Password File (password.ini)

The password file is not a complete configuration file like the other examples. Use this file
with another .ini file. In the other .ini file, set the passwordFile parameter (in the [Misc]
section) to the path to the password file. See Password Configuration File for more information.

```plaintext
; This is a sample password configuration file.
; Point to this file in the "passwordFile" parameter of the [Misc] section.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; Option and values are separated by an equal sign.

[Passwords]
; The database administrator's Vertica password (not Linux password),
; and used if dbPromptForPassword is False.
; dbPassword=myDBsecret

; The password for the rsync user account.
; serviceAccessPass=myrsyncpw

; The password for the dest_dbuser Vertica account, for replication tasks only.
; dest_dbPassword=destDBsecret
```

## Requirements for Eon Mode Databases

Backing up and restoring work the same way in Eon Mode as they do when backing up an Enterprise Mode database to S3. Because Eon Mode uses a different architecture, there are some additional requirements.

### Configuration Files

You must back up Eon Mode databases to AWS S3 or S3-compatible storage such as an on-premise data store that supports the S3 protocol. Therefore you must set values for `s3_backup_path` and `s3_backup_file_system_path` in the `vbr` configuration file. A backup path is valid for only one database; you cannot use the same path to store backups for multiple databases.

If your database runs on-premise, you can still back up to AWS S3; you are not restricted to on-premise backups.

For more about these configuration parameters, see [S3].
Configuration for Databases Running on AWS

In addition to having access to the S3 bucket used for the database's communal storage, you must have access to the S3 backup location. Verify that the credential you use for access to communal storage also has access to the backup location. For more information about configuring S3 access for Vertica, see Configuring Backups to and from S3.

While your backup location may be in a different region, backup and restore operations across different S3 regions are incompatible with VPC endpoints.

Configuration for Databases Running On-Premise

If your database runs on-premise, then your communal storage is not on AWS but on another storage platform that uses the S3 protocol. This means there can be two endpoints and two sets of credentials, depending on where you back up. This additional information is stored in environment variables, not parameters in the configuration file. See Backing up an on-premise database in Eon Mode.

Backups of Eon Mode on-premise databases do not support AWS IAM profiles.

Eon Mode on-premise databases support the following vbr tasks: backup (full only), restore (full or subset), listbackup, quick-check, full-check, quick-repair, collect-garbage, remove.

Database Configuration

When restoring a backup of an Eon Mode database, the restore database must satisfy the following requirements:

- Share the same name as the backup database.
- Have the same number of nodes as the backup database.
- Have the same node names as the nodes of the backup database.
- Use the same catalog directory location and communal storage location as the backup database.
- Use the same port numbers as the backup database.
For object restore, have the same shard subscriptions. If the shard subscriptions have changed, you cannot do object restores but can do a full restore. Shard subscriptions can change when you add or remove nodes or rebalance your cluster.

## Setting Up Backup Locations

**Caution:**
It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

Full and object-level backups reside on *backup hosts*, the computer systems on which backups and archives are stored. On the backup hosts, Vertica saves backups in a specific *backup location* (directory).

You must set up your backup hosts before you can create backups.

The storage format type at your backup locations must support fcntl lockf (POSIX) file locking.

## Configuring Backup Hosts and Connections

You use `vbr` to back up your database to one or more hosts (known as *backup hosts*) that can be outside of your database cluster.

You can use one or more backup hosts or a single S3 bucket to back up your database. Use the `vbr` configuration file to specify which backup host each node in your cluster should use.

Before you back up to hosts outside of the local cluster, configure the target backup locations to work with `vbr`. The backup hosts you use must:

- [Have sufficient backup disk space.](#)
- Be accessible from your database cluster through SSH.
- Have passwordless SSH access for the Database Administrator account.
- Have either the Vertica rpm or Python 3.7 and rsync 3.0.5 or later installed.
If you are using a stateful firewall, configure your tcp_keepalive_time and tcp_keepalive_intvl sysctl settings to use values less than your firewall timeout value.

**Configuring TCP Forwarding on Database Hosts**

vbr depends on TCP forwarding to forward connections from database hosts to backup hosts. For copycluster and replication tasks, you must enable TCP forwarding on both sets of hosts. SSH connections to backup hosts do not require SSH forwarding.

If it is not already set by default, set AllowTcpForwarding = Yes in /etc/ssh/sshd_config and then send a SIGHUP signal to sshd on each host. See the Linux sshd documentation for more information.

If TCP forwarding is not enabled, tasks requiring it fail with the following message: "Errors connecting to remote hosts: Check SSH settings, and that the same Vertica version is installed on all nodes."

On a single-node cluster, vbr uses a random high-number port to create a local ssh tunnel. This fails if PermitOpen is set to restrict the port. Comment out the PermitOpen line in sshd_config.

**Creating Configuration Files for Backup Hosts**

Create separate configuration files for full or object-level backups, using distinct names for each configuration file. Also, use the same node, backup host, and directory location pairs. Specify different backup directory locations for each database.

**Note:**

For optimal network performance when creating a backup, Vertica recommends that you give each node in the cluster its own dedicated backup host.

**Preparing Backup Host Directories**

Before vbr can back up a database, you must prepare the target backup directory. Run vbr with a task type of init to create the necessary manifests for the backup process. You
need to perform the init process only once. After that, Vertica maintains the manifests automatically.

**Estimating Backup Host Disk Requirements**

Wherever you plan to save data backups, consider the disk requirements for historical backups at your site. Also, if you use more than one archive, multiple archives potentially require more disk space. Vertica recommends that each backup host have space for at least twice the database node footprint size. Follow this recommendation regardless of the specifics of your site's backup schedule and retention requirements.

To estimate the database size from the `used_bytes` column of the `storage_containers` system table as in the following example:

```
=> SELECT SUM(used_bytes) FROM storage_containers WHERE node_name='v_mydb_node0001';

<table>
<thead>
<tr>
<th>total_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>302135743</td>
</tr>
</tbody>
</table>

(1 row)
```

**Making Backup Hosts Accessible**

You must verify that any firewalls between the source database nodes and the target backup hosts allow connections for SSH and rsync on port 50000.

The backup hosts must be running identical versions of rsync and Python as those supplied in the Vertica installation package.

**Setting Up Passwordless SSH Access**

For `vbr` to access a backup host, the database superuser must meet two requirements:

- Have an account on each backup host, with write permissions to the backup directory.
- Have passwordless SSH access from each database cluster host to the corresponding backup host.

How you fulfill these requirements depends on your platform and infrastructure.
SSH access among the backup hosts and access from the backup host to the database node is not necessary.

If your site does not use a centralized login system (such as LDAP), you can usually add a user with the `useradd` command or through a GUI administration tool. See the documentation for your Linux distribution for details.

If your platform supports it, you can enable passwordless SSH logins using the `ssh-copy-id` command to copy a database administrator's SSH identity file to the backup location from one of your database nodes. For example, to copy the SSH identity file from a node to a backup host named `backup01`:

```bash
$ ssh-copy-id -i dbadmin@backup01
Password:
```

Try logging into the machine with "ssh dbadmin@backup01". Then, check the contents of the `~/.ssh/authorized_keys` file to verify that you have not added extra keys that you did not intend to include.

```bash
$ ssh backup01
Last login: Mon May 23 11:44:23 2011 from host01
```

Repeat the steps to copy a database administrator's SSH identity to all backup hosts you use to back up your database.

After copying a database administrator's SSH identity, you should be able to log in to the backup host from any of the nodes in the cluster without being prompted for a password.

### Increasing the SSH Maximum Connection Settings for a Backup Host

If your configuration requires backing up multiple nodes to one backup host (n:1), increase the number of concurrent SSH connections to the SSH daemon (`sshd`). By default, the number of concurrent SSH connections on each host is 10, as set in the `sshd_config` file with the `MaxStartups` keyword. The `MaxStartups` value for each backup host should be greater than the total number of hosts being backed up to this backup host. For more information on configuring `MaxStartups`, refer to the man page for that parameter.
See Also

- Backup Configuration Options
- Enable Secure Shell (SSH) Logins

Configuring Hard-Link Local Backup Hosts

When specifying the backupHost parameter for your hard-link local configuration files, use the database host names (or IP addresses) as known to admintools. Do not use the node names. Host names (or IP addresses) are what you used when setting up the cluster. Do not use localhost for the backupHost parameter.

Listing Host Names

To query node names and host names:

```sql
=> SELECT node_name, host_name FROM node_resources;

+----------+---------+
| node_name | host_name     |
+----------+---------+
| v_vmart_node0001 | 192.168.223.11 |
| v_vmart_node0002 | 192.168.223.22 |
| v_vmart_node0003 | 192.168.223.33 |
+----------+---------+
(3 rows)
```

Because you are creating a local backup, use square brackets [ ] to map the host to the local host. For more information, refer to [Mapping].

[Mapping]

- `v_vmart_node0001 = [[:/home/dbadmin/data/backups`
- `v_vmart_node0002 = [[:/home/dbadmin/data/backups`
- `v_vmart_node0003 = [[:/home/dbadmin/data/backups`

Configuring Backups to and from S3

Vertica supports backing up to Amazon (AWS) S3 in both Enterprise Mode and Eon Mode. To back up to AWS, you add parameters to your backup configuration file. You can create these backups from your local cluster or from Amazon EC2 virtual servers.
In Eon Mode, if your cluster runs on-premise, meaning your communal storage is not on AWS, you can back up to AWS or to another destination supporting the S3 protocol. Some additional configuration is required.

See Additional Considerations for AWS for information about configuring authentication and encryption on AWS.

**Creating an S3 Configuration File (Required for All Database Types)**

To back up any cluster to an S3 destination, you must add an [S3] section to your backup configuration file. This section describes the backup location. For more information, refer to [S3]. Vertica also provides a sample S3 configuration file that you can copy and edit.

For Eon Mode databases running on-premise, see the additional requirements in the next section.

**Backing up an on-premise database in Eon Mode**

You can back up an Eon Mode database that is running on-premise to either AWS or a Pure Storage FlashBlade appliance, both of which support the S3 protocol. You must specify the following in environment variables:

- The endpoint for your communal storage, VBR_COMMUNAL_STORAGE_ENDPOINT_URL. Include the scheme (http or https).
- If the backup location is not on AWS, the endpoint for the backup location, VBR_BACKUP_STORAGE_ENDPOINT_URL. Include the scheme (http or https).
- Credentials for your communal storage, VBR_COMMUNAL_STORAGE_ACCESS_KEY_ID and VBR_COMMUNAL_STORAGE_SECRET_ACCESS_KEY.
- Credentials for your backup location, VBR_BACKUP_STORAGE_ACCESS_KEY_ID and VBR_BACKUP_STORAGE_SECRET_ACCESS_KEY.

If the backup location is on AWS, do not set VBR_BACKUP_STORAGE_ENDPOINT_URL.

For on-premise databases you must specify your credentials via these environment variables. You cannot use other methods of credentialing with cross-endpoint backups.

Following is a summary of the environment variables:

```
$ export VBR_COMMUNAL_STORAGE_ENDPOINT_URL=communal_storage_endpoint
```
Additional Considerations for AWS

If you are using Amazon S3 (AWS) as your backup location, you need to do some additional one-time configuration. You also must take additional steps if the cluster you are backing up is running on EC2 instances. Finally, you might choose to encrypt your backups, which requires additional steps.

By default, bucket-access is restricted to the communal storage bucket. For one-time operations with other buckets like backing up and restoring the database, you should use an AWS access key.

**Configuring Amazon S3 Storage for Backup**

Vertica supports using Amazon S3 cloud storage as a backup location. As with any storage location, you must initialize an S3 storage location with the `vbr task init`.

Because S3 storage does not support file locking, Vertica uses either your local file system or an Amazon EC2 file system to handle file locks during a backup. You identify this location using the `s3_backup_file_system_path` parameter in your vbr configuration file. During a backup, Vertica creates a locked identity file on your local or EC2 instance, and a duplicate file in your S3 backup location. As long as the files match, Vertica proceeds with the backup, releasing the lock when the backup is complete. As long as the files remain identical, you can use the S3 location for backup and restore tasks.

If the files in your locking location become out of sync with the files in your backup location, backup and restore tasks fail with an error message. You can resolve locking inconsistencies by rerunning the `init` task with the `--s3-force-init` parameter.

A typical S3 locking file reset command takes the following form:

```
/opt/vertica/bin/vbr --task init --s3-force-init -c filename.ini
```
Note:
If a backup fails, confirm that your Vertica cluster has permission to access your S3 storage location.

Configuring EC2 Authentication for Amazon S3

If you are backing up to S3 from an EC2-based cluster, you must provide authentication to your S3 host. Regardless of the authentication type you choose, your credentials do not leave your EC2 cluster. Vertica supports the following authentication types:

- AWS credential file
- Environment variables
- IAM role

AWS credential file - You can manually create a configuration file on your EC2 initiator host at ~/.aws/credentials.

```
[default]
aws_access_key_id = YOUR_ACCESS_KEY
aws_secret_access_key = YOUR_SECRET_KEY
```

For more information on credential files, refer to Amazon Web Services documentation.

Environment variables - Amazon Web Services provides the following environment variables:

- AWS_ACCESS_KEY_ID
- AWS_SECRET_ACCESS_KEY

Use these variables on your initiator to provide authentication to your S3 host. When your session ends, AWS deletes these variables. For more information, refer to the AWS documentation.

IAM role - Create an AWS IAM role and grant that role permission to access your EC2 cluster and S3 resources. This method is recommended for managing long-term access. For more information, refer to Amazon Web Services documentation.

Encrypting Backups

Backups made to Amazon S3 can be encrypted using native server-side S3 encryption capability. For more information on Amazon S3 encryption, refer to Amazon documentation.
Note:
Vertica supports server-side encryption only. Client-side encryption is not supported.

Vertica supports the following forms of S3 encryption:

- Server-Side Encryption with Amazon S3-Managed Keys (SSE-S3)
  - Encrypts backups with AES-256
  - Amazon manages encryption keys
- Server-Side Encryption with AWS KMS-Managed Keys (SSE-KMS)
  - Encrypts backups with AES-256
  - Requires an encryption key from Amazon Key Management Service
  - Your S3 bucket must be from the same region as your encryption key
  - Allows auditing of user activity

When you enable encryption of your backups, Vertica encrypts backups as it creates them. If you enable encryption after creating an initial backup, only increments added after you enabled encryption are encrypted. To ensure that your backup is entirely encrypted, create new backups after enabling encryption.

To enable encryption, add the following settings to your configuration file:

- s3_encrypt_transport - Encrypts your backups during transmission. You must enable this parameter if you are using SSE-KMS encryption.
- s3_encrypt_at_rest - Enables encryption of your backups. If you enable encryption and do not provide a KMS key, Vertica uses SSE-S3 encryption.
- s3_sse_kms_key_id - If you are using KMS encryption, use this parameter to provide your key ID.

For more information on these settings, refer to [S3 configuration settings](#).

The following example shows a typical configuration for KMS encryption of backups.

```
[S3]
s3_encrypt_transport = True
s3_encrypt_at_rest = sse
s3_sse_kms_key_id = 6785f412-1234-4321-8888-6a774ba2aaaa
```
Creating Backups

Caution:
It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

You should perform full backups of your database regularly. You should also perform a full backup in the following circumstances:

Before:
- You upgrade Vertica to another release.
- You drop a partition.
- You add, remove, or replace nodes in your database cluster.

After:
- You load a large volume of data.
- You add, remove, or replace nodes in your database cluster. Always create a new full backup in this case.
- You recover a cluster from a crash.

If:
- The epoch in the latest backup is earlier than the current ancient history mark.

