shared secret authentication.

```sql
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib identity='alice@example.com';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib username='alice';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib shared_secret='my_shared_secret';
ALTER SESSION
```

Once set, these parameters are only last for the duration of your session.

### Saving Parameters in a Configuration File

If you have access to the `VoltageSecureConfigure` function, you can save the SecureData parameters in a configuration file stored in the Vertica Distributed Filesystem (DFS). This filesystem is used by Vertica to store data that can be accessed by all nodes.

You must supply a file name for your configuration file. You can choose to store your SecureData parameters in a user-specific file by supplying just a file name, such as `securedata.conf`. Behind the scenes, your configuration file is stored in DFS under a directory named for your username. This directory prevents your configuration file from conflicting with other users' files. You do not use this directory name when accessing your configuration file.
You can also store the configuration parameters in an absolute file named
/voltagesecure/conf. All users who have access to the SecureData integration functions
can use this configuration file in their function calls.

Important: All users that have access to the VoltageSecureConfigure function can write to
the global /voltagesecure/conf file. Users do not need to be able to write to this file in
order to use it in calls to the other SecureData integration functions. If you are the
database administrator, only grant VoltageSecureConfigure access to users who need to
save their own configuration files or administer the shared configuration file. Under most
circumstances, you can have most users just use the settings in the shared configuration
file along with some session variables, without having access to VoltageSecureConfigure.

Values in the session parameters override values in configuration files. This behavior lets you
set values globally that are the same for most users (such as the policy_url) while still
allowing users to override the values they need to (such as username and password).

You create the SecureData parameter configuration file using the VoltageSecureConfigure
function. You call this function with the parameters you want to save to the configuration file.
Values that you do not set in this function call are not set in the configuration file. You must
supply those values to the other SecureData integration functions using session parameters.

If you choose to save either the password or shared secret to your configuration file, you do
not directly pass them to the VoltageSecureConfigure function. Instead, you set the value in
the appropriate session variable, and then set either VoltageSecureConfigure's store_
password or store_shared_secret parameter to true. When either of these parameters
are true, VoltageSecureConfigure reads the value from the session variable and saves it in the
configuration file.

Caution: Under normal circumstances, users are not able to directly read data from files
stored in DFS. However, all users who have access to UDx functions that read from the DFS
could access these files from within Vertica.

In addition, these files are stored as plain text in every node's filesystem. Anyone with the
proper filesystem access on the nodes can read the file's contents.

You should take both of these facts into consideration when deciding whether to store
sensitive information such as passwords or shared secrets in either the shared or per-user
configuration files.
Example: Creating a User-Specific Configuration File

The following example shows how you can create a user-specific configuration file. This example does not store information such as the password or shared secret, so you must still set session parameters for these values before you can call the other SecureData integration functions.

```sql
=> \x
Expanded display is on.
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
                                  username='alice', identity='alice@example.com',
                                  policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml'
                           ) OVER ();

-| RECORD 1 |---------------------------------------------------------------
-| config_dfs_path | voltage.conf |
-| policy_url | https://voltage-pp-0000.example.com/policy/clientPolicy.xml |
-| allow_short_fpe | |
-| identity | alice@vertica.com |
-| username | alice |
-| enable_file_cache | |
```
Encrypting and Decrypting Data

Once you have set up authentication with the SecureData appliance, call the VoltageSecureProtect and VoltageSecureAccess functions to encrypt and decrypt your data. At a minimum, you pass these functions the value to be encrypted or decrypted and value's FPE format (or 'auto' to have SecureData simply encrypt the value while preserving its format). If you specify an FPE format, it must match one of the formats defined by your SecureData Appliance.

The following example demonstrates setting up the session parameters and making simple calls to VoltageSecureProtect and VoltageSecureAccess.

```sql
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib identity='alice@example.com';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib username='alice';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib shared_secret='my_secret';
ALTER SESSION
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='ssn');
VoltageSecureProtect
---------------------
376-69-6789
(1 row)

=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='auto');
VoltageSecureProtect
---------------------
820-31-5110
(1 row)

=> SELECT VoltageSecureAccess('376-69-6789' USING PARAMETERS format='ssn');
VoltageSecureAccess
---------------------
123-45-6789
(1 row)
```

Note that in the previous example, the last four digits of the social security number remained unchanged when the value was encrypted using the ssn format. However, it was completely encrypted when using the auto format. Leaving part of the value unencrypted is one of the features of SecureData’s format-preservation. In this example, the SecureData Appliance’s ssn format is defined to leave the last four digits of the social security number unencrypted. This format allows unprivileged users to be able to use the last four digits of the social security number to authenticate an individual without having access to their full social security number.
Encrypting Data During Load

When handling sensitive data, you often want to encrypt it as you load it. Encrypting on load means that the unencrypted values are never stored in your database. The following example demonstrates loading data using a COPY statement. Suppose you have a data file with customer information with the following fields: id number, first name, last name, social security number, card verification number, and date of birth. Here is a sample of this data:

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>ssn</th>
<th>cc_num</th>
<th>cvv</th>
<th>dob</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

Suppose you want to encrypt the social security number and the credit card number columns. Then you can call VoltageSecureProtect to encrypt these columns in the COPY statement you use to load the data as following example demonstrates:

```
=> CREATE TABLE customers (id INTEGER, first_name VARCHAR, last_name VARCHAR,
                        ssn VARCHAR(11), cc_num VARCHAR(25), cvv VARCHAR(5), dob DATE);
CREATE TABLE
=> COPY customers (id, first_name, last_name, ssn_raw FILLER VARCHAR(11),
                   cc_num_raw FILLER VARCHAR(25), cvv, dob,
                   ssn AS VoltageSecureProtect(ssn_raw USING PARAMETERS format='ssn',
                                                config_dfs_path='voltage.conf'),
                   cc_num AS VoltageSecureProtect(cc_num_raw USING PARAMETERS format='cc',
                                                    config_dfs_path='voltage.conf'))
                   FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
Rows Loaded
----------
100
(1 row)
```

```
=> SELECT * FROM customers ORDER BY id ASC LIMIT 10;
```

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>ssn</th>
<th>cc_num</th>
<th>cvv</th>
<th>dob</th>
</tr>
</thead>
<tbody>
<tr>
<td>5345</td>
<td>Thane</td>
<td>Ross</td>

<td>Ware</td>
<td>661-57-0394</td>
<td>186 09915 59049 254</td>
<td>586</td>
<td>1967-08-08</td>
</tr>
</tbody>
</table>
```
Caution: Always use the same FPE format to encrypt data in a column. If you use different FPE formats in the same column (such as loading some data using 'ssn' and other data using 'auto') there is no way to tell which format was used for any particular row. In this case, you will not be able to recover the unencrypted data because you cannot tell correctly decrypted values from incorrectly decrypted ones. Formats that deal with the same source format (such as ssn and ssn-all) are still incompatible, as they encrypt and decrypt the data in different ways.

---

### Encrypting Non-VARCHAR Data

The VoltageSecureProtect function only encrypts VARCHAR values. If you need to encrypt other data types, such as DATE or INTEGER, you must cast these values to VARCHAR in your function call. The following example demonstrates how you can encrypt the date of birth (dob) column whose data type is DATE from the previous example.

```sql
=> CREATE TABLE customers2 (id INTEGER, first_name VARCHAR, last_name VARCHAR, ssn VARCHAR(11),
                          cc_num VARCHAR(25), cvv VARCHAR(5), dob DATE);
CREATE TABLE
=> COPY customers2 (id, first_name, last_name, ssn, cc_num, cvv, dob)
               AS VoltageSecureProtect(dob::VARCHAR USING PARAMETERS
                          format='birthday',
                          config_dfs_path='voltage.conf')::DATE)
FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
Rows Loaded
----------
  100
(1 row)

=> SELECT * FROM customers2 ORDER BY id ASC LIMIT 10;
  id | first_name | last_name | ssn     | cc_num | cvv | dob
-----------------------------|-----------|----------|---------|-------|-----|-----
 5345 | Thane      | Ross     | 559-32-0670 | 376765616314013 | 618 | 1902-03-09
 5346 | Talon      | Wilkins  | 548-48-0784 | 4716511693424923 | 111 | 2023-07-22
 5347 | Daquan     | Phelps   | 785-34-0092 | 3422613491834   | 294 | 2091-01-18
 5348 | Basia      | Lopez    | 011-85-0705 | 4595818418314683 | 503 | 1921-08-17
 5349 | Kaseem     | Hendrix  | 672-57-0309 | 4556 078 73 7944 | 693 | 1962-08-23
 5350 | Omar       | Lott     | 825-45-0131 | 6462 0541 0799 6261 | 555 | 1930-01-12
 5351 | Neil       | Cooke    | 637-50-0105 | 646 59756 30983 538 | 818 | 2008-01-01
 5352 | Illana     | Middleton| 831-47-0929 | 648 23640 68684 267 | 883 | 1956-09-07
 5353 | Garrett    | Williamson| 408-73-0287 | 5334 2702 1360 8378 | 869 | 2079-03-25
 5354 | Hanna      | Ware     | 694-97-0394 | 543 38494 19219 254 | 586 | 1903-07-16

(10 rows)
```

**Note:** The birthday FPE format used in this example is a custom format. To encrypt dates, you must create your own FPE format. Be sure to match your custom FPE format to...
standard Vertica date format of YYY-MM-DD.

In the example, the dob column is cast to VARCHAR when passed to VoltageSecureProtect. The value the function returns is cast back to a DATE for storage in the table.

For data types such as DATE, you cannot use the auto FPE format. When SecureData encrypts a value using auto, it uses the full range of numbers and letters. It only preserves the number of characters and any separators. Attempting to encrypt a date using auto usually results in an invalid date:

```sql
=> SELECT VoltageSecureProtect('07-16-1969' USING PARAMETERS format='auto',
                       config_dfs_path='/voltagesecure/conf');
VoltageSecureProtect
--------------------
45-86-8651
(1 row)
```

```sql
=> SELECT VoltageSecureProtect('07-16-1969' USING PARAMETERS format='auto',
                       config_dfs_path='/voltagesecure/conf'):DATE;
ERROR 2992: Date/time field value out of range: "45-86-8651"
HINT: Perhaps you need a different "datestyle" setting
```

Decrypting Values in Queries

To decrypt encrypted values, call VoltageSecureAccess on the encrypted column's values in your query. The following example demonstrates querying the table from the previous example and decoding the SSN column. Instead of relying on session variables, this example uses the globally-accessible configuration file.

```sql
=> SELECT id,
       first_name,
       last_name,
       VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
                          config_dfs_path='/voltagesecure/conf') AS ssn,
       dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;
```

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>ssn</th>
<th>dob</th>
</tr>
</thead>
<tbody>
<tr>
<td>5346</td>
<td>Talon</td>
<td>Wilkins</td>
<td>540-48-0784</td>
<td>1941-09-17</td>
</tr>
<tr>
<td>5347</td>
<td>Daquan</td>
<td>Phelps</td>
<td>785-34-0092</td>
<td>1963-05-08</td>
</tr>
<tr>
<td>5348</td>
<td>Basia</td>
<td>Lopez</td>
<td>911-85-0705</td>
<td>1940-04-29</td>
</tr>
<tr>
<td>5349</td>
<td>Kaseem</td>
<td>Hendrix</td>
<td>672-57-0309</td>
<td>1942-03-11</td>
</tr>
<tr>
<td>5350</td>
<td>Omar</td>
<td>Lott</td>
<td>825-45-0131</td>
<td>1956-02-17</td>
</tr>
<tr>
<td>5352</td>
<td>Illana</td>
<td>Middleton</td>
<td>831-47-0929</td>
<td>1949-12-29</td>
</tr>
<tr>
<td>5353</td>
<td>Garrett</td>
<td>Williamson</td>
<td>408-73-0207</td>
<td>1955-11-06</td>
</tr>
<tr>
<td>5354</td>
<td>Hanna</td>
<td>Ware</td>
<td>694-97-0394</td>
<td>1967-08-08</td>
</tr>
</tbody>
</table>
Important: The VoltageSecureAccess function has no way of determining if the values you are passing it are actually encrypted or not. All this function does is take the input and transform it using the decryption key. If you pass it values from an unencrypted column, you will get back scrambled values. For example:

```sql
=> SELECT first_name,
    VoltageSecureAccess(first_name USING PARAMETERS format='auto',
                         config_dfs_path='/voltagesecure/conf')
    AS decrypted_first_name
FROM customers LIMIT 10;
```

<table>
<thead>
<tr>
<th>first_name</th>
<th>decrypted_first_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Omar</td>
<td>Rftd</td>
</tr>
<tr>
<td>Illana</td>
<td>Clfkow</td>
</tr>
<tr>
<td>Hanna</td>
<td>Bodng</td>
</tr>
<tr>
<td>Keith</td>
<td>Hklnw</td>
</tr>
<tr>
<td>Constance</td>
<td>Cigctmgtw</td>
</tr>
<tr>
<td>Kirk</td>
<td>Jwdv</td>
</tr>
<tr>
<td>Eagan</td>
<td>Hiksm</td>
</tr>
<tr>
<td>Branden</td>
<td>Ytgngp</td>
</tr>
<tr>
<td>Hope</td>
<td>Tqzc</td>
</tr>
<tr>
<td>Keane</td>
<td>Pdcax</td>
</tr>
</tbody>
</table>

(10 rows)

**Decrypting Non-VARCHAR Columns**

Similarly to encryption, you must cast any non-VARCHAR columns to VARCHAR when calling VoltageSecureAccess. If your query depends on the original data type of the column, you must also cast the return value of the function back to the column's original data type. The following example demonstrates decrypting the dob column from the customer2 table from a previous example.

```sql
=> SELECT id, first_name, last_name,
    VoltageSecureAccess(dob::VARCHAR USING PARAMETERS format='birthday',
                         config_dfs_path='/voltagesecure/conf')::DATE AS dob
FROM customers2 ORDER BY id LIMIT 10;
```

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>dob</th>
</tr>
</thead>
<tbody>
<tr>
<td>5345</td>
<td>Thane</td>
<td>Ross</td>
<td>1996-05-09</td>
</tr>
<tr>
<td>5346</td>
<td>Talon</td>
<td>Wilkins</td>
<td>1941-09-17</td>
</tr>
<tr>
<td>5347</td>
<td>Daquan</td>
<td>Phelps</td>
<td>1963-05-08</td>
</tr>
<tr>
<td>5348</td>
<td>Basia</td>
<td>Lopez</td>
<td>1940-04-29</td>
</tr>
<tr>
<td>5349</td>
<td>Kaseem</td>
<td>Hendrix</td>
<td>1942-03-11</td>
</tr>
<tr>
<td>5350</td>
<td>Omar</td>
<td>Lott</td>
<td>1956-02-17</td>
</tr>
<tr>
<td>5351</td>
<td>Nell</td>
<td>Cooke</td>
<td>1995-02-14</td>
</tr>
</tbody>
</table>
In the previous example, casting the VoltageSecureAccess return value to DATE is not necessary, as the table is simply being displayed. However, if you create a query a for client application, you likely need this final cast to return the data type to the one the client expects.
Granting Users Access to the Voltage SecureData Integration Functions

By default, Vertica users do not have access to the Voltage SecureData Integration Functions. Users attempting to call the integration functions without the correct privileges will receive the following error:

```
=> SELECT id,
    first_name,
    last_name,
    VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
        config_dfs_path='/voltagesecure/conf') AS ssn,
    dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;
ERROR 6482: Failed to parse Access Policies for table "customers" [Function public.VoltageSecureProtect(varchar) does not exist, or permission is denied for public.VoltageSecureProtect(varchar)]
```

Users must have EXECUTE access to the integration functions in order to use them. These functions are part of the PUBLIC schema. The functions in the Voltage SecureData integration library are:

<table>
<thead>
<tr>
<th>Function Signature</th>
<th>Function Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VoltageSecureAccess(VARCHAR)</td>
<td>Function</td>
</tr>
<tr>
<td>VoltageSecureConfigure()</td>
<td>Transform Function</td>
</tr>
<tr>
<td>VoltageSecureProtect(VARCHAR)</td>
<td>Function</td>
</tr>
<tr>
<td>VoltageSecureProtectAllKeys(VARCHAR)</td>
<td>Transform Function</td>
</tr>
</tbody>
</table>

The following example demonstrates granting the user named Alice access to the VoltageSecureAccess function to be able to decrypt data.

```
=> \c vmart dbadmin
You are now connected to database "vmart" as user "dbadmin".
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureProtect(VARCHAR) TO alice;
GRANT PRIVILEGE
=> \c vmart alice
You are now connected to database "vmart" as user "alice".
=> SELECT id, first_name, last_name,
    VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
        config_dfs_path='/voltagesecure/conf')
    AS ssn,
```
See GRANT (User Defined Extension) for a detailed explanation of granting access to UDxs to users.

Creating Roles for SecureData Users

Instead of granting access to each function to individual users, you can create roles that you grant access to the functions. Then you can grant users who need to access the SecureData functions access to these roles.

Consider creating at least two roles: one for access to the VoltageSecureConfigure function and another for access to the other functions. In most cases, not all users need to access VoltageSecureConfigure, especially if you choose to create a single, global configuration file. See Configuring Access to SecureData for more information about using VoltageSecureConfigure.

The following example:

- Creates two roles: secure_data_users, who are granted access to the protect and access functions, and secure_data_admins, who are granted access to the SecureDataConfigure function.
- Grants the secure_data_user role to a user named Alice
- Sets the new role as her default role.
- Switches to Alice
- Calls several of the SecureData functions.
=> \c vmart dbadmin
You are now connected to database "vmart" as user "dbadmin".
=> CREATE ROLE secure_data_users;
CREATE ROLE
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureAccess(varchar)
    TO secure_data_users;
GRANT PRIVILEGE
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureProtect(varchar)
    TO secure_data_users;
GRANT PRIVILEGE
=> GRANT EXECUTE ON TRANSFORM FUNCTION
    public.VoltageSecureProtectAllKeys(varchar)

=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
    username='alice', identity='alice@example.com',
    policy_url='https://voltage.example.com/policy/clientPolicy.xml'
) OVER ();
ERROR 3457: Function VoltageSecureConfigure() does not exist, or permission
is denied for VoltageSecureConfigure()
HINT: No function matches the given name and argument types. You may need to
add explicit type casts

Note that Alice can use the global configuration file, despite not being able to access the
VoltageSecureConfigure function.

In the previous example, the global configuration file includes the shared secret or
password. See Configuring Access to SecureData for a discussion of the security
implications of saving sensitive information to a SecureData configuration file.
Automating Encryption and Decryption with Access Policies

You can automate encryption and decryption by creating access policies. These policies let you show users with specific roles unencrypted values while users without those roles see encrypted ones. Alternatively, you can create an access policy that masks unencrypted data stored in the database when queried by users who lack a specific role.

Users do not explicitly call the SecureData integration functions when you create access policies to automatically encrypt and decrypt data. However, they still must have access to the SecureData functions and have any necessary session variables set. See Configuring Access to SecureData and Granting Users Access to the Voltage SecureData Integration Functions for the necessary configuration for the access policies to work. If a user who does not have access to the SecureData integration functions queries a table with an access policy that calls these functions, the query generates an error.

Automatically Decrypting Table Columns for Privileged Users

To decrypt an encrypted column automatically, create an access policy for the encrypted column that calls VoltageSecureAccess if the user has a role enabled. If the user does not have the role enabled, just return the encrypted value.

The following example:

1. Creates a role named see_ssn and grants it to the user named Alice, as well as granting Alice access to the customers table.

2. Creates an access policy on the customers table's ssn column that decrypts the column’s value if the user has the see_ssn role enabled.

3. Switches to the user named Alice.

4. Queries the customers table, without the see_ssn role enabled.

5. Enables the see_ssn role and queries the table again.
CREATE ROLE see_ssn;
GRANT see_ssn TO alice;
GRANT ALL ON TABLE customers TO alice;
GRANT PRIVILEGE CREATE ACCESS POLICY ON customers FOR COLUMN ssn
CASE
    WHEN enabled_role('see_ssn') THEN VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
    config_dfs_path='/voltagesecure/conf')
    ELSE ssn
END ENABLE;
CREATE ACCESS POLICY

\c vmart alice;
Password:
You are now connected to database "vmart" as user "alice".

SELECT first_name, last_name, ssn FROM customers WHERE id < 5355 ORDER BY id ASC;

first_name | last_name | ssn
-----------|-----------|--------
Gil        | Reeves    | 997-92-0657
Robert     | Moran     | 715-02-0455
Hall       | Rice      | 938-83-0659
Micah      | Trevino   | 495-57-0860
(4 rows)

SET ROLE see_ssn;
SET
SELECT first_name, last_name, ssn FROM customers WHERE id < 5355 ORDER BY id ASC;

first_name | last_name | ssn
-----------|-----------|--------
Gil        | Reeves    | 232-28-0657
Robert     | Moran     | 725-79-0455
Hall       | Rice      | 285-90-0659
Micah      | Trevino   | 853-60-0860
(4 rows)

In the above example, you could combine the see_ssn role with a role that grants users access to the SecureData integration functions. Users who do not have the see_ssn role do not need to have access to the SecureData functions in order to see the encrypted values.

Note: The above example assumes that the shared configuration file (/voltagesecure/conf) contains all of the credentials necessary to authenticate with the SecureData Appliance, including the password or shared secret. This configuration may not be secure enough to meet your requirements. See the caution in VoltageSecureConfigure for more information. In production use, consider having each privileged user set their identity, username, and password or shared secret in session variables. Unprivileged users do not need to set these values.
Automatically Encrypting Columns for Unprivileged Users

You can also create access policies that encrypt values. Use this technique to prevent some users from seeing values in columns that aren't sensitive enough to require encryption in the database, but should not be seen by all users. This technique is the opposite of the encryption-on-the-fly: users that have a specific role enabled get the value from the table; if they do not have the role, the access policy encrypts the value.

The following example:

1. Creates a role named see_dob and assigns it to the user Alice.

2. Creates an access policy on the dob column of the customers table. It returns the value in the column if the user has the see_dob role active and encrypts the value if not.

3. Switches to the user named Alice.

4. Queries the customers table including the dob column.

5. Sets the see_dob role and queries customers again.

```sql
=> CREATE ROLE see_dob;
CREATE ROLE

=> GRANT see_dob TO alice;
GRANT ROLE

=> CREATE ACCESS POLICY ON customers FOR COLUMN dob
CASE
    WHEN enabled_role('see_dob') THEN dob
    ELSE VoltageSecureProtect(dob::varchar USING PARAMETERS format='birthday',
                                 config_dfs_path='/voltagesecure/conf')::date
END ENABLE;
CREATE ACCESS POLICY

=> \c vmart alice
Password:
You are now connected to database "vmart" as user "alice".

=> SELECT first_name, last_name, dob FROM customers ORDER BY id ASC LIMIT 10;
first_name | last_name | dob
---------------
Gil        | Reeves    | 2048-08-09
Robert     | Moran     | 1917-03-05
Hall       | Rice      | 2022-01-07
Micah      | Trevino   | 2018-06-01
<table>
<thead>
<tr>
<th>first_name</th>
<th>last_name</th>
<th>dob</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gil</td>
<td>Reeves</td>
<td>1955-11-04</td>
</tr>
<tr>
<td>Robert</td>
<td>Moran</td>
<td>1991-12-01</td>
</tr>
<tr>
<td>Hall</td>
<td>Rice</td>
<td>1977-07-07</td>
</tr>
<tr>
<td>Micah</td>
<td>Trevino</td>

<tr>
<td>Alfreda</td>
<td>McDaniel</td>
<td>1975-02-08</td>
</tr>
</tbody>
</table>

Note: The values you pass to VoltageSecureProtect and VoltageSecureAccess must be VARCHARs. In the previous example, the dob column’s data type is DATE, so its value has to be cast to VARCHAR when passed to VoltageSecureProtect. The encrypted value has to be cast back to a DATE value because its output needs to match the table schema.