Ideally, schedule ongoing backups to back up your data. You can run the Vertica `vbr` command from a cron job or other task scheduler.

You can also back up selected objects. Use object backups to supplement full backups, not to replace them. Backup types are described in Types of Backups.

Running `vbr` does not affect active database applications. `vbr` supports creating backups while concurrently running applications that execute DML statements, including COPY, INSERT, UPDATE, DELETE, and SELECT.
Backup Locations and Contents

Full and object-level backups reside on backup hosts, the computer systems on which backups and archives are stored.

Vertica saves backups in a specific backup location, the directory on a backup host. This location can contain multiple backups, both full and object-level, including associated archives. The backups are also compatible, allowing you to restore any objects from a full database backup. Backup locations for Eon Mode databases must be on S3.

Note:
Vertica does not recommend concurrent backups. If you must run multiple backups concurrently, use separate backup and temp directories for each. Having separate backup directories detracts from the advantage of sharing data among historical backups.

Before backup up, you must prepare your backup locations using the `vbr init task`, as in the following example:

```
$ vbr -t init -c full_backup.ini
```

For more information about backup locations, see Setting Up Backup Locations.

Backups contain all committed data for the backed-up objects as of the start time of the backup. Backups do not contain uncommitted data or data committed during the backup. Backups do not delay mergeout or load activity.

Backing Up HDFS Storage Locations

If your Vertica cluster uses HDFS storage locations, you must do some additional configuration before you can perform backups. See Backing Up HDFS Storage Locations in Integrating with Apache Hadoop.

HDFS storage locations support only full backup and restore. You cannot perform object backup or restore on a cluster that uses HDFS storage locations.
Impact of Backups on Vertica Nodes

While a backup is taking place, the backup process can consume additional storage. The amount of space consumed depends on the size of your catalog and any objects that you drop during the backup. The backup process releases this storage when the backup is complete.

Best Practices for Creating Backups

When creating backup configuration files:

- Create separate configuration files to create full- and object-level backups.
- Use a unique snapshot name in each configuration file.
- Use the same backup host directory location for both kinds of backups:
  - Because the backups share disk space, they are compatible when performing a restore.
  - Each cluster node must also use the same directory location on its designated backup host.
- For best network performance, use one backup host per cluster node.
- Use one directory on each backup node to store successive backups.
- For future reference, append the major Vertica version number to the configuration file name (mybackup9x).

The selected objects of a backup can include one or more schemas or tables, or a combination of both. For example, you can include schema S1 and tables T1 and T2 in an object-level backup. Multiple backups can be combined into a single backup. A schema-level backup can be integrated with a database backup (and a table backup integrated with a schema-level backup, and so on).

Types of Backups

vbr supports the following kinds of backups:

- Full backups
- Object-level backups
- Hard-link local backups
The vbr configuration file includes the snapshotName parameter. Use different snapshot names for different types of backups, including different combinations of objects in object-level backups. Backups with the same snapshot name form a time sequence limited by restorePointLimit, so if you give all your backups the same snapshot name, they will eventually interfere with each other.

**Full Backups**

A full backup is a complete copy of the database catalog, its schemas, tables, and other objects. This type of backup provides a consistent image of the database at the time the backup occurred. You can use a full backup for disaster recovery to restore a damaged or incomplete database. You can also restore individual objects from a full backup.

When a full backup already exists, vbr backs up new or changed data since the last full backup occurred, rather than making another complete copy. You can specify the number of historical backups to keep.

Archives contain a collection of same-name backups. Each archive can have a different retention policy. For example, suppose that TBak is the name of an object-level backup of table T, and you create a daily backup each week. These seven backups become part of the TBak archive. Keeping a backup archive lets you revert back to any one of the saved backups.

**Object-Level Backups**

An object-level backup consists of one or more schemas or tables or a group of such objects. The conglomerate parts of the object-level backup do not contain the entire database. When an object-level backup exists, you can restore all of its contents or individual objects. Object-level backups are supported for Enterprise Mode databases only.

| Note: Vertica does not support object level backups on Hadoop Distributed File System (HDFS) storage. |

Object-level backups contain the following object types:

| Selected objects | Objects you choose to be part of an object-level backup. For example, if you specify tables T1 and T2 to include in an object-level backup, they are the selected objects. |
Dependent objects | Objects that must be included as part of an object-level backup, due to dependencies. Suppose you want to create an object-level backup that includes a table with a foreign key. To do so, table constraints require that you include the primary key table, and vbr enforces this requirement. Projections anchored on a table in the selected objects are also dependent objects.

Principal objects | The objects on which both selected and dependent objects depend are called principal objects. For example, each table and projection has an owner, and each is a principal object.

---

**Hard-Link Local Backups**

You can make a faster local backup, either for the full database or for specific objects, directly on the database nodes. Typically you use this kind of backup temporarily before performing a disruptive operation. Do not rely on this kind of backup for long-term use; it cannot protect you from node failures because data and backups are on the same nodes.

A checkpoint backup is called a hard-link local backup. It consists of a complete copy of the database catalog, and a set of hard file links to corresponding data files. You must save a hard-link local backup on the file system used by the catalog and database files.

Hard-link local backups are supported in Enterprise Mode only.

**Creating Full Backups**

Before you create a database backup, verify the following:

- You have prepared your backup directory with the vbr init task:
  
  ```
  $ vbr -t init -c full_backup.ini
  ```

- Your database is running. It is unnecessary for all nodes to be up in a K-safe database. However, any nodes that are DOWN are not backed up.
- All of the backup hosts are up and available.
- The backup host (either on the database cluster or elsewhere) has sufficient disk space to store the backups.
- The user account of the user who starts vbr has write access to the target directories on the host backup location. This user can be dbadmin or another assigned role. However, you cannot run vbr as root.
- Each backup has a unique file name.
- If you want to keep earlier backups, `restorePointLimit` is set to a number greater than 1 in the configuration file.
- If you are backing up an Eon Mode database, you have met the Requirements for Eon Mode Databases.

Run `vbr` from a terminal. Use the database administrator account from an initiator node in your database cluster. The command requires only the `-task backup` and `--config-file` arguments (or their short forms, `-t` and `-c`).

If your configuration file does not contain the database administrator password, `vbr` prompts you to enter the password. It does not display what you type.

`vbr` requires no further interaction after you invoke it.

The following example shows a full backup:

```
$ vbr -t backup -c full_backup.ini
Starting backup of database VT08.
Participating nodes: v_vmart_node0001, v_vmart_node0002, v_vmart_node0003, v_vmart_node0004.
Snapshotting database.
Snapshot complete.
Approximate bytes to copy: 2315056043 of 2356089422 total.
[==============================================] 100%
Copying backup metadata.
Finalizing backup.
Backup complete!
```

By default, no output appears, other than the progress bar. To include additional progress information, use the `--debug` option, with a value of 1, 2, or 3.

## Creating Object-Level Backups

Use object-level backups to back up individual schemas or tables. Object-level backups are especially useful for multi-tenanted database sites. For example, an international airport could use a multi-tenanted database to represent different airlines in its schemas. Then, tables could maintain various types of information for the airline, including ARRIVALS, DEPARTURES, and PASSENGER information. With such an organization, creating object-level backups of the specific schemas would let you restore by airline tenant, or any other important data segment.

To create one or more object-level backups, create a configuration file specifying the backup location, the object-level backup name, and a list of objects to include (one or more schemas and tables). You can use the `includeObjects` and `excludeObjects` parameters together with wildcards to specify the objects of interest. For more information
about specifying the objects to include, see Including and Excluding Objects Using Wildcards.

For more information about configuration files for full or object-level backups, see Sample VBR .ini Files and Configuration File Reference.

While not required, Vertica recommends that you first create a full backup before creating any object-level backups.

**Note:**
Apache Kafka uses internal configuration settings to maintain the integrity of your data. When backing up your Kafka data, Vertica recommends that you perform a full database backup rather than an object-level backup.

**Performing the Backup**

Before you can create a backup, you must prepare your backup directory with the `vbr-init task`. You must also create a configuration file specifying which objects to back up.

Run `vbr` from a terminal using the database administrator account from a node in your database cluster. You cannot run `vbr` as root.

You can create an object-level backup as in the following example.

```
$ vbr --task backup --config-file objectbak.ini
Preparing...
Found Database port: 5433
Copying...
[==================================================] 100%
All child processes terminated successfully.
Committing changes on all backup sites...
backup done!
```

**Naming Conventions**

Give each object-level backup configuration file a distinct and descriptive name. For instance, at an airport terminal, schema-based backup configuration files use a naming convention with an airline prefix, followed by further description, such as:

AIR1_daily_arrivals_backup
AIR2_hourly_arrivals_backup
AIR2_hourly_departures_backup
When database and object-level backups exist, you can recover the backup of your choice.

**Caution:**
Do not change object names in an object-level configuration file if a backup already exists. Doing so overwrites the original configuration file, and you cannot restore it from the earlier backup. Instead, create a different configuration file.

**Understanding Object-Level Backup Contents**

Object-level backups comprise only the elements necessary to restore the schema or table, including the selected, dependent, and principal objects. An object-level backup includes the following contents:

- **Storage:** Data files belonging to any specified objects
- **Metadata:** Including the cluster topology, timestamp, epoch, AHM, and so on
- **Catalog snippet:** Persistent catalog objects serialized into the principal and dependent objects

Some of the elements that AIR2 comprises, for instance, are its parent schema, tables, named sequences, primary key and foreign key constraints, and so on. To create such a backup, `vbr` saves the objects directly associated with the table. It also saves any dependencies, such as foreign key (FK) tables, and creates an object map from which to restore the backup.

**Note:**
Because the data in local temp tables persists only within a session, local temporary tables are excluded when you create an object-level backup. For global temporary tables, `vbr` stores the table's definition.

**Making Changes After an Object-Level Backup**

Be aware how changes made after an object-level backup affect subsequent backups. Suppose you create an object-level backup and later drop schemas and tables from the database. In this case, the objects you dropped are also dropped from subsequent backups. If you do not save an archive of the object backup, such objects could be lost permanently.
Changing a table name after creating a table backup does not persist after restoring the backup. Suppose that, after creating a backup, you drop a user who owns any selected or dependent objects in that backup. In this case, restoring the backup re-creates the object and assigns ownership to the user performing the restore. If the owner of a restored object still exists, that user retains ownership of the restored object.

To restore a dropped table from a backup:

1. Rename the newly created table from t1 to t2.
2. Restore the backup containing t1.
3. Restore t1. Tables t1 and t2 now coexist.

For information on how Vertica handles object overwrites, refer to the objectRestoreMode parameter in [Misc] Miscellaneous Settings.

K-safety can increase after an object backup. Restoration of a backup fails if both of the following conditions occur:

- An increase in K-safety occurs.
- Any table in the backup has insufficient projections.

**Changing Principal and Dependent Objects**

If you create a backup and then drop a principal object, restoring the backup restores that principal object. If the owner of the restored object has also been dropped, Vertica assigns the restored object to the current dbadmin.

You can specify how Vertica handles object overwrites in the vbr configuration file. For more information, refer to the objectRestoreMode parameter in [Misc] Miscellaneous Settings.

Identity and auto-increment sequences are dependent objects because they cannot exist without their tables. An object-level backup includes such objects, along with the tables on which they depend.

Named sequences are not dependent objects because they exist autonomously. A named sequence remains after you drop the table in which the sequence is used. In this case, the named sequence is a principal object. Thus, you must back up the named sequence with the table. Then you can regenerate it, if it does not already exist when you restore the table. If the sequence does exist, vbr uses it, unmodified. Sequence values could repeat, if you restore the full database and then restore a table backup to a newer epoch.
**Considering Constraint References**

When database objects are related through constraints, you must back them up together. For example, a schema with tables whose constraints reference only tables in the same schema can be backed up. However, a schema containing a table with an FK/PK constraint on a table in another schema cannot. To back up the second table, you must include the other schema in the list of selected objects.

**Configuration Files for Object-Level Backups**

`vbr` automatically associates configurations with different backup names but uses the same backup location.

Always create a cluster-wide configuration file and one or more object-level configuration files pointing to the same backup location. Storage between backups is shared, preventing multiple copies of the same data. For object-level backups, using the same backup location causes `vbr` to encounter fewer OID conflict prevention techniques. Avoiding OID conflict prevention results in fewer problems when restoring the backup.

When using cluster and object configuration files with the same backup location, `vbr` includes additional provisions to ensure that the object-level backups can be used following a full cluster restore. One approach to restoring a full cluster is to use a full database backup to bootstrap the cluster. After the cluster is operational again, you can restore the most recent object-level backups for schemas and tables.

Attempting to restore a full database using an object-level configuration file fails, resulting in this error:

```
VMart=> /tmp/vbr --config-file=Table2.ini -t restore
Preparing...
Invalid metadata file. Cannot restore.
restore failed!
```

See [Restoring All Objects From an Object-Level Backup](#) for more information.

**Backup Epochs**

Each backup includes the epoch to which its contents can be restored. When `vbr` restores data, Vertica updates to the current epoch.
vbr attempts to create an object-level backup five times before an error occurs and the backup fails.

Creating Hard-Link Local Backups

You can use the hardLinkLocal option to create a full- or object-level backup with hard file links on a local database host.

Creating hard-link local backups can provide the following advantages over a remote host backup:

- Speed — A hard-link local backup is significantly faster than a remote host backup. When backing up, vbr does not copy files if the backup directory exists on the same file system as the database directory.
- Reduced network activities — The hard-link local backup minimizes network load because it does not require rsync to copy files to a remote backup host.
- Less disk space — The backup includes a copy of the catalog and hard file links. Therefore, the local backup uses significantly less disk space than a backup with copies of database data files. However, a hard-link local backup saves a full copy of the catalog each time you run vbr. Thus, the disk size increases with the catalog size over time.

Hard-link local backups can help you during experimental designs and development cycles. Database designers and developers can create hard-link local object backups of schemas and tables on a regular schedule during design and development phases. If any new developments are unsuccessful, developers can restore one or more objects from the backup.

Planning Hard-Link Local Backups

If you plan to use hard-link local backups as a standard site procedure, design your database and hardware configuration appropriately. Consider storing all of the data files on one file system per node. Such a configuration has the advantage of being automatically set up for hard-link local backups.
**Specifying Backup Directory Locations**

The `backupDir` parameter of the configuration file specifies the location of the top-level backup directory. Hard-link local backups require that the backup directory be located on the same Linux file system as the database data. The Linux operating system cannot create hard file links to another file system.

Do not create the hard-link local backup directory in a database data storage location. For example, as a best practice, the database data directory should not be at the top level of the file system, as it is in the following example:

```
/home/dbadmin/data/VMart/v_vmart_node0001
```

Instead, Vertica recommends adding another subdirectory for data above the database level, such as in this example:

```
/home/dbadmin/data/dbdata/VMart/v_vmart_node0001
```

You can then create the hard-link local backups subdirectory as a peer of the data directory you just created, such as in this example:

```
/home/dbadmin/data/backups
/home/dbadmin/data/dbdata
```

When you specify the hard-link backup location, be sure to avoid these common errors when adding the `hardLinkLocal=True` parameter to the configuration file:

<table>
<thead>
<tr>
<th>If ...</th>
<th>Then...</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>You specify a backup directory on a <strong>different</strong> node</td>
<td><code>vbr</code> issues an error message and aborts the backup.</td>
<td>Change the configuration file to include a backup directory on the same host and file system as the database files. Then, run <code>vbr</code> again.</td>
</tr>
<tr>
<td>You specify a backup location on the same node, but a backup destination directory on a <strong>different</strong> file system from the database and catalog files.</td>
<td><code>vbr</code> issues a warning message and performs the backup by copying (not linking) the files from one file system to the other.</td>
<td>No action required, but copying consumes more disk space and takes longer than linking.</td>
</tr>
</tbody>
</table>
**Creating the Backup**

Before creating a full hard-link local database backup of an Enterprise Mode database, verify the following:

- Your database is running. All nodes need not be up in a K-safe database for vbr to run. However, be aware that any nodes that are DOWN are not backed up.
- The user account that starts vbr (dbadmin or other) has write access to the target backup directories.

Hard-link backups are not supported in Eon Mode.

When you create a full or object-level hard link local backup, that backup contains the following:

<table>
<thead>
<tr>
<th>Backup</th>
<th>Catalog</th>
<th>Database files</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full backup</td>
<td>Full copy</td>
<td>Hard file links to all database files</td>
</tr>
<tr>
<td>Object-level backup</td>
<td>Full copy</td>
<td>Hard file links for all objects listed in the configuration file, and any of their dependent objects</td>
</tr>
</tbody>
</table>

Run the vbr script from a terminal using the database administrator account from a node in your database cluster. You cannot run vbr as root.

Hard-link backups use the same vbr arguments as other backups. Configuring a backup as a hard-link backup is done entirely in the configuration file. The following example shows the syntax:

```
$ vbr --task backup --config fullbak.ini
```

**Creating Hard-Link Local Backups for External Media Storage**

You can use hard-link local backups as a staging mechanism to back up to tape or other forms of storage media. The following steps present a simplified approach to saving, and then restoring, hard-link local backups from tape storage:

1. Create a configuration file by copying an existing one or one of the samples described in Sample VBR .ini Files.
2. Edit the configuration file (localbak.ini in this example) to include the `hardLinkLocal=True` parameter in the [Transmission] section.

3. Run vbr with the configuration file:

   ```
   $ vbr --task backup --config-file localbak.ini
   ```

4. Copy the hard-link local backup directory with a separate process (not vbr) to tape or other external media.

5. If the database becomes corrupted, transfer the backup files from tape to their original backup directory and restore as explained in `Restoring Hard-Link Local Backups`.

**Note:**

Vertica recommends that you preserve the directory containing the hard-link backup after copying it to other media. If you delete the directory and later copy the files back from external media, the copied files will no longer be links. Instead, they will use as much disk space as if you had done a full (not hard-link) backup.

Restoring hard-link local backups requires some additional (manual) steps. Do not use them as a substitute for regular full backups (Creating Full Backups).

**Hard-Link Local Backups in Disaster Recovery**

Hard-link local backups are only as reliable as the disk on which they are stored. If the local disk becomes corrupt, so does the hard-link local backup. In this case, you are unable to restore the database from the hard-link local backup because it is also corrupt.

All sites should maintain full backups externally for disaster recovery because hard-link local backups do not actually copy any database files.

**Incremental or Repeated Backups**

Vertica recommends, as a best practice, that you take frequent backups if database contents diverge in significant ways. Always take backups after any event that significantly modifies the database, such as performing a rebalance. Mixing many backups with significant differences can weaken data K-safety. For example, taking backups both before and after a rebalance is not a recommended practice in cases where the backups are all part of one archive.
Each time you back up your database with the same configuration file, vbr creates an additional backup and might remove the oldest backup. The backup operation copies new storage containers, which can include:

- Data that existed the last time you performed a database backup
- New and changed data since the last full backup

Use the restorePointLimit parameter in the configuration file to increase the number of stored backups. If a backup task would cause this limit to be exceeded, vbr deletes the oldest backup after a successful backup.

When you run a backup task, vbr first creates the new backup in the specified location, which might temporarily exceed the limit. It then checks whether the number of backups exceeds the value of restorePointLimit, and, if necessary, deletes the oldest backups until only restorePointLimit remain. If the requested backup fails or is interrupted, vbr does not delete any backups.

When you restore a database, you can choose to restore from any retained backup rather than the most recent, so raise the limit if you expect to need access to older backups.

## Restoring Backups

You can use the `vbr restore task` to restore your full database or selected objects from backups created by vbr. Typically you use the same configuration file for both operations. The minimal restore command is:

```
$ vbr --task restore --config-file config-file.ini
```

You must log in using the database administrator's account (not root).

For full restores, the database must be DOWN. For object restores, the database must be UP.

Usually you restore to the cluster that you backed up, but you can also restore to an alternate cluster if the original one is no longer available.

Restoring must be done on the same architecture as the backup from which you are restoring. You cannot back up an Enterprise Mode database and restore it in Eon Mode or vice versa.

You can perform restore tasks on Permanent node types. You cannot restore data on Ephemeral, Execute, or Standby nodes. To restore or replicate to these nodes, you must
first change the destination node type to PERMANENT. For more information, refer to Setting Node Type.

**Restoring and Replicating Objects to a Newer Version of Vertica**

Vertica supports object replication and restoration to a target database up to one minor version later than the current database version. For example, you can replicate or restore objects from a version 9.1.x database to a version 9.2.0 database. The restore or replication process from one version to another is the same as it is to the same version.

If your restored or replicated objects require a U Dx library that is not present in the later version of your database, Vertica displays the following error:

```
ERROR 2858: Could not find function definition
```

You can resolve this issue by installing compatible libraries in your target database.

**Restoring HDFS Storage Locations**

If your Vertica cluster uses HDFS storage locations, you must do some additional configuration before you can restore. See Backing Up HDFS Storage Locations Backing Up HDFS Storage Locations in Integrating with Apache Hadoop.

HDFS storage locations support only full backup and restore. You cannot perform object backup or restore on a cluster that uses HDFS storage locations.

**Restoring a Database from a Full Backup**

You can restore a full database backup to the database that was backed up or to an alternate cluster with the same architecture. One reason to restore to an alternate cluster is to set up a test cluster on which to investigate a problem in production.

To restore a full database backup, you must verify that:

- The database is DOWN. You cannot restore a full backup when the database is running.
- All of the backup hosts are available.
• The backup directory exists and contains the backups from which to restore the data.
• The cluster to which you are restoring the backup has:
  • The same number of nodes as the one used to create the backup
  • The same architecture (Enterprise Mode or Eon Mode) as the one used to create the backup
  • Identical node names
• The target database must already exist on the cluster to which you are restoring data.
  • Database can be completely empty, without any data or schema.
  • The database name must match the name in the backup
  • All of the node names in the database must match the names of the nodes in the configuration file.
• The user performing the restore is the database administrator.
• If you are restoring an Eon Mode database, you have met the Requirements for Eon Mode Databases.

You can use only a full database backup to restore a complete database. If you have saved multiple backup archives, you can restore from either the last backup or a specific archive.

Restoring from a full database backup injects the OIDs from each backup into the restored catalog of the full database backup. The catalog also receives all archives. Additionally, the OID generator and current epoch are set to the current epoch.

You can also restore a full backup to a different database than the one you backed up. See Restoring a Database to an Alternate Cluster.

**Important:**
When you restore an Eon Mode database, the communal storage remains in its original location even if you restore into a new database. Do not restart the original database; running two databases against the same communal storage can cause data corruption.

**Restoring the Most Recent Backup**

Usually, when a node or cluster is DOWN, you want to return the cluster to its most-recent state. Doing so requires restoring a full database backup. You can restore any full database backup from the archive by identifying the name in the configuration file.
To restore from the most recent backup, use the `vbr restore task` with the configuration file. If your `password configuration file` does not contain the database superuser password, `vbr` prompts you to enter it.

The following example shows how you can use the `db.ini` configuration file for restoration:

```
> vbr --task restore --config-file db.ini
Copying...
1871652633 out of 1871652633, 100%
All child processes terminated successfully.
restore done!
```

**Restoring an Archive**

If you saved multiple backups, you can specify an archive to restore. To list the archives that exist to choose one to restore, use the `vbr --listbackup` task, with a specific configuration file. See [Viewing Backups](#).

To restore from an archive, add the `--archive` parameter to the command line. The value is the `date_timestamp` suffix of the directory name that identifies the archive to restore. For example:

```
$ vbr --task restore --config-file fullbak.ini --archive=20121111_205841
```

The `--archive` parameter identifies the archive created on 11-11-2012 (`archive20121111`), at time 205841 (20:58:41). You need specify only the `_archive` suffix, because the configuration file identifies the backup name of the subdirectory, and the OID identifier indicates the backup is an archive.

**Restore Failures in Eon Mode**

When a restore operation fails, `vbr` can leave extra files in the communal storage location. Because communal storage is in S3, those extra files cost you money. To remove them, restart the database and call `CLEAN_COMMUNAL_STORAGE` with an argument of `true`.

**Restoring a Database to an Alternate Cluster**

Vertica supports restoring a full backup to an alternate cluster.
Requirements

The process is similar to the process for Restoring a Database from a Full Backup, with the following additional requirements.

The destination database must:

- Be DOWN.
- Share the same name as the source database.
- Have the same number of nodes as the source database.
- Have the same names as the source nodes.
- Use the same catalog directory location as the source database.
- Use the same port numbers as the source database.

Procedure

1. Copy the vbr configuration file that you used to create the backup to any node on the destination cluster.
2. If you are using a stored password, copy the password configuration file to the same location as the vbr configuration file.
3. From the destination node, issue a vbr restore command, such as:

   ```
   $ vbr -t restore -c full.ini
   ```

4. After the restore has completed, start the restored database.

Restoring All Objects From an Object-Level Backup

To restore everything in an object-level backup to the database from which it was taken, use the vbr restore task with the configuration file you used to create the backup, as in the following example:

```
$ vbr --task restore --config-file MySchema.ini
Copying...
1871652633 out of 1871652633, 100%
All child processes terminated successfully.
restore done!
```
The database must be UP.

You can specify how Vertica reacts to duplicate objects by setting the `objectRestoreMode` parameter in the configuration file.

This feature is available for Enterprise Mode databases only. In Eon Mode you can restore selected objects from a full backup instead; see Restoring Individual Objects.

Object-level backup and restore are not supported for HDFS storage locations.

**Restoring Objects to a Changed Cluster**

Unlike restoring from a full database backup, `vbr` supports restoring object-level backups after adding nodes to the cluster. Any nodes that were not in the cluster when you created the object-level backup do not participate in the restore. You can rebalance your cluster after the restore to distribute data among the new nodes.

You cannot restore an object-level backup after removing nodes, altering node names, or changing IP addresses. Trying to restore an object-level backup after such changes causes `vbr` to fail and display this message:

```
Preparing...
Topology changed after backup; cannot restore.
restore failed!
```

**Projection Epoch After Restore**

All object-level backup and restore events are treated as DDL events. If a table does not participate in an object-level backup, possibly because a node is down, restoring the backup affects the projection in the following ways:

- Its epoch is reset to 0.
- It must recover any data that it does not have by comparing epochs and other recovery procedures.

**Catalog Locks During Restore**

As with other databases, Vertica transactions follow strict locking protocols to maintain data integrity.
When restoring an object-level backup into a cluster that is UP, `vbr` begins by copying data and managing storage containers. If necessary, `vbr` splits the containers. This process does not require any database locks.

After completing data-copying tasks, `vbr` first requires a table object lock (O-lock) and then a global catalog lock (GCLX).

Sometimes, other database operations, such as DML statements, are in progress when the process attempts to get an O-lock on the table. In such cases, `vbr` is blocked from progress until the DML statement completes and releases the lock. After securing an O-lock first, and then a GCLX lock, `vbr` blocks other operations that require a lock on the same table.

While `vbr` holds its locks, concurrent table modifications are blocked. Database system operations, such as the Tuple Mover (TM) transferring data from memory to disk, are canceled to permit the object-level restore to complete.

**Catalog Restore Events**

Each object-level backup includes a section of the database catalog, called a *snippet*. A snippet contains the selected objects, their dependent objects, and principal objects. A catalog snippet is similar in structure to the database catalog but consists of a subset representing the object information. Objects being restored can be read from the catalog snippet and used to update both global and local catalogs.

Each object from a restored backup is updated in the catalog. If the object no longer exists, `vbr` drops the object from the catalog. Any dependent objects that are not in the backup are also dropped from the catalog.

`vbr` uses existing dependency verification methods to check the catalog and adds a restore event to the catalog for each restored table. That event also includes the epoch at which the event occurred. If a node misses the restore table event, it recovers projections anchored on the given table.

**Restoring and Replicating Objects to a Newer Version of Vertica**

Vertica supports object replication and restoration to a target database up to one minor version later than the current database version. For example, you can replicate or restore objects from a version 9.1.x database to a version 9.2.0 database. The restore or replication process from one version to another is the same as it is to the same version.
If your restored or replicated objects require a UDx library that is not present in the later version of your database, Vertica displays the following error:

```
ERROR 2858:  Could not find function definition
```

You can resolve this issue by installing compatible libraries in your target database.

**Catalog Size Limitations**

Object level restores can fail if your catalog size is greater than five percent of the total memory available in the node performing the restore. In this situation, Vertica recommends restoring individual objects from the backup. For more information, refer to [Restoring Individual Objects](#).

**See Also**

- Failure Recovery
- Transactions

**Restoring Individual Objects**

You can use `vbr` to restore individual tables and schemas from a full or object-level backup: qualify the restore task with `--restore-objects`, and specify the objects to restore as a comma-delimited list:

```
$ vbr --task=restore --config-file=filename --restore-objects='objectname[,,...]' [--archive=archive-id]
```

The following requirements and restrictions apply:

- The database must be running, and nodes must be UP.
- Tables must include their schema names.
- Do not embed spaces before or after comma delimiters of the `--restore-objects` list; otherwise, `vbr` interprets the space as part of the object name.
- Object-level restore is not supported for HDFS storage locations. To restore an HDFS storage location you must do a full restore.

By default, `--restore-objects` restores the specified objects from the most recent backup. You can restore from an earlier backup with the `--archive` parameter.
The following example uses the `db.ini` configuration file, which includes the database administrator's password:

```
> vbr --task restore --config-file=db.ini --restore-objects=saleschema,public.sales_table,public.customer_info
Preparing...
Found Database port: 5433
Copying...
[==============================================] 100%
All child processes terminated successfully.
All extract object child processes terminated successfully.
Copying...
[==============================================] 100%
All child processes terminated successfully.
restore done!
```

**Object Dependencies**

When you restore an object, Vertica does not always restore dependent objects. For example, if you restore a schema containing views, Vertica does not automatically restore the tables of those views. One exception applies: if database tables are linked through foreign keys, you must restore them together, unless `drop_foreign_constraints` is set in the `vbr` configuration file to true.

**Note:**
You must also set `objectRestoreMode` to `coexist`, otherwise Vertica ignores `drop_foreign_constraints`.

**Duplicate Objects**

You can specify how restore operations handle duplicate objects by configuring `objectRestoreMode`. By default, it is set to `createOrReplace`, so if a duplicate object exists, the restore operation overwrites it with the archived version.

**Eon Mode Considerations**

Restoring objects to an Eon Mode database can leave unneeded files in cloud storage. These files have no effect on database performance or data integrity. However, they can incur extra cloud storage expenses. To remove these files, restart the database and call `CLEAN_COMMUNAL_STORAGE` with an argument of true.
Restoring Objects to an Alternate Cluster

You can use the restore task to copy objects from one database to another. You might do this to "promote" tables from a development environment to a production environment, for example. All restrictions described in Restoring Individual Objects apply when restoring to an alternate cluster.

To restore to an alternate database, you must make changes to a copy of the configuration file that was used to create the backup. The changes are in the [Mapping] and [NodeMapping] sections. Essentially, you create a configuration file for the restore operation that looks to vbr like a backup of the target database, but it actually describes the backup from the source database. See Restore Object from Backup to an Alternate Cluster (object_restore_to_other_cluster.ini) for an example configuration file.