In the previous example, users who do not have the see_dob role enabled must have access to the SecureData functions in order to see the masked values. If they do not have access to the SecureData functions, querying the customers table results in an error message. The following example creates a new user named Bob and grants him access to the customers table, without any access to the SecureData functions.

```sql
=> CREATE USER bob;
CREATE USER
=> GRANT ALL ON TABLE customers TO bob;
GRANT PRIVILEGE
=> \c vmart bob
You are now connected to database "vmart" as user "bob".
=> SELECT * FROM customers LIMIT 10;
ERROR 6482: Failed to parse Access Policies for table "customers"
[Function public.VoltageSecureProtect(varchar) does not exist, or permission is denied for public.VoltageSecureProtect(varchar)]
```
Querying eFPE Encrypted Columns

You can use a feature in Voltage SecureData called Embedded Format Preserving Encryption to encrypt your data. You choose to use eFPE when you define the format in your SecureData Appliance. This format is slightly different than the standard FPE format. It uses key rotation, and embeds identification information in the encrypted value. Due to these factors, calls to VoltageSecureProtect using an eFPE format may not result in the same encrypted value, depending on key rotation schedules and the identity of the caller. This feature makes querying columns encrypted using an eFPE format more challenging.

When you want to search a standard FPE encrypted column for a value, you can just encrypt the plain text with VoltageSecureProtect and use the output in your query. For example, suppose you want to search for the customers table for an entry with the social security number 559-32-0670. Then you could use the following query:

```sql
=> SELECT id, first_name, last_name FROM customers
   where ssn = VoltageSecureProtect('559-32-0670' USING PARAMETERS
       format='ssn',
       config_dfs_path='voltage.conf');
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>5345</td>
<td>Thane</td>
<td>Ross</td>
</tr>
</tbody>
</table>

(1 row)
```

Querying a column that uses eFPE format encryption is not as simple, as you do not know which embedded key was used to encrypt the data. You could just use the VoltageSecureAccess function to decrypt the entire contents of the table column and search the result for the value you need. However, this is inefficient, as the SecureData function has to be called for every row of data in the table.

A better solution is to use the VoltageSecureProtectAllKeys function. This function is similar to VoltageSecureProtect. However, instead of returning a single encrypted value, it returns a table containing the value encrypted with each of the keys defined for the eFPE format.

```sql
=> SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
    format='cc_num',
    config_dfs_path='/voltagesecure/conf')
    OVER ();
```

```
data | protected
-------|----------
376765616314013 | ZJ1C58C9L9R4013
376765616314013 | UBOSG9K3EXZ4013
376765616314013 | X5FD4K01UEE4013
376765616314013 | M7ZTIQVCPB4013
376765616314013 | XMVMRU9JUVU4013

(5 rows)
```
In the previous example, the cc_num column is encrypted using an eFPE format. The output from VoltageSecureProtectAllKeys shows that this eFPE format has 5 keys defined. The content of the protected column contains the same value encrypted with each of the keys.

To use this function in a query for a value in an eFPE column, use a JOIN on the table you are searching and the result table from VoltageSecureProtectAllKeys. The following example demonstrates querying the customers table to find all rows that have a cc_num value that matches the unencrypted credit card value 376765616314013.

```
=> SELECT id, first_name, last_name FROM customers3 u
JOIN (SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
    format='cc_num',
    config_dfs_path='/voltagesecure/conf')
    OVER () pak
ON u.cc_num = pak.protected;
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>5345</td>
<td>Thane</td>
<td>Ross</td>
</tr>
</tbody>
</table>
```

(1 row)
Voltage SecureData Integration

Function Reference

The functions in this section are part of the Vertica voltagesecure library for integrating with Voltage SecureData. These functions are automatically installed when you install or upgrade Vertica. However, you must re-install the voltagesecure library to distribute the CA certificate to all nodes in the Vertica cluster. See Verifying the Vertica Server's Access to the SecureData CA Certificate for instructions.

VoltageSecureAccess

Sends encrypted values to Voltage SecureData for decryption.

Syntax

\[
\text{VoltageSecureAccess('encrypted_value' \text{ USING PARAMETERS format='format\_name'}} \\
\quad [, \text{ config\_dfs\_path='filename']} \\
\quad [, \text{ identity='sd\_identity'}])
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{encrypted_value}</td>
<td>A VARCHAR value that was encrypted using SecureData. You must cast other data types (for example DATE values) to VARCHAR when calling this function.</td>
</tr>
<tr>
<td>\text{format_name}</td>
<td>A string containing the name of \text{encrypted_value}'s FPE format. This format must match the format used to encrypt the value, or the result will be a random value. SecureData has no way to tell if the value passed to it was actually encrypted or not, or what FPE format was used.</td>
</tr>
<tr>
<td>\text{filename}</td>
<td>String containing the file name of the configuration file to use when authenticating with the SecureData appliance. You must create this file using VoltageSecureConfigure. If you do not supply this parameter, you must set session parameters to configure access to SecureData. See Configuring Access to SecureData. Any values set in session parameters</td>
</tr>
</tbody>
</table>
override the values in this file.

**sd_identity**

A string containing the identity to use when decrypting the data. Because SecureData uses the identity to determine encryption keys, this identity must match the identity used to encrypt the data. If supplied, this value overrides any identity value set in the configuration file or session parameter.

### Examples

The following example shows a simple call to `VoltageSecureAccess`. In this example, all of the connection information necessary to access the SecureData Appliance has been set in session parameters.

=> SELECT VoltageSecureAccess('376-69-6789' USING PARAMETERS format='ssn');

```
VoltageSecureAccess
+------------------+
123-45-6789
(1 row)
```

This example demonstrates decrypting an encrypted column within a query.

=> SELECT id, first_name, last_name, VoltageSecureAccess(ssn USING PARAMETERS format='ssn', config_dfs_path='/voltagesecure/conf') AS ssn, dob FROM customers WHERE dob < '1970-1-1' ORDER BY id ASC LIMIT 10;

```
id | first_name | last_name | ssn | dob
+---|------------|----------|-----|------
5346 | Talon | Wilkins | 540-48-0784 | 1941-09-17
5347 | Daquan | Phelps | 785-34-0092 | 1963-05-08
5348 | Basia | Lopez | 811-85-0705 | 1940-04-29
5349 | Kaseem | Hendrix | 672-57-0309 | 1942-03-11
5350 | Omar | Lott | 825-45-0131 | 1956-02-17
5352 | Illana | Middleton | 831-47-0929 | 1949-12-29
5353 | Garrett | Williamson | 408-73-0207 | 1955-11-06
5354 | Hanna | Ware | 694-97-0394 | 1967-08-08
5355 | Quinn | Pruitt | 818-91-0359 | 1965-11-14
5356 | Clayton | Santiago | 102-56-0010 | 1958-02-02
```

**VoltageSecureConfigure**

Saves SecureData access configuration parameters to a file in the Vertica Distributed Filesystem (DFS). You then pass the file's name to the other SecureData integration functions. This function can store the configuration file in the user's own DFS directory or in a globally-accessible file named `/voltagesecure/conf`.

**Syntax**

```sql
SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='filename'
    [, allow_short_fpe=Boolean]
    [, allow_file_cache=Boolean]
    [, identity=sd_identity]
    [, policy_url=url]
    [, store_password=Boolean]
    [, store_shared_secret=Boolean]
    [, username=sd_user]
) OVER ();
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>config_dfs_path='filename'</code></td>
<td>Required. A string containing the path for the configuration file in DFS. This is either:</td>
</tr>
<tr>
<td></td>
<td>- A file name (without any path information). The function automatically stores the file in a</td>
</tr>
</tbody>
</table>
DFS directory named for the user. Creating this directory prevent different user's files from overwriting one another.

- The absolute path /voltagesecure/conf. All users can use this file in calls to the other functions in the SecureData library. This path is the only absolute one that VoltageSecureConfigure allows for this parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allow_short_fpe=<strong>Boolean</strong></td>
<td>A Boolean value. When set to True, SecureData ignores the lower length limit for encoding FPE values. Usually, SecureData does not use FPE to encrypt data shorter than a lower limit (usually, 8 bits). See the SecureData Architecture Guide's section on Data Length Restrictions for more information.</td>
</tr>
<tr>
<td>enable_file_cache=<strong>Boolean</strong></td>
<td>A Boolean value. When set to True, Vertica caches the SecureData policy file and encryption keys to disk, rather than just to memory. Defaults to false.</td>
</tr>
<tr>
<td>identity=sd_boolean</td>
<td>A string containing identity to use with the SecureData Appliance. This is usually in the form of an email address. When SecureData uses LDAP authentication, it uses this value to authenticate the user.</td>
</tr>
<tr>
<td>policy_url=url</td>
<td>A string containing the URL of the SecureData policy file. The Vertica SecureData library uses the contents of this file, such as the formats that the SecureData Appliance supports.</td>
</tr>
</tbody>
</table>
It also uses the URL of this file to determine the location of the SecureData Appliance.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_password=Boolean</td>
<td>A Boolean value. When set to true, Vertica stores the LDAP password stored in the password session parameter in the configuration file. Defaults to false.</td>
</tr>
<tr>
<td>store_shared_secret=Boolean</td>
<td>A Boolean value. When set to true, Vertica stores the shared secret set in the shared_secret session parameter in the configuration file. Defaults to false.</td>
</tr>
<tr>
<td>username=sd_user</td>
<td>A string containing the user name for authenticating with SecureData.</td>
</tr>
</tbody>
</table>

Notes

- Any SecureData session variables that are set override values from the configuration file. See Configuring Access to SecureData for more information.

- The SecureData integration only supports one configuration for the SecureData Appliance at a time. All users that access the SecureData integration must use the same value for policy_url, allow_short_fpe, and enable_file_cache. Having users with different settings for these values making simultaneous queries can result in errors.

- Under normal circumstances, users are not able to directly read data from files stored in DFS. However, all users who have access to UDx functions that read from the DFS could access these files from within Vertica. In addition, these files are stored as plain text in every node's filesystem. Anyone with the proper filesystem access on the nodes can read the file's contents. You should take both of these facts into consideration when deciding whether to store sensitive information such as passwords or shared secrets in either the shared or per-user configuration files.
Example

The following example demonstrates saving configuration information to a configuration file named voltage.conf in the user's own Vertica DFS directory.

```sql
=> \x
Expanded display is on.
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
                                username='alice', identity='alice@example.com', store_
                                password=false,
                                policy_url='https://voltage-pp-
                                0000.example.com/policy/clientPolicy.xml'
                          ) OVER ();

- [ RECORD 1 ]-------------------------------------------------------------------------
  config_dfs_path | voltage.conf
  policy_url      | https://voltage-pp-0000.example.com/policy/clientPolicy.xml
  allow_short_fpe |
  identity        | alice@vertica.com
  username        | alice
  enable_file_cache |
```

VoltageSecureProtect

Calls SecureData to encrypt a value.

Syntax

```
VoltageSecureProtect(value USING PARAMETERS format=format_name
                      [,config_dfs_path=config_file] [,identity=sd_identity]);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>VARCHAR containing the value to encrypt. You must cast other data types (for example DATE values) to VARCHAR when calling this function.</td>
</tr>
<tr>
<td>format=\textit{format_name}</td>
<td>String defining SecureData FPE format of value, or 'auto' to have SecureData encrypt the entire value while</td>
</tr>
</tbody>
</table>
preserving its overall format. If you pass
the name of an FPE format, it must
match one of the formats SecureData
defines. The `value`'s format must match
the FPE format. For example,
VoltageSecureProtect returns an error if
you set `format_name` to 'ssn' but
`value` contains a credit card number.

Caution: Always use the same
FPE format to encrypt data in a
column. If you use different
FPE formats in the same column
(such as loading some data using
'ssn' and other data using
'auto') there is no way to tell
which format was used for any
particular row. In this case, you will
not be able to recover the
unencrypted data because you
cannot tell correctly decrypted
values from incorrectly decrypted
ones. Formats that deal with the
same source format (such as ssn and
ssn-all) are still incompatible, as they
encrypt and decrypt the data in
different ways.

| config_dfs_path= config_file | String containing the file name of the
configuration file to use when
authenticating with the SecureData
appliance. You must create this file using
VoltageSecureConfigure. If you do not
supply this parameter, you must set
session parameters to configure access
to SecureData. See Configuring Access
to SecureData. Any values set in session
parameters override the values in this
file. |
| identity= sd_identity | String containing the identity to use |
when authenticating with SecureData. SecureData uses this value as a basis for the encryption key. This value usually takes the form on an email address. If supplied, it overrides any values set in the configuration file or session parameters.

Examples

The following example demonstrates encrypting a social security number (SSN) value using both the ssn and auto FPE formats. This example assumes that all of the necessary SecureData authentication information have already been set in session variables.

```sql
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='ssn');
VoltageSecureProtect
---------------------
376-69-6789
(1 row)

=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='auto');
VoltageSecureProtect
---------------------
820-31-5110
(1 row)
```

The following example demonstrates calling VoltageSecureProtect to encrypt two table columns in a COPY statement. These calls use the user's private configuration file saved in DFS.

```sql
=> COPY customers (id, first_name, last_name, ssn_raw FILLER VARCHAR(11),
  cc_num_raw FILLER VARCHAR(25), cvv, dob,
  ssn AS VoltageSecureProtect(ssn_raw USING PARAMETERS
   format='ssn',
   config_dfs_path='voltage.conf'),
  cc_num AS VoltageSecureProtect(cc_num_raw USING PARAMETERS
   format='cc',
   config_dfs_path='voltage.conf'))
   FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
Rows Loaded
-----------
100
(1 row)
```

The following example demonstrates using VoltageSecureProtect in a query to locate a particular value in an encrypted column.

```sql
=> SELECT id, first_name, last_name FROM customers
   WHERE ssn = VoltageSecureProtect('559-32-0670' USING PARAMETERS
```
See Also

- VoltageSecureAccess
- VoltageSecureProtectAllKeys
- Encrypting and Decrypting Data

**VoltageSecureProtectAllKeys**

This function helps you locate values in a column encrypted using an Embedded Format Preserving Encryption (eFPE) format. These formats use key rotation, so the encrypted value you get back for a piece of plain text changes over time. You pass this function an unencrypted value. It returns a table consisting of two columns: the unencrypted value and the value encrypted with each of the keys defined for the eFPE. The number of rows in the table are determined by the number of keys the eFPE format contains. Usually, you use the output of this function in a join to locate a matching encrypted value in a table.

**Syntax**

```
VoltageSecureProtectAllKeys(value USING PARAMETERS format='eFPE_format'
                          [, config_dfs_path=config_file]
                          [, identity=sd_identity] )
```

**Parameters**

<table>
<thead>
<tr>
<th>value</th>
<th>VARCHAR containing the value to encrypt. You must cast other data types (for example DATE values) to VARCHAR when calling this function.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>format=eFPE_format</code></td>
<td>String containing the name of an eFPE format defined by SecureData. This format must be an eFPE format defined by your SecureData Appliance, or the function returns an error. This format must also match the format of value. VoltageSecureProtectAllKeys returns an error if value’s format does not match the one you specify in <code>eFPE_format</code>.</td>
</tr>
<tr>
<td><code>config_dfs_path=config_file</code></td>
<td>String containing the file name of the configuration file to use when authenticating with the SecureData appliance. You must create this file using VoltageSecureConfigure. If you do not supply this parameter, you must set session parameters to configure access to SecureData. See Configuring Access to SecureData. Any values set in session parameters override the values in this file.</td>
</tr>
<tr>
<td><code>identity=sd_identity</code></td>
<td>String containing the identity to use when authenticating with SecureData. SecureData uses this value as a basis for the encryption key. This value usually takes the form on an email address. If supplied, it overrides any values set in the configuration file or session parameters.</td>
</tr>
</tbody>
</table>

### Examples

The following example demonstrates a simple call to VoltageSecureProtectAllKeys.

```sql
=> SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
  format='cc_num',
  config_dfs_path='/voltagesecure/conf')

<table>
<thead>
<tr>
<th>data</th>
<th>protected</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Vertica Analytic Database (9.1.x)  Page 5312 of 6174
In this example, the cc_num eFPE format has five keys defined for it, so the return value is a table containing five rows.

The following example shows a more common use: querying a table column that is encrypted using an eFPE format.

```sql
=> SELECT id, first_name, last_name FROM customers u 
JOIN (SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS format='cc_num', 
config_dfs_path='/voltagesecure/conf') 
OVER () ) pak 
ON u.cc_num = pak.protected;
```

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>5345</td>
<td>Thane</td>
<td>Ross</td>
</tr>
</tbody>
</table>

(1 row)

In the previous example, the customers3 table is joined to the output from VoltageSecureProtectAllKeys. Any rows in the customers3 table where the encrypted cc_num column value matches values from the protected column of VoltageSecureProtectAllKeys matches appear in the output.

This function returns an error if you use it on a non-eFPE format:

```sql
=> SELECT first_name, last_name, ssn FROM customers u 
JOIN ( 
SELECT VoltageSecureProtectAllKeys('232-28-0657' USING PARAMETERS format='ssn', 
config_dfs_path='/voltagesecure/conf') 
OVER () ) pak ON u.ssn = pak.protected;
ERROR 5861: Error calling processPartition() in User Function VoltageSecureProtectAllKeys at [ProtectAllKeys.cpp:21], error code: 1711, message: Error getting key numbers: eFPE format required
```

Vertica Plug-In for Informatica

Important: The Vertica Plug-in for Informatica should only be used with versions of Informatica up to and including 9.6.

Informatica's PowerCenter family of products lets you collect, transform, and store data. The products support a wide variety of data sources, including databases, message queues, and many different file formats.

The PowerCenter Client consists of four main applications:

- Use Designer to create sources, targets, and mappings.
- Use Workflow Manager to create workflows for those sources, targets and mapping you created in Designer.
- Use Workflow Monitor to monitor running workflows.
- Use Repository Manager to manage repository resources, such as moving folders and objects and managing permissions and users.

The PowerCenter Server enables you to access, read, and write to Vertica.

PowerCenter 9.6.1 HotFix 2 includes the PowerExchange (PWX) Connector for Vertica. Informatica developed this PWX Connector as an alternative to the Vertica plug-in. The PWX connection includes additional capabilities and performance improvements when connected to Vertica.
History of Integration Between Vertica and Informatica

Prior to the PowerExchange (PWX) Connector for Vertica, Vertica developed and supported two connectors for Informatica and Vertica:

- In 2009, Vertica developed the Vertica Plug-in for Informatica. This connector used the native method of loading data from Informatica into Vertica.

- In 2013, Vertica replaced the earlier Vertica Plug-in for Informatica with a Java plug-in that supports all operating system platforms. This plug-in runs on generic JDBC and ODBC connections and includes new and improved features compared to the native plug-in.

This document describes how to use the Vertica Java plug-in for connecting from Informatica to Vertica.

In 2014, Informatica released the PWX Connector for Vertica. This connector includes enhancements to the partitioning and pushdown capabilities of Informatica.

The following timeline shows the history of plug-ins for connecting from Informatica to Vertica:

Vertica recommends that you use the new PWX Connector for Vertica with Informatica PowerCenter 9.6.1 HotFix 2 or later to connect to your Vertica database.

**Important:** The Vertica Plug-in for Informatica should only be used with versions of Informatica up to and including 9.6.

For detailed information about using the PWX Connector for Vertica, see Vertica Integration with Informatica: Connection Guide.
How the Plug-in Is Configured with Vertica and Informatica PowerCenter

The following illustration provides an overview of the configuration.

This manual provides information for installing plug-in components, using the plug-in to access Vertica as source or target database, and implementing and modifying plug-in features.
# Preparing to Install Informatica Plug-in

**Important**: The Vertica Plug-in for Informatica should only be used with versions of Informatica up to and including 9.6.

The following table provides recommended steps.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Follow the procedures in <a href="#">Installing the Vertica Plug-in for PowerCenter</a> to download and install plug-in components.</td>
<td>You must install both client and server components.</td>
</tr>
<tr>
<td>2</td>
<td>Review the sample for using the plug-in with PowerCenter in <a href="#">Using the Vertica Plug-in with Informatica PowerCenter</a>.</td>
<td>The sample shows how to import Vertica as source and target. I also provides steps that show you how to specify and connect to your Vertica database and include it in your workflows.</td>
</tr>
<tr>
<td>3</td>
<td>Set plug-in features according to your specific needs. Features are listed and described in <a href="#">Accessing and Setting Plug-in Features</a>.</td>
<td>Be aware of situations where the use of one feature depends on another. For example, to take advantage of the increased performance of <a href="#">EnableStreamingBatchInsert</a>, you must set Copy Local Method to None.</td>
</tr>
<tr>
<td>4</td>
<td>Check <a href="#">Vertica Plug-in For Information Best Practices</a> for required memory settings and other tips. Memory requirements are highly dependent upon Informatica and Vertica dedicated resources.</td>
<td></td>
</tr>
</tbody>
</table>
Installing the Vertica Plug-in for PowerCenter

Important: The Vertica Plug-in for Informatica should only be used with versions of Informatica up to and including 9.6.

You must download and install a client and a server component for the Vertica Plug-in for Informatica.

As a first step, download both the client and server components of the plug-in from the myVertica portal.

The client portion of the plug-in (vertica-informatica-client-2.0.1.zip) includes the following files:

- vertica.xml contains the metadata definition needed by the PowerCenter repository to allow communication between PowerCenter and Vertica.
- verticacli9.dll is a library file you add to your Windows registry.
- vertica-infa951-x86.reg is a registry file you can use to register the dll on 32-bit machines for Informatica PowerCenter 9.5.1.
- vertica-infa951-x64.reg is a registry file you can use to register the dll on 64-bit machines for Informatica PowerCenter 9.5.1.

The server portion includes the file vertica-informatica-plugin-server.jar.

Note: Each server type requires the Java 6.0 run-time environment.

Installing the Vertica plug-in is a multi-step process. The following sections explain these steps in greater detail, using a simple example.

1. Register the plug-in's metadata with the PowerCenter Repository Service with which you want to access Vertica. Follow the procedures in Registering the Plug-in's Metadata.

2. Add the verticacli9.dll library file to the Windows registry. Follow the procedures in Adding the Library File to the Windows Registry.

3. Copy the server plug-in to the PowerCenter server javalib directory. Follow the procedures in Copying the Plug-in Library on the Server.
Registering the Plug-in's MetaData

The PowerCenter repository needs information about the Vertica plug-in in order to enable clients to use it. This information is supplied in an XML-format file named vertica.xml. Perform the following to register the plug-in's metadata.

Switch to Exclusive Mode

Before you can register the plug-in's metadata, you must logon to PowerCenter and switch to exclusive mode to ensure that the repository does not change while you are registering the plug-in.

1. Place or copy the file vertica.xml to your system.

2. Open a browser and log into the PowerCenter domain's Administration Console.

3. Select the Domain tab, and click Services and Nodes.
4. In the Domain Navigator, click the entry for the repository that you want to connect to Vertica.

5. Under the Properties tab, click Edit to edit the Repository Properties section.

6. In the Operating Mode list box, choose Exclusive, and then click OK.
7. In the Restart Service prompt, click OK to confirm switching to exclusive mode.

The Repository Service may take from a few moments to several minutes to restart and re-enable itself.

8. Wait until you see the notice, This PowerCenter Repository Service is available.
Register the Plug-in

1. On the Plug-ins tab, click the icon for registering a plug-in.

2. On the Choose a plug-in field, click Browse and select the `vertica.xml` in the folder where you earlier placed the file.

3. Under the Repository Authentication section, enter your repository username and password.

   Note: If you are upgrading from a previously installed plug-in version, select the checkbox, Update existing plug-in registration. Otherwise leave the box cleared.

4. Click OK to upload the metadata file. The PowerCenter Administration Console uploads the metadata file and registers the Vertica plug-in data.
Switch Back to Normal Mode

2. In the Operating Mode list box, choose Normal.

3. In the Restart Service prompt, click OK to confirm switching to normal mode.

   The Repository Service may take from a few moments to several minutes to restart and re-enable itself.

Adding the Library File to the Windows Registry

For each PowerCenter client system that you want to use with Vertica, you must install a copy of the `verticacli9.dll` file in the client binary folder. This folder is named `client\bin` in the PowerCenter install directory. The following path is typical of a PowerCenter installation for Informatica version 9.5.1:

```
C:\Informatica\9.5.1\clients\PowerCenterClient\client\bin
```

Copy and Register the `verticacli9.dll`

Copy the library file to the client binary directory (i.e., `client\bin`).

Then, add a registry entry to the Windows registry. Adding this entry tells the PowerCenter Designer to load the plug-in library. Perform one of the following to register the plug-in library.

Note: The registry file is specific to Informatica PowerCenter version 9.5.1. The Vertica Plug-in for Informatica has only been tested with this version. If you want to try to use it with another version of PowerCenter, you will need to manually add configuration information to the Windows registry, as explained below.

Register the `verticacli9.dll` Using a Registry File for Informatica PowerCenter 9.5.x
1. Double-click the registry file in Windows Explorer:
   - Use vertica-infa951-x86.reg to register the dll on 32 bit machines.
   - Use vertica-infa951-x64.reg to register the dll on 64 bit machines.
2. When asked if you want to add the contents of the file to the registry, click Yes.

Register the verticacli9.dll Manually for all Other Versions of Informatica (9.6.x, 10.x, et. al.)

1. Start the registry editor by typing regedit.exe in the Windows Start menu's command run command box.
2. Navigate to the correct location in the registry.
   - For 32-bit versions of Windows:
     ```plaintext
     HKEY_LOCAL_MACHINE\SOFTWARE\Informatica\PowerMart Client Tools\x.x.x\Plugins\Informatica
     ```
   - For 64-bit versions of Windows:
     ```plaintext
     HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\Informatica\PowerMart Client Tools\x.x.x\Plugins\Informatica
     ```
     Where x.x.x is the version of Informatica you are using (for example 9.5.1).
3. Right-click in the right pane of the Registry Editor window. Select New then select String Value.
4. Change the name of the string value from New Value #1 to VERTICA.
5. Double-click the new VERTICA entry. When prompted for a new value, enter verticacli9.dll.
6. Exit the registry editor.

**Copying the Plug-in Library on the Server**

The final step in setting up the Vertica plug-in for Informatica is to copy the Vertica server-side plug-in file to the proper directory on the PowerCenter server.
- vertica-informatica-plugin-server.jar (for both 32 and 64 bit servers)

Copy the library file to your server's binary directory, which is the \bin\javalib subdirectory in the PowerCenter server install directory. The full path to this directory for Windows is usually:

C:\Informatica\9.5.1\server\bin\javalib

Note: In addition to the file vertica-informatica-plugin-server.jar, you must also have the appropriate JDBC driver installed in the same directory (/bin/javalib). The JDBC driver you install must match your version of Vertica.

The following sample screen shows a typical Windows path for these files.

For all supported server operating systems (Linux, AIX, HP-UX), you download and install the same file, vertica-informatica-plugin-server.jar.

Copy the file to the server/bin/javalib subdirectory of the directory where PowerCenter is installed.

**Unregistering the Plug-in**

Perform this procedure only if you need to unregister the plug-in.
1. Follow the procedure, Switch to Exclusive Mode.

2. Click the trashcan icon to unregister a plug-in.

3. In the Unregister plug-in pop-up, enter your Username and Password to unregister the plug-in, and then click OK.

4. Follow the procedure, Switch Back to Normal Mode.

**Updating the Plug-in**

Follow this procedure only if you need to update the plug-in.

1. Follow the procedure, Switch to Exclusive Mode.

2. On the Plug-ins tab, click the icon for registering a plug-in.

3. On the Choose a plug-in field, click Browse and select the location of the vertica.xml file.

4. Check the box, Update existing plug-in registration.

5. Enter your Username and Password to unregister the plug-in, and then click OK.
6. Follow the procedure, Switch Back to Normal Mode.
Using the Vertica Plug-in with Informatica PowerCenter

Once you have installed the Vertica Plug-in for Informatica, you can use Vertica as a source or target in Informatica PowerCenter.

The simple examples in this section walk you through importing source and target, mapping, configuring, and starting your workflow.

Importing a Source Database Table

Note: Set up a DSN for your Vertica database before you perform the procedures that follow.

The following example that shows how to import a source table from a Vertica database.

1. In Informatica PowerCenter Designer, select the folder in the repository where you want to create your Vertica source.

2. Click the Source Analyzer icon.

3. From the Sources list box, select Import from Database.
4.  From the Import Tables dialog box, choose the name of your ODBC data source, and enter Username and Password.

5.  Click Connect. Under Select tables, choose the schema public.
6. Choose a table and Click OK. For this example, choose only the table, datatypes_src. (You can choose a number of tables.)

   The table appears in the Source Analyzer panel.

7. Change the table’s database type to VERTICA. To do so, double-click the name of the table to launch the Edit Tables dialog box.

8. From the Table tab, Database type list box, choose VERTICA.

   Note: As of Informatica Version 9.6.1 Hot Fix 2 and later, if you want to use the version of Vertica you downloaded and installed, select the Vertica option from the dropdown menu. If you intend to use the new Vertica Connector from Informatica, select VERTICA from the dropdown menu.

9. Click OK. You have imported a source table. Next, follow the procedure in, Importing a Target Database Table.
Importing a Target Database Table

Note: Set up a DSN for your Vertica database before you perform the procedures that follow.

The following example shows how to import a target table from a Vertica database.

1. In Informatica PowerCenter Designer, select the folder in the repository where you want to create your Vertica target.

2. Click the Target Designer icon.

3. From the Targets list box, choose Import from Database.
4. From the Import Tables dialog box, choose the name of your ODBC data source, and enter Username and Password.

5. Click Connect. Under Select tables, choose the schema public.
6. Choose a table and Click OK. For this example, choose only the table, datatypes_tgt.

The table appears in the Target Designer panel.

7. Change the table's database type to VERTICA. Double-click the name of the table to launch the Edit Tables dialog box.

8. From the Table tab, Database type list box, choose VERTICA.

   Note: As of Informatica Version 9.6.1 Hot Fix 2 and later, if you want to use the version of Vertica you downloaded and installed, select the Vertica option from the dropdown menu. If you intend to use the new Vertica Connector from Informatica, select VERTICA from the dropdown menu.

9. Click OK. You have imported a target table. Next, follow the procedure in, Mapping Between Source and Target Tables.

**Mapping Between Source and Target Tables**

Perform this procedure to create mapping between source and target tables.
1. In Informatica PowerCenter Designer, select the folder in the repository where you want to create your Vertica mapping.

2. Click the Mapping Designer icon.

3. From the Mappings list box, select Create.

4. Enter a mapping name and click OK.

5. Choose the source, datatypes_src, and drag it to the Mapping Designer window. An Application Source Qualifier also appears; your source is mapped to Informatica. (This example sets up a basic workflow and is not meant to be a realistic sample. Note also that this example shows that configuration changes would be required where both source and/or target are in Vertica databases.)

6. Drag your target, datatypes_tgt, to the Mapping Designer window.

7. From the Layout list box, select Autolink by Name.

8. Confirm the from and to transformations, and click OK.
9. Save your work. Next, follow the procedure in, you create a workflow that uses your mapping. Follow the procedure in, Creating a Workflow.

**Creating a Workflow**

Perform this procedure to create a workflow using the table mapping you previously created.

1. In Informatica PowerCenter, click the Workflow button to launch the Workflow Manager.

2. From the Workflows list box, select Create.
3. In the Create Workflow dialog box, enter a name for your new workflow and click OK.

4. From the Tasks list box, select Create.
5. Enter a name for your new task, and click Create.

6. In the Mappings dialog box, choose the mapping to associate with the session and click OK.

7. Click Done on the Create Task dialog box.
8. In the Workflow Designer, drag your task to the right of Start.

9. Select the link tasks icon, and link Start to your task. Save your work.

Next you configure your workflow connection to your database. Follow the procedure in, Configuring Your Workflow Connections.

**Configuring Your Workflow Connections**

Perform this procedure to configure your workflow connection to your database.

1. While in Workflow Manager, from the Connections list box, select Relational.

2. From the Relational Connection Browser dialog box, select your Vertica connection object and click and click New.

3. From the Select Subtype dialog box, select VerticaConnection and click OK.
4. Fill in the details within the Connection Object Definition dialog box.

   a. Fill in the Name, User Name, and Password.

   b. Enter the connection string, which must have the format:
      \texttt{jdbc:vertica://<ip>:<port>/dbname}

   c. In the JDBC Driver Name field, enter \texttt{com.vertica.jdbc.Driver}

   d. If you are connecting to a database that is running Vertica Release 9.1.x, select \texttt{EnableStreamingBatchInsert}.

      \textbf{Important:} If you are running Vertica Release 7.x on either source or target database, enable (check off) \texttt{EnableStreamingBatchInsert}. Note that if you are running a previous version of Vertica you can still check \texttt{EnableStreamingBatchInsert}; previous versions will not experience the performance improvements, but setting the option has no detrimental impact.

   e. If your Vertica database is SSL enabled, check \texttt{EnableSSLConnection}, and enter a Trust Store Path and Trust Store Password.

      \textbf{Note:} You must enter a complete path for Trust Store Path (e.g., $C:\Users\Administrator\Desktop\verticastore$).

   f. Click OK.
Next you configure your source and target for the workflow. Follow the procedure in, Configuring Source and Target and Starting Your Workflow.

**Configuring Source and Target and Starting Your Workflow**

Perform this procedure to configure source and target for your workflow. (This procedure assumes all previous procedures have been completed.)

1. While in Workflow Designer, double-click your task to launch the Edit Tasks dialog box.

2. Click the Mapping tab.

3. Configure the source.

   a. Under the Sources folder, select your source. The VERTICA_READER is listed under Readers.
b. Click the down arrow icon to bring up the Relational Connection Browser dialog box.

c. Choose your object and click OK.

4. Configure the target.
   a. Under the Targets folder, select your target. The VERTICA_WRITER is listed under Writers.
   b. Click the down arrow icon to bring up the Relational Connection Browser dialog.
   c. Choose your object and click OK. Save your work.

5. While in Workflow Manager, from the Workflows list box, select Start Workflow. (The Workflow Monitor opens.)
Accessing and Setting Plug-in Features

You can access the Vertica plug-in features through any workflow task. This section discusses how to access the features available through the Vertica plug-in.

Accessing VERTICA_READER Plug-in Attributes

Note that, when you use Vertica as source/reader, the plug-in supports only pass-through partitioning. When you use Vertica as target/writer, the plug-in supports pass-through partitioning and key range partitioning. (Note that the key value partitioning source should not be through the Vertica plug-in.)

1. While in Workflow Manager, double-click any task.
2. In the Edit Tasks dialog, select the Mappings tab.
3. Select your source qualifier (this example uses SQ_datatypes_src).
4. Minimize the Readers and Connections areas to focus on Properties.
Plug-in features are listed under the Properties area.

The table that follows lists and describes the plug-in attributes for source/reader.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema Name</td>
<td>Schema Name allows you to override the default schema name of the mapped table. If you have only one source, you can override the schema name by simply entering the new schema name. Where you have many sources in a mapping that all go to the one source qualifier, you override schema names with the following format. Use a semicolon as separator: <code>&lt;old_table_name&gt;==&lt;new_schema_name&gt;; &lt;another_table_name&gt;==&lt;another_new_schema_name&gt;</code></td>
</tr>
</tbody>
</table>

**Important**: In the format given above, you do not actually enter the schema name to change the schema name. Instead, you enter the table...
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name in the schema name field (to the left of the equal sign). You then provide the new schema name as given in the format above (to the right of the equal sign; the equal sign acts to set the new name). Use a semicolon as separator for multiple schema name changes.</td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>datatype_src=newschemaname</td>
</tr>
<tr>
<td>Table Name</td>
<td>Table Names changes are similar to Schema Name changes in regards to how you format the changes. If you have only one table name to change, you just enter the new table name. If you have more than one table name to change, you use the following format:</td>
</tr>
<tr>
<td></td>
<td>&lt;old_table_name&gt;=&lt;new_table_name&gt;; &lt;another_table_name&gt;=&lt;another_new_table_name&gt;</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>datatypes_src=newname;othertablename_src=newerone</td>
</tr>
<tr>
<td>Important:</td>
<td>If using the Schema Name option along with the Table Name option, note that the Schema Name entry uses the old table name versus the replacement name you have added here in the Table Name option. An example follows.</td>
</tr>
<tr>
<td></td>
<td>Schema Name entry:</td>
</tr>
<tr>
<td></td>
<td>• tbl1=new-schema-name</td>
</tr>
<tr>
<td></td>
<td>Table Name entry:</td>
</tr>
<tr>
<td></td>
<td>• tbl1=tbl2</td>
</tr>
<tr>
<td></td>
<td>That is, you would not specify tbl2 under the Schema Name entry.</td>
</tr>
<tr>
<td>Select Distinct</td>
<td>If selected, returns only distinct values.</td>
</tr>
<tr>
<td>Number of Sorted Ports</td>
<td>Sorts incoming data, specifying order by ports.</td>
</tr>
</tbody>
</table>
| User Defined      | Allows you to do overrides to your mapping, enabling you to do very specific
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
</table>
| Join                   | joins (e.g., inner and outer joins). When you click the arrow to the right of the field, a **SQL** box pops up. What you enter in the box becomes a custom join clause added to the generated SQL statement. Basically you can enter a typical join statement with SELECT being assumed. Examples:  
  - `s1.a.col = s2.b.col`  
    (where `s1` and `s2` are schema names)  
  - `a JOIN b ON a.col = b.col`  
  - `a.col = b.col` |
| Pre SQL                | Enter complete SQL statements that run before you read a table. For example, truncate or add data to a table before you read it. |
| Post SQL               | Enter complete SQL statements that run after you read a table.                                                                         |
| Modulus Partitioning   | If selected, performs modulus partitioning (no replication of data) rather than straight pass-through partitioning. Check this option only if using pass-through partitioning. |
| Time UTC Conversion    | If selected, keeps time synchronized when you are using Vertica as both source and target. Time data changes to UTC time zone. Select this option and the writer option only when using Vertica as both source and target.  
  If unchecked, when you are using Vertica as both source and target, time data changes to the JVM time zone. |
| SQL Query              | Overrides the entire query rather than overriding just a portion of a query.                                                             |
| Source Filter          | Allows you to do overrides to your mapping by overriding the **WHERE** clause (similar to the way User Defined Join allows you to override a join clause). |
Accessing VERTICA_WRITER Plug-in Attributes

1. While in Workflow Manager, double-click any task.
2. In the Edit Tasks dialog box, select the Mappings tab.
3. Select your source qualifier (this example uses datatypes_tgt).
4. Minimize the Readers and Connections areas to focus on Properties.

Plug-in features are listed under the Properties area.

The table that follows lists and describes the plug-in attributes for target/writer.
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema Name</td>
<td>Change the schema name by entering a new name in this field.</td>
</tr>
<tr>
<td>Truncate Target Table</td>
<td>Select this option if you have a workflow that should truncate its targeted table before loading data.</td>
</tr>
<tr>
<td>Pre SQL</td>
<td>Enter complete SQL statements that run before you write to a table.</td>
</tr>
<tr>
<td>Post SQL</td>
<td>Enter complete SQL statements that run after you write to a table.</td>
</tr>
<tr>
<td>Target Table Name</td>
<td>Change the target table name by entering a new name in this field.</td>
</tr>
<tr>
<td>Copy Direct</td>
<td>When selected, writes directly to the ROS container. More efficient for bulk loading.</td>
</tr>
<tr>
<td>Reject file directory</td>
<td>Reject file directory and Reject file name work in tandem to record rejected rows. In this field you specify the directory path for the reject file.</td>
</tr>
<tr>
<td>Reject file name</td>
<td>Specify the name of the file that holds the rejected rows.</td>
</tr>
<tr>
<td></td>
<td>There is one log file per partition. If there are multiple log files, a number is appended to the file names. For example, rejects.txt would become rejects_01.txt and rejects_02.txt.</td>
</tr>
<tr>
<td>Insert</td>
<td>If selected, makes insert the update strategy for the target.</td>
</tr>
<tr>
<td>Delete</td>
<td>If selected, makes delete the update strategy for the target.</td>
</tr>
<tr>
<td>Update</td>
<td>List box offers standard update options for target.</td>
</tr>
<tr>
<td>Time UTC Conversion</td>
<td>If selected, keeps time synchronized when you are using Vertica as both source and target. Time data changes to UTC time zone. Select this option and the reader option only when using Vertica as both source and target.</td>
</tr>
<tr>
<td></td>
<td>If unchecked, when you are using Vertica as both source and target, time data changes to the JVM time zone.</td>
</tr>
<tr>
<td>Copy Local Method</td>
<td>Choose method from list box.</td>
</tr>
<tr>
<td></td>
<td><strong>None.</strong> The default; in this case, no local copy method is used to stream data.</td>
</tr>
</tbody>
</table>
|                         | **Important:** To take advantage of increased performance of Vertica...
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>EnableStreamingBatchInsert</strong>, you must set Copy Local Method to <strong>None</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

**Delimited.** Creates a stream with pipes and newline delimiters. This method fails if there are pipes or newline delimiters in the data you are transmitting.

**Native Varchar** Converts to new format. Use if data is mostly some form of strings.

**Native binary** Serializes Java objects to Vertica objects.

**Target Number**

**Default behavior.** The Target Number default is zero. If you leave the default (or set Target Number to any number less than or equal to 1), the plug-in uses the IP address you specify in the **Connection String** when configuring workflow connections. See **Configuring Your Workflow Connections** for more information on where you specify the IP address.

In regards to load balancing, the Target Number default operates as follows.

- If the IP Address you specified in the **Connection String** is not a Vertica node, the plug-in targets that IP Address. Any load balancing policy enabled on the IP Address is used.

- If the node you specified in the Connection String is a Vertica node, note the following:

  Vertica native connection load balancing is off by default; in this case, the plug-in uses the IP address you specify in the connection string.

  If Vertica load balancing is enabled, then the plug-in targets nodes as defined by the load balancing scheme on the Vertica node.

**Non-default behavior.** You override the plug-in’s default behavior by setting the option Target Number to a value greater than 1 (up to 16). When the value of the Target Number is set to greater than 1, the plug-in targets that number of Vertica nodes and uses ROUNDROBIN as its load balancing scheme. This overrides the native Vertica load balancing scheme.

For information on native connection load balancing, refer to About **Native Connection Load Balancing** in the Administrator’s Guide. For information on setting a load balancing policy on a Vertica server, refer to **SET_LOAD_BALANCE_POLICY** in the SQL Reference Manual.
Setting EnableStreamingBatchInsert

If you are connecting to a database that is running Vertica Release 9.1.x, for best performance, you should always implement EnableStreamingBatchInsert.

If you are running an earlier version of Vertica, setting EnableStreamingBatchInsert has no impact on performance.

Find the full procedure for accessing the setting in the section, Configuring Your Workflow Connections. For a workflow that is already set up:

1. While in Workflow Manager, select a task.
2. From the Connections list box, select Relational.
3. Click Edit.
4. In the Connection Object Definition dialog box, check off EnableStreamingBatchInsert.
5. Click OK. Save your work.

Important: To take advantage of increased performance of EnableStreamingBatchInsert, you must set Copy Local Method to None.

Enabling SSL

If your Vertica database is SSL enabled, then within the Connection Object Definition dialog, check EnableSSLConnection, and enter a Trust Store Path and Trust Store Password.

Note: You must enter a complete path for Trust Store Path (e.g., C:\Users\Administrator\Desktop\verticastore).

For a simple example of where to access the SSL setting, refer to Configuring Your Workflow Connections.
Vertica Plug-in For Information Best Practices

This section includes memory requirement considerations and other tips for using the Vertica Plug-in for Informatica.

Setting Memory Properties for a Task

OpenText recommends that you increase memory allocation to improve performance.

**Note:** The default buffer size for Informatica PowerCenter is set very conservatively. These settings can cause PowerCenter to send Vertica many small batches, rather than a few large batches. The overhead of these many small batches can cause loading performance issues. To resolve these performance issues, you should change PowerCenter's batch size settings. Your specific settings depend upon your system resources and needs.

Perform the following procedure to increase memory allocation for a task.

1. While in Workflow Manager, double-click the task that connects to Vertica.
2. In the Edit Tasks dialog box, under the Mapping tab, select Memory Properties. Considering your task requirements and your system limitations, set the following attributes.

   **Note:** Allocate more memory than mentioned here according to your system limitations and needs. The settings given may not be realistic for the tasks you intend to perform.

   a. Set Default buffer block size to at least 16 MB.

   b. Set Maximum Memory Allowed for Auto Memory Attributes to at least 512 MB.

   c. Set Maximum Percentage of Total Memory Allowed for Auto Memory Attributes to
at least 25.

Setting JVM Memory Properties

OpenText recommends the following settings for your JVM (Java Virtual Machine).

1. Log on to the PowerCenter domain’s Administration Console.
2. Select the Domain tab, and click Services and Nodes.
3. In the Domain Navigator, click the entry for the PowerCenter Integration Service.
4. Click Edit next to the Custom Properties section.
5. In the Edit Custom Properties dialog box, click **New**.
   
   a. Enter a name.
   
   b. Set a minimum heap memory size to at least 1024 m. Enter `-Xms=1024m`.
   
   c. Click **OK**.

6. In the Edit Custom Properties dialog box, click **New** again.
   
   a. Enter a name.
   
   b. Set a maximum heap memory size to at least double the minimum you just entered.

   Enter `-Xmx=2048m`
c. Click OK.

<table>
<thead>
<tr>
<th>Custom Properties</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>JVM1</td>
<td>-Xms=1024m</td>
</tr>
<tr>
<td>JVM2</td>
<td>-Xmx=2048m</td>
</tr>
</tbody>
</table>

Communicating when Informatica and Vertica Are on Different Networks

This best practice concerns communication with a Vertica cluster from Informatica when Informatica and Vertica are on separate networks. If Informatica and Vertica are on the same network, you do not need to implement the changes described here.

If Informatica and Vertica are on separate networks:

- Set up a public network for import/export and specify an export address for your individual nodes. See Using Public and Private IP Networks in the Administrator’s Guide, specifically the section, Identify the Database or Nodes Used for Import/Export. See also ALTER DATABASE and ALTER NODE in the SQL Reference manual for subnet and node-related tasks.
The Vertica plug-in for Informatica accesses the EXPORT_ADDRESS column of the V_Catalog schema. (For information on viewing the EXPORT_ADDRESS column, see the SQL Reference manual, specifically the section NODES in the V_Catalog Schema.)

- Once the public network is set-up properly, and an export address is assigned to each node, Informatica can then read and write to a Vertica cluster on a different network.

**Important:** If you are using the Vertica plug-in for Informatica on Vertica Release 6.x, the Informatica user must have the PSEUDOSUPERUSER role to access the export addresses on the different network. For general information on the PSEUDOSUPERUSER role, see the Administrator's Guide, PSEUDOSUPERUSER Role. If you are using Vertica Release 7.0.x, the Informatica user does not need the PSEUDOSUPERUSER role.

## Modifying powrmart.ini

When reading or importing a table, you can receive a pop-up warning, such as the following, concerning a missing DLL.

![Warning](image)

You can make a correction so that the warning no longer appears by adding the line `Vertica Database=PMODBC.DLL` to the powrmart.ini file in the section ODBC_DLL. See the following example.

1. Using the Import Tables option in the Informatica PowerCenter Designer, the system displays a pop-up warning about a missing DLL. Click OK.
2. The system displays another pop-up letting you know that Informatica is using EXTODBC.DLL to support Vertica. Click OK.
3. Open the powrmart.ini file for editing.

4. Add the following line in the section ODBC DLL.

   Vertica Database=PMODBC.DLL

---

**Deleting Records on a Target Table**

Follow these notes to delete records on a target table.

1. On the target table, you must have defined a primary key. From Edit Tasks, select the Properties tab, and, under General Options, set Treat Source row as to Delete.
2. Also on the target table, from the Edit Tasks dialog, choose the Mapping tab. Under Properties, check-off Delete.
Vertica Error Messages

Welcome to the Vertica Error Codes guide. This guide is mainly for developers who need to understand how Vertica's error codes relate to error states returned by the ODBC and JDBC drivers.
The Different Ways Vertica Reports Errors

Vertica reports warnings and errors via two different mechanisms: SQLSTATEs and error messages. SQLSTATEs are intended for use by client applications, such as those accessing Vertica via ODBC or JDBC. Error messages are displayed to interactive users (for example, users connected to Vertica through vsql) and written to error logs.
About SQLSTATE

Vertica reports the success or failure of each statement it executes to client applications using a five-character SQLSTATE value. Many of these values are defined by the SQL standard. Others (identified by the letter "V" in their values) are Vertica-specific.

SQLSTATE values are grouped into classes which are defined by the first two characters in the SQLSTATE value. The last three characters indicate a specific condition within a class. For example, the SQLSTATE class 22 represents all data errors. The specific SQLSTATE value 22012 represents a division by zero error. SQLSTATE classes let an application that does not recognize a specific SQLSTATE value to still get a general idea of the result.
Warning and Error Messages

Each error and warning message displayed to interactive users or written to a log file by Vertica has its own numeric error code assigned to it. For example:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Message Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR 3117</td>
<td>Division by zero</td>
</tr>
<tr>
<td>WARNING 4098</td>
<td>No projections found</td>
</tr>
<tr>
<td>ERROR 5617</td>
<td>Multiple WITH clauses not allowed</td>
</tr>
</tbody>
</table>

The error code number is not related to the SQLSTATE value. However, error and warning messages do correspond to a specific SQLSTATE. They are just a more-specific human-readable message compared to the SQLSTATE, which is mainly intended for client applications.

For example, all warning messages displayed by Vertica correspond to the SQLSTATE class 01. The warning message "WARNING 3084: Design Workspace couldn't be dropped" corresponds to the SQLSTATE value 01000 ERRCODE_WARNING.

Error codes do not change between Vertica releases, but individual error and warning messages may be added or removed in new releases. Your client application should not depend on particular error code appearing from one release to the next. Instead, it should use the SQLSTATE value to determine the result of executing a statement.

See the SQL State List for a list of all the SQLSTATE classes and values defined by Vertica. This table also links to lists of error or warning messages that are associated with each SQLSTATE value.
# SQL State List

The following table lists the SQLSTATE classes and individual SQLSTATE codes.

<table>
<thead>
<tr>

**Warning Messages Associated with SQLSTATE 01000**

This topic lists the warnings associated with the SQLSTATE 01000.

**SQLSTATE 01000 Description**

ERRCODE_WARNING
Warning messages associated with this SQL State

WARNING 2362: Cannot begin transaction; transaction is already running
WARNING 3084: Design couldn’t be dropped
WARNING 3152: Duplicate values in columns marked as UNIQUE will now be ignored for the remainder of your session or until reenable_duplicate_key_error() is called
WARNING 3372: Failed to disable profiling: string
WARNING 3373: Failed to enable profiling: string
WARNING 3539: Incorrect results are possible. Please contact Vertica Support if unsure
WARNING 3791: Invalid view string: string
WARNING 4071: NO COMMIT option will be ignored for external table "string"
WARNING 4088: No new valid default roles specified. Retaining previous set of default roles for user string
WARNING 4098: No projections found
WARNING 4182: No rows are inserted into table "string" because ON COMMIT DELETE ROWS is the default for create temporary table
WARNING 4116: No super projections created for table string.
WARNING 4246: Only GLOBAL scope is supported for clearing string profiles
WARNING 4463: Projection string is not up to date
WARNING 4468: Projection <string> is not available for query processing. Execute the select start_refresh () function to copy data into this projection.
The projection must have a sufficient number of buddy projections and all nodes must be up before starting a refresh
WARNING 4792: Storage option "string" will be ignored for external table "string"
WARNING 4871: System view string for tuning rule string is currently invalid
WARNING 4873: System view for tuning rule string does not exist
WARNING 4996: This request may deadlock the system. Please report the details to technical support
WARNING 5068: Total declared length of columns of one of the constraints exceeds the limit, truncation may happen
WARNING 5119: Udx code didn’t respond when Vertica tried to get function prototype for string in library string: string
WARNING 5448: View string is currently invalid
WARNING 5451: Violations of some of foreign key constraints may not be reported because of no privilege on the foreign tables
WARNING 5642: Projection string is not persistent or not up to date; it will not be copied
WARNING 5643: Projection string is prejoin projection; it will not be copied
WARNING 5717: No statistics has been exported. Either the DB is empty or you try to export an external table or you do not have access to the available objects
WARNING 5724: Segmentation clause contains a string - data loads may be slowed significantly
WARNING 5727: Sort clause contains a string - data loads may be slowed significantly
WARNING 5741: View string depends on other relations
WARNING 5819: Design could not be reset
WARNING 5821: Detected keys sharing the same case-insensitive key name
WARNING 5860: Due to the data isolation of temp tables with an on-commit-delete-rows policy, the compute_flextable_keys() and compute_flextable_keys_and_build_view() functions cannot access this table’s data. The build_flextable_view() function can be used with a user-provided keys table to create a view, but involves a DDL commit which will delete the table’s rows

WARNING 5873: Failed to add table string of hcatalog schema string to catalog: string

WARNING 5875: Failed to alter table string of hcatalog schema string to catalog: string

WARNING 5880: Failed to describe table string in hcatalog database string: string

WARNING 5881: Failed to describe table string in schema string: HCatalog database string does not exist

WARNING 5884: Failed to list hcatalog tables of hcatalog schema string: string

WARNING 5886: Failed to mirror table string in schema string: string

WARNING 5909: Found and ignored keys with names longer than the maximum column-name length limit

WARNING 5912: HASH() arguments contain expressions that reference table columns

WARNING 5917: Ignored some keys since the total key count exceeds the view column limit

WARNING 5922: Insufficient privileges to alter table string

WARNING 5923: Insufficient privileges to drop table string

WARNING 5991: Projection basename "string" hint was ignored. "string" is used as the basename

WARNING 5993: Projection is irregularly segmented by column

WARNING 6053: The view creation involved a DDL commit which deleted the table’s rows

WARNING 6256: Error while analyzing constraint(s) string on string

WARNING 6257: Error while creating LTT for analyzing constraints on string

WARNING 6356: No partitions have been swapped. Neither table has partitions fall in range

WARNING 6417: Swapped partitions are not immediately moved to a new storage location

WARNING 6515: Projection with name "string" already exists in schema "string" for anchor table "string.string"

WARNING 6565: Inequa1 query trees produced the same hash code query1:

```
  string
  query2:
  string
```

WARNING 6594: Unknown RangeTblEntry: value

WARNING 6608: string is an invalid argument for hint string

WARNING 6765: Error parsing distrib value string in Distrib hint’s arguments. The whole hint will be ignored

WARNING 6773: Failed to compare plans for query 'string'

WARNING 6797: Hint string can accept at most one argument, the hint with value arguments is ignored

WARNING 6798: Hint string can be specified only once for each join, if multiple instances listed only the first is considered

WARNING 6799: Hint string is not feasible and will be ignored

WARNING 6801: Hint string requires exactly two arguments, the hint with value arguments is ignored

WARNING 6813: Inherited privileges are globally disabled; schema parameter is set but has no effect

WARNING 6814: Inherited privileges are globally disabled; table parameter is set but has no effect

WARNING 6815: Inherited privileges are globally disabled; view parameter is set but has no effect

WARNING 6818: Input operations specified for Hint string is not feasible and will be ignored

WARNING 6922: Projection name was changed to string because it conflicts with the basename of the table string

WARNING 6990: Text index has invalid tokenizer
WARNING 6991: The active saved plan for this query has incompatible output column set. Continuing with the original query

WARNING 7000: The projection 'string' was used to enforce the enabled key constraint 'string', and may be regenerated to validate a DML statement on the base table

WARNING 7020: Unable to find the following query in the export file: 'string'

WARNING 7030: Unexpected group clause found during query comparison

WARNING 7031: Unexpected group clause found during query hashing

WARNING 7033: Unexpected sort clause found during query comparison

WARNING 7036: Unknown Expr:value during query comparison

WARNING 7037: Unknown Expr:value found

WARNING 7038: Unknown Expr:value found during query hashing

WARNING 7039: Unknown Inequality OpOid:value found during query hashing

WARNING 7040: Unknown Logic OpExpr:value found during query comparison

WARNING 7041: Unknown Logic OpExpr:value found during query hashing

WARNING 7044: Unknown OpExpr:value found during query comparison

WARNING 7045: Unknown OpExpr:value found during query hashing

WARNING 7046: Unknown RangeTblEntry:value found during query comparison

WARNING 7047: Unknown RangeTblEntry:value found during query hashing

WARNING 7048: Unknown Sublink:value found during query comparison

WARNING 7049: Unknown Sublink:value found during query hashing

WARNING 7052: Unsupported JoinExpr Type found during query comparison

WARNING 7053: Unsupported JoinExpr Type found during query hashing

WARNING 7070: View "string" will include privileges from schema "string"

WARNING 7074: You appear to be using an old version of HDFS that may have stability problems under high load. See the Vertica documentation for supported HDFS versions

WARNING 7186: Inherited privileges are globally disabled. Privileges will be materialized and visibility of table string may change

WARNING 7264: Updates on the target table with a prejoin projection might ignore PK constraints and cause data integrity violations

WARNING 7265: Inherited privileges are globally disabled. Privileges will be materialized and visibility of view string may change

WARNING 7709: Could not drop table 'string'. Please remove manually if necessary.
Detail: string

WARNING 7752: Cannot make a local query plan for "try local" hint, please check hash function, segment quantity, segment boundary, etc

WARNING 7793: The cache will be set to 1 instead

WARNING 7942: Unknown expression found during hashing: value

WARNING 7994: Not converged before max_iterations [value]

WARNING 8012: The parameter [string] is not defined for this function

WARNING 8086: Encoding option specified for attribute (string) of external table (string) will be ignored

WARNING 8275: The following shards missed the string due to missing primary subscriber (probably down): string

WARNING 8343: Not converged before max_iterations value
WARNING 8413: Lambda provided without regularization type: default for regularization is [string]; lambda will have no effect
WARNING 8414: max_depth is set to value while max_breadth to value. This means the size of trees may become limited by string first
WARNING 8506: CGD optimizer could not invert covariance matrix which is required for calculating statistics. Coefficients are not affected
WARNING 8519: Parameters [string] are not supported for optimizer [string], only for [string]
WARNING 8526: Regularization type [string] may cause optimizer [string] to not converge
WARNING 8531: string Directory for errors files was not created. Unable to write errors for this instance of COPY command
WARNING 8547: Not converged before maximum inner iterations value
WARNING 8557: Feature string not applicable in Eon mode
WARNING 8580: Failed to convert internal form to readable form: string
WARNING 8581: Failed to convert to internal form: string
WARNING 8582: Failed to describe hcatalog tables of hcatalog schema string: string
WARNING 8583: Given lambda value [value] will result in all zero coefficients; use a value lower than lambda max for this dataset [value]
WARNING 8602: Caught exception while parsing JSON
WARNING 8621: The following string provided is not valid JSON: string

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Warning Messages Associated with SQLSTATE 01004

This topic lists the warnings associated with the SQLSTATE 01004.

SQLSTATE 01004 Description

ERRCODE_WARNING_STRING_DATA_RIGHT_TRUNCATION

Warning messages associated with this SQLState

WARNING 7166: client_label exceeded maximum length; truncated to 255 characters

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.
Warning Messages Associated with SQLSTATE 01006

This topic lists the warnings associated with the SQLSTATE 01006.

SQLSTATE 01006 Description

ERRCODE_WARNING_PRIVILEGE_NOT_REVOKED

Warning messages associated with this SQLState

WARNING 4925: The string "string" cannot be string string "string"

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Warning Messages Associated with SQLSTATE 01007

This topic lists the warnings associated with the SQLSTATE 01007.

SQLSTATE 01007 Description

ERRCODE_WARNING_PRIVILEGE_NOT_GRANTED

Warning messages associated with this SQLState

WARNING 5682: USAGE privilege on schema "string" also needs to be granted to "string"

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.
Warning Messages Associated with SQLSTATE 01V01

This topic lists the warnings associated with the SQLSTATE 01V01.

SQLSTATE 01V01 Description

ERRCODE_WARNING_DEPRECATED_FEATURE

Warning messages associated with this SQLState

WARNING 2693: Configuration parameter string has been deprecated; setting it has no effect
WARNING 4736: set_local_segment_threshold has been deprecated; setting it has no effect
WARNING 7399: Created prejoin projection 'string'. Prejoin projections have been deprecated and will be removed in a future version
WARNING 7585: Using prejoin projection 'string'. Prejoin projections have been deprecated and will be removed in a future version
WARNING 8000: Creating projection "string" with explicit range segmentation. Range segmentation for projections has been deprecated and will be removed in a future version
WARNING 8142: Query uses projection "string" which is explicitly range segmented. Range segmented projections have been deprecated and will be removed in a future version
WARNING 8461: drop_partition has been deprecated and will be removed in a future version
WARNING 8462: merge_partitions has been deprecated and will be removed in a future version
WARNING 8463: merge_projection_partitions has been deprecated and will be removed in a future version

Error Messages Associated with SQLSTATE 08000

This topic lists the errors associated with the SQLSTATE 08000.
SQLSTATE 08000 Description

ERRCODE_CONNECTION_EXCEPTION

Error messages associated with this SQLState

ERROR 2029: string from stdin failed: string
ERROR 2708: Connection to database [string] is invalid
ERROR 2896: Could not receive data from server: string
ERROR 2908: Could not send data to server: string
ERROR 3276: Error while waiting on socket. value
ERROR 4342: Password encryption failed
ERROR 5197: Unknown authentication method (value) requested by server
ERROR 7662: MD5 password hash requested when MD5 is not allowed

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 08001

This topic lists the errors associated with the SQLSTATE 08001.

SQLSTATE 08001 Description

ERRCODE_SQLCLIENT_UNABLE_TO_ESTABLISH_SQLCONNECTION

Error messages associated with this SQLState

ERROR 2322: Cancel() -- connect() failed:
ERROR 2324: Cancel() -- socket() failed:
ERROR 2823: Could not connect to server [string]: string
   Is the server running and accepting
   TCP/IP connections on port string?
ERROR 2824: Could not connect to server: string
   Is the server running on host [string] and accepting
   TCP/IP connections on port string?
ERROR 2839: Could not create socket: string
ERROR 2865: Could not get client address from socket: string
ERROR 2869: Could not get socket error status: string
ERROR 2912: Could not set socket to close-on-exec mode: string
ERROR 2913: Could not set socket to non-blocking mode: string
ERROR 2914: Could not set socket to TCP no delay mode: string
ERROR 7801: Could not translate host name "string" to address using family "string": string

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 08003

This topic lists the errors associated with the SQLSTATE 08003.

SQLSTATE 08003 Description

ERRCODE_CONNECTION_DOES_NOT_EXIST

Error messages associated with this SQLState

ERROR 4717: Server closed the connection unexpectedly
   This probably means the server terminated abnormally
   before or while processing the request

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 08006

This topic lists the errors associated with the SQLSTATE 08006.
SQLSTATE 08006 Description

ERRCODE_CONNECTION_FAILURE

Error messages associated with this SQLState

ERROR 2323: Cancel() -- send() failed: string
ERROR 2606: Client failed when looking for pending signals
ERROR 4539: Received no response from stringstring
ERROR 8466: Received no response from (string), operation (string)
ERROR 8503: Cannot get a reply from node: string

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 08V01

This topic lists the errors associated with the SQLSTATE 08V01.

SQLSTATE 08V01 Description

ERRCODE_PROTOCOL_VIOLATION

Error messages associated with this SQLState

ERROR 2055: string Unexpected message type string reading from stdin
ERROR 2257: Bind message has value parameter formats but value parameters
ERROR 2258: Bind message has value result formats but query has value columns
ERROR 3334: Expected a RowDescription Message
ERROR 3335: Expected a SendExport Message
ERROR 3575: Insufficient data left in message
ERROR 3631: Invalid CLOSE message subtype value
ERROR 3651: Invalid DESCRIBE message subtype value
ERROR 3699: Invalid message format
ERROR 3701: Invalid message type
ERROR 3702: Invalid message type value
ERROR 3755: Invalid string in message
ERROR 3887: Lost synchronization with server: length value
ERROR 4074: No data left in message
ERROR 4718: Server did not identify with a pid & key
ERROR 5181: Unexpected message type 0xhex value
ERROR 5208: Unknown message from server
ERROR 5872: Expected to flush an end-of-batch client message but received a message of type value.
  Attempting to recover...
ERROR 6863: MARS operation not supported for your client version. Parameter not changed

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 09000

This topic lists the errors associated with the SQLSTATE 09000.

SQLSTATE 09000 Description

ERRCODE_TRIGGERED_ACTION_EXCEPTION

Error messages associated with this SQLState

ERROR 7353: A problem during the execution of writeModel.
  Detail: string
ERROR 7356: A problem occurred during the execution of a BFGS iteration.
  Detail: string
ERROR 7358: A problem occurred during the execution of a MinMax iteration.
  Detail: string
ERROR 7359: A problem occurred during the execution of a Newton iteration.
  Detail: string
ERROR 7360: A problem occurred during the execution of a robust_zscore iteration.
  Detail: string
ERROR 7361: A problem occurred during the execution of a zscore iteration.
  Detail: string
ERROR 7362: A problem occurred during the execution of an iteration.
  Detail: string
ERROR 7373: Cannot check if all columns are numeric.
  Detail: string
ERROR 7377: Cannot compute input column list.
  Detail: string
ERROR 7378: Cannot find the current user.
  Detail: string
ERROR 7383: Cannot make inf clause.
  Detail: string
ERROR 7384: Cannot make null clause.
  Detail: string
ERROR 7395: Could not compute evaluation metrics.
  Detail: string
ERROR 7396: Could not create view 'string'.
  Detail: string
ERROR 7497: Problem in balance.
  Detail: string
ERROR 7498: Problem in balance: Unknown exception
ERROR 7503: Problem in detect_outliers.
  Detail: string
ERROR 7504: Problem in detect_outliers: Unknown exception
ERROR 7505: Problem in initializing centers table.
  Detail: string
ERROR 7506: Problem in kmeans.
  Detail: string
ERROR 7507: Problem in kmeans: Unknown exception
ERROR 7516: Problem in normalize.
  Detail: string
ERROR 7517: Problem in normalize: Unknown exception
ERROR 7524: Problem in writing initial model to DFS.
  Detail: string
ERROR 7593: Could not randomly pick value distinct centers after trying value times
ERROR 7626: A problem during the execution of computing the number of detected outliers.
  Detail: string
ERROR 7731: Problem in calculating alpha for Linear Regression.
  Detail: string
ERROR 7732: Problem in calculating Hessian matrix for Linear Regression.
  Detail: string
ERROR 7733: Problem in strongWolfeLineSearch.
  Detail: string
ERROR 7734: Problem in zoom.
  Detail: string
ERROR 7761: A problem during the execution of computing the mad.
  Detail: string
ERROR 7762: A problem during the execution of computing the median.
  Detail: string
ERROR 7763: A problem occurred during the execution of a mad computation.
  Detail: string
ERROR 7764: A problem occurred during the execution of median computation.
   Detail: string
ERROR 7769: Kmeans++ exceeded max number of retries for choosing initial center
ERROR 7784: Could not remove blob named string.
   Detail: Unexpected exception
ERROR 7785: Could not remove the blob named string.
   Detail: string
ERROR 7805: No input columns provided
ERROR 7826: Numeric overflow occurred during execution of kmeans++
ERROR 7827: Numeric overflow occurred when computing total sum of squares
ERROR 7828: Numeric overflow occurred when computing total within-cluster sum of squares
ERROR 7829: Numeric overflow occurred when computing within-cluster sum of squares
ERROR 7844: Input table string is empty
ERROR 7845: No input columns left after excluding
ERROR 7851: No rows remain after filtering rows with null and infinity values
ERROR 7858: Only found value non-empty clusters. You may want to try again or use a better set of initial centers; or there may be fewer than k distinct datapoints in the table
ERROR 7947: A problem occurred during table renaming.
   Detail: string
ERROR 7949: A problem occurred during the execution of mode computation.
   Detail: string
ERROR 7952: A problem occurred during the execution of computing mode for the first MiniBatch.
   Detail: string
ERROR 7953: A problem occurred during the execution of computing mode.
   Detail: string
ERROR 7955: A problem occurred during the execution of MiniBatch Table Merging.
   Detail: string
ERROR 7961: Problem in impute.
   Detail: string
ERROR 7962: Problem in impute: Unknown exception
ERROR 7975: A problem occurred during training of SVM model.
   Detail: string
ERROR 7988: Input table is empty
ERROR 7992: No rows remain after filtering rows containing NULL, NaN or INF
ERROR 8000: Problem in normalize_fit.
   Detail: string
ERROR 8001: Problem in normalize_fit: Unknown exception
ERROR 8020: Unexpected empty result from query
ERROR 8035: A problem occurred during the execution of DROP TABLE impute_201701_80425147_p1.
   Detail: string
ERROR 8036: A problem occurred during the execution of DROP TABLE impute_201701_80425147_p1,impute_201701_80425147_p2.
   Detail: string
ERROR 8045: A blob container cannot be initialized more than once
ERROR 8046: A problem during the execution of computing the max weight.
  Detail: string
ERROR 8047: A problem during the execution of sse_linear_reg
ERROR 8055: A problem occurred during the execution of computing weight table.
  Detail: string
ERROR 8056: A problem occurred during the execution of saving weight table to vectors.
  Detail: string
ERROR 8078: Could not link model string to catalog object.
  Details: string
ERROR 8102: Invalid value [string] for parameter [string]. Valid values are [string]
ERROR 8113: Model name cannot be empty
ERROR 8134: Problem in factor function.
  Detail: string
ERROR 8241: A problem occurred during the execution of
  a mode imputation with partition by.
  Detail: string
ERROR 8242: A problem occurred during the execution of
  a mode imputation without partition by.
  Detail: string
ERROR 8243: A problem occurred during the execution of a mean
  imputation with partition by.
  Detail: string
ERROR 8244: A problem occurred during the execution of a mean
  imputation.
  Detail: string
ERROR 8291: A problem occurred during the execution of coordinate descent covariance.
  Detail: string
ERROR 8293: A problem occurred during the execution of offsets query (averages of all columns).
  Detail: string
ERROR 8301: Parameter [string] cannot be redefined
ERROR 8306: Problem in creating model [string].
  Detail: string
ERROR 8307: Problem in creating model [string]: Unknown exception
ERROR 8308: Problem in cross_validation.
  Detail: string
ERROR 8309: Problem in cross_validation: Unknown exception
ERROR 8315: Type [string] of parameter [string] is not supported
ERROR 8318: Empty string cannot be passed into extra_levels parameter
ERROR 8319: Invalid JSON for extra_levels: [string]
ERROR 8320: Problem in one_hot_encoder_fit.
  Detail: string
ERROR 8321: Problem in one_hot_encoder_fit: Unknown exception
ERROR 8344: Parameter [string] was provided and cannot be included again in cv_hyperparams
ERROR 8346: The total number of models to be trained is very large [value]. It could take very long time to finish
ERROR 8369: Could not train any tree. Increase sampling_size
ERROR 8399: A problem in model summary.
   Detail: string

ERROR 8405: Could not create catalog object for model [string]
   Detail: string

ERROR 8406: Could not create catalog object for temporary model.
   Detail: string

ERROR 8407: Could not link temporary model to catalog object.
   Details: string

ERROR 8420: Problem in creating temporary model.
   Detail: string

ERROR 8421: Problem in creating temporary model: Unknown exception.

ERROR 8499: A problem occurred during training of a Naive Bayes model.
   Detail: string

ERROR 8507: Could not upgrade model to latest version, during import. Please run upgrade_model().
   DETAIL: string

ERROR 8508: Could not upgrade model to latest version, during import. Please run upgrade_model(). Unknown Exception.

ERROR 8523: One of the folds does not have enough data to train. Please try to reduce the number of folds.

ERROR 8529: Unsupported model format version for upgrade.

ERROR 8565: Relation [string] has no valid rows.

ERROR 8566: Relation [string] is empty.

ERROR 8571: Cannot upgrade an incomplete model: [value]. Skipping this model.

ERROR 8572: Error while initializing model upgrade task.
   Details: string

ERROR 8573: Error while performing upgrade for model: string.
   Details: Model file: string does not exists

ERROR 8574: Error while performing upgrade for model[value].
   Details: Model does not exists

ERROR 8575: Error while performing upgrade for model[value].
   Details: string

ERROR 8576: Error while performing upgrade.
   Details: string

ERROR 8577: Error while upgrade models.
   DETAILS: string

ERROR 8590: Schema value not found.

ERROR 8626: A problem occurred during training of PCA model.
   Detail: string

ERROR 8627: A problem occurred during training of SVD model.
   Detail: string

Error Messages Associated with SQLSTATE 0A000

This topic lists the errors associated with the SQLSTATE 0A000.

SQLSTATE 0A000 Description
ERRCODE_FEATURE_NOT_SUPPORTED

Error messages associated with this SQLState
ERROR 2009: string can not be used in function string
ERROR 2013: string clause is not supported for expressions
ERROR 2014: string Concatenated GZIP/BZIP is not supported with NATIVE/NATIVE VARCHAR formats
ERROR 2036: string is not a legal time unit
ERROR 2058: string VIEW is not supported
ERROR 2089: A correlated column in a subquery expression is not supported
ERROR 2114: ADD COLUMN over temporary tables is not supported
ERROR 2130: Aggregate function string (value) is not supported
ERROR 2133: Aggregate function calls cannot contain subqueries
ERROR 2138: Aggregate functions can only be called on columns of a table
ERROR 2161: ALL subquery with a correlated expression is not supported
ERROR 2165: ALTER COLUMN TYPE over temporary tables is not supported
ERROR 2166: ALTER TABLE does not support ADD COLUMN with other clauses
ERROR 2167: ALTER TABLE does not support ALTER COLUMN TYPE with other clauses
ERROR 2168: ALTER TABLE does not support DROP COLUMN with other clauses
ERROR 2169: ALTER TABLE does not support SET SCHEMA with other clauses
ERROR 2178: An expression containing a correlated subquery with aggregate function is not supported
ERROR 2183: Analytic functions are not allowed in an ORDER BY on a UNION/INTERSECT/EXCEPT
ERROR 2184: Analytic functions are not supported in the ORDER BY of an analytic function OVER clause
ERROR 2190: Analytics query with having clause expression that involves aggregates and subquery is not supported
ERROR 2192: ANALYZE_CONSTRAINTS is currently not supported in non-default locales
ERROR 2208: Another Design/Deployment is in progress
ERROR 2210: ANTI join with segmented inner not supported
ERROR 2220: Argument string must not contain subqueries
ERROR 2226: Argument to seeded random must be a constant
ERROR 2233: Array References are not supported
ERROR 2235: ArrayExpr is not supported
ERROR 2329: Cannot accept a value of type any
ERROR 2330: Cannot accept a value of type anyarray
ERROR 2331: Cannot accept a value of type anyelement
ERROR 2332: Cannot accept a value of type internal
ERROR 2333: Cannot accept a value of type language_handler
ERROR 2334: Cannot accept a value of type opaque
ERROR 2335: Cannot accept a value of type trigger
ERROR 2340: Cannot add IDENTITY/AUTO-INCREMENT columns
ERROR 2350: Cannot alter type of column "string" since it is referenced in the constraint "string"
ERROR 2351: Cannot alter type of column "string" since it is referenced in the default expression of column "string"
ERROR 2352: Cannot alter type of column "string" since it is referenced in the partition expression
ERROR 2353: Cannot alter type of column "string" since it is referenced in the segmentation expression of projection "string"
ERROR 2354: Cannot alter type of column with a default expression
ERROR 2360: Cannot assign to system column "string"
ERROR 2363: Cannot broadcast non-subquery outer input to a join
ERROR 2368: Cannot change owner of temporary table
ERROR 2377: Cannot convert column "string" from "string" to type "string"
ERROR 2392: Cannot delete from a view
ERROR 2399: Cannot display a value of type any
ERROR 2400: Cannot display a value of type anyelement
ERROR 2401: Cannot display a value of type internal
ERROR 2402: Cannot display a value of type language_handler
ERROR 2403: Cannot display a value of type opaque
ERROR 2404: Cannot display a value of type trigger
ERROR 2407: Cannot drop a table column when a node is down
ERROR 2411: Cannot drop column "string" since it is referenced in the partition expression
ERROR 2412: Cannot drop column "string" since it is referenced in the primary key constraint
ERROR 2425: Cannot export virtual string string
ERROR 2443: Cannot insert into a view
ERROR 2458: Cannot mergeout uncommitted data in the presence of savepoints
ERROR 2461: Cannot moveout uncommitted data in the presence of savepoints
ERROR 2503: Cannot set a subfield to DEFAULT
ERROR 2504: Cannot set an array element to DEFAULT
ERROR 2532: Cannot update a view
ERROR 2533: Cannot Update/Merge tables involved in prejoins with Limit clause on unsorted output
ERROR 2549: Cannot use DISTINCT with user-defined transform functions
ERROR 2552: Cannot use meta function or non-deterministic function in PARTITION BY expression
ERROR 2556: Cannot use SAVEPOINT with uncommitted tuple mover enabled
ERROR 2558: Cannot use subquery in EXECUTE parameter
ERROR 2559: Cannot use subquery in expressions within COPY
ERROR 2560: Cannot use subquery in PARTITION BY expression
ERROR 2561: Cannot use subquery in SEGMENTED BY expression
ERROR 2562: Cannot use Vertica's built-in file source and a UDSource in the same query
ERROR 2569: Catalog object string does not exist
ERROR 2602: Clause "NO PROJECTION" conflicts with the column list
ERROR 2603: Clause "NO PROJECTION" is supported only on temporary tables
ERROR 2618: CoerceToDomain is not supported
ERROR 2619: CoerceToDomainValue is not supported
ERROR 2628: Column "string" in PARTITION BY expression is not allowed, since it contains NULL values
ERROR 2646: Column string has the NOT NULL constraint set and has no default value defined
ERROR 2648: Column string in PARTITION BY expression is not allowed, since it is not present in some projections
ERROR 2649: Column string in PARTITION BY expression is not allowed, since it may contain NULL values
ERROR 2652: Column string occurred multiple times in the definition of Projection string
ERROR 2660: Column column string is no longer at position value in table string
ERROR 2667: Column name list is not allowed in CREATE TABLE / AS EXECUTE
ERROR 2672: Column type int2 is not supported
ERROR 2673: Column type int4 is not supported
ERROR 2676: Command string is not supported
ERROR 2679: COMMENT not supported for system objects
ERROR 2680: COMMENT not supported for this object type
ERROR 2692: Conditional UNION/INTERSECT/EXCEPT statements are not implemented
ERROR 2698: Conflicting or redundant column options
ERROR 2721: ConvertRowtypeExpr is not supported
ERROR 2725: Copy cannot return rejected rows from executor nodes
ERROR 2726: Copy cannot return rejected rows from more than one file
ERROR 2739: COPY force not null is available only in CSV mode, but CSV mode is not supported
ERROR 2740: COPY force quote is available only in CSV mode, but CSV mode is not supported
ERROR 2741: COPY FROM does not support the BINARY option
ERROR 2742: COPY FROM does not support the CSV option
ERROR 2743: COPY FROM does not support the OIDS option
ERROR 2744: COPY LOCAL does not support rejected row numbers with exceptions or rejected data options
ERROR 2751: COPY quote is available only in CSV mode, but CSV mode is not supported
ERROR 2770: Correlated EXISTS/NOT EXISTS subquery containing having clause with aggregates is not supported
ERROR 2772: Correlated EXISTS/NOT EXISTS subquery with limit 0 is not supported
ERROR 2773: Correlated EXISTS/NOT EXISTS with aggregate COUNT is not supported
ERROR 2776: Correlated EXISTS/NOT EXISTS with User Defined Aggregate is not supported
ERROR 2777: Correlated expression in ON clause is not supported
ERROR 2778: Correlated expression in set operator subquery is not supported
ERROR 2779: Correlated expressions in SELECT list of subquery are not supported
ERROR 2780: Correlated subqueries cannot have more than one level
ERROR 2781: Correlated subqueries with analytics in the select list is not supported
ERROR 2782: Correlated subqueries with no group by and a non-strict expression containing an aggregate in the select list is not supported
ERROR 2783: Correlated subquery column in select/gby/oby not supported
ERROR 2784: Correlated subquery could not be flattened as a join
ERROR 2785: Correlated subquery could not get flattened, a correlated expression could not be treated as a join
ERROR 2786: Correlated subquery expression without aggregates and with limit is not supported
ERROR 2787: Correlated subquery expressions under OR not supported
ERROR 2788: Correlated subquery in expression with operator <> is not supported
ERROR 2790: Correlated subquery with aggregate and limit 0 is not supported
ERROR 2792: Correlated subquery with aggregate function COUNT is not supported
ERROR 2793: Correlated subquery with distinct/group by is not supported
ERROR 2794: Correlated subquery with having clause expression that involves aggregates and subquery is not supported
ERROR 2795: Correlated subquery with NOT IN is not supported
ERROR 2796: Correlated subquery with outer joins and uncorrelated exists is not supported
ERROR 2797: Correlated subquery with User Defined Aggregate is not supported
ERROR 2854: Could not find array type for data type string
ERROR 2856: Could not find column string in table string
ERROR 2942: CREATE ASSERTION is not supported
ERROR 2943: CREATE FUNCTION / INOUT parameters are not supported
ERROR 2944: CREATE FUNCTION / OUT parameters are not supported
ERROR 2980: Data type not supported
ERROR 2981: Data type not supported (value)
ERROR 2983: Database "string" does not exist
ERROR 2987: Database references are not supported: "string.string.string"
ERROR 3026: Defining query must have a from clause
ERROR 3115: DistinctExpr not supported
ERROR 3116: Distrib overrides are too restrictive. Can not find completed Join Order
ERROR 3118: DML on projection/view is not supported
ERROR 3119: DML query with a predicate that could not be pushed below joins and does not refer solely to the target table is not supported
ERROR 3123: DROP ASSERTION is not supported
ERROR 3126: DROP COLUMN over temporary tables is not supported
ERROR 3132: DROP SEQUENCE does not support CASCADE
ERROR 3141: Dropping local and global objects in one statement is not supported
ERROR 3157: Dynamic load not supported
ERROR 3163: Embedded SQL involving local objects is not supported
ERROR 3174: ENCODED BY is supported in CREATE TABLE ... AS SELECT statement only
ERROR 3246: Error parsing distrib overrides (unexpected end of override); string
ERROR 3247: Error parsing distrib value; string
ERROR 3291: Event ANY_ROW is not supported
ERROR 3317: Executing when OPT:PLAN_ALL_NODES_ACTIVE option is set
ERROR 3343: Explicit JOIN clause contains a join predicate between relations previously joined
ERROR 3351: Expressions in COPY may not contain aggregate functions
ERROR 3352: Expressions in COPY may not contain analytic or Time Series Aggregate Functions
ERROR 3353: Expressions not supported in Times Series Aggregate Function
ERROR 3357: External tables only support files or a User Defined Source
ERROR 3403: FieldSelect is not supported
ERROR 3404: FieldStore is not supported
ERROR 3417: Final phase output size mismatch
ERROR 3420: First argument of date_part must be a constant string
ERROR 3434: For INSERT SELECT statement, replicated/broadcasted source data not supported
ERROR 3436: For SELECT DISTINCT, ORDER BY expressions must appear in the SELECT clause
ERROR 3451: Function string can't be used as a case expression
ERROR 3452: Function string can't be used in a boolean
ERROR 3453: Function string can't be used in a WHEN clause
ERROR 3454: Function string can't be used in as a segment expression
ERROR 3455: Function string can't be used with an operator
ERROR 3488: Group By, Order By, Aggregates, Having & limits not allowed in update/delete
ERROR 3510: IGNORE NULLS argument must be a Boolean constant
ERROR 3553: INHERITS not supported
ERROR 3566: Input of anonymous composite types is not implemented
ERROR 3600: Interpolated predicates can accept arguments of the same type only
ERROR 3601: Interpolated predicates can be part of AND expressions only
ERROR 3613: Interval units "string" not supported
ERROR 3821: Joins with an interpolated predicate can have a conjunctive expression containing equality predicates. The equality predicates cannot have expressions or column references with different modifiers
ERROR 3822: Joins with an interpolated predicate cannot have expressions or column references with different modifiers in any of the expressions
ERROR 3857: Library built with unsupported version of Vertica SDK [Version: string, Revision: string]
ERROR 3876: Locale must be a constant
ERROR 3900: MATCH PARTIAL is not supported
ERROR 3972: Multi-column subquery expressions can only be used with the =, <=>, and <> operators
ERROR 3973: Multi-column subquery type ALL can only be used with the = and <=>, operators
ERROR 3974: Multi-column subquery type ANY can only be used with the =, <=>, and <> operators
ERROR 4106: No single-source bulk loads have been executed in this session
ERROR 4147: Node issuing the query cannot be marked as down
ERROR 4160: Non-equality correlated subquery expression is not supported
ERROR 4170: Not a Star or Snow-Flake Query block
ERROR 4171: Not a Star or Snow-Flake Query block; dimension table not a star or snowflake
ERROR 4172: Not a Star or Snow-Flake Query block; no fact table found
ERROR 4173: Not a Star or Snow-Flake Query block; there are multiple fact tables
ERROR 4197: NULL value found in a column used by a subquery
ERROR 4228: ON COMMIT DROP not supported in CREATE TABLE
ERROR 4238: Only a temporary table projection can be pinned
ERROR 4248: Only inner joins are allowed in the projection defining query
ERROR 4256: Only relations and subqueries are allowed in the FROM clause
ERROR 4258: Only super user can call export_catalog with an output file name
ERROR 4259: Only super user can get the rebalance data script
ERROR 4263: Only superuser can drop system schema
ERROR 4264: Only superuser can rebalance data
ERROR 4265: Only superuser can rebalance data for replicated projections
ERROR 4266: Only superuser can rebalance data for segmented projections
ERROR 4280: Operator string (value) is not supported
ERROR 4281: Operator string is not supported for row expressions
ERROR 4298: ORDER BY on a UNION/INTERSECT/EXCEPT result must be on one of the result columns
ERROR 4299: ORDER mode not supported
ERROR 4306: OUTER join with broadcasted outer data not supported
ERROR 4307: OUTER or SEMI join - done through CROSS join and FILTER - with replicated outer and segmented inner not supported
ERROR 4308: OUTER relation in OUTER join is not the fact table nor a snowflake dimension table
ERROR 4309: Outer replicated/segmented input to a join cannot be resegmented
ERROR 4310: LEFTOUTER/SEMI/ANTI join with replicated/broadcasted outer data not supported
ERROR 4328: PARTITION AUTO can only be used with single-phase user defined transform functions
ERROR 4329: PARTITION AUTO cannot be used with pattern matching
ERROR 4331: PARTITION BY expression cannot return a tuple

Error Messages Associated with SQLSTATE 22008

This topic lists the errors associated with the SQLSTATE 22008.

SQLSTATE 22008 Description

ERRCODE_DATETIME_FIELD_OVERFLOW

Error messages associated with this SQLState

ERROR 2992: Date/time field value out of range: "string"
ERROR 4065: next_day(infinity, DOW) is not defined

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.
Error Messages Associated with SQLSTATE 22009

This topic lists the errors associated with the SQLSTATE 22009.

SQLSTATE 22009 Description

ERRCODE_INVALID_TIME_ZONE_DISPLACEMENT_VALUE

Error messages associated with this SQLState

ERROR 3768: Invalid timezone interval displacement
ERROR 5044: Timezone displacement out of range: "string"

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 2200B

This topic lists the errors associated with the SQLSTATE 2200B.

SQLSTATE 2200B Description

ERRCODE_ESCAPE_CHARACTER_CONFLICT

Error messages associated with this SQLState

ERROR 2699: Conflicting or redundant options
Error Messages Associated with SQLSTATE 2200D

This topic lists the errors associated with the SQLSTATE 2200D.

SQLSTATE 2200D Description

ERRCODE_INVALID_ESCAPE_OCTET

Error messages associated with this SQLState

ERROR 3285: ESCAPE strings must be a single octet, not "value"

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 22011

This topic lists the errors associated with the SQLSTATE 22011.

SQLSTATE 22011 Description

ERRCODE_SUBSTRING_ERROR

Error messages associated with this SQLState

ERROR 4034: Negative count not allowed
ERROR 4035: Negative length not allowed

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.