The following example uses two databases, named source and target. The source database contains a table named sales. The following source_snapshot.ini configuration file is used to back up the source database:

```
[Misc]
snapshotName = source_snapshot
restorePointLimit = 2
objectRestoreMode = createOrReplace

[Database]
dbName = source
dbUser = dbadmin
dbPromptForPassword = True

[Transmission]

[Mapping]
v_source_node0001 = 192.168.50.168:/home/dbadmin/backups/
```
The target_snapshot.ini file starts as a copy of source_snapshot.ini. Because the [Mapping] section describes the database that vbr operates on, we must change the node names to point to the target nodes. We must also add the [NodeMapping] section and change the database name:

```
[Misc]
snapshotName = source_snapshot
restorePointLimit = 2
objectRestoreMode = createOrReplace

[Database]
dbName = target
dbUser = dbadmin
dbPromptForPassword = True

[Transmission]

[Mapping]
v_target_node0001 = 192.168.50.151:/home/dbadmin/backups/

[NodeMapping]
v_source_node0001 = v_target_node0001
```

As far as vbr is concerned, we are restoring objects from a backup of the target database. In reality, we are restoring from the source database.

The following command restores the sales table from the source backup into the target database:

```
$ vbr --task restore --config-file target_snapshot.ini --restore-objects sales
Starting object restore of database target.
Participating nodes: v_target_node0001.
Objects to restore: sales.
Enter vertica password:
Restoring from restore point: source_snapshot_20160204_191920
Loading snapshot catalog from backup.
Extracting objects from catalog.
Syncing data from backup to cluster nodes.
[==================================================] 100%
Finalizing restore.
Restore complete!
```

**Restoring Hard-Link Local Backups**

You restore from hard-link local backups the same way you restore from full backups, using the restore task. If you have used hard-link local backups to back up to external media, you need to take some additional steps.
Transferring Backups to and from Remote Storage

When a full hard-link local backup exists, you can transfer the backup to other storage media, such as tape or a locally-mounted NFS directory. Transferring hard-link local backups to other storage media may copy the data files associated with the hard file links.

You can use a different directory when you return the backup files to the hard-link local backup host. However, you must also change the backupDir parameter value in the configuration file before restoring the backup.

Complete the following steps to restore hard-link local backups from external media:

1. If the original backup directory no longer exists on one or more local backup host nodes, re-create the directory.

   The directory structure into which you restore hard-link backup files must be identical to what existed when the backup was created. For example, if you created hard-link local backups at the following backup directory, you can then re-create that directory structure:

   ```
   /home/dbadmin/backups/localbak
   ```

2. Copy the backup files to their original backup directory, as specified for each node in the configuration file. For more information, refer to [Mapping].

3. Restore the backup, using one of three options:

   a. To restore the latest version of the backup, move the backup files to the following directory:

   ```
   /home/dbadmin/backups/localbak/node_name/snapshotname
   ```

   b. To restore a different backup version, move the backup files to this directory:

   ```
   /home/dbadmin/backups/localbak/node_name/snapshotname_archivedate_timestamp
   ```

4. When the backup files are returned to their original backup directory, use the original configuration file to invoke vbr. Verify that the configuration file specifies hardLinkLocal = true. Then restore the backup as follows:

   ```
   $ vbr --task restore --config-file localbak.ini
   ```
Ownership of Restored Objects

For a full restore, objects have the owners that they had in the backed-up database.

When performing an object restore, Vertica inserts data into existing database objects. By default, the restore does not affect the ownership, storage policies, or permissions of the restored objects. If, however, the restored object does not already exist, Vertica re-creates it. In this situation, the restored object is owned by the user performing the restore. Vertica does not restore dependent grants, roles, or client authentications with restored objects.

If the storage policies of a restored object are not valid, vbr applies the default storage policy. Restored storage policies can become invalid due to HDFS storage locations, table incompatibility, and unavailable min-max values at restore time.

Sometimes, Vertica encounters a catalog object that it does not need to restore. When this situation occurs, Vertica generates a warning message for that object and the restore continues.

Examples

Suppose you have a full backup, including Schema1, owned by the user Alice. Schema1 contains Table1, owned by Bob, who eventually passes ownership to Chris. The user dbadmin performs the restore. The following scenarios might occur that affect ownership of these objects.

**Scenario 1:**

Schema1.Table1 has been dropped at some point since the backup was created. When dbadmin performs the restore, Vertica re-creates Schema1.Table1. As the user performing the restore, dbadmin takes ownership of Schema1.Table1. Because Schema1 still exists, Alice retains ownership of the schema.

**Scenario 2:**

Schema1 is dropped, along with all contained objects. When dbadmin performs the restore, Vertica re-creates the schema and all contained objects. Dbadmin takes ownership of Schema1 and Schema1.Table1.

**Scenario 3:**
Schema1 and Schema1.Table1 both exist in the current database. When the user, dbadmin, rolls back to an earlier backup, the ownership of the objects remains unchanged. Alice owns Schema1 and Bob owns Schema1.Table1.

Scenario 4:

Schema1.Table1 exists and dbadmin wants to roll back to an earlier version. In the time since the backup was made, ownership of Schema1.Table1 has changed to Chris. When dbadmin restores Schema1.Table1, Alice remains owner of Schema1 and Chris remains owner of Schema1.Table1. The restore does not revert ownership of Schema1.Table1 from Chris to Bob.

Copying the Database to Another Cluster

Caution:

It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

You can use vbr to copy the entire database to another Vertica cluster. This feature helps you perform tasks such as copying a database between a development and a production environment. Copying your database to another cluster is essentially a simultaneous backup and restore operation. The data is backed up from the source database cluster and restored to the destination cluster in a single operation.

Note:

The copycluster task is not compatible with HDFS Storage Locations. Copycluster uses the Linux rsync tool to copy files from the source cluster to the target cluster. HDFS storage backup and restore is based on use of snapshots. Data in an HDFS storage location is backed up to HDFS itself. Vertica cannot transfer data to a remote HDFS cluster the same way that it can for a Linux cluster.

The directory locations for the Vertica catalog, data, and temp directories must be identical on the source and target database. Use the following vsql query to view the source database directory locations. This example sets expanded display, for illustrative purposes, and lists the columns of most interest: node_name, storage_path, and storage_usage.

```sql
=> \x
Expanded display is on.
```
Vertica Documentation
Administrator's Guide

VMart=> select node_name, storage_path, storage_usage from disk_storage;

- [ RECORD 1 ]-+----------------------------------+-
node_name | v_vmart_node0001
storage_path | /home/dbadmin/VMart/v_vmart_node0001_catalog/Catalog
storage_usage | CATALOG

- [ RECORD 2 ]-+----------------------------------+-
node_name | v_vmart_node0001
storage_path | /home/dbadmin/VMart/v_vmart_node0001_data
storage_usage | DATA, TEMP

- [ RECORD 3 ]-+----------------------------------+-
node_name | v_vmart_node0001
storage_path | /home/dbadmin/SSD/schemas
storage_usage | DATA

- [ RECORD 4 ]-+----------------------------------+-
node_name | v_vmart_node0001
storage_path | /home/dbadmin/SSD/tables
storage_usage | DATA

- [ RECORD 5 ]-+----------------------------------+-
node_name | v_vmart_node0001
storage_path | /home/dbadmin/SSD/schemas
storage_usage | DATA

- [ RECORD 6 ]-+----------------------------------+-
node_name | v_vmart_node0002
storage_path | /home/dbadmin/VMart/v_vmart_node0002_catalog/Catalog
storage_usage | CATALOG

- [ RECORD 7 ]-+----------------------------------+-
node_name | v_vmart_node0002
storage_path | /home/dbadmin/VMart/v_vmart_node0002_data
storage_usage | DATA, TEMP

- [ RECORD 8 ]-+----------------------------------+-
node_name | v_vmart_node0002
storage_path | /home/dbadmin/SSD/tables
storage_usage | DATA

Notice the directory paths for the Catalog, Data, and Temp storage. These paths are the same on all nodes in the source database and must be the same in the target database.

Note:
When copying a database to another cluster, if the target data is different, vbr overwrites all existing data. To retain existing data on the target cluster, create a full database backup of the target before invoking the copycluster vbr task.

Identifying Node Names for Target Cluster

Before you can configure the target cluster, you need to know the exact names that admintools supplied to all nodes in the source database.

To see the node names, run a query such as:
You can also find the node names by running admintools from the command line. For example, for the VMart database, you can enter a command such as:

```bash
$ /opt/vertica/bin/admintools -t node_map -d VMART
```

<table>
<thead>
<tr>
<th>DATABASE</th>
<th>NODENAME</th>
<th>HOSTNAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMART</td>
<td>v_vmart_node0001</td>
<td>192.168.223.xx</td>
</tr>
<tr>
<td>VMART</td>
<td>v_vmart_node0002</td>
<td>192.168.223.yy</td>
</tr>
<tr>
<td>VMART</td>
<td>v_vmart_node0003</td>
<td>192.168.223.zz</td>
</tr>
</tbody>
</table>

### Configuring the Target Cluster

Configure the target to allow the source database to connect to it and restore the database. The target cluster must:

- Have the same number of nodes as the source cluster.
- Have a database with the same name as the source database. The target database can be completely empty.
- Have the same node names as the source cluster. The node names listed in the NODES system tables on both clusters must match.
- Be accessible from the source cluster.
- Have the same database administrator account, and all nodes must allow a database administrator of the source cluster to log in through SSH without a password.

**Note:**

Passwordless access *within* the cluster is not the same as passwordless access *between* clusters. The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.

- Have adequate disk space for the `vbr --task copycluster` command to complete.
Creating a Configuration File for CopyCluster

You must create a configuration file specifically for copying your database to another cluster. In the configuration file, specify the host names of nodes in the target cluster as the backup hosts. You must define backupHost; however, vbr ignores the backupDir option and always stores the data in the catalog and data directories of the target database.

You cannot use an object-level backup with the copycluster command. Instead, you must perform a full database backup.

The following example shows how you can set up vbr to copy a database on a 3-node cluster, v_vmart, to another cluster, test-host.

```
[Misc]
snapshotName = CopyVmart
tempDir = /tmp/vbr

[Database]
dbName = vmart
dbUser = dbadmin
dbPassword = password
dbPromptForPassword = False

[Transmission]
ectrypt = False
port_rsync = 50000

[Mapping]
; backupDir is not used for cluster copy
v_vmart_node0001= test-host01
v_vmart_node0002= test-host02
v_vmart_node0003= test-host03
```

Copying the Database

You must stop the target cluster before you invoke copycluster.

To copy the cluster, run vbr from a node in the source database using the database administrator account:

```
$ vbr -t copycluster -c copycluster.ini
Starting copy of database VMART.
Participating nodes: vmart_node0001, vmart_node0002, vmart_node0003, vmart_node0004.
Enter vertica password:
Snapshotting database.
Snapshot complete.
```
If the copycluster task is interrupted, the destination cluster retains any data files that have already transferred. If you attempt the operation again, Vertica does not need to resend these files.

**Replicating Objects to an Alternate Cluster**

You can replicate tables and schemas from one database to alternate databases in your organization. One reason you might use object replication is to copy tables and schemas between test, staging, and production clusters. Another might be to immediately replicate certain objects after an important change, like loading data, without waiting for the next scheduled job.

You use the `vbr replicate` task to do object replication.

Replication does not copy all object types. Catalog objects that are not copied during replication include:

- Users and roles
- Grants
- Access policies (column and row)
- Client authentication and profiles

To copy an entire database, use the `copycluster` task described in [Copying the Database to Another Cluster](#). After you use `copycluster`, you can then use the `replicate` task to update tables and schemas instead of doing another full copy.

**Advantages of Alternate Database Replication**

Replicating objects is generally faster than exporting and importing them. The first replication of an object replicates the entire object. Subsequent replications copy only data that has changed since the last replication. Vertica replicates data as of the current epoch on the target database. Used with a cron job, you can replicate key objects to create a backup database.
In situations where the target database is down, or you plan to replicate the entire database, Vertica recommends that you try Copying the Database to Another Cluster

**How DOWN Nodes Affect Replication**

You can replicate objects if some nodes are down in either the source or destination database, so long as the nodes themselves remain available. "DOWN node" here refers to the Vertica process being down on a node that is still visible on the network.

The effect of DOWN nodes on a replication task depends on whether they are present in the source or destination database.

<table>
<thead>
<tr>
<th>Location</th>
<th>Effect on Replication</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOWN source nodes</td>
<td>Vertica can replicate objects from a source database containing DOWN nodes. If nodes in the source database are DOWN, set the corresponding nodes in the target database to DOWN as well.</td>
</tr>
<tr>
<td>DOWN destination nodes</td>
<td>Vertica can replicate objects when the destination database has DOWN nodes. If nodes in the destination database are DOWN, you must exclude the corresponding source database nodes using the --nodes parameter on the vbr command line.</td>
</tr>
</tbody>
</table>

**Replication to Alternate Database Process Flow**

To replicate objects to an alternate database, begin in the SOURCE database and complete the following process:

1. Verify replication requirements
2. Edit your vbr configuration file
3. Replicate objects
4. Monitor object replication

**Verify Replication Requirements**

First verify that your source and target databases meet the following requirements.

Both the source and target databases must:
- Have the same Linux user associated with the dbadmin account.
- Be UP.
- Have the same number of nodes.
- Allow a database administrator of the source cluster to log in on all nodes through SSH without a password.

**Note:**
Passwordless access within the cluster is not the same as passwordless access between clusters. The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.

**Edit Your vbr Configuration File for Replication**

Add the following parameters to the configuration file that you are using to replicate objects:

1. In the [Misc] section, add the following parameter:

   ```
   ; Identify the objects that you want to replicate
   objects = schema.objectName
   ```

2. In the [Misc] section, set a unique snapshot name. Replication tasks can run concurrently with some other vbr tasks, but only if the snapshot names are different.

   ```
   snapshotName = name
   ```

3. In the [Database] section, set the following parameters:

   ```
   ; parameters used to replicate objects between databases
   dest_dbName =
   dest_dbUser =
   dest_dbPromptForPassword =
   ```

   If you are using a stored password, be sure to configure the `dest_dbPassword` parameter in your Password Configuration File.

4. In the [Mapping] section, map your source nodes to your target hosts:

   ```
   [Mapping]
   v_source_node0001 = targethost01
   v_source_node0002 = targethost02
   v_source_node0003 = targethost03
   ```
Replicate Objects

To replicate objects, use the vbr replicate task:

```
vbr -t replicate -c configfile.ini
```

The replicate task can run concurrently with backup and with object replicate tasks in either direction. Replication cannot run concurrently with tasks that require that the database be down (full restore and copycluster). Each concurrent task must have a unique snapshot name. As a best practice, therefore, create a separate configuration file for each object replication. Consider replicating a schema rather than individual tables if you need many of the tables.

Restoring and Replicating Objects to a Newer Version of Vertica

Vertica supports object replication and restoration to a target database up to one minor version later than the current database version. For example, you can replicate or restore objects from a version 9.1.x database to a version 9.2.0 database. The restore or replication process from one version to another is the same as it is to the same version.

If your restored or replicated objects require a U Dx library that is not present in the later version of your database, Vertica displays the following error:

```
ERROR 2858: Could not find function definition
```

You can resolve this issue by installing compatible libraries in your target database.

Monitoring Object Replication

You can monitor object replication in the following ways:

- View vbr logs on the source database
- Check database logs on the source and destination databases
- Query `REMOTE_REPLICATION_STATUS` on the source database
Including and Excluding Objects Using Wildcards

When specifying objects to back up, restore, or replicate, you can specify groups using wildcards (globs). Further, after you specify a list to include, you can specify another list to exclude. For example, you might include all tables in a schema and then exclude tables matching a given pattern.

You can use wildcards in your vbr.ini file or as vbr command line parameters.

Wildcards

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Matches 0 or more characters. Case-insensitive.</td>
</tr>
</tbody>
</table>
| \         | Escapes the next character. To include a literal ? or * in your table or schema name, use the \ character immediately before the escaped character. To escape the \ character itself, use a double \\.
| "         | Escapes the . character. To include a literal . in your table or schema name, wrap the character in double quotation marks. |

Matching Schemas

Any pattern without a . character represents a schema. For example, the pattern

```
includeObjects = customer*,s?
```

matches any schema beginning with the word customer and any schema consisting of s and one letter.

When you back up or restore a schema without referencing any of the tables of that schema, vbr automatically includes all of the tables in that schema. If you include a schema
by name alone, you cannot exclude individual tables from that schema. For example, the following is invalid syntax.

```
; invalid:
includeObjects = VMart
excludeObjects = VMart.?table?
```

You can exclude objects from an included schema by identifying the schema with the pattern `<schemaname>.*`. The following example shows a valid way to include a schema and exclude specific tables and patterns.

```
--include-objects 'VMart.*'
--exclude-objects 'VMart.sales,VMart.*account'
```

### Matching Tables

Any pattern including the `. ` character represents a table. For example, in a configuration file, the following pattern:

```
includeObjects = sales.newclients,sales.??
```

would match any table named newclients belonging to the schema sales, and any table name with two characters belonging to the sales schema.

You can also match all schemas and tables in a database or backup by using the pattern `*.*`. For example, you could restore all of the tables and schemas in a backup using this command:

```
--include-Objects '*,*'
```

Because a `vbr` parameter is evaluated on the command line, you must enclose the wildcards in single quote marks to prevent Linux from misinterpreting them.

### Testing Wildcard Patterns

You can test the results of any pattern by using the `--dry-run` parameter with a backup or restore command. Commands that include `--dry-run` do not affect your database. Instead, `vbr` displays the result of the command without executing it. For more information on `--dry-run`, refer to the `vbr Reference`. 
Using Wildcards with Backups

You can identify objects to include in your object backup tasks using the `includeObjects` and `excludeObjects` parameters in your configuration file. A typical configuration file might include this content:

```
[Misc]
snapshotName = dbobjects
restorePointLimit = 1
enableFreeSpaceCheck = True
includeObjects = VMart.*,online_sales.*
excludeObjects = *.temp*
```

In this example, the backup would include all tables from the VMart and online_sales schemas, while excluding any table containing the string 'temp' in its name belonging to any schema.

After it evaluates included objects, `vbr` evaluates excluded objects and removes excluded objects from the included set. If, for example, you included `schema1.table1` and then excluded `schema1.table1`, that object would be excluded. If no other objects were included in the task, the task would fail. The same is true for wildcards. If an exclusion pattern removes all included objects, the task fails.

Using Wildcards with Restore

You can identify objects to include in your restore tasks using the `--include-objects` and `--exclude-objects` parameters.

**Note:**
Take extra care when using wildcard patterns to restore database objects. Depending on your object restore mode settings, restored objects can overwrite your existing objects. Test the impact of a wildcard restore with the `--dry-run vbr` parameter before performing the actual task.

As with backups, `vbr` evaluates excluded objects after it evaluates included objects and removes excluded objects from the included set. If no objects remain, the task fails.

A typical restore command might include this content. (Line wrapped in the documentation for readability, but this is one command.)

```
vbr -t restore -c verticaconfig --include-objects 'customers.*,sales?'
   --exclude-objects 'customers.199?,customers.200?'
```
This example includes the schema customers, minus any tables with names matching 199 and 200 plus one character, as well as all any schema matching 'sales' plus two characters.

Another typical restore command might include this content.

```bash
vbr -t restore -c replicateconfig --include-objects '*.transactions,flights.*'
   --exclude-objects 'flights.DTW*,flights.LAS*,flights.LAX*'
```

This example includes any table named transactions, regardless of schema, and any tables beginning with DTW, LAS, or LAX belonging to the schema flights. Although these three-letter airport codes are capitalized in the example, vbr is case-insensitive.

## Managing Backups

### Caution:

It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

vbr provides several tasks related to managing backups: listing them, checking their integrity, selectively deleting them, and more. In addition, vbr has parameters to allow you to restrict its use of system resources.

## Viewing Backups

You can view backups in any of three ways:

- Use `vbr` to list the backups that reside on the local or remote backup host (requires a configuration file).
- View historical information about backups using the `DATABASE_BACKUPS` systems table. Because the `database_backups` system table contains historical information, it is not updated when you delete the backups.
- Open the `vbr` log file to check the status of a backup. The log file resides on the node where you have run vbr, in the directory specified by the `tempDir vbr configuration parameter`. The default name of this directory is `/tmp/vbr`. 
List Backups with vbr

To list backups on the backup hosts, use vbr --task listbackup with a specific configuration file. The following example shows how you can list backups, using a full backup configuration file, bak.ini:

```
dbadmin@doch01 ~]$ vbr --task listbackup --config-file /home/dbadmin/bak.ini
```

The vbr output information includes the following:

- **backup**: The name of the generated backup. Vertica names the backup by combining the name of the vbr configuration file with a timestamp. Use the timestamp to identify an archive when you perform a restore.
- **backup_type**: The type of the backup, either full or object.
- **epoch**: The epoch when the backup was created.
- **objects**: The objects being backed up. For a full backup, this field is blank.
- **nodes (hosts)**: The hosts that received the backup and the database node names that provided the backups.
- **version**: The version of Vertica used to create the backup.
- **file_system_type**: The storage location file system of the Vertica hosts that comprise this backup, either Linux or HDFS. For information on backing up HDFS hosts, refer to Backing Up HDFS Storage Locations.

The following example shows a list of full backups of a three node cluster to a single backup host, bkhost:

<table>
<thead>
<tr>
<th>backup</th>
<th>backup_type</th>
<th>epoch</th>
<th>objects</th>
<th>nodes (hosts)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bak_20160414_134452 (bkhost), v_vmart_node0003 (bkhost)</td>
<td>full</td>
<td>749</td>
<td>v_vmart_node0001 (bkhost), v_vmart_node0002</td>
<td></td>
</tr>
<tr>
<td>bak_20160413_174544 (bkhost), v_vmart_node0003 (bkhost)</td>
<td>full</td>
<td>659</td>
<td>v_vmart_node0001 (bkhost), v_vmart_node0002</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**
The listbackup task fails if you attempt to view backups on a cluster without a database when the backups were made to local hosts using the [shortcut](#). Vbr requires a database to provide the location of the mapped local host.

**Viewing All Backups in a Location**

You can use the `--list-all` parameter with the `listbackup` task to view a list of all the snapshots stored on the hosts and paths listed in the specified configuration file:

```bash
dbadmin@doca01 ~]$ vbr --task listbackup --list-all --config-file /home/dbadmin/Nightly.ini
```

The following example shows a `--list-all` task using the configuration file `Nightly.ini`. That configuration file references the hosts `doca01`, `doca02`, and `doca03` and the path `/vertica/backup`. The output shows that these locations contain not just the backups created using `Nightly`, but also backups created using a configuration file called `Weekly.ini`.

<table>
<thead>
<tr>

<td>(doca03) [Linux]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You can also use the the `--json` and `--list-output-file` parameters with the `listbackup` task to output the same content in JSON delimited format to a display or to an output file. For more information, refer to `vbr Reference`.

**Query database_backups**

Use the following query to list historical information about backups. The `objects` column lists which objects were included in object-level backups. Do not use the `backup_timestamp` value when restoring an archive. Instead, Use the values provided by `vbr --task listbackup`, when restoring an archive.

```sql
\V Mart=> SELECT * FROM v_monitor.database_backups;
-[ RECORD 1 ]----------------------------------------------
backup_timestamp | 2013-05-10 14:41:12.673381-04
node_name         | v_vmart_node0003
snapshot_name     | schemabak
backup_epoch      | 174
```
Checking Backup Integrity

Vertica can confirm the integrity of your backup files and the manifest that identifies them. By default, backup integrity checks output their results to the command line.

**Perform a Quick Check**

The quick-check task gathers all backup metadata from the backup location specified in the configuration file and compares that metadata to the backup manifest. A quick check does not verify the objects themselves. Instead, this task outputs an exceptions list of any discrepancies between objects in the backup location and objects listed in the backup manifest.

Use the following form to perform quick check task:
Perform a Full Check

The full-check task verifies all objects listed in the backup manifest against filesystem metadata. A full check includes the same steps as a quick check. You can include the optional --report-file parameter to output results to a delimited JSON file. This task outputs an exceptions list that identifies the following inconsistencies:

- Incomplete restore points
- Damaged restore points
- Missing backup files
- Unreferenced files

Use the following form to perform a full check task:

$ vbr -t full-check -c configfile.ini --report-file=path/filename

For example:

$ vbr -t full-check -c backupconfig.ini --report-file=logging/fullintegritycheck.json

Repairing Backups

Vertica can reconstruct backup manifests and remove unneeded backup objects.

Performing a Quick Repair

The quick-repair task rebuilds the backup manifest, based on the manifests contained in the backup location.

Use the following form to perform a quick repair task:

$ vbr -t quick-repair -c configfile.ini
Performing Garbage Collection

The collect-garbage task rebuilds your backup manifest and deletes any backup objects that do not appear in the manifest. You can include the optional --report-file parameter to output results to a delimited JSON file.

Use the following form to perform a garbage collection task:

```
$ vbr -t collect-garbage -c configfile.ini --report-file=path/filename
```

Removing Backups

You can remove existing backups and restore points using vbr. When you use the remove task, vbr updates the manifests affected by the removal and maintains their integrity. If the backup archive contains multiple restore points, removing one does not affect the others. When you remove the last restore point, vbr removes the backup entirely.

**Note:**
Vertica does not support removing backups through the file system.

Use the following form to perform a remove task:

```
$ vbr -t remove -c configfile.ini --archive timestamp
```

You can remove multiple restore points using the archive parameter. To obtain the timestamp for a particular restore point, use the listbackup task.

- To remove multiple restore points, use a comma separator:
  --archive="restore_point1, restore_point2"

- To remove an inclusive range of restore points, use a colon:
  --archive="restore_point1: restore_point2"

- To remove all restore points, specify an archive value of all:
  --archive="all"

The following example shows how you can remove a restore point from an existing backup.

```
$ vbr -t remove -c backup.ini --archive 20160414_134452
Removing restore points: 20160414_134452
Remove complete!
```
Estimating Log File Disk Requirements

One of the vbr configuration parameters is tempDir. This parameter specifies the database host location where vbr writes its log files and some other temp files (of negligible size). The default location is the /tmp/vbr directory on each database host. You can change the default location by specifying a different path in the configuration file.

The temporary storage directory also contains local log files describing the progress, throughput, and any errors encountered for each node. Each time you run vbr, the script creates a separate log file, each named with a timestamp. When using default settings, the log file typically uses about 4KB of space per node per backup.

The vbr log files are not removed automatically, so you must delete older log files manually, as necessary.

Allocating Resources

By default, vbr allows a single rsync connection (for Linux file systems), 10 concurrent threads (for S3 connections), and unlimited bandwidth for any backup or restore operation. You can change these values in your configuration file. See Configuration File Reference for details of these parameters.

Connections

You might want to increase the number of concurrent connections. If you have many Vertica files, more connections can provide a significant performance boost as each connection increases the number of concurrent file transfers.

For more information, refer to the total_bwlimit_backup, total_bwlimit_restore, concurrency_backup, concurrency_restore, s3_concurrency_backup, and s3_concurrency_restore parameters.

Bandwidth Limits

You can limit network bandwidth use through the total_bwlimit_backup and total_bwlimit_restore data transmission parameters. For more information, refer to
Troubleshooting Backup and Restore

These tips can help you avoid issues related to backup and restore with Vertica and to troubleshoot any problems that occur.

Check the Logs

The vbr log is separate from the Vertica log. The default location is /tmp/vbr, but you can change this location by setting the tempdir parameter in the configuration file. (See [Misc] Miscellaneous Settings.) vbr logs are not included in Scrutinize reports.

If you cannot find an explanation for an error or unexpected results in the log, try increasing the logging level. You can set the level using the -d debug option on the vbr command line. Specify an integer value from 0 (the default) to 3 (the most verbose). For example:

```bash
$ vbr -t backup -c full_backup.ini --debug 3
```

As you increase the logging level, the file size of the log increases.

Check Status of Backup Nodes

Backups fail if you run out of disk space on the backup hosts or if vbr cannot reach them all. Check that you have sufficient space on each backup host and that you can reach each host via ssh.

Sometimes vbr leaves rsync processes running on the database or backup nodes. These processes can interfere with new ones. If you get an rsync error in the console, look for runaway processes and kill them.

Object Replication Fails

Confirm that you have excluded all DOWN nodes from your object replication.

If you do not exclude the DOWN node, replication fails with the following error:
Error connecting to a destination database node on the host <hostname>: <error> ...

Restoring an Archive Produces an Error

You might see an error like the following when restoring an archive:

```
$ vbr --task restore --archive prd_db_20190131_183111 --config-file /home/dbadmin/backup.ini
IOError: [Errno 2] No such file or directory: '/tmp/vbr/vbr_20190131_183111_s0rpYR/prd_db.info'
```

The problem is that the archive name is not in the correct format. Specify only the date/timestamp suffix of the directory name that identifies the archive to restore, as described in Restoring an Archive. For example:

```
$ vbr --task restore --archive 20190131_183111 --config-file /home/dbadmin/backup.ini
```

Backup or Restore Fails When Using an HDFS Storage Location

When performing a backup of a cluster that includes HDFS storage locations, you might see an error like the following:

```
ERROR 5127: Unable to create snapshot No such file /usr/bin/hadoop:
check the HadoopHome configuration parameter
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back up these locations. See Backing Up HDFS Storage Locations.

Object-level backup and restore are not supported with HDFS storage locations. You must use full backup and restore.

Could Not Connect to Endpoint URL (Eon Mode)

When performing a cross-endpoint operation, you can see a connection error if you failed to specify the endpoint URL for your communal storage (VBR_COMMUNAL_STORAGE_ENDPOINT_URL). When the endpoint is missing but you specify credentials for communal storage, vbr attempts to use those credentials to access AWS. This access fails, because
those credentials are for your on-premise storage, not AWS. When performing cross-endpoint operations, verify that all of the environment variables described in Backing up an on-premise database in Eon Mode are set correctly.

vbr Reference

vbr allows you to back up and restore either the full database, or one or more schema and table objects of interest. You can also copy a cluster and list backups you created previously.

Most tasks cannot run concurrently; however, replication tasks can run concurrently with each other and with backups. Concurrent tasks must not use the same snapshot name.

Eon Mode databases using cross-endpoint configurations support the following vbr tasks: backup (full only), restore (full only), listbackup, quick-check, full-check, quick-repair, collect-garbage, remove.

vbr is located in the Vertica binary directory (/opt/vertica/bin/vbr on most installations).

Syntax

`/opt/vertica/bin/vbr { command }`