ERROR 4036: Negative or zero substring start position not allowed
ERROR 4039: Negative substring length not allowed
ERROR 4784: Start position cannot be 0

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 22012

This topic lists the errors associated with the SQLSTATE 22012.

SQLSTATE 22012 Description

ERRCODE_DIVISION_BY_ZERO

Error messages associated with this SQLState

ERROR 3117: Division by zero

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 22015

This topic lists the errors associated with the SQLSTATE 22015.

SQLSTATE 22015 Description

ERRCODE_INTERVAL_FIELD_OVERFLOW
Error messages associated with this SQLState

ERROR 3606: Interval field value out of range: “string”

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 22019

This topic lists the errors associated with the SQLSTATE 22019.

SQLSTATE 22019 Description

ERRCODE_INVALID_ESCAPE_CHARACTER

Error messages associated with this SQLState

ERROR 2729: COPY DELIMITER for column string must be a single character
ERROR 2730: COPY delimiter must be a single character
ERROR 2731: COPY ENCLOSED BY cannot be a whitespace character
ERROR 2732: COPY ENCLOSED BY for column string cannot be a whitespace character
ERROR 2733: COPY ENCLOSED BY for column string must be a single character
ERROR 2734: COPY ENCLOSED BY must be a single character
ERROR 2736: COPY ESCAPE AS for column string must be a single character
ERROR 2737: COPY ESCAPE must be a single character
ERROR 2758: COPY TRIM for column string must be an empty string or a single character
ERROR 2759: COPY trim must be an empty string or a single character
ERROR 3284: ESCAPE strings must be a single character, not "value"

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.
Error Messages Associated with SQLSTATE 2201B

This topic lists the errors associated with the SQLSTATE 2201B.

SQLSTATE 2201B Description

ERRCODE_INVALID_REGULAR_EXPRESSION

Error messages associated with this SQLState

ERROR 3742: Invalid regexp match_param: 'character'
ERROR 4552: Regexp match or recursion limit exceeded (rc value)
ERROR 4553: Regexp pattern error at offset value: string
ERROR 4554: Regexp pattern study error: string
ERROR 5064: Too many regular expression subexpressions

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 2201G

This topic lists the errors associated with the SQLSTATE 2201G.

SQLSTATE 2201G Description

ERRCODE_INVALID_ARGUMENT_FOR_WIDTH_BUCKET_FUNCTION

Error messages associated with this SQLState

ERROR 2939: Count must be greater than zero
ERROR 3888: Lower and upper bounds must be finite
ERROR 3889: Lower bound cannot equal upper bound
ERROR 4277: Operand, lower bound and upper bound cannot be NaN

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 22021
This topic lists the errors associated with the SQLSTATE 22021.

SQLSTATE 22021 Description
ERRCODE_CHARACTER_NOT_IN_REPERTOIRE

Error messages associated with this SQLState
ERROR 4551: Regexp encountered an invalid UTF-8 character

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 22023
This topic lists the errors associated with the SQLSTATE 22023.

SQLSTATE 22023 Description
ERRCODE_INVALID_PARAMETER_VALUE
Error messages associated with this SQLState

ERROR 2007: string can not be greater than PASSWORD_MAX_LENGTH value
ERROR 2008: string can not be set to a negative number
ERROR 2028: string exceptions and rejected_data can not be the same filename
ERROR 2042: string must be a positive integer
ERROR 2048: string Path [string] is a directory
ERROR 2049: string Path [string] is a socket

This topic lists the errors associated with the SQLSTATE 42725.

SQLSTATE 42725 Description

ERRCODE_AMBIGUOUS_FUNCTION

Error messages associated with this SQLState

ERROR 3459: Function string is not unique
ERROR 4289: Operator is not unique: string

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 42803

This topic lists the errors associated with the SQLSTATE 42803.

SQLSTATE 42803 Description

ERRCODE_GROUPING_ERROR
Error messages associated with this SQLState

ERROR 2134: Aggregate function calls in subqueries cannot refer to columns in parent (outer) query
ERROR 2135: Aggregate function calls may not be nested
ERROR 2140: Aggregates not allowed in GROUP BY clause
ERROR 2141: Aggregates not allowed in JOIN conditions
ERROR 2142: Aggregates not allowed in WHERE clause
ERROR 2219: Argument string must not contain aggregates
ERROR 2543: Cannot use aggregate function in EXECUTE parameter
ERROR 2544: Cannot use aggregate function in function expression in FROM
ERROR 2640: Column "string.string" must appear in the GROUP BY clause or be used in an aggregate function
ERROR 4300: ORDER/GROUP BY expression not found in targetlist
ERROR 4634: Rule WHERE condition may not contain aggregate functions
ERROR 4667: SEGMENTED BY expression may not contain aggregate functions
ERROR 4841: Subquery uses ungrouped column "string.string" from outer query
ERROR 6139: All non-aggregate expressions in the projection SELECT list must appear in the GROUP BY clause
ERROR 6187: Cannot use aggregate expressions in the projection SELECT list without a GROUP BY clause
ERROR 6277: Grouping functions not allowed in GROUP BY clause
ERROR 6278: Grouping functions not allowed in JOIN conditions
ERROR 6279: Grouping functions not allowed in WHERE clause
ERROR 7085: Aggregate function calls cannot contain grouping functions
ERROR 7099: Grouping functions cannot be nested
ERROR 7182: Grouping function arguments need to be group by expressions

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE 42804

This topic lists the errors associated with the SQLSTATE 42804.

SQLSTATE 42804 Description

ERRCODE_DATATYPE_MISMATCH
Error messages associated with this SQLState

ERROR 2217: Argument string must be type float, not type string
ERROR 2218: Argument string must be type integer, not type string
ERROR 2222: Argument string must not return a set
ERROR 2244: Argument of string must be type boolean, not type string
ERROR 2255: Argument of string must not return a set
ERROR 2311: Array assignment requires type string but expression is of type string
ERROR 2322: Array assignment to "string" requires type string but expression is of type string
ERROR 2334: Array subscript must have type integer
ERROR 2358: Cannot assign to field "string" of column "string" because its type string is not a composite type
ERROR 2527: Cannot subscript type string because it is not an array
ERROR 2630: Column "string" is of type string but default expression is of type string
ERROR 2631: Column "string" is of type string but expression is of type string
ERROR 2846: Could not determine actual result type for function "string" declared to return type string
ERROR 2850: Could not determine row description for function returning record
ERROR 3429: For 'string', types string and string are inconsistent
ERROR 3447: Function "string" in FROM has unsupported return type string
ERROR 3545: Index expression may not return a set
ERROR 3801: IS DISTINCT FROM requires = operator to yield boolean
ERROR 3943: Mismatched types in VALUES LESS THAN expressions
ERROR 4069: No column alias was provided
ERROR 4199: Number of aliases does not match number of columns
ERROR 4284: Operator string must not return a set
ERROR 4285: Operator string must return type boolean, not type string
ERROR 4317: Parameter $value of type string cannot be coerced to the expected type string
ERROR 4625: Row comparison operator must not return a set
ERROR 4626: Row comparison operator must yield type boolean, not type string
ERROR 4883: Subfield "string" is of type string but expression is of type string
ERROR 6480: Column "string" is of type string but expression in Access Policy is of type string. It will be coerced at execution time
ERROR 7221: Argument of type string must be type boolean, not string
ERROR 7222: Argument of type string must be type boolean, not type string
ERROR 7389: Column "string" is of type string but set using expression is of type string
ERROR 7788: Column must be a string type
ERROR 7929: Column to be added/refreshed is of type string but default/set-using expression is of type string
Error Messages Associated with SQLSTATE 42809

This topic lists the errors associated with the SQLSTATE 42809.

SQLSTATE 42809 Description

ERRCODE_WRONG_OBJECT_TYPE

Error messages associated with this SQLState

ERROR 2037: string is not a supported analytic function
ERROR 2131: Aggregate function calls cannot contain analytic function calls
ERROR 2132: Aggregate function calls cannot contain sequence function calls
ERROR 2668: Column notation .string applied to type string, which is not a composite type
ERROR 2755: COPY requires relation string to be a Table, not a string
ERROR 2810: Could not add location [string]: Directory not empty
ERROR 2811: Could not add location [string]: Not a directory
ERROR 3114: DISTINCT specified, but string is not an aggregate function
ERROR 3421: First argument to modularhash_wrapper must be an integer constant
ERROR 3422: First argument to modularhash_wrapper must be of type integer, not string
ERROR 3463: Function string(string) is not an aggregate
ERROR 3552: Inherited relation "string" is not a table
ERROR 3669: Invalid function given
ERROR 3965: modularhash_wrapper must have two arguments: an integer constant and a call to modularhash_internal
ERROR 3966: modularhash_wrapper second argument is not modularhash_internal or a constant
ERROR 4215: Object "string" is not a projection
ERROR 4270: Op ANY/ALL (array) requires array on right side
ERROR 4271: Op ANY/ALL (array) requires operator not to return a set
ERROR 4272: Op ANY/ALL (array) requires operator to yield boolean
ERROR 4542: Record type has not been registered
ERROR 4657: Second argument to string must be a non-negative integer constant
ERROR 4931: The argument to string cannot be null
ERROR 4932: The argument to string must be a constant
ERROR 4987: Third argument to string must be a constant
ERROR 5111: Type string is not composite
ERROR 6036: Table "string" is not a flex table
ERROR 6691: CAST and current_date/current_time functions are not supported as analytic functions
ERROR 6951: Skip lazy projection creation for table string.string since the object referenced by the hint is either invalid or of the wrong type (expected string)

This topic lists the errors associated with the SQLSTATE 42P20.

SQLSTATE 42P20 Description

ERRCODE_WINDOWING_ERROR

Error messages associated with this SQLState

ERROR 2011: string cannot use the WITHIN GROUP clause
ERROR 2041: string may only have one sort expression in the WITHIN GROUP clause
ERROR 2043: string must contain an ORDER BY clause within its analytic clause
ERROR 2044: string must NOT contain an ORDER BY clause or WINDOWING clause within its analytic clause
ERROR 2045: string must NOT contain WINDOWING clause within its analytic clause
ERROR 2047: string only supports the Integer, Float, Interval and Numeric data types
ERROR 2182: Analytic functions are allowed only in a SELECT list and/or ORDER BY clause
ERROR 2185: Analytic functions are not supported in the PARTITION BY of an OVER clause
ERROR 2188: Analytic functions must have a FROM clause
ERROR 2189: Analytic functions not allowed in string
ERROR 2305: Can’t cast the window bound into Int
ERROR 2306: Can’t cast the window bound into the same data type of the ORDER BY column
ERROR 2465: Cannot override ORDER BY clause of window "string"
ERROR 2466: Cannot override PARTITION BY clause of window "string"
ERROR 2524: Cannot specify frame clause of window "string"
ERROR 3435: For range moving window, OrderBy expression must be one of Int, Float, Time, Timestamp, Interval, Date or Numeric
ERROR 3446: Frame clause not allowed without windowing order by
ERROR 3839: Keyword "ALL" is invalid in analytic functions
ERROR 4362: PERCENTILE_CONT/PERCENTILE_DISC must have the WITHIN GROUP clause
ERROR 4363: PERCENTILE_CONT/PERCENTILE_DISC must NOT contain an ORDER BY clause or WINDOWING clause within its analytic clause
ERROR 4811: Subqueries are not supported in the PARTITION BY of a timeseries OVER clause
ERROR 5006: Time Series Aggregate Functions are not supported in the PARTITION BY of a timeseries OVER clause
ERROR 5010: Time Series timestamp alias/Time Series Aggregate Functions not allowed in string
ERROR 5460: Window "string" is already defined
ERROR 5461: Window frame cannot end with PRECEDING if start is CURRENT ROW
ERROR 5462: Window frame cannot end with PRECEDING or CURRENT ROW if start is FOLLOWING
ERROR 5463: Window frame cannot end with UNBOUNDED PRECEDING
ERROR 5464: Window frame cannot start with UNBOUNDED FOLLOWING
ERROR 5466: Window frame logical offset must be a non-negative number to be consistent with the sort column type
ERROR 5467: Window frame logical offset must be an Interval (Day to Second or Year to Month) to be consistent with the sort column type
ERROR 5468: Window frame logical offset must be an Interval (Day to Second) to be consistent with the sort column type
ERROR 5469: Window frame logical offset must be an interval to be consistent with the sort column type
ERROR 5470: Window frame logical offset must be Int when the sort column type is Int
ERROR 5471: Window frame logical offset must be the same type as the sort column type (Interval Day to Second)
ERROR 5472: Window frame logical offset must be the same type as the sort column type (Interval Year to Month)
ERROR 5473: Window frame logical or physical offset must be a constant
ERROR 5474: Window frame logical or physical offset must be non-negative number or interval
ERROR 5475: Window frame physical offset must be non-negative number
ERROR 5477: Window ordering clause can only contain a single sort key if RANGE is used
ERROR 5478: Windowing not supported for User Defined Analytic functions
ERROR 6276: Grouping functions cannot appear within Analytic functions
ERROR 6900: Partition Prepass/Batch may only be used with Live Aggregate Projection
ERROR 7838: Windowing not supported for analytic usage of BOOL_XOR

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

This topic lists the errors associated with the SQLSTATE V1001.

SQLSTATE V1001 Description

ERRCODE_LOST_CONNECTIVITY

Error messages associated with this SQLState

ERROR 2709: Connection to spread closed
ERROR 4048: NetworkReceive: Decompression failed
ERROR 4054: NetworkSend on string: failed to open connection to node string (string)
ERROR 4140: Node string was not successfully added to the cluster
ERROR 4142: Node failure during execution
ERROR 4533: Receive: Decompression failed
ERROR 4534: Receive on string: Message receipt from string failed [string]
ERROR 4541: ReceiveFiles on string: Unexpected end of stream from string [string]
ERROR 4547: ReceiveFiles on string: Open failed on node [string] (string)
ERROR 4572: RemoteSend: Open failed on node [string], IPAddr is [string], port is [value] (string)
ERROR 4683: Send: Connection not open [string tag:value plan value]
ERROR 4684: Send: Open failed on node [string] (string)
ERROR 4689: SendFiles on string: Open failed on node [string] (string)
ERROR 5579: Failure in send on socket string: string
ERROR 5624: NetworkReceive on string: failed to open connection to node string (string)
ERROR 5625: NetworkReceive on string: Message receipt from string failed: string
ERROR 5658: Send on string: Open failed on node [string] (Address lookup for string(string) failed)
ERROR 7116: Receive on string: open failed for node string (string) --- has query been cancelled?
ERROR 8537: DataTargetProxy on string: handle is canceled
ERROR 8538: DataTargetProxy on string: Unexpected end of stream from string [string]

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE V1002

This topic lists the errors associated with the SQLSTATE V1002.

SQLSTATE V1002 Description

ERRCODE_K_SAFETY_VIOLATION

Error messages associated with this SQLState

ERROR 2406: Cannot drop value nodes from a value node cluster with value nodes down - cluster would appear partitioned and database would shutdown. Bring some nodes up and try again
ERROR 2529: Cannot support K=value on only value nodes
ERROR 2957: Current system KSafe level is not fault tolerant
ERROR 4477: Projection KSafe value can not be met with only value nodes
ERROR 4478: Projection KSafe override value cannot be less than current system K-safe value value
ERROR 8556: Cannot drop node as with active subscribers
ERROR 8657: KSAFE > 0 for temporary table unsupported in Eon mode, no buddy projections created

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE V1003

This topic lists the errors associated with the SQLSTATE V1003.

SQLSTATE V1003 Description

ERRCODE_CLUSTER_CHANGE

Error messages associated with this SQLState

ERROR 2094: A node has come UP which missed ALTER COLUMN check
ERROR 2095: A node has come UP which missed drop partition keys check
ERROR 2096: A node has come UP which missed partitioning check
ERROR 2097: A node has entered the cluster since the session started
ERROR 2098: A node has entered the cluster since the session was started
ERROR 2099: A node has entered/left the database cluster
ERROR 5312: Up node set changed during restore
ERROR 5523: A node has come UP which missed ADD COLUMN statement
ERROR 6876: No nodes up!
ERROR 7214: Node types changed during restore
ERROR 8480: A node has come UP which missed ADD COLUMN O LOCK

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.
Error Messages Associated with SQLSTATE V2000

This topic lists the errors associated with the SQLSTATE V2000.

SQLSTATE V2000 Description

ERRCODE_AUTH_FAILED

Error messages associated with this SQLState

ERROR 3493: GSS error: string. Error details: (string/string)
ERROR 3718: Invalid old password
ERROR 6635: An error occurred during GSS authentication
ERROR 6636: An error occurred during kerberos authentication

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE V2001

This topic lists the errors associated with the SQLSTATE V2001.

SQLSTATE V2001 Description

ERRCODE_LICENSE_ISSUE

Error messages associated with this SQLState

ERROR 2382: Cannot create another node. The current license permits value node(s) and the database catalog already contains value node(s)
ERROR 3248: Error parsing license end date
ERROR 3863: License issue: string
ERROR 6164: Cannot alter STANDBY node. The current license permits value node(s) and the database catalog already contains value node(s)
ERROR 6549: Cannot install new license to the database. New license permits value node(s) but the database catalog already contains value node(s)
ERROR 7018: Unable to audit license: database lacks an active license!
ERROR 8263: No license found
ERROR 8268: No license found
ERROR 8277: Unable to overwrite existing licenses
ERROR 8450: Cannot drop the license. The remaining licenses permit value node(s) and the database catalog contains value node(s)
ERROR 8454: Some/All of your Vertica licenses have expired
ERROR 8458: Unsupported licensable feature

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE VC001

This topic lists the errors associated with the SQLSTATE VC001.

SQLSTATE VC001 Description

ERRCODE_CONFIG_FILE_ERROR

Error messages associated with this SQLState

ERROR 3833: Kerberos keytab file must be owned by the database user, and have no permissions for "group" or "other"
ERROR 4951: The Kerberos keytab file is either empty or too small in size to be valid

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.
Error Messages Associated with SQLSTATE VD001

This topic lists the errors associated with the SQLSTATE VD001.

SQLSTATE VD001 Description

ERRCODE_DESIGNER_FUNCTION_ERROR

Error messages associated with this SQLState

ERROR 2010: string cannot be NULL
ERROR 2012: string clause does not exist in the query
ERROR 2202: Anchor table for projection string does not exist, so it cannot be added to deployment
ERROR 2204: Anchor table of projection string is a Session scoped table
ERROR 2205: Anchor table of projection string is a System table
ERROR 2211: API string not available in old DBD engine
ERROR 2212: API cannot take query input file and query string, only one can be set
ERROR 2304: Can only load value string under the string design type
ERROR 2328: Cannot string as design was created already
ERROR 2336: Cannot add another Comprehensive design to deployment string
ERROR 2337: Cannot add design projections in extend catalog type deployment string in workspace string
ERROR 2338: Cannot add design to deployment string because design string has not been populated
ERROR 2369: Cannot clear design tables from design string because there are populated designs
ERROR 2375: Cannot compute projections to be dropped for only incremental designs deployment
ERROR 2394: Cannot design encoding for Projection string as it does not have any AUTO encoded columns
ERROR 2395: Cannot design encoding for Projection string as it is not SAFE -- Create its buddies
ERROR 2396: Cannot design/depoly for virtual system schema string
ERROR 2423: Cannot execute deployment when there are non-up-to-date safe projections for table string
ERROR 2454: Cannot load invalid query: string
ERROR 2456: Cannot load queries as design was populated already
ERROR 2463: Cannot output design projections because design is not available
ERROR 2464: Cannot output query because query id is invalid
ERROR 2471: Cannot populate drop projections in extend catalog type deployment string in workspace string
ERROR 2477: Cannot refresh projections for table value as it was dropped
ERROR 2480: Cannot remove any design table from design string because there are populated designs
ERROR 2485: Cannot remove workspace string because it does not exist
ERROR 2492: Cannot retrieve design tables for design string in workspace string
ERROR 2493: Cannot retrieve information for design string in workspace string
ERROR 2507: Cannot set k-safety when design string has been populated
ERROR 2657: Column 'string' does not exist in Table string
ERROR 2658: Column 'string' is duplicated in the column list
ERROR 3053: Deployment string already exists in workspace string
ERROR 3054: Deployment got canceled
ERROR 3056: Deployment ksafety should be equal or greater than design ksafety. Deployment ksafety is value and design ksafety is value
ERROR 3057: Deployment name cannot be NULL
ERROR 3058: Deployment Projections status is set to Error
ERROR 3060: Design string already exists
ERROR 3061: Design string already exists for workspace string
ERROR 3063: Design string has already been added to deployment string
ERROR 3064: Design string has not been populated in workspace string so projection cannot be added
ERROR 3065: Design string hasn't been populated
ERROR 3066: Design string in workspace string is not available
ERROR 3067: Design string is already populated
ERROR 3068: Design string is populated, remove design first (designer_remove_design)
ERROR 3071: Design name cannot have more than value characters
ERROR 3072: Design name may contain only alphanumeric or underscore characters
ERROR 3073: Design did not complete successfully, so deployment did not start
ERROR 3074: Design K-safety should be 0
ERROR 3077: Design name cannot have character '.'
ERROR 3079: Optimization objective cannot be NULL
ERROR 3080: Design query with design_query_id value does not exist
ERROR 3081: Design Query with design_query_id string does not exist
ERROR 3082: Design string does not exist
ERROR 3087: design_override_type string for query (design_query_id value) already exists
ERROR 3088: design_override_type string for table string already exists
ERROR 3089: design_override_type string for table string does not exist
ERROR 3100: Did not find any projections to design encodings for
ERROR 3101: Did not find design projections for projection ids given
ERROR 3102: Did not find design projections for tablePattern string
ERROR 3103: Did not find design tables to add
ERROR 3104: Did not find design tables to remove
ERROR 3105: Did not find projection id value in deployment string in workspace string
ERROR 3106: Did not find projections for design string in workspace string
ERROR 3107: Did not find rows in deployment table for deployment string in workspace string
ERROR 3108: Did not find rows in designs table for workspace string
ERROR 3140: Dropping design without getting design projections, API call is of no use
ERROR 3166: Empty design name is not allowed
ERROR 3188: Error after projection refresh: string
ERROR 3194: Error creating workspace: Invalid workspace name
ERROR 3195: Error deleting deployment status table
ERROR 3202: Error during deployment while setting k-safety before deployment starts
ERROR 3203: Error during design: string
ERROR 3205: Error during drop projections: string
ERROR 3208: Error during projection creation: string
ERROR 3214: Error during remove design string
ERROR 3215: Error during rename projections: string
ERROR 3241: Error opening query input file [string]
ERROR 3250: Error querying deployment projections statements table
ERROR 3251: Error querying deployment projections table
ERROR 3252: Error querying design projections table for design string in workspace string
ERROR 3253: Error querying: string
ERROR 3266: Error status for projections to add for table string
ERROR 3267: Error status for projections to drop for table string
ERROR 3268: Error updating deployment projections table
ERROR 3270: Error while loading statistics into design tables for design string
ERROR 3277: Error writing to [string]
ERROR 3356: External table string is not a design table
ERROR 3358: Failed during select mark_design_ksafe(value)
ERROR 3415: Filename cannot be NULL
ERROR 3480: Given design string does not exist
ERROR 3489: Group-by override value on query value cannot be satisfied
ERROR 3543: Incremental design needs a query or an input query file to be set
ERROR 3574: INSERT query without SELECT is not supported: string
ERROR 3649: Invalid Deploy Operation string string
ERROR 3650: Invalid deploy status string string
ERROR 3740: Invalid query input file [string]
ERROR 3795: Invalid design creator name
ERROR 3817: Join override value on query value cannot be satisfied
ERROR 3824: K cannot be value (maximum allowed is value)
ERROR 3825: K must be equal to or greater than value, cannot reduce current k-safety level
ERROR 3827: K-safety cannot be NULL
ERROR 3867: List of projections cannot be NULL
ERROR 3898: mark_design_ksafe(value) failed; some projections may not be k-safe
ERROR 4031: Namespace for LOCAL temporary tables cannot be used to add design tables
ERROR 4057: New k-safety cannot be less than 0
ERROR 4078: No deployment data in string.string
ERROR 4080: No drop entries found for deployment string in workspace string
ERROR 4099: No projections found for the projection ids string string
ERROR 4117: No tables found in schema string
ERROR 4118: No tables found in the table pattern given
ERROR 4119: No tables to design projections for
ERROR 4235: One of the design tables no longer exist
ERROR 4311: Override (design_override_id value) is ignored because the table string is no longer a design table
ERROR 4312: Override (design_override_id value) is ignored because the table does not exist
ERROR 4313: override_type string for query (design_query_id value) does not exist
ERROR 4314: override_type string is invalid
ERROR 4460: Projection string does not exist
ERROR 4461: Projection string does not exist
ERROR 4466: Projection string to be refreshed was dropped
ERROR 4475: Projection id cannot be NULL
ERROR 4476: Projection id list cannot be NULL
ERROR 4479: Projection name cannot be NULL
ERROR 4497: Query Id cannot be NULL
ERROR 4498: Query referencing EPOCH column is not supported
ERROR 4499: Query referencing local temporary table string is not supported: string
ERROR 4500: Query referencing projection string is not supported: string
ERROR 4501: Query without referencing any catalog table is not supported: string
ERROR 4503: Query table string does not exist
ERROR 4504: Query table contains multiple entries with qid = value
ERROR 4505: Query weight must be a positive number
ERROR 4525: Rebalance data cannot proceed when there are non-up-to-date projections in the catalog
ERROR 4526: Rebalance data failed during select mark_design_ksafe(value)
ERROR 4651: Schema string does not exist
ERROR 4652: Schema string is not a designer created schema, so it cannot be dropped
ERROR 4655: Schema name cannot be NULL
ERROR 4721: Session scoped table string is not a design table
ERROR 4783: Start deploy: deploy is already running on this node
ERROR 4819: Subqueries in UPDATE/DELETE is not supported: string
ERROR 4866: System table string is not a design table
ERROR 4874: Systems tables within system schema string cannot be added as design tables
ERROR 4885: Table string does not exist
ERROR 4886: Table string does not exist anymore in the catalog
ERROR 4888: Table string has no statistics or data. As a result, the proposed projections on this table may be suboptimal
ERROR 4890: Table string is not a design table
ERROR 4891: Table string is not a design table, referenced in query (qid=value): string
ERROR 4902: Table name cannot be NULL
ERROR 4907: Table pattern cannot be NULL
ERROR 4920: Terminated after SO enum. See log for the content of the SOs
ERROR 4942: The design table entry with table name string.string is corrupted, as that table has been renamed in the Vertica catalog
ERROR 4976: There are value nodes. Deployment K = value is not possible
ERROR 4977: There are no projections to add in deployment string for workspace string so no projections can be dropped
ERROR 4980: There is 1 node. Deployment K = value is not possible
ERROR 4981: There is more than one design string in workspace string
ERROR 4983: There is no design tables system table in workspace string
ERROR 4991: This invalid query cannot be loaded: string
ERROR 4994: This non-SELECT query is not supported: string
ERROR 4995: This query is not supported in DBDesigner
ERROR 5363: User string does not have privileges to access design table: string
ERROR 5364: User string does not have privileges to access table: string
ERROR 5390: User has insufficient privileges on table string
ERROR 5480: Workspace string cannot be a virtual system schema
ERROR 5481: Workspace string does not exist
ERROR 5482: Design string is configured for extend_catalog so no designs can be computed
ERROR 5483: Design string is configured for extend_catalog so remove drops is not supported
ERROR 5484: Design string is configured for extend_catalog so there are no design tables
ERROR 5485: Design string is configured for extend_catalog, there are no design tables
ERROR 5486: Workspace cannot be NULL
ERROR 5487: Design name cannot be NULL
ERROR 5564: Deployment Parallelism cannot be less than zero
ERROR 5565: Deployment parallelism cannot be NULL
ERROR 5573: Error generating results set
ERROR 5575: Error querying designs table
ERROR 5588: Fenced mode false is not supported for string functions
ERROR 5589: Fenced mode is not supported for SQL functions
ERROR 5591: Hurryup parameter cannot be NULL
ERROR 5597: Invalid input query: 'string'
ERROR 5650: Query without referencing any design tables is not supported: string
ERROR 5657: Segmentation type of the projection string is not supported for encoding design, skipping
ERROR 5694: Weight for query_text 'string' is 'value'. Only positive weight values are accepted
ERROR 5747: analyzeStats flag cannot be NULL
ERROR 5773: Cannot output deployment script because design is not available
ERROR 5792: continueAfterError flag cannot be NULL
ERROR 5817: Deploy flag cannot be NULL
ERROR 5855: Did not find any tables to analyze correlations on
ERROR 5857: dropDesignAndCtx flag cannot be NULL
ERROR 5858: dropProjs flag cannot be NULL
ERROR 5866: Error while analyzing correlations for design table string.string
ERROR 5867: Error while analyzing count distincts for design table string.string
ERROR 5868: Error while analyzing count distincts on correlation sample for design table string.string
ERROR 5869: Error while analyzing segmentation skew for design table string.string
ERROR 5870: Error while dropping existing correlations in design table string
ERROR 5871: Error while loading or analyzing correlations in design tables for design string
ERROR 5907: Force option cannot be NULL
ERROR 5908: forceRecomputation flag cannot be NULL
ERROR 5919: Input cannot be NULL
ERROR 5938: isAdminUser flag cannot be NULL
ERROR 5939: K-safety of incremental designs must match the current system k-safety (which is value)
ERROR 5979: onlyScript flag cannot be NULL
ERROR 6040: Table string has no correlations
ERROR 6041: Table string has no data. As a result, no correlations were analyzed on this table
ERROR 6042: Table string has no statistics or data. As a result, no correlations were analyzed on this table
ERROR 6043: Table string has no statistics or data. As a result, no correlations were read into this table
ERROR 6049: The mode of analyzing correlations cannot be NULL
ERROR 6050: The mode of analyzing correlations is invalid
ERROR 6096: User has insufficient privileges on table string.string
ERROR 6223: Design K-safety should be in [0,value] range
ERROR 6247: Error during deployment: no projections found for deployment string
ERROR 6489: Error querying v_catalog.projections table
ERROR 7191: Projection with expressions string is not supported for encoding design
ERROR 7192: Projection with expressions string is not supported for encoding design, skipping
ERROR 7379: Cannot generate unique name for Database Designer schema
ERROR 8487: No new projections recommended for deployment by DBD

Error Messages Associated with SQLSTATE VX002

This topic lists the errors associated with the SQLSTATE VX002.

SQLSTATE VX002 Description

ERRCODE_DATA_CORRUPTED

Error messages associated with this SQLState

ERROR 2940: CRC Check Failure Details:
    File Name: string
    File Offset: value
    Compressed size in file: value
    Memory Address of Read Buffer: value
    Pointer to Compressed Data: value
    Memory Contents:
        string

ERROR 3030: Delete: could not find a data row to delete (data integrity violation?)

ERROR 3218: Error finalizing ROS DataTarget

ERROR 3219: Error flushing data file [string]

ERROR 3409: FclColumnReader: block string @ value 's CRC value doesn't match record value

ERROR 3410: FclColumnReader: Decompression error in string at offset value

ERROR 4762: Sort Order Violation:
    Row Position: value
    Column Index: value
    Last Row: string
    This Row: string

ERROR 5704: Delete (Join): could not find a data row to delete (data integrity violation?)

ERROR 6767: Error reading from orc parser input stream [string]: file shorter than expected, read to value, requested to value

ERROR 7767: Error reading from parquet parser input stream [string]: file shorter than expected, read to value, requested to value

ERROR 7859: Block[value] has unknown type. (size: value, type: value, pad: value, count: value, position: value)

ERROR 7860: Block[value]->count is not consistent with other blocks. (value != value)

Error Messages Associated with SQLSTATE VX003

This topic lists the errors associated with the SQLSTATE VX003.

SQLSTATE VX003 Description

ERRCODE_INDEX_CORRUPTED

Error messages associated with this SQLState

ERROR 3544: Index corruption. string: string

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.

Error Messages Associated with SQLSTATE VX004

This topic lists the errors associated with the SQLSTATE VX004.

SQLSTATE VX004 Description

ERRCODE_PLAN_TO_SQL_INTERNAL_ERROR

Error messages associated with this SQLState

ERROR 8643: Optimizer-generated annotated query has unexpected error. Please report to Vertica

Note: The Vertica User Community contains knowledge base articles, blogs, and forum posts that may help you resolve these errors.
Glossary

The Vertica Glossary defines terms that are common and specific to Vertica.
Access Rank

Determines the speed at which a column can be accessed. Columns are stored on disk from the highest ranking to the lowest ranking in which the highest ranking columns are placed on the fastest disks and the lowest ranking columns are placed on the slowest disks.
Administration Host

The host on which the Vertica rpm package was manually installed. Always run the Administration Tools on this host if possible.
Administration Tools

One of the ways you can manage a Vertica database is provided in the form of a graphical user interface, called Administration Tools.

This tool allows you to perform various tasks quickly and easily, some of which are:

- View the state of the database cluster
- Create a database
- Start a database
- Stop a database
- Run Database Designer
- Connect to a database using vsql

Using the following command, always run the Administration Tools on the Administration Host if possible.