```
... [ --archive timestamp ]
... [ --config-file file ]
... [ --debug level]
... [ --nodes node1 [, node2, ... ] ]
... [ --showconfig ]
```

Where command is one of the following:

</table>
## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `--archive timestamp` | Used with the `--task restore` and `--task remove` commands. Specifies the timestamp of the backup to restore or remove:  
    ```
    > vbr --task restore --config-file myconfig.ini --archive=20160115_182640
    ``` |
| `-c file`  
`--config-file file` | Indicates the configuration file to use as an absolute or relative path to the location from which you start vbr. If no file exists, an error occurs and vbr cannot continue. |
| `-nodes node1[,...]` | Specifies any nodes, in a comma-separated list, on which to perform a vbr task. The nodes listed match the names in the Mapping section of the configuration file.  
**Caution:** Do not try to restore the entire database cluster from a partial database backup created from a subset of the nodes. Data loss could result. |
<p>| <code>-debug level</code> | Specifies the level of debugging messages (from 0 to 3) that vbr provides. Level 3 indicates verbose, while level 0, the default, indicates no messages. |
| <code>-report-file path/filename</code> | Optional. Outputs a delimited JSON file that describes the results of the associated full backup integrity check or garbage collection task. |
| <code>-restore-objects objects</code> | Specifies the individual objects to restore from a full or object-level backup. If you are using wildcards, use <code>--include-objects</code> and <code>--exclude-objects</code> instead. |
| <code>-s3-force-init</code> | Used with the <code>--task init</code> command. Forces the init task to succeed on S3 storage targets when there is an identity/lock file mismatch. |
| <code>-showconfig</code> | The configuration values being used to perform the task, displayed in raw JSON format before vbr starts begins. |</p>
<table>

<td>Used with the --task listbackup command. Displays a JSON delimited list of all backups stored on the hosts and paths listed in the specified configuration file.</td>
</tr>
<tr>
<td>--list-output-file path/filename</td>
<td>Used with the --task listbackup command. Outputs a file containing a JSON delimited list of all backups stored on the hosts and paths listed in the specified configuration file.</td>
</tr>
<tr>
<td>--dry-run</td>
<td>Used with the --task command for backup, restore and replicate tasks. Performs a test run of the specified command without actually performing the task. You can use this command to evaluate the impact of a particular vbr command without actually performing that command. For example, you could see the size of a potential backup, or the objects contained in that backup. Any task performed with the dry-run parameter has no impact on your database.</td>
</tr>
<tr>
<td>--include-objects pattern</td>
<td>Specifies database objects or patterns of objects to restore from a full or object-level backup. Use commas to delimit multiple objects and wildcard patterns. For more information, refer to Including and Excluding Objects Using Wildcards. You cannot use this parameter with the --restore-objects parameter.</td>
</tr>
<tr>
<td>--exclude-objects pattern</td>
<td>Along with --include-objects, specifies database objects or patterns of objects to restore from a full or object-level backup. You can use --include-objects to specify a group of objects and then use --exclude-objects to remove objects from the set. Use commas to delimit multiple objects and wildcard patterns. For more information, refer to Including and Excluding Objects Using Wildcards.</td>

</tbody>
</table>

**Interrupting vbr**

To cancel a backup, use Ctrl+C or send a SIGINT to the Python process running vbr. vbr stops the backup process after it has completed copying the data. Canceling a vbr backup with Ctrl+C immediately closes the session.

The files generated by an interrupted backup process remain in the target backup location directory. The next backup process picks up where the interrupted process left off.

Backup operations are atomic, so that interrupting a backup operation does not affect the previous backup. Vertica replaces the previous backup only as the very last step of backing up your database.

The `restore` or `copycluster` operations overwrite the database catalog directory. Thus, interrupting either of these processes leaves the database unusable until you restart the process and allow it to finish.

**See Also**

- Configuration File Reference
- Sample VBR .ini Files

**Configuration File Reference**

The `vbr` configuration file options are grouped into sections within the configuration file. Sections may appear in any order and may be repeated. For example, you can have one `[Database]` section, then another section, and then another `"[Database]"` section.

Section headings (like `"[Database]"`) are case-sensitive.
### Miscellaneous Settings

This section collects basic settings, including the name and location of your backup. The section also indicates whether you are keeping more than a single backup file, as specified by the `restorePointLimit` parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Configuration Setting and Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>snapshotName</td>
<td>snapshotName</td>
<td>The base name of the backup. This name is used in the directory tree structure that <code>vbr</code> creates for each node. Each iteration in this series (up to <code>restorePointLimit</code>) consists of the <code>snapshotName</code> and a timestamp for a specific backup. Each series of backups should have a unique and descriptive <code>snapshotName</code>. Full and object-level backups also cannot share names. For most <code>vbr</code> tasks, the <code>snapshotName</code> serves as a useful identifier in diagnostics and system tables. For object restore and replication tasks, <code>snapshotName</code> is used to build schema names in coexist mode operations. A <code>snapshotName</code> can contain up to 240 characters. The <code>snapshot</code> name may contain only the following characters; all others are invalid:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• a–z</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A–Z</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 0–9</td>
</tr>
<tr>

<td>• Underscore (_)</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default</td>
<td>Configuration Setting and Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>tempDir</td>
<td>/tmp/vbr</td>
<td>Specifies an absolute path to a temporary storage area on the cluster nodes. The tmp path must be the same on all nodes in the cluster. vbr uses this directory as a temporary location for log files, lock files, and other bookkeeping information while it is copying files from the source cluster node to the destination backup location. vbr also writes backup logs to this location. Do not specify the same location as your database's data or catalog directory. Any unexpected files or directories in your data or catalog location can cause errors during database start or restore. The file system at this location must support fcntl lockf (POSIX) file locking.</td>
</tr>
<tr>
<td>restorePointLimit</td>
<td>1</td>
<td>Specifies the number of historical backups to retain in addition to the most recent backup. For example, if you set restorePointLimit=3, Vertica saves three historical backups, in addition to the most recent backup, for a total of four backups. By default, Vertica maintains a current backup and one historical backup. Enter a positive integer. Saves multiple backups to the same location, which are shared through hard links. In such cases, listbackup displays the common backup prefix but indicates unique time and date suffixes: my_archive20111111_205841</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default</td>
<td>Configuration Setting and Description</td>
</tr>
<tr>
<td>-----------</td>
<td>---------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td>objects</td>
<td>None</td>
<td>For an object-level backup or object replication, specifies the object (schema or table) names to include. To specify more than one object, enter multiple names in a comma-separated list. To identify objects using wildcards, use the includeObjects parameter instead. Specify table names in the form schema.objectname. For example, to make backups of the table customers from the schema finance, enter <code>finance.customers</code>. If a public table and a schema have the same name, vbr backs up only the schema. Use the schema.objectname convention to avoid confusion. Object names can include UTF-8 alphanumeric characters. Object names cannot include escape characters, single quote ('), or double quote (&quot;) characters. Specify non-alphanumeric characters with a backslash () followed by a hex value. For instance, if the table name is my table (my followed by a space character, then table), enter the object name as follows: <code>objects=my\20table</code> If an object name includes a period use double quotes around the name. This parameter conflicts with the includeObjects parameter. Use one or the other in your configuration file. If you do not specify any objects, vbr...</td>
</tr>
</tbody>
</table>
### Parameter: objectRestoreMode

<table>
<thead>
<tr>
<th>Default</th>
<th>Configuration Setting and Description</th>
</tr>
</thead>
</table>
| createOrReplace | Specifies how vbr handles objects of the same name when restoring schema or table backups. **Valid Values:**  
  - `createOrReplace` — vbr creates any objects that do not exist. If an object does exist, vbr overwrites it with the version from the archive.  
  - `create` — vbr creates any objects that do not exist and does not replace existing objects. If an object being restored does exist, the restore fails.  
  - `coexist` — vbr creates the restored version of each object with a name of the form `<backup>_<timestamp>_<object_name>`. This approach allows existing and restored objects to exist simultaneously. If the appended information pushes the schema name past the maximum length of 128 characters, Vertica truncates the name. You can perform a reverse lookup of the original schema name by querying the system table `TRUNCATED_SCHEMA`.  

In all modes, vbr restores data with the current epoch. Object restore mode settings do not apply to backups and full restores.

### Parameter: retryCount

<p>| Default | 2 | (Deprecated) Specifies the number of backup attempts to make. If the backup |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Configuration Setting and Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fails after exceeding the number of retry attempts, vbr reports an error and stops processing.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>retryDelay</td>
<td>1</td>
<td>(Deprecated) Specifies the number of seconds to wait between backup retry attempts, if a failure occurs.</td>
</tr>
<tr>
<td>passwordFile</td>
<td>None</td>
<td>Specifies the file name of the password configuration file.</td>
</tr>
<tr>
<td>enableFreeSpaceCheck</td>
<td>True</td>
<td>When enabled, vbr confirms that the specified backup locations contain sufficient free space and inodes to allow a successful backup. If a backup location has insufficient resources, vbr displays an error message and cancels the backup. If vbr cannot determine the amount of available space or number of inodes in the backupDir, it displays a warning and continues with the backup. If you do not include this setting in your configuration file, vbr performs the space check by default.</td>
</tr>
<tr>
<td>SnapshotEpochLagFailureThreshold</td>
<td>3600</td>
<td>When performing a backup, replication, or copycluster task, specifies the maximum acceptable difference, in seconds, between the current epoch and the backup epoch. If the time between the current epoch and the backup epoch exceeds the value specified in this parameter, vbr displays an error message. A value of 0 disables this check. If you do not include this setting in your configuration file, vbr performs this check using the default value. Backups do not contain information committed after the backup epoch.</td>
</tr>
</tbody>
</table>
### Database Access Settings

Sets options for accessing the database.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbName</td>
<td>N/A</td>
<td>Specifies the name of the database to back up. If you do not supply a database name, vbr selects the current database to back up. OpenText recommends that you provide a</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>database name.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dbUser</td>
<td>Current user name</td>
<td>Identifies the Vertica user used for database operations performed by <code>vbr</code>. In the case of the replicate task, this user is the source database user. You must be logged on as the database administrator to back up the database. The password, if you choose to save it, is stored in the Password Configuration File.</td>
</tr>
<tr>
<td>dbPromptForPassword</td>
<td>True</td>
<td>Controls whether <code>vbr</code> prompts for a password. If you set this parameter to False (indicating no prompt at runtime), then you must also set the database administrator password in the <code>dest_dbPassword</code> parameter. If you do not supply a password in the configuration file, <code>vbr</code> prompts for one at runtime.</td>
</tr>
</tbody>
</table>

`vbr` uses destination database parameters only to replicate objects to alternate clusters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_dbName</td>
<td>N/A</td>
<td>Specifies the name of the destination database.</td>
</tr>
<tr>
<td>dest_dbUser</td>
<td>N/A</td>
<td>Identifies the Vertica user name in the destination database to be used for loading the replicated data. This user must have default superuser privileges.</td>
</tr>
<tr>
<td>dest_dbPromptForPassword</td>
<td>N/A</td>
<td>Controls whether <code>vbr</code> prompts for a password for the destination database. If you set this parameter to False (indicating no prompt at runtime), then you must also enter the destination database administrator password in the <code>dest_dbPassword</code> parameter. If you do not supply a password in the configuration file, <code>vbr</code> prompts for one at runtime.</td>
</tr>
</tbody>
</table>
### [Transmission] Data Transmission

Sets options for transmitting the data when using backup hosts.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encrypt</td>
<td>False</td>
<td>Controls whether the transmitted data is encrypted while it is being copied to the target backup location. Choose this option if you are performing a backup over an untrusted network (for example, backing up to a remote host across the Internet). Do not use this parameter with hard-link local backups; vbr issues a warning and ignores this value. <strong>Note:</strong> Encrypting data transmission causes significant processing overhead and slows transfer. One of the processor cores of each database node is consumed during the encryption process. Use this option only if you are concerned about the security of the network used when transmitting backup data.</td>
</tr>
<tr>
<td>port_rsync</td>
<td>50000</td>
<td>Changes the default port number for the rsync protocol. Change this value if the default rsync port is in use on your cluster, or you need rsync to use another port to avoid a firewall restriction.</td>
</tr>
<tr>
<td>total_bwlimit_backup</td>
<td>0</td>
<td>The total bandwidth limit in KBps for backup connections. Vertica distributes this bandwidth evenly among the number of connections set in concurrency_backup. The default value of 0 allows unlimited bandwidth. The total network load allowed by this value</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>is the number of nodes multiplied by the value of this parameter. For example, a three node cluster and a total_bwlimit_backup value of 100 would allow 300Kbytes/sec of network traffic.</td>
</tr>
<tr>
<td>concurrency_backup</td>
<td>1</td>
<td>The maximum number of backup TCP rsync connection threads per node. To improve local and remote backup, replication, and copy cluster performance, you can increase the number of threads available to perform backups. Increasing the number of threads allocates more CPU resources to the backup task and can, for remote backups, increase the amount of bandwidth used. The optimal value for this setting depends greatly on your specific configuration and requirements. Values higher than 16 produce no additional benefit.</td>
</tr>
<tr>
<td>total_bwlimit_restore</td>
<td>0</td>
<td>The total bandwidth limit in KBps for restore connections. vbr distributes this bandwidth evenly among the number of connections set in concurrency_restore. The default value of 0 allows unlimited bandwidth. The total network load allowed by this value is the number of nodes multiplied by the value of this parameter. For example, a three node cluster and a total_bwlimit_restore value of 100 would allow 300Kbytes/sec of network traffic.</td>
</tr>
<tr>
<td>concurrency_restore</td>
<td>1</td>
<td>The maximum number of restore TCP rsync connections per node. The maximum number of restore TCP rsync connection threads per node. To improve local and remote restore, replication, and</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>copy</td>
<td></td>
<td>copy cluster performance, you can increase the number of threads available to perform restores. Increasing the number of threads allocates more CPU resources to the restore task and can, for restores of remote backups, increase the amount of bandwidth used. The optimal value for this setting depends greatly on your specific configuration and requirements. Values higher than 16 produce no additional benefit.</td>
</tr>
<tr>
<td>serviceAccessUser</td>
<td>None</td>
<td>The user name used for simple authentication of rsync connections. This user is neither a Linux nor Vertica user name. It is simply an arbitrary identifier used by the rsync protocol. If you do not provide a user name, vbr leaves rsync running without authentication, creating a potential security risk. If you choose to save the password, store it in the Password Configuration File.</td>
</tr>
<tr>
<td>hardLinkLocal</td>
<td>False</td>
<td>Creates a full- or object-level backup using hard file links on the local file system, rather than copying database files to a remote backup host. Add this configuration parameter manually to the Transaction section of the configuration file, as described in Full Hardlink Backup/Restore.</td>
</tr>
<tr>
<td>copyOnHardLinkFailure</td>
<td>False</td>
<td>If a hard-link local backup cannot create links, copy the data instead. Copying takes longer than linking, so the default behavior is to return an error if links cannot be created on any node.</td>
</tr>
</tbody>
</table>
[Mapping]

You have one [Mapping] section for all of the nodes in your database cluster. The section must appear in your configuration file because it specifies all the database nodes being included in the backup. It also includes the backup host and directory for each node. If you have objects being replicated to an alternate database, the [Mapping] section also maps the target database nodes to the source database backup locations.

If you edit an existing configuration file to add a Mapping in the current style, you must combine information from all existing Mappings into the new section.

**Note:**
The [S3] and [Mapping] configuration sections are mutually exclusive. If you include both, your backup fails with the error message "Config has conflicting sections (Mapping, S3), specify only one of them."

Unlike other sections of the configuration file, the [Mapping] section does not use named parameters. Instead, it uses entries of the following format:

```
dbNode = backupHost:backupDir
```

For example:

```
[Mapping]
v_sec_node0001 = pri_bsrv01:/archive/backup
v_sec_node0002 = pri_bsrv02:/archive/backup
v_sec_node0003 = pri_bsrv03:/archive/backup
```

The following table describes these three elements (node, destination host, path) in more detail.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbNode</td>
<td>The name of the database node, as recognized by Vertica. This value is not the node's host name, but rather the name Vertica uses internally to identify the node, usually in the form of:</td>
</tr>
<tr>
<td></td>
<td>v_node00x</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>To find database node names in your cluster, query the node_name column of the NODES system table.</td>
</tr>
<tr>
<td>backupHost</td>
<td>Indicates the target host name or IP address on which to store this node's backup. The backupHost name is different from dbNode. The copycluster command uses this value to identify the target database node host name.</td>
</tr>
<tr>
<td></td>
<td>Performance Consideration:</td>
</tr>
<tr>
<td></td>
<td>Although supported, backups to an NFS host may have poor performance, particularly on networks shared with rsync operations.</td>
</tr>
<tr>
<td>backupDir</td>
<td>Identifies the full path to the directory on the backup host or node where the backup will be stored.</td>
</tr>
<tr>
<td></td>
<td>Directory Requirements:</td>
</tr>
<tr>
<td></td>
<td>• Must already exist when you run vbr with the --task backup option</td>
</tr>
<tr>
<td></td>
<td>• Must be writable by the user account used to run vbr.</td>
</tr>
<tr>
<td></td>
<td>• Must be unique to the database you are backing up. Multiple databases cannot share the same backup directory.</td>
</tr>
<tr>
<td></td>
<td>• The file system at this location must support fcntl lockf file locking.</td>
</tr>
</tbody>
</table>

**Map to the localhost**

vbr does not support the special localhost name as a backup host. To back up a database node to its own disk, use empty square brackets for the hostname in the [Mapping] section of the configuration file.