```
$ /opt/vertica/bin/adminTools
```

**Note:** Throughout the Vertica documentation, you might see Administration Tools referred to as Admin Tools or admintools or adminTools. They all refer to the same utility.

For more information, see Administration Tools.
Agent

A daemon process that runs on each Vertica cluster node. The agent is used by certain clients, such as Management Console, to administer Vertica.

Agents monitor Vertica database clusters and communicate with their clients to provide the following functionality:

- Provide local access, command, and control over database instances on a given node, using functionality similar to Administration Tools
- Report log-level data from the Administration Tools and Vertica log files
- Cache details from long-running jobs—such as create/start/stop database operations—that you can view through your browser
- Track changes to data-collection and monitoring utilities and communicate updates to clients
- Specifically for MC, communicate between all cluster nodes and MC through a webhook subscription, which automates information sharing and reports on cluster-specific issues like node state, alerts, events, and so on

The agent runs on port 5444, which must be accessible to agent clients.
**Anchor Table**

Database table that is the source for data in a projection. The anchor table and its projection must be in the same schema. The privileges to create, access, or alter a projection are based on the anchor tables that the projection references, as well as the schemas that contain them.

In the following simple statement, public data is the anchor table:

```
=> CREATE PROJECTION publicdataproj AS (SELECT * FROM publicdata);
```
Ancient History Mark (AHM)

Also known as AHM, the ancient history mark is the oldest epoch whose data is accessible to historical queries. Any data that precedes the AHM is eligible to be purged.

For detailed information, see Understanding Vertica Epochs in the Vertica Knowledgebase.
Apportioned Load

An *apportioned load* is a divisible load, such that you can load a single data file on more than one node. Each load starts at a different offset, requiring a parser that supports apportioning. Some of the parsers built into Vertica support apportioned load. Using the SDK, you can write parsers that perform apportioned loads.
**Authentication Service (AS)**

A service that usually runs on the same host as the Kerberos Key Distribution Center (KDC). The AS issues tickets for a requested service. The tickets are in turn given to users for access to the service. The AS answers requests from clients that do not send credentials with a request. The AS is generally used to gain access to the ticket-granting service (TGS) by issuing a ticket-granting ticket (TGT).
Automatic Tuple Mover (ATM)

The Automatic Tuple Mover (ATM) refers to the Tuple Mover operations that occur automatically at regular intervals set by configuration parameters. For example, two configuration parameters control the TM mergeout and moveout intervals, which are both ATM activities. Conversely, invoking the `do_tm_task` function is not an ATM activity. For information about changing the TM configuration parameters, see Tuple Mover Parameters in the Administrator's Guide for further information.
Bitstring

A sequence of bits.
**Buddy Projection**

Required for K-safety. Two projections are considered to be buddies if they contain the same columns and have the same hash segmentation, using different node ordering.

For more information, see:

- High Availability With Projections
- Designing Segmented Projections for K-Safety
- GET_PROJECTION_STATUS
**Bulk Loading**

A process of loading large amounts of data, such as an initial load of historic data.
C-Store

A research project at MIT, Brandeis, Brown, and the University of Massachusetts (Boston), on which Vertica is based.
Cardinality

Refers to the number of unique values for a given column in a relational table:

- **High cardinality**: Refers to columns containing values that are highly unique, such as a customer ID or an employee e-mail address. For example, in the Vertica VMart schema, the employee_dimension table contains an employee_key column. This column contains values that uniquely identify each employee. Since the values in this column are unique and could be numerous, the column's cardinality type is referred to as high cardinality.

- **Normal cardinality**: Refers to columns containing values that are less unique, such as job titles and street addresses. An example of a normal-cardinality column would be job_title or employee_first_name in the employee_dimension table, where many employees could share the same job title or same first name.

- **Low cardinality**: Refers to a low number of unique values, relative to the overall number of records in a table. For example, in the employee_dimension table, the column called employee_gender would contain two unique values: 'Male' or 'Female'. Since there are only two values possible in this column, cardinality is low.
Catalog

A set of files that contains information (metadata) about the objects—such as nodes, tables, constraints, and projections—in a database. Vertica maintains a catalog on each node in the cluster.
Catalog Path

A storage location used to store the database catalog.
**Checkpoint Epoch**

Every time the Tuple Mover performs a move-out operation for a given projection, it records a checkpoint epoch for that projection, representing an epoch up to which the projection has no data in the WOS. The minimum checkpoint epoch across all projections on a given node is that node’s checkpoint epoch, which represents a point in time up to which all the data was moved out to disk. If a K-safe=1 database experiences a single-node failure, the node's recovery process attempts to rebuild the data beyond the checkpoint epochs from other nodes. If all nodes fail, such as during a power outage, Vertica recovers the database back to the minimum checkpoint epochs across all nodes, or last good epoch (LGE).
Cluster

The concept of Cluster in the Vertica Analytics Platform is a collection of hosts with the Vertica software packages (RPM or DEB) that are in one admin tools domain. You can access and manage a cluster from one admintools initiator host.
Columnar Tables

Vertica database tables consisting of structured data columns. The term differentiates these tables from Flex (or Flexible) tables, which minimally contain one column of unstructured, or semi-structured data. Flex tables can also have structured data columns, but they are not required. Compare with Flexible Tables.
Control node

In a large-cluster arrangement, Vertica Analytic Database delegates control message responsibilities to a subset of nodes, called control nodes, to improve control message performance. Control nodes communicate with each other, and non-control nodes are assigned to a control node for control message communications. See Large Cluster in the Administrator’s Guide.
Correlated columns

Two columns are correlated if the value of one column is related to the value of the other column. For example, state name and country name columns are strongly correlated because the city name usually, but perhaps not always, identifies the state name. The city of Conshohoken is uniquely associated with Pennsylvania, whereas the city of Boston exists in Georgia, Indiana, Kentucky, New York, Virginia, and Massachusetts. In this case, city name is strongly correlated with state name.
Critical Node

A critical node is a node whose failure would cause the database to become unsafe and force a shutdown. Nodes can become critical for the following reasons:

- A node has the only copy of a particular projection.
- Fewer than half of your nodes are active.

The `V_MONITOR.CRITICAL_NODES` system table lists the critical nodes, if any, in your cluster.
Current epoch

The epoch into which data (COPY, INSERT, UPDATE, and DELETE operations) is currently being written.
Data Collector

A utility that collects and retains database monitoring information.

Note: Data Collector works in conjunction Workload Analyzer, which intelligently monitors the performance of SQL queries and workloads and recommends tuning actions based on observations of the actual workload history.

Data Collector retains history of important system activities and records essential performance and resource utilization counters. You can use information retained by the Data Collector in the following ways:

- As a reference for what actions users have taken
- To locate performance bottlenecks
- To identify potential improvements to Vertica configuration

Data Collector is on by default. If you need to change this behavior, see Data Collector Parameters in the Administrator's Guide. See also the SQL Reference Manual for information about data collection control functions.
Data Path

A storage location that contains actual database data files.
Database

A cluster of nodes that, when active, can perform distributed data storage and SQL statement execution through administrative, interactive, and programmatic user interfaces.
Database Designer

A tool that analyzes a logical schema definition, sample queries, and sample data, and creates a physical schema (projections) in the form of a SQL script that you deploy automatically or manually. The script creates a minimal set of superprojections to ensure K-safety, and, optionally, non-superprojections. In most cases, the projections created by the Database Designer provide excellent query performance within physical constraints.

The Database Designer can create two distinct design types. The design you choose depends on what you are trying to accomplish:

- **Comprehensive Design**
- **Incremental Design**

You can also create custom designs if the Database Designer does not meet your needs. For detailed information, see Creating a Database Design.
Database superuser

The automatically-created database user who has the same name as the Linux database administrator account and who can bypass all GRANT/REVOKE authorization, or any user that has been granted the PSEUDOSUPERUSER role. Do not confuse the concept of a database superuser with Linux superuser (root) privilege. A database superuser cannot have Linux superuser privilege.
**DELTAVAL (delta encoding)**

Stores only the differences between sequential data values instead of the values themselves.
Derived Column

A column whose values are calculated by an expression at load time. The expression is specified within the COPY statement, and the column exists in the target database.
Dimension Table

Sometimes called a lookup or reference table, a dimension table is one of a set of companion tables to a large (fact/anchor) table in a star schema. It contains the PRIMARY KEY column corresponding to the join columns in fact tables. For example, a business might use a dimension table to contain item codes and descriptions.

Dimension tables can be connected to other dimension tables to form a hierarchy of dimensions in a snowflake schema.
**Directed Query**

A saved set of instructions that direct the optimizer to generate a query plan for a given query. The query plan consists of SQL annotated with hints. A directed query pairs two components:

- **Input query**: A query that triggers use of this directed query when it is active.
- **Annotated query**: A SQL statement with embedded optimizer hints. The annotated query is used by the optimizer in creating a query plan for the specified input query.
Encoding

The process of converting data into a standard format. In Vertica, encoded data can be processed directly, while compressed data cannot. Vertica uses a number of different encoding strategies, depending on column data type, table cardinality, and sort order.
Enterprise Mode

A database mode that optimizes your database for analytic speed. This is the "original" mode of the Vertica database—the only mode it supported until the introduction of Eon Mode in Vertica 9.1. In this mode, data is stored by the database nodes. This proximity allows nodes to operate on locally stored data for most queries, reducing query times. An Enterprise Mode database is harder to scale up and down than an Eon Mode database, which is optimized for scalability.
Eon Mode

Eon Mode is the database mode that optimizes your database for scalability. This mode separates data storage from computing resources. By separating the two, you can add or remove nodes from your cluster to adjust growing or shrinking analytic workloads. Scaling the cluster size does not affect running queries. Eon Mode is especially well-suited for cloud environments. Currently, Eon Mode only works in AWS.
**Epoch**

A logical unit of time in which a single change is made to data in your Vertica database.

For detailed information, see Understanding Vertica Epochs in the Vertica Knowledgebase.
Epoch Map

A catalog object that provides mapping between time and epochs. Specifically, an epoch map contains a list of epoch numbers and their associated timestamps.
**Executor Node**

Any node that participates in executing a specific SQL statement. The initiator node can, and usually does, also function as an executor node.
External Procedure

A procedure external to Vertica that you create, maintain, and store on the server.
Event Series

Tables with a time column, most typically a timestamp data type.
Flexible Tables

Vertica database tables that minimally contain two columns:

__identity__: A real column with an incrementing IDENTITY value for partitioning and sorting. Used if no other columns serve this purpose.

__raw__: A real LONG VARBINARY column containing unstructured, or semi-structured data.

You can create Flex tables with additional real columns, but they are not required. Compare with Columnar Tables.
Flattening (subqueries and views)

Occurs when a subquery or named view is internally rewritten so the subquery is combined with the outer query block. The result sets of the original and flattened queries are exactly the same, but the flattened query usually benefits from significant performance improvements.
**Full Backup**

Consists of copying each catalog and all data files (ROS containers) on each node, as well as the complete /opt/vertica/config directory.
GENERAL Pool

A special built-in pool that represents the total amount of RAM available to the resource manager for use by queries. Other pools can borrow memory from the GENERAL pool. See also Built-In Pools.
Grant

Vertica defines GRANT in two ways:

1. Grant a user privileges to access database objects using any GRANT statement, except GRANT (Authentication).

2. Associate a user-defined authentication method with a user through GRANT (Authentication). This operation differs from GRANT <privileges> as authentication methods are “associated” with a user or role and privileges are “granted” to a user or role.

Examples

Grant Access Privileges to a User

This example shows how to grant a user, Joe, privileges to access the online_sales schema:

```sql
=> GRANT USAGE ON SCHEMA online_sales TO Joe;
```

Associate an Authentication Method with a User

This example shows how to associate the v_ldap authentication method to user jsmith:

```sql
=> GRANT AUTHENTICATION v_ldap TO jsmith;
```
Grouped ROS

A grouped ROS is a highly-optimized, read-oriented physical storage structure organized by projection. A grouped ROS makes heavy use of compression and indexing. Unlike a ROS, a grouped ROS stores data for two or more grouped columns in one disk file.
Hash Segmentation

Specifies how to segment projection data for distribution across some or all cluster nodes. You can specify segmentation for a table and a projection. If a table definition specifies segmentation, Vertica uses it for that table's auto-projections.

It is strongly recommended that you use Vertica's built-in HASH function, which distributes data evenly across the cluster, and facilitates optimal query execution.

For more detailed information, see Projection Segmentation.
**Historical Data**

Refers to any data in memory or physical storage other than the current epoch. Historical data includes all COPY, INSERT, UPDATE, and DELETE operations, including deleted rows. This allows Vertica to run a historical query on data written up to and including the epoch representing the specified date and time.
**Historical Query**

A query that retrieves data from a snapshot of the database, taken at a specific timestamp or epoch. For details, see *Historical Queries* in Analyzing Data.
Immutable (Invariant) Functions

When run with a given set of arguments, immutable functions such as $\text{AVG()}$ always produce the same result, regardless of environment or session settings such as locale.

Some immutable functions can take an optional stable argument; in this case they are treated as Stable functions.
**Initiator Node**

In the context of a client connection, the initiator node is the node associated with the specific host to which the connection was made. The initiator node can, and usually does, also function as an executor node, and is generally where the most descriptive log messages reside.
**K-Safety**

K-safety sets fault tolerance for the database cluster, where \( K \) can be set to 0, 1, or 2. The value of \( K \) specifies how many copies Vertica creates of segmented projection data. If K-safety for a database is set to 1 or 2, Vertica creates \( K+1 \) instances, or *buddies*, of each projection segment. Vertica distributes these buddies across the database cluster, such that projection data is protected in the event of node failure. If any node fails, the database can continue to process queries so long as buddies of data on the failed node remain available elsewhere on the cluster.

For more information, see Using Database Designer.
**Last Epoch**

The last epoch is the current epoch minus one. SELECT statements under READ COMMITTED isolation read from the last epoch.
**Last Good Epoch (LGE)**

A term used in manual recovery, LGE (Last Good Epoch) refers to the most recent epoch that can be recovered.
Live Aggregate Projection

A live aggregate projection contains columns with values that are aggregated from columns in its anchor table. When you load data into the table, Vertica aggregates the data before loading it into the live aggregate projection. On subsequent loads—for example, through `INSERT` or `COPY`—Vertica recalculates aggregations with the new data and updates the projection.
Locale

Locale specifies the user’s language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate GROUP BY and ORDER BY clauses, joins, and the analytic ORDER BY clause.

The default locale for a Vertica database is en_US@collation=binary (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default en_US@collation=binary collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to en_US_POSIX. You can set the locale back to the default locale and collation by issuing the vsql meta-command \locale. For example:

```
=> set locale to '';
INFO 2567: Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET
=> \locale en_US@collation=binary;
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> \locale
en_US@collation-binary;
```

You can set locale through ODBC, JDBC, and ADO.net.
Logical Schema

Consists of a set of tables and referential integrity constraints in a Vertica database. The objects in the logical schema are visible to SQL users. The logical schema does not include projections, which make up the physical schema.
Location Label

A label assigned to a storage location. Location labels identify the location so you can create object storage policies. The labeled location you use in a storage policy becomes the default storage location for the object.
Management Console

A database management tool that provides a unified view of your Vertica database and lets you monitor multiple clusters from a single point of access. See Management Console in Vertica Concepts.
MC Super (superuser administrator)

Called Super on the MC interface, the MC super is the Linux user account that gets created when you configure MC. See Configuring MC and SUPER Role (mc).
**MC-managed Database**

A Vertica database that an MC SUPER or ADMIN user creates on MC or imports into the MC interface, along with the database cluster. When MC users are granted database privileges, their privileges are defined through the MC itself and pertain only to databases managed on the MC. See About MC Privileges and Roles.
Manual Recovery

The process of recovery after an unclean shutdown of the database, where the administrator must accept recovery from the Last Good Epoch, which could lead to loss of some recently loaded data. See Failure Recovery.
**Mergeout**

Mergeout is the Tuple Mover process that consolidates ROS containers and purges deleted records.
**Meta-Functions**

Used to query or change the internal state of Vertica and are not part of the SQL standard. See [Vertica Meta-functions](#) in the SQL Reference Manual.
**Metadata**

Data that describes the data in a database, such as data type, compression, constraints, and so forth, for each column in the tables. Metadata is stored in the Vertica catalog.
Moveout

The Tuple Mover operation of moving data from the WOS (Write Optimized Store), which is kept in memory, to the ROS (Read Optimized Store), which is kept on disk.
Node

A host configured to run an instance of Vertica. It is a member of the database cluster. For a database to have the ability to recover from the failure of a node requires a database K-safety value of at least 1 (3+ nodes).
Non-Repeatable Read

Occurs in a READ COMMITTED isolation level when two identical queries in the same transaction produce different results. This occurs when another transaction commits changes that alter the results of the query after the first query has completed and before the second query has begun.
NUL

Represents a character whose ASCII/Unicode code is zero, sometimes qualified "ASCII NUL".
**NULL**

Means *no value*, and is true of a field (column) or constant but not of a character.
OID

An object identifier (OID) is an identifier used to name an object. Structurally, an OID consists of a node in a hierarchically-assigned namespace, formally defined using the International Telecommunication Union-Telecommunication's (ITU-T) Abstract Syntax Notation standard (ASN.1). Vertica database objects are always assigned an OID. The OID can be used directly in some statements, such as `HAS_TABLE_PRIVILEGE`.

*Source: Wikipedia*
Parallel Load

*Parallel load* is the process of loading data on any available node in the cluster (not necessarily the local node). Use this approach in combination with wildcards (such as *.dat) to load data files in parallel in a distributed manner. See COPY ON ANY NODE in COPY Parameters.
Path (quality plan)

The execution strategy of the Vertica cost-based query optimizer, denoting a sub operation in the query plan.
Partitioning

Specifies how data is organized within individual nodes. Partitioning attempts to introduce hot spots within the node, providing a convenient way to drop data and reclaim the disk space.

Note: Partitioning and segmentation are terms often used interchangeably for other databases, but they have completely separate goals in Vertica regarding data localization. See Partitioning and Segmentation in the Administrator's Guide for details.
**Phantom Read**

Occurs in a READ COMMITTED isolation level when two identical queries in the same transaction produce different collections of rows. This occurs because a table lock is not acquired on SELECT during the initial query.
**Physical Schema**

Consists of a set of projections used to store data on disk. The projections in the physical schema are based on the objects in the logical schema.
Physical Schema Design

A usable K=1 design based on an analysis of the sample data files and queries (if available). The physical schema design contains segmented (fact table) superprojections and replicated (dimension table) superprojections.
Primary Column

A column that is loaded from raw data, and not derived from an expression.
**Projection**

Optimized collections of table columns that provide physical storage for data. A projection can contain some or all of the columns of one or more tables.

For conceptual information about Vertica projections, see Physical Schema in Vertica Concepts. For information about using and managing projections, see Working with Projections in the Administrator's Guide.
**Projection set**

A group of buddy projections that are safe for a given level of K-safety. When K=1, there are two buddies in a set; when K=2, there are three buddies. The Database Designer assigns all projections in a projection set the same base name so they can be identified as a group.

A projection must be part of a projection set before it is refreshed. Once a projection set is created (by creating buddies), the set is refreshed in a single transaction.
Query Cluster Level

Determines the number of sets used to group similar queries. The query cluster level can be any integer from one (1) to the number of queries to be included in the physical schema design.

Queries are generally grouped based on the columns they access and the way in which they are used. The following work loads typically use different types of queries and are placed in different query clusters: drill downs, large aggregations, and large joins. For example, if a reporting tool and dashboard both access the same database, the reporting tool is likely to use a drill down to access a subset of data and the dashboard is likely to use a large aggregation to look across a large range of data. In this case, there would be at least two (2) query clusters.
**Query Optimizer**

The component that evaluates different strategies for running a query and picks the best one.
Recovery

Vertica can restore the database to a fully functional state after one or more nodes in the system experiences a software- or hardware-related failure. Vertica recovers nodes by querying replicas of the data stored on other nodes. For example, a hardware failure can cause a node to lose database objects or to miss changes made to the database (INSERTs, UPDATEs, and so on) while offline. When the node comes back online, queries other nodes in the cluster to recover lost objects and catch up with database changes.
Referential Integrity

Consists of a set of constraints (logical schema objects) that define primary key and foreign key columns.

- Each small table must have a PRIMARY KEY constraint.
- The large table must contain columns that can be used to join the large table to smaller tables.
- Outer join queries produce the same results as the corresponding inner join query if there is a FOREIGN KEY constraint on the outer table. Note that the inner table of the outer join query must always have a PRIMARY KEY constraint on its join columns.
Refresh (projections)

Ensures that all projections on a node are up-to-date (can participate in query execution). This process could take a long time, depending on how much data is in the table(s).

For more information, see Refreshing Projections.
Resegmentation

A process that Vertica performs automatically during query execution that distributes the rows of an existing projection or intermediate relation evenly to each node in the cluster. At the end of resegmentation, every row from the input relation is on exactly one node. Vertica resegments data when the input does not have the segmentation required to compute the requested result efficiently and correctly.
Resource Pool

A resource pool comprises a pre-allocated subset of the system resources, with an associated queue. A resource pool is created using the `CREATE RESOURCE POOL` command as described in the SQL Reference Manual.
Resource Manager

In a single-user environment, the system can devote all resources to a single query and get the most efficient execution for that one query. However, in a environment where several concurrent queries are expected to run at once, there is tension between providing each query the maximum amount of resources (thereby getting fastest run time for that query) and serving multiple queries simultaneously with a reasonable run time. The Resource Manager provides options and controls for resolving this tension, while ensuring that every query eventually gets serviced and that true system limits are respected at all times.
Role

A role groups together a set of privileges that can be assigned to a user or another role. You can use roles to quickly grant or revoke privileges on multiple tables, schemas, functions or other database entities to one or more users with a single command.

Vertica's implementation of roles conforms to the SQL Standard T331 for basic roles.
Rollback

Transaction rollbacks restore a database to an earlier state by discarding changes made by that transaction. Statement-level rollbacks discard only the changes initiated by the reverted statements. Transaction-level rollbacks discard all changes made by the transaction.

With a ROLLBACK statement, you can explicitly roll back to a named savepoint within the transaction, or discard the entire transaction. Vertica can also initiate automatic rollbacks in two cases:

- An individual statement returns an ERROR message. In this case, Vertica rolls back the statement.
- DDL errors, systemic failures, dead locks, and resource constraints return a ROLLBACK message. In this case, Vertica rolls back the entire transaction.

Explicit and automatic rollbacks always release any locks that the transaction holds.
**ROS (Read Optimized Store)**

Read Optimized Store (ROS) is a highly optimized, read-oriented, disk storage structure, organized by projection. ROS makes heavy use of compression and indexing.

The Tuple Mover is the Vertica database optimizer component that moves data from memory (WOS) to disk (ROS). The Tuple Mover runs in the background, performing tasks automatically at time intervals determined by its configuration parameters.

For more information, see Loading Batches Directly into ROS.
ROS Container

A ROS (Read Optimized Store) container is a set of rows stored in a particular group of files. ROS containers are created by operations like Moveout or COPY DIRECT. You can query the STORAGE_CONTAINERS system table to see ROS containers. The ROS container layout can differ across nodes due to data variance. Segmentation can deliver more rows to one node than another. Two data loads could fit in the WOS on one node and spill on another.
Savepoint

A savepoint is a special marker inside a transaction that allows commands that execute after the savepoint to be rolled back. The transaction is restored to the state that preceded the savepoint.

Vertica supports two types of savepoints:

- An implicit savepoint is automatically established after each successful command within a transaction. This savepoint is used to roll back the next statement if it returns an error. A transaction maintains one implicit savepoint, which it rolls forward with each successful command. Implicit savepoints are available to Vertica only and cannot be referenced directly.

- Named savepoints are labeled markers within a transaction that you set through SAVEPOINT statements. A named savepoint can later be referenced in the same transaction through RELEASE SAVEPOINT, which destroys it, and ROLLBACK TO SAVEPOINT, which rolls back all operations that followed the savepoint. Named savepoints can be especially useful in nested transactions: a nested transaction that begins with a savepoint can be rolled back entirely, if necessary.
Segmentation

Defines how physical data storage (projections) is stored in a database cluster using the `CREATE PROJECTION` statement. The goal is to distribute data evenly across multiple nodes in the database so that all nodes can participate in query execution.

Note: Partitioning and segmentation are terms often used interchangeably for other databases, but they have completely separate goals in Vertica regarding data localization. See Partitioning and Segmentation in the Administrator's Guide for details.
Session

An occurrence of a user interacting with a database through the use of SQL statements. You can start a session using vsq1 or a JDBC application. In Vertica, the scope of a session is the same as that of a connection. Connecting to the database starts a session, and exiting ends it.

Session-scoped data is preserved beyond the lifetime of a single transaction. Terminating a session truncates a table and deletes all rows.
**Snapshot Isolation**

An **historical query** that gets data from the latest epoch (AT LATEST EPOCH). For details, see **Historical Queries**.
**Spread**

An open source toolkit used in Vertica to provide a high performance messaging service that is resilient to network faults. Spread daemons start automatically when a database starts up for the first time, and the spread process runs on control nodes in the cluster.
Sort-Merge Join

If both inputs are pre-sorted, merge joins do not have to do any pre-processing. Vertica uses the term sort-merge join to refer to the case when one of the inputs must be sorted prior to the merge join. Vertica sorts the inner input side but only if the outer input side is already sorted on the join keys.
Stable functions

When run with a given set of arguments, stable functions produce the same result within a single query or scan operation. However, a stable function can produce different results when issued under different environments or at different times, such as change of locale and time zone—for example, SYSDATE() and 'today'.

See also Immutable (Invariant) Functions.
**Storage Location**

A directory path used by Vertica to store catalog, actual data files, and temporary data files. You can also create storage locations for users, and then grant one or more users access to the storage. You can also create a storage location with a location label, for use in storage policies.
Storage Policy

A database object you create to associate a labeled location as the default storage location for the object. Database object can be a database, schema, table, or min- and max- ranges of a partition.
**Strict**

Indicates that a function always returns null when any of its input arguments is null.
Superprojection

A projection that includes all columns in an anchor table. Vertica uses superprojections to ensure support for all queries and other DML operations.

Under certain conditions, Vertica automatically creates a table's superprojection immediately on table creation. Vertica also creates a superprojection when you first load data into that table, if none already exists. `CREATE PROJECTION` can create a superprojection if it specifies to include all table columns. A table can have multiple superprojections.

For more information, see How Projections are Created.
**Temp Location**

A storage location used as temp space by Vertica.
**Temp Space**

Disk space temporarily occupied by temporary files created by certain query execution operations, such as hash joins and sorts, in the case when they have to spill to disk. Such operations might also be encountered during queries, recovery, refreshing projections, and so on. If a temp location is provided to the database, Vertica uses it as temp space.
**Top-K Projection**

A projection that configures the projection data for a Top-K query. A Top-K query is one that retrieves the top $k$ rows from a group of tuples.

A Top-K projection is a type of live aggregate projection.
**Transaction**

One or more operations that are executed as a unit of work. At the user level, transactions occur in the current session by a user or script running one or more SQL statements. When you commit a transaction, any changes you make to data in tables using INSERT, DELETE, UPDATE, MERGE, and COPY during the transaction become permanent. If you roll back the transaction, all changes made to table data are undone.

Vertica supports Atomicity, Consistency, Isolation, and Durability (ACID) for SQL transactions.
The Tuple Mover manages WOS and ROS data storage. It performs two operations:

- **Moveout** moves data from WOS to ROS. During moveout operations, the Tuple Mover also enforces storage policies for the storage location.

- **Mergeout** combines small ROS containers into larger ones and purges deleted data.

The Tuple Mover automatically performs these tasks in the background, at intervals that are set by its configuration parameters.

For detailed information, see Tuple Mover Operations.
UDx

User-Defined Extensions (UDxs) are functions contained in external shared libraries that are developed in C++, Python, Java, or R using the Vertica SDK. The external libraries are defined in the Vertica catalog using the CREATE LIBRARY statement. They are best suited for analytic operations that are difficult to perform in SQL, or need to be performed frequently enough that their speed is a major concern.
**Up-To-Date (Projection)**

A projection is up-to-date (or up to date) if it is eligible to participate in query execution. Projections on empty tables are up-to-date upon creation. If the table has data loaded already, newly created projections are marked not up-to-date until refreshed. If a projection is refreshed while a node is down, that projection can be marked up-to-date even though it is missing data on one of the nodes. This is because the node will build the data during the recovery process before participating in queries.
User-Defined SQL Function

User-Defined SQL Functions let you define and store commonly-used SQL expressions as a function. User-Defined SQL Functions are useful for executing complex queries and combining Vertica built-in functions. You simply call the function name you assigned in your query.

A User-Defined SQL Function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.
**View**

A named logical relation specified by an associated query that can be accessed similarly to a table in the FROM clause of a SQL statement. The results of the query are not stored but obtained on the fly when the SQL referencing the view is executed.
Volatile functions

Regardless of their arguments or environment, volatile functions can return a different result with each invocation—for example, `UUID_GENERATE()`.
**vsqI**

vsqI is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.

For more information, see *Installing the vsqI Client* and the more general topic, *Using vsqI*. 
Window (analytic)

An analytic function's OVER clause specifies how to partition, sort, and frame function input with respect to the current row. The input data is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses.
Workload Analyzer (WLA)

An advisor tool that analyzes system information held in SQL system tables (monitoring APIs) and returns a set of tuning recommendations. See Analyzing Workloads in the Administrator's Guide for details.
WOS (Write Optimized Store)

Write Optimized Store (WOS) is a memory-resident data structure for short-term data storage. The WOS is typically accessed by data manipulation language (DML) statements that load or remove data: INSERT, COPY, UPDATE, and DELETE. To support very fast data load speeds, WOS stores records without data compression or indexing. A projection in WOS is sorted only when it is queried. It remains sorted as long as no further data is inserted into it. WOS organizes data by epoch and holds both committed and uncommitted transaction data.

For more information, see Use of WOS for Trickle Loads.

Description

The precise terms and conditions for copying, distribution and modification follow.

TERMS AND CONDITIONS

0. Definitions.

"This License" refers to version 3 of the GNU General Public License.

"Copyright" also means copyright-like laws that apply to other kinds of works, such as semiconductor masks.

"The Program" refers to any copyrightable work licensed under this License. Each licensee is addressed as "you". "Licensees" and "recipients" may be individuals or organizations.

To "modify" a work means to copy from or adapt all or part of the work in a fashion requiring copyright permission, other than the making of an exact copy. The resulting work is called a "modified version" of the earlier work or a work "based on" the earlier work.

A "covered work" means either the unmodified Program or a work based on the Program.

To "propagate" a work means to do anything with it that, without permission, would make you directly or secondarily liable for infringement under applicable copyright law, except executing it on a computer or modifying a private copy. Propagation includes copying, distribution (with or without modification), making available to the public, and in some countries other activities as well.

To "convey" a work means any kind of propagation that enables other parties to make or receive copies. Mere interaction with a user through a computer network, with no transfer of a copy, is not conveying.

An interactive user interface displays "Appropriate Legal Notices" to the extent that it includes a convenient and prominently visible feature that (1) displays an appropriate copyright notice, and (2) tells the user that there is no warranty for the work (except to the extent that warranties are provided), that licensees may convey the work under this License, and how to view a copy of this License. If the interface presents a list of user commands or options, such as a menu, a prominent item in the list meets this criterion.

The "source code" for a work means the preferred form of the work for making modifications to it. "Object code" means any non-source form of a work.

A "Standard Interface" means an interface that either is an official standard defined by a recognized standards body, or, in the case of interfaces specified for a particular programming language, one that is widely used among developers working in that language.

The "System Libraries" of an executable work include anything, other than the work as a whole, that (a) is included in the normal form of packaging a Major Component, but which is not part of that Major Component, and (b) serves only to enable use of the work with that Major Component, or to implement a Standard Interface for which an implementation is available to the public in source code form. A "Major Component", in this context, means a major essential component (kernel, window system, and so on) of the specific operating system (if any) on which the executable work runs, or a compiler used to produce the work, or an object code interpreter used to run it.

The "Corresponding Source" for a work in object code form means all the source code needed to generate, install, and (for an executable work) run the object code and to modify the work, including scripts to control those activities. However, it does not include the work's System Libraries, or general-purpose tools or generally available free programs which are used unmodified in performing those activities but which are not part of the work. For example, Corresponding Source includes interface definition files associated with source files for the work, and the source code for shared libraries and dynamically linked subprograms that the work is specifically designed to require, such as by intimate data communication or control flow between those subprograms and other parts of the work.

The Corresponding Source need not include anything that users can regenerate automatically from other parts of the Corresponding Source.

The Corresponding Source for a work in source code form is that same work.

2. Basic Permissions.

All rights granted under this License are granted for the term of copyright on the Program, and are irrevocable provided the stated conditions are met. This License explicitly affirms your unlimited permission to run the unmodified Program. The output from running a covered work is covered by this License only if the output, given its content, constitutes a covered work. This License acknowledges your rights of fair use or other equivalent, as provided by copyright law.

You may make, run and propagate covered works that you do not convey, without conditions so long as your license otherwise remains in force. You may convey covered works to others for the sole purpose of having them make modifications exclusively for you, or provide you with facilities for running those works, provided that you comply with the terms of this License in conveying all material for which you do not control copyright. Those thus making or running the covered works for you must do so exclusively on your behalf, under your direction and
control, on terms that prohibit them from making any copies of your copyrighted material outside their relationship with you.

Conveying under any other circumstances is permitted solely under the conditions stated below. Sublicensing is not allowed; section 10 makes it unnecessary.

3. Protecting Users' Legal Rights From Anti-Circumvention Law.

No covered work shall be deemed part of an effective technological measure under any applicable law fulfilling obligations under article 11 of the WIPO copyright treaty adopted on 20 December 1996, or similar laws prohibiting or restricting circumvention of such measures.

When you convey a covered work, you waive any legal power to forbid circumvention of technological measures to the extent such circumvention is effected by exercising rights under this License with respect to the covered work, and you disclaim any intention to limit operation or modification of the work as a means of enforcing, against the work's users, your or third parties' legal rights to forbid circumvention of technological measures.

You may convey verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice; keep intact all notices stating that this License and any non-permissive terms added in accord with section 7 apply to the code; keep intact all notices of the absence of any warranty; and give all recipients a copy of this License along with the Program.

You may charge any price or no price for each copy that you convey, and you may offer support or warranty protection for a fee.

5. Conveying Modified Source Versions.

You may convey a work based on the Program, or the modifications to produce it from the Program, in the form of source code under the terms of section 4, provided that you also meet all of these conditions:

a) The work must carry prominent notices stating that you modified it, and giving a relevant date.

b) The work must carry prominent notices stating that it is released under this License and any conditions added under section 7. This requirement modifies the requirement in section 4 to "keep intact all notices".

c) You must license the entire work, as a whole, under this License to anyone who comes into possession of a copy. This License will therefore apply, along with any applicable section 7 additional terms, to the whole of the work, and all its parts, regardless of how they are packaged. This License gives no permission to license the work in any other way, but it does not invalidate such permission if you have separately received it.
d) If the work has interactive user interfaces, each must display Appropriate Legal Notices; however, if the Program has interactive interfaces that do not display Appropriate Legal Notices, your work need not make them do so.

A compilation of a covered work with other separate and independent works, which are not by their nature extensions of the covered work, and which are not combined with it such as to form a larger program, in or on a volume of a storage or distribution medium, is called an "aggregate" if the compilation and its resulting copyright are not used to limit the access or legal rights of the compilation's users beyond what the individual works permit. Inclusion of a covered work in an aggregate does not cause this License to apply to the other parts of the aggregate.

6. Conveying Non-Source Forms.

You may convey a covered work in object code form under the terms of sections 4 and 5, provided that you also convey the machine-readable Corresponding Source under the terms of this License, in one of these ways:

a) Convey the object code in, or embodied in, a physical product (including a physical distribution medium), accompanied by the Corresponding Source fixed on a durable physical medium customarily used for software interchange.

b) Convey the object code in, or embodied in, a physical product (including a physical distribution medium), accompanied by a written offer, valid for at least three years and valid for as long as you offer spare parts or customer support for that product model, to give anyone who possesses the object code either (1) a copy of the Corresponding Source for all the software in the product that is covered by this License, on a durable physical medium customarily used for software interchange, for a price no more than your reasonable cost of physically performing this conveying of source, or (2) access to copy the Corresponding Source from a network server at no charge.

c) Convey individual copies of the object code with a copy of the written offer to provide the Corresponding Source. This alternative is allowed only occasionally and noncommercially, and only if you received the object code with such an offer, in accord with subsection 6b.

d) Convey the object code by offering access from a designated place (gratis or for a charge), and offer equivalent access to the Corresponding Source in the same way through the same place at no further charge. You need not require recipients to copy the Corresponding Source along with the object code. If the place to copy the object code is a network server, the Corresponding Source may be on a different server (operated by you or a third party) that supports equivalent copying facilities, provided you maintain clear directions next to the object code saying where to find the Corresponding Source. Regardless of what server hosts the Corresponding Source, you remain obligated to ensure that it is available for as long as needed to satisfy these requirements.
e) Convey the object code using peer-to-peer transmission, provided you inform other peers where the object code and Corresponding Source of the work are being offered to the general public at no charge under subsection 6d.

A separable portion of the object code, whose source code is excluded from the Corresponding Source as a System Library, need not be included in conveying the object code work.

A "User Product" is either (1) a "consumer product", which means any tangible personal property which is normally used for personal, family, or household purposes, or (2) anything designed or sold for incorporation into a dwelling. In determining whether a product is a consumer product, doubtful cases shall be resolved in favor of coverage. For a particular product received by a particular user, "normally used" refers to a typical or common use of that class of product, regardless of the status of the particular user or of the way in which the particular user actually uses, or expects or is expected to use, the product. A product is a consumer product regardless of whether the product has substantial commercial, industrial or non-consumer uses, unless such uses represent the only significant mode of use of the product.

"Installation Information" for a User Product means any methods, procedures, authorization keys, or other information required to install and execute modified versions of a covered work in that User Product from a modified version of its Corresponding Source. The information must suffice to ensure that the continued functioning of the modified object code is in no case prevented or interfered with solely because modification has been made.

If you convey an object code work under this section in, or with, or specifically for use in, a User Product, and the conveying occurs as part of a transaction in which the right of possession and use of the User Product is transferred to the recipient in perpetuity or for a fixed term (regardless of how the transaction is characterized), the Corresponding Source conveyed under this section must be accompanied by the Installation Information. But this requirement does not apply if neither you nor any third party retains the ability to install modified object code on the User Product (for example, the work has been installed in ROM).

The requirement to provide Installation Information does not include a requirement to continue to provide support service, warranty, or updates for a work that has been modified or installed by the recipient, or for the User Product in which it has been modified or installed. Access to a network may be denied when the modification itself materially and adversely affects the operation of the network or violates the rules and protocols for communication across the network.

Corresponding Source conveyed, and Installation Information provided, in accord with this section must be in a format that is publicly documented (and with an implementation available to the public in source code form), and must require no special password or key for unpacking, reading or copying.

7. Additional Terms.
"Additional permissions" are terms that supplement the terms of this License by making exceptions from one or more of its conditions. Additional permissions that are applicable to the entire Program shall be treated as though they were included in this License, to the extent that they are valid under applicable law. If additional permissions apply only to part of the Program, that part may be used separately under those permissions, but the entire Program remains governed by this License without regard to the additional permissions.

When you convey a copy of a covered work, you may at your option remove any additional permissions from that copy, or from any part of it. (Additional permissions may be written to require their own removal in certain cases when you modify the work.) You may place additional permissions on material, added by you to a covered work, for which you have or can give appropriate copyright permission.

Notwithstanding any other provision of this License, for material you add to a covered work, you may (if authorized by the copyright holders of that material) supplement the terms of this License with terms:

a) Disclaiming warranty or limiting liability differently from the terms of sections 15 and 16 of this License; or

b) Requiring preservation of specified reasonable legal notices or author attributions in that material or in the Appropriate Legal Notices displayed by works containing it; or

c) Prohibiting misrepresentation of the origin of that material, or requiring that modified versions of such material be marked in reasonable ways as different from the original version; or

d) Limiting the use for publicity purposes of names of licensors or authors of the material; or

e) Declining to grant rights under trademark law for use of some trade names, trademarks, or service marks; or

f) Requiring indemnification of licensors and authors of that material by anyone who conveys the material (or modified versions of it) with contractual assumptions of liability to the recipient, for any liability that these contractual assumptions directly impose on those licensors and authors.

All other non-permissive additional terms are considered "further restrictions" within the meaning of section 10. If the Program as you received it, or any part of it, contains a notice stating that it is governed by this License along with a term that is a further restriction, you may remove that term. If a license document contains a further restriction but permits relicensing or conveying under this License, you may add to a covered work material governed by the terms of that license document, provided that the further restriction does not survive such relicensing or conveying.
If you add terms to a covered work in accord with this section, you must place, in the relevant source files, a statement of the additional terms that apply to those files, or a notice indicating where to find the applicable terms.

Additional terms, permissive or non-permissive, may be stated in the form of a separately written license, or stated as exceptions; the above requirements apply either way.

8. Termination.

You may not propagate or modify a covered work except as expressly provided under this License. Any attempt otherwise to propagate or modify it is void, and will automatically terminate your rights under this License (including any patent licenses granted under the third paragraph of section 11).

However, if you cease all violation of this License, then your license from a particular copyright holder is reinstated (a) provisionally, unless and until the copyright holder explicitly and finally terminates your license, and (b) permanently, if the copyright holder fails to notify you of the violation by some reasonable means prior to 60 days after the cessation.

Moreover, your license from a particular copyright holder is reinstated permanently if the copyright holder notifies you of the violation by some reasonable means, this is the first time you have received notice of violation of this License (for any work) from that copyright holder, and you cure the violation prior to 30 days after your receipt of the notice.

Termination of your rights under this section does not terminate the licenses of parties who have received copies or rights from you under this License. If your rights have been terminated and not permanently reinstated, you do not qualify to receive new licenses for the same material under section 10.

You are not required to accept this License in order to receive or run a copy of the Program. Ancillary propagation of a covered work occurring solely as a consequence of using peer-to-peer transmission to receive a copy likewise does not require acceptance. However, nothing other than this License grants you permission to propagate or modify any covered work. These actions infringe copyright if you do not accept this License. Therefore, by modifying or propagating a covered work, you indicate your acceptance of this License to do so.

10. Automatic Licensing of Downstream Recipients.

Each time you convey a covered work, the recipient automatically receives a license from the original licensors, to run, modify and propagate that work, subject to this License. You are not responsible for enforcing compliance by third parties with this License. An "entity transaction" is a transaction transferring control of an organization, or substantially all assets of one, or subdividing an organization, or merging organizations. If propagation of a covered work results from an entity transaction, each party to that transaction who receives a copy of the work also receives whatever licenses to the work the party's predecessor in interest had or could give
under the previous paragraph, plus a right to possession of the Corresponding Source of the work from the predecessor in interest, if the predecessor has it or can get it with reasonable efforts.

You may not impose any further restrictions on the exercise of the rights granted or affirmed under this License. For example, you may not impose a license fee, royalty, or other charge for exercise of rights granted under this License, and you may not initiate litigation (including a cross-claim or counterclaim in a lawsuit) alleging that any patent claim is infringed by making, using, selling, offering for sale, or importing the Program or any portion of it.

11. Patents.

A "contributor" is a copyright holder who authorizes use under this License of the Program or a work on which the Program is based. The work thus licensed is called the contributor's "contributor version".

A contributor's "essential patent claims" are all patent claims owned or controlled by the contributor, whether already acquired or hereafter acquired, that would be infringed by some manner, permitted by this License, of making, using, or selling its contributor version, but do not include claims that would be infringed only as a consequence of further modification of the contributor version. For purposes of this definition, "control" includes the right to grant patent sublicenses in a manner consistent with the requirements of this License.

Each contributor grants you a non-exclusive, worldwide, royalty-free patent license under the contributor’s essential patent claims, to make, use, sell, offer for sale, import and otherwise run, modify and propagate the contents of its contributor version.

In the following three paragraphs, a "patent license" is any express agreement or commitment, however denominated, not to enforce a patent (such as an express permission to practice a patent or covenant not to sue for patent infringement). To "grant" such a patent license to a party means to make such an agreement or commitment not to enforce a patent against the party.

If you convey a covered work, knowingly relying on a patent license, and the Corresponding Source of the work is not available for anyone to copy, free of charge and under the terms of this License, through a publicly available network server or other readily accessible means, then you must either (1) cause the Corresponding Source to be so available, or (2) arrange to deprive yourself of the benefit of the patent license for this particular work, or (3) arrange, in a manner consistent with the requirements of this License, to extend the patent license to downstream recipients. "Knowingly relying" means you have actual knowledge that, but for the patent license, your conveying the covered work in a country, or your recipient’s use of the covered work in a country, would infringe one or more identifiable patents in that country that you have reason to believe are valid.

If, pursuant to or in connection with a single transaction or arrangement, you convey, or propagate by procuring conveyance of, a covered work, and grant a patent license to some of
the parties receiving the covered work authorizing them to use, propagate, modify or convey a specific copy of the covered work, then the patent license you grant is automatically extended to all recipients of the covered work and works based on it.

A patent license is "discriminatory" if it does not include within the scope of its coverage, prohibits the exercise of, or is conditioned on the non-exercise of one or more of the rights that are specifically granted under this License. You may not convey a covered work if you are a party to an arrangement with a third party that is in the business of distributing software, under which you make payment to the third party based on the extent of your activity of conveying the work, and under which the third party grants, to any of the parties who would receive the covered work from you, a discriminatory patent license (a) in connection with copies of the covered work conveyed by you (or copies made from those copies), or (b) primarily for and in connection with specific products or compilations that contain the covered work, unless you entered into that arrangement, or that patent license was granted, prior to 28 March 2007.

Nothing in this License shall be construed as excluding or limiting any implied license or other defenses to infringement that may otherwise be available to you under applicable patent law.

If conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot convey a covered work so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not convey it at all. For example, if you agree to terms that obligate you to collect a royalty for further conveying from those to whom you convey the Program, the only way you could satisfy both those terms and this License would be to refrain entirely from conveying the Program.

13. Use with the GNU Affero General Public License.

Notwithstanding any other provision of this License, you have permission to link or combine any covered work with a work licensed under version 3 of the GNU Affero General Public License into a single combined work, and to convey the resulting work. The terms of this License will continue to apply to the part which is the covered work, but the special requirements of the GNU Affero General Public License, section 13, concerning interaction through a network will apply to the combination as such.

14. Revised Versions of this License.

The Free Software Foundation may publish revised and/or new versions of the GNU General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies that a certain numbered version of the GNU General Public License "or any later version" applies to it, you have the option of following the terms and conditions either of that numbered version or of
any later version published by the Free Software Foundation. If the Program does not specify a version number of the GNU General Public License, you may choose any version ever published by the Free Software Foundation.

If the Program specifies that a proxy can decide which future versions of the GNU General Public License can be used, that proxy's public statement of acceptance of a version permanently authorizes you to choose that version for the Program.

Later license versions may give you additional or different permissions. However, no additional obligations are imposed on any author or copyright holder as a result of your choosing to follow a later version.

15. Disclaimer of Warranty.