```
[Mapping]
NodeName = []:/backup/path
```

**Map to the Same Database**

The following example shows how you can specify a Mapping section that indicates a single node to be backed up (v_vmart_node0001). The node is assigned to the backup host (v_
srv01, and the backup directory (/home/ dbadmin/ backups). Although you are backing up a single node cluster, and the backup host and the database node are the same system, you specify them differently.

Specify the backup host and directory, using a colon (:) as a separator:

```plaintext
[Mapping]
v_vmart_node0001 = srv01:/home/dbadmin/backups
```

**Map to an Alternate Database**

Before you can replicate objects to an alternate database, you must also create a [NodeMapping] section in your vbr configuration file. The NodeMapping section points source nodes to their target database nodes.

Restore an alternate database, by adding mapping information in the following form:

```plaintext
[Mapping]
targetNode: sourceDBNode_backuphost:sourceDB_backuppath
```

Your mapping section should resemble this example:

```plaintext
[Mapping]
v_sec_node0001 = pri_bsrv01:/archive/backup
v_sec_node0002 = pri_bsrv02:/archive/backup
v_sec_node0003 = pri_bsrv03:/archive/backup
```

**[NodeMapping]**

vbr uses the node mapping section exclusively to restore objects from a backup of one database to another, different, database. Be sure to update the [Mapping] section of your configuration file to point your target database nodes to their source backup locations. The target database must have at least as many UP nodes as the source database.

Use the following format to specify node mapping:

```plaintext
source_node = target_node
```
For example, you can use the following mapping to restore content from one 4-node database to an alternate 4-node database.

```
[NodeMapping]
v_sourcedb_node0001 = v_targetdb_node0001
v_sourcedb_node0002 = v_targetdb_node0002
v_sourcedb_node0003 = v_targetdb_node0003
v_sourcedb_node0004 = v_targetdb_node0004
```

See Restoring a Database to an Alternate Cluster for a complete example.

[S3]

Sets options for storing backup data on S3.

**Note:** The [S3] and [Mapping] configuration sections are mutually exclusive. If you include both, your backup fails with the error message "Config has conflicting sections (Mapping, S3), specify only one of them."

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s3_backup_file_system_path</td>
<td></td>
<td>Specifies the host and path that you are using to handle file locking during the backup process. vbr must be able to create a passwordless ssh connection to the location that you specify here. To use a local NFS file system, specify a value of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>s3_backup_file_system_path = []:path</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To use a host, specify a value of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>s3_backup_file_system_path = [host_name]:path</td>
</tr>
<tr>
<td>s3_backup_path</td>
<td></td>
<td>Specifies the S3 bucket name and backup path for the backup to S3. When you back up to S3, all nodes back up to same S3 bucket. You must create the backup location on S3 before performing a backup. This value takes the following form:</td>
</tr>
<tr>
<td>Parameter</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>s3_backup_path</td>
<td></td>
<td><code>s3://backup_bucket/database_backup_path/</code></td>
</tr>
<tr>
<td>s3_encrypt_transport</td>
<td>True</td>
<td>When True, uses SSL encryption to encrypt data moving between your Vertica cluster and your S3 instance. If you are backing up or restoring from an Amazon EC2 cluster, you must set this parameter to True.</td>
</tr>
<tr>
<td>s3_concurrency_backup</td>
<td>10</td>
<td>The maximum number of concurrent backup threads for backup to S3. For very large data volumes (greater than 10TB), you might need to reduce this value to avoid vbr failures.</td>
</tr>
<tr>
<td>s3_concurrency_restore</td>
<td>10</td>
<td>The maximum number of concurrent restore threads for restoring from S3. For very large data volumes (greater than 10TB), you might need to reduce this value to avoid vbr failures.</td>
</tr>
<tr>
<td>s3_encrypt_at_rest</td>
<td>None</td>
<td>To enable at-rest encryption of your backups to S3, specify a value of sse. For more information on encrypting your S3 backups.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This value takes the following form:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>s3_encrypt_at_rest = sse</code></td>
</tr>
<tr>
<td>s3_sse_kms_key_id</td>
<td>None</td>
<td>If you are using the Amazon Key Management Security, use this parameter to provide your key ID. If you enable encryption and do not include this parameter, vbr uses SS3-S3 encryption.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This value takes the following form:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>s3_sse_kms_key_id = &lt;key_id&gt;</code></td>
</tr>
</tbody>
</table>

### Password Configuration File

For improved security, you can store passwords in a separate configuration file and then restrict read access to that file. Set the `passwordFile` parameter in your `vbr` configuration file to point to this file. See [Misc] Miscellaneous Settings.
See Password File (password.ini) for an example.

**[Passwords] Password Settings**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbPassword</td>
<td>None</td>
<td>The database administrator's Vertica password, and used if dbPromptForPassword is False.</td>
</tr>
<tr>
<td>serviceAccessPass</td>
<td>None</td>
<td>The password for the rsync user account.</td>
</tr>
<tr>
<td>dest_dbPassword</td>
<td>None</td>
<td>The password for the dest_dbuser Vertica account, for replication tasks only.</td>
</tr>
</tbody>
</table>

**Recovering the Database**

You need to recover your Vertica database when you restart failed nodes or the database. The following sections describe several scenarios.

To monitor a recovery in progress, view the log messages posted to the vertica.log file on each host.

**See Also**

- Failure Recovery

**Failure Recovery**

Vertica can restore the database to a fully functional state after one or more nodes in the system experiences a software- or hardware-related failure. Vertica recovers nodes by querying replicas of the data stored on other nodes. For example, a hardware failure can cause a node to lose database objects or to miss changes made to the database (INSERTs, UPDATEs, and so on) while offline. When the node comes back online, queries other nodes in the cluster to recover lost objects and catch up with database changes.

K-safety sets fault tolerance for the database cluster, where K can be set to 0, 1, or 2. The value of K specifies how many copies Vertica creates of segmented projection data. If
K-safety for a database is set to 1 or 2, Vertica creates K+1 instances, or *buddies*, of each projection segment. Vertica distributes these buddies across the database cluster, such that projection data is protected in the event of node failure. If any node fails, the database can continue to process queries so long as buddies of data on the failed node remain available elsewhere on the cluster.

**Note:**
You can monitor the cluster state through the View Database Cluster state menu option.

### Recovery Scenarios

Vertica begins the database recovery process when you restart failed nodes or the database. The mode of recovery for a K-safe database depends on the type of failure:

- One or more nodes in the database failed, but the database continued to operate.
- The database shut down cleanly.
- The database shut down uncleanly.

In the first two cases, node recovery is automatic; in the third case (unclean shutdown), recovery requires manual intervention by the database administrator. The following sections discuss these cases in greater detail.

**Recovery of failed nodes**

One or more nodes failed but the remaining nodes in the database filled in for them, so database operations continued without interruption. Use Administration Tools to restart failed nodes through the Restart Vertica on Host option. While restarted nodes recover their data from other nodes, their status is set to RECOVERING. Except for a short period at the end, the recovery phase has no effect on database transaction processing. After recovery is complete, the restarted nodes status changes to UP.

**Recovery after clean shutdown**

The database was shut down cleanly through Administration Tools. To restart the database, use the Start Database option. On restart, all nodes whose status was UP before the shutdown resume a status of UP. If the database contained one or more failed nodes on shutdown and they are now available, they begin the recovery process as described above.

**Recovery after unclean shutdown**

Reasons for unclean shutdown include:

- A critical node failed, leaving part of the database's data unavailable.
- A site-wide event such as a power failure causes all nodes to reboot.
Vertica processes on the nodes exited due to a software or hardware failure.

Unclean shutdown can put the database in an inconsistent state—for example, Vertica might have been in the middle of writing data from WOS to disk at the time of failure, and this process was left incomplete. When you restart the database through the Administration Tools, Vertica determines that normal startup is not possible and uses the **Last Good Epoch** to determine when data was last consistent on all nodes. When you restart the database, Vertica prompts you to accept recovery with the suggested epoch. If accepted, the database recovers and all data changes after the Last Good Epoch are lost. If not accepted, startup is aborted.

Instead of accepting the recommended epoch, you can recover from a backup. You can also choose an epoch that precedes the Last Good Epoch, through the Administration Tools Advanced Menu option Roll Back Database to Last Good Epoch. This is useful in special situations—for example the failure occurs during a batch of loads, where it is easier to restart the entire batch, even though some of the work must be repeated. In most cases, you should accept the recommended epoch.

### Epochs and Node Recovery

The checkpoint epoch (CPE) for both the source and target projections are updated as ROS containers are moved. The start and end epochs of all storage containers, such as ROS containers, are modified to the commit epoch. When this occurs, the epochs of all columns without an actual data file rewrite advance the CPE to the commit epoch of move_partitions_to_table. If any nodes are down during the TM moveout and/or during the move partition, they will detect that there is storage to recover, and will recover from other nodes with the correct epoch upon rejoining the cluster.

### Manual Recovery Notes

- You can manually recover a database where up to K nodes are offline—for example, they were physically removed for repair or not reachable at the time of recovery. When the missing nodes are restored, they recover and rejoin the cluster as described earlier in [Recovery Scenarios](#).
- You can manually recover a database if the nodes to be restarted can supply all partition segments, even if more than K nodes remain down at startup. In this case, all data is available from the remaining cluster nodes, so the database can successfully start.
The default setting for the `HistoryRetentionTime` configuration parameter is 0, so Vertica only keeps historical data when nodes are down. This setting prevents use of the Administration Tools Roll Back Database to Last Good Epoch option because the AHM remains close to the current epoch and a rollback is not permitted to an epoch that precedes the AHM. If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window to remove loaded data—for example:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = 86400;
```

See Epoch Management Parameters in the Administrator's Guide.

When a node is down and manual recovery is required, it can take a full minute or longer for Vertica processes to time out while the system tries to form a cluster. Wait approximately one minute until the system returns the manual recovery prompt. Do not press CTRL-C during database startup.

## Restarting Vertica on a Host

When one node in a running database cluster fails, or if any files from the catalog or data directories are lost from any one of the nodes, you can check the status of failed nodes using either the Administration Tools or the Management Console.

### Restarting Vertica on a Host Using the Administration Tools

1. Run Administration Tools.
2. From the Main Menu, select Restart Vertica on Host and click OK.
3. Select the database host you want to recover and click OK.

   **Note:**
   You might see additional nodes in the list, which are used internally by the Administration Tools. You can safely ignore these nodes.

4. Verify recovery state by selecting View Database Cluster State from the Main Menu.
After the database is fully recovered, you can check the status at any time by selecting View Database Cluster State from the Administration Tools Main Menu.

Restarting Vertica on a Host Using the Management Console

1. Connect to a cluster node (or the host on which MC is installed).
2. Open a browser and connect to MC as an MC administrator.
3. On the MC Home page, double-click the running database under the Recent Databases section.
4. Within the Overview page, look at the node status under the Database sub-section and see if all nodes are up. The status will indicate how many nodes are up, critical, down, recovering, or other.
5. If a node is down, click Manage at the bottom of the page and inspect the graph. A failed node will appear in red.
6. Click the failed node to select it and in the Node List, click the Start node button.

Restarting the Database

If you lose the Vertica process on more than one node (for example, due to power loss), or if the servers are shut down without properly shutting down the Vertica database first, the database cluster indicates that it did not shut down gracefully the next time you start it.

The database automatically detects when the cluster was last in a consistent state and then shuts down, at which point an administrator can restart it.

From the Main Menu in the Administration Tools:

1. Verify that the database has been stopped by clicking Stop Database.
   A message displays: No databases owned by <dbadmin> are running
2. Start the database by selecting Start Database from the Main Menu.
3. Select the database you want to restart and click OK.

   If you are starting the database after an unclean shutdown, messages display, which indicate that the startup failed. Press RETURN to continue with the recovery process.
An epoch represents committed changes to the data stored in a database between two specific points in time. When starting the database, Vertica searches for last good epoch.

4. Upon determining the last good epoch, you are prompted to verify that you want to start the database from the good epoch date. Select Yes to continue with the recovery.

Caution:
If you do not want to start from the last good epoch, you may instead restore the data from a backup and attempt to restart the database. For this to be useful, the backup must be more current than the last

Vertica continues to initialize and recover all data prior to the last good epoch.

If recovery takes more than a minute, you are prompted to answer <Yes> or <No> to "Do you want to continue waiting?"

When all the nodes' status have changed to RECOVERING or UP, selecting <No> lets you exit this screen and monitor progress via the Administration Tools Main Menu. Selecting <Yes> continues to display the database recovery window.

**Note:**

Be sure to reload any data that was added after the last good epoch date to which you have recovered.

---

### Recovering the Cluster From a Backup

To recover a cluster from a backup, refer to the following topics:

- Backing Up and Restoring the Database
- Restoring a Database from a Full Backup
Phases of a Recovery

The phases of a Vertica recovery are the same regardless of whether you are recovering by table or node. In the case of a recovery by table, tables become individually available as they complete the final phase. In the case of a recovery by node, the database objects only become available after the entire node completes recovery.

When you perform a recovery in Vertica, each recovered table goes through the following phases:

<table>
<thead>
<tr>
<th>Order</th>
<th>Phase</th>
<th>Description</th>
<th>Lock Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Historical</td>
<td>Vertica copies any historical data it may have missed while in a state of DOWN or INITIALIZING.</td>
<td>none</td>
</tr>
<tr>
<td>2</td>
<td>Historical Dirty</td>
<td>Vertica recovers any DML transactions that committed after the node or table began recovery.</td>
<td>none</td>
</tr>
<tr>
<td>3</td>
<td>Current Replay Delete</td>
<td>Vertica replays any delete transactions that took place during the recovery.</td>
<td>T-lock</td>
</tr>
<tr>
<td>4</td>
<td>Aggregate Projections</td>
<td>Vertica recovers any aggregate projections.</td>
<td>T-lock</td>
</tr>
</tbody>
</table>

After a table completes the last phase, Vertica considers it fully recovered. At this point, the table can participate in DDL and DML operations.

Exporting a Catalog

When you export a catalog you can quickly move a catalog to another cluster. Exporting a catalog transfers schemas, tables, constraints, projections, and views. System tables are not exported.

Exporting catalogs can also be useful for support purposes.

See the EXPORT_CATALOG function in the SQL Reference Manual for details.
Best Practices for Disaster Recovery

To protect your database from site failures caused by catastrophic disasters, maintain an off-site replica of your database to provide a standby. In case of disaster, you can switch database users over to the standby database. The amount of data loss between a disaster and fail over to the offsite replica depends on how frequently you save a full database backup.

The solution to employ for disaster recovery depends upon two factors that you must determine for your application:

- **Recovery point objective (RPO):** How much data loss can your organization tolerate upon a disaster recovery?
- **Recovery time objective (RTO):** How quickly do you need to recover the database following a disaster?

Depending on your RPO and RTO, Vertica recommends choosing from the following solutions:

1. **Dual-load:** During each load process for the database, simultaneously load a second database. You can achieve this easily with off-the-shelf ETL software.
2. **Periodic Incremental Backups:** Use the procedure described in Copying the Database to Another Cluster to periodically copy the data to the target database. Remember that the script copies only files that have changed.
3. **Replication solutions provided by Storage Vendors:** Although some users have had success with SAN storage, the number of vendors and possible configurations prevent Vertica from providing support for SANs.

The following table summarizes the RPO, RTO, and the pros and cons of each approach:

<table>
<thead>
<tr>
<th></th>
<th>Dual Load</th>
<th>Periodic Incremental</th>
<th>Storage Replication</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RPO</strong></td>
<td>Up to the minute data</td>
<td>Up to the last backup</td>
<td>Recover to the minute</td>
</tr>
<tr>
<td><strong>RTO</strong></td>
<td>Available at all times</td>
<td>Available except when backup in progress</td>
<td>Available at all times</td>
</tr>
<tr>
<td><strong>Pros</strong></td>
<td>• Standby database can have different configuration</td>
<td>• Built-in scripts • High performance due to compressed</td>
<td>Transparent to the database</td>
</tr>
<tr>
<td></td>
<td>Dual Load</td>
<td>Periodic Incremental</td>
<td>Storage Replication</td>
</tr>
<tr>
<td>----------------</td>
<td>---------------------------------------------------------------------------</td>
<td>----------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>Cons</td>
<td>• Can use the standby database for queries</td>
<td>file transfers</td>
<td>• More expensive</td>
</tr>
<tr>
<td></td>
<td>• Possibly incur additional ETL licenses</td>
<td>Need identical standby system</td>
<td>• Media corruptions are also replicated</td>
</tr>
<tr>
<td></td>
<td>• Requires application logic to handle errors</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Query Performance with Failed Nodes**

When a node fails within a Vertica cluster, the cluster detects the failure within milliseconds. The impact of a node failure on currently running queries depends on the K-safety level of your cluster and the location of your data within the cluster.

**K-Safety 0 Cluster**

If a node fails in a cluster with a K-safety of 0, any currently running queries roll back and the cluster shuts down. You cannot run further queries until you restore the failed node.

**K-Safety 1 or Greater Cluster**

The failure of a node can invalidate the query plan for a currently running query. If the running query does not require the failed node, the query continues to run. If a currently running query does require the failed node, the query rolls back. Vertica then automatically reconfigures the query plan to use alternate nodes and automatically retries the query. By default, Vertica makes three attempts to rerun the query before canceling it.

In clusters with a failed node, the database optimizer chooses different segmentations of buddy projections to distribute the workload throughout the cluster. Query performance within a cluster containing a failed node can, however, deteriorate, as one node must now do the work of two nodes. The extent of the performance impact varies depending on the queries that you run and the location of the data that you are querying. Query performance remains affected until the failed node has been completely restored.
Recovery By Table

Vertica supports node recovery on a per-table basis. Unlike node-based recovery, recovering by table makes tables available as they recover, before the node itself is completely restored. You can prioritize your most important tables so they become available as soon as possible. Recovered tables support all DDL and DML operations.

To enhance recovery speed, Vertica recovers multiple tables in parallel. The maximum number of tables recoverable at one time is set by the MAXCONCURRENCY parameter in the RECOVERY resource pool.

After a node has fully recovered, it enables full Vertica functionality.

Prioritizing Table Recovery

You can specify the order in which Vertica recovers tables. This feature ensures that your most critical tables become available as soon as possible. To specify the recovery order of your tables, assign an integer priority value. Tables with higher priority values recover first. For example, a table with a priority of 1000 is recovered before a table with a value of 500. Table priorities have the maximum value of a 64-bit integer.

If you do not assign a priority, or if multiple tables have the same priority, Vertica restores tables by OID order. Assign a priority with a query such as this:

```sql
=> SELECT set_table_recover_priority('avro_basic', '1000');
    set_table_recover_priority
-----------------------------
Table recovery priority has been set.
(1 row)
```

View assigned priorities with a query using this form:

```
SELECT table_name,recover_priority FROM v_catalog.tables;
```

The next example shows prioritized tables from the VMart sample database. In this case, the table with the highest recovery priorities are listed first (DESC). The shipping_dimension table has the highest priority and will be recovered first. (Example has hard Returns for display purposes.)
Viewing Table Recovery Status

View general information about a recovery querying the V_MONITOR.TABLE_RECOVERY_STATUS table. You can also view detailed information about the status of the recovery the table being restored by querying the V_MONITOR.TABLE_RECOVERIES table.
Collecting Database Statistics

The Vertica cost-based query optimizer relies on data statistics to produce query plans. If statistics are incomplete or out-of-date, the optimizer is liable to use a sub-optimal plan to execute a query.

When you query a table, the Vertica optimizer checks for statistics as follows:

1. If the table is partitioned, the optimizer checks whether the partitions required by this query have recently been analyzed. If so, it retrieves those statistics and uses them to facilitate query planning.
2. Otherwise, the optimizer uses table-level statistics, if available.
3. If no valid partition- or table-level statistics are available, the optimizer assumes uniform distribution of data values and equal storage usage for all projections.

Statistics Management Functions

Vertica provides two functions that generate up-to-date statistics on table data: `ANALYZE_STATISTICS` and `ANALYZE_STATISTICS_PARTITION` collect table-level and partition-level statistics, respectively. After computing statistics, the functions store them in the database catalog.

Both functions perform the following operations:

- Collect statistics using **historical queries** (at epoch latest) without any locks.
- Perform fast data sampling, which expedites analysis of relatively small tables with a large number of columns.
- Include data from WOS.
- Recognize deleted data instead of ignoring delete markers.

Vertica also provides several functions that help you management database statistics—for example, to export and import statistics, validate statistics, and drop statistics.

After you collect the desired statistics, you can run **Workload Analyzer** to retrieve hints about under-performing queries and their root causes, and obtain tuning recommendations.
**Collecting Table Statistics**

`ANALYZE STATISTICS` collects and aggregates data samples and storage information from all nodes that store projections of the target tables.

You can set the scope of the collection at several levels:

- **Database**
- **Table**
- **Table columns**

`ANALYZE STATISTICS` can also control the size of the data sample that it collects.

**Analyze All Database Tables**

If `ANALYZE STATISTICS` specifies no table, it collects statistics for all database tables and their projections. For example:

```sql
=> SELECT ANALYZE_STATISTICS ('');
ANALYZE_STATISTICS
-----------------------
 0
(1 row)
```

**Analyze a Single Table**

You can compute statistics on a single table as follows:

```sql
=> SELECT ANALYZE_STATISTICS ('public.store_orders_fact');
ANALYZE_STATISTICS
-----------------------
 0
(1 row)
```

When you query system table `PROJECTION_COLUMNS`, it confirms that statistics have been collected on all table columns for all projections of `store_orders_fact`:

```sql
=> SELECT projection_name, statistics_type, table_column_name, statistics_updated_timestamp
    FROM projection_columns WHERE projection_name ilike 'store_orders_fact%' AND table_schema='public';
```
### Analyze Table Columns

Within a table, you can narrow scope of analysis to a subset of its columns. Doing so can save significant processing overhead for big tables that contain many columns. It is especially useful if you frequently query these tables on specific columns.

**Important:**
If you collect statistics on specific columns, be sure to include all columns that you are likely to query. If a query includes other columns in that table, the query optimizer regards the statistics as incomplete for that query and ignores them in its plan.

For example, instead of collecting statistics on all columns in `store_orders_fact`, you can select only those columns that are frequently queried: `product_key`, `product_version`, `order_number`, and `quantity_shipped`:

```sql
=> SELECT DROP_STATISTICS('public.store_orders_fact');
=> SELECT ANALYZE_STATISTICS ('public.store_orders_fact', 'product_key, product_version, order_number, quantity_ordered');
ANALYZE_STATISTICS
---------------------
 0
(1 row)
```

If you query `PROJECTION_COLUMNS` again, it returns the following results:

```sql
=> SELECT projection_name, statistics_type, table_column_name, statistics_updated_timestamp
   FROM projection_columns WHERE projection_name ilike 'store_orders_fact%' AND table_schema='public';
projection_name | statistics_type | table_column_name | statistics_updated_timestamp
-----------------|-----------------|-------------------|----------------------------------------
store_orders_fact_b0 | FULL | product_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | product_version | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | store_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | vendor_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | employee_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | order_number | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | date_ordered | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | date_shipped | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | quantity_ordered | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | shipper_name | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | product_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | product_version | 2019-04-04 18:06:55.747329-04
... (20 rows)
```
In this case, columns statistics_type is set to FULL only for those columns on which you ran ANALYZE_STATISTICS. The remaining table columns are set to ROWCOUNT, indicating that only row statistics were collected for them.

**Note:**
ANALYZE_STATISTICS always invokes ANALYZE_ROW_COUNT on all table columns, even if ANALYZE_STATISTICS specifies a subset of those columns.

### Data Collection Percentage

By default, Vertica collects a fixed 10-percent sample of statistical data from disk. Specifying a percentage of data to read from disk gives you more control over deciding between sample accuracy and speed.

The percentage of data you collect affects collection time and accuracy:

- A smaller percentage is faster but returns a smaller data sample, which might compromise histogram accuracy.
- A larger percentage reads more data off disk. Data collection is slower, but a larger data sample enables greater histogram accuracy.

For example:

Collect data on all projections for `shipping_dimension` from 20 percent of the disk:
=> SELECT ANALYZE_STATISTICS ('shipping_dimension', 20);
ANALYZE_STATISTICS
-------------
0
(1 row)

Collect data from the entire disk by setting the `percent` parameter to 100:

=> SELECT ANALYZE_STATISTICS ('shipping_dimension', 'shipping_key', 100);
ANALYZE_STATISTICS
-------------
0
(1 row)

## Sampling Size

ANALYZE_STATISTICS constructs a column histogram from a set of rows that it randomly selects from all collected data. Regardless of the percentage setting, the function always creates a statistical sample that contains up to (approximately) the smaller of:

- $2^{17}$ (131,072) rows
- Number of rows that fit in 1 GB of memory

If a column has fewer rows than the maximum sample size, ANALYZE_STATISTICS reads all rows from disk and analyzes the entire column.

**Note:**
The data collected in a sample range does not indicate how data should be distributed.

The following table shows how ANALYZE_STATISTICS, when set to different percentages, obtains a statistical sample from a given column:

<table>
<thead>
<tr>
<th>Number of column rows</th>
<th>%</th>
<th>Number of rows read</th>
<th>Number of sampled rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;=<code>max-sample-size</code></td>
<td>20</td>
<td>All</td>
<td>All</td>
</tr>
<tr>
<td>400K</td>
<td>10</td>
<td><code>max-sample-size</code></td>
<td><code>max-sample-size</code></td>
</tr>
<tr>
<td>4000K</td>
<td>10</td>
<td>400K</td>
<td><code>max-sample-size</code></td>
</tr>
</tbody>
</table>

**Note:**
When a column specified for ANALYZE_STATISTICS is first in a
projection's sort order, the function reads all data from disk to avoid a biased sample.

Collecting Partition Statistics

**ANALYZE_STATISTICS_PARTITION** collects and aggregates data samples and storage information for a range of partitions in the specified table. Vertica writes the collected statistics to the database catalog.

Requirements and Restrictions

The following requirements and restrictions apply to running **ANALYZE_STATISTICS_PARTITION** on a table:

- If you specify multiple partitions, they must be continuous. Different collections can overlap—for example, given partition keys of 1 through 99, successive calls to **ANALYZE_STATISTICS_PARTITION** can collect statistics for partitions 1-60 and 50-99. Similarly, one collection of statistics can be a subset of an earlier collection. In all cases, Vertica stores only the most recent statistics for each partition range. Thus, given the previous example, Vertica uses only statistics from the second collection for partition keys 50 through 60.
- The table must be partitioned and cannot contain unpartitioned data.
- The table partition expression must specify a single column. The following expressions are supported:
  - Expressions that specify only the column—that is, partition on all column values. For example:
    ```
    PARTITION BY ship_date GROUP BY CALENDAR_HIERARCHY_DAY(ship_date, 2, 2)
    ```
  - If the column is a **DATE** or **TIMESTAMP/TIMESTAMPTZ**, the partition expression can specify a [supported date/time function](https://www.vertica.com/docs/9.3.x/Vertica_Power_Analytics_Guide/HTML rookie/Rendering/Date%20and%20Time%20Expressions.htm) that returns that column or any portion of it, such as month or year. For example, the following partition expression specifies to partition on the year portion of column `order_date`:
    ```
    PARTITION BY YEAR(order_date)
    ```
  - Expressions that perform addition or subtraction on the column. For example:
    ```
    PARTITION BY YEAR(order_date) -1
    ```
• The table partition expression cannot coerce the specified column to another data type.
• Vertica collects no statistics from the following projections:
  • Live aggregate and Top-K projections
  • Projections that are defined to include an SQL function within an expression

Supported Date/Time Functions

ANALYZE_STATISTICS_PARTITION can collect partition-level statistics on tables where the partition expression specifies one of the following date/time functions:

• DATE
• DATE_PART
• DAY
• DAYOFMONTH
• DAYOFYEAR
• DAYS
• EXTRACT
• HOUR
• MINUTE
• MONTH
• QUARTER
• WEEK
• WEEK_ISO
• YEAR
• YEAR_ISO

Narrowing the Collection Scope

Like ANALYZE_STATISTICS, ANALYZE_STATISTICS_PARTITION lets you narrow scope of analysis to a subset of a table's columns. You can also control the size of the data sample that it collects. For details on these options, see Collecting Table Statistics.

Example

The following table stores sales data and is partitioned by order dates:
CREATE TABLE public.store_orders_fact
(
    product_key int,
    product_version int,
    store_key int,
    vendor_key int,
    employee_key int,
    order_number int,
    date_ordered date NOT NULL,
    date_shipped date NOT NULL,
    quantity_ordered int,
    shipper_name varchar(32)
);

ALTER TABLE public.store_orders_fact PARTITION BY date_ordered::DATE GROUP BY CALENDAR_HIERARCHY_DAY
(date_ordered::DATE, 2, 2) REORGANIZE;
ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_product FOREIGN KEY (product_key, product_version) references public.product_dimension (product_key, product_version);
ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_vendor FOREIGN KEY (vendor_key) references public.vendor_dimension (vendor_key);
ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_employee FOREIGN KEY (employee_key) references public.employee_dimension (employee_key);

At the end of each business day you might call ANALYZE_STATISTICS_PARTITION and collect statistics on all data of the latest (today's) partition:

```sql
=> SELECT ANALYZE_STATISTICS_PARTITION('public.store_orders_fact', CURRENT_DATE::VARCHAR(10), CURRENT_DATE::VARCHAR(10));
ANALYZE_STATISTICS_PARTITION
-----------------------------
0
(1 row)
```

The function produces a set of fresh statistics for the most recent partition in store.store_sales_fact. If you query this table each morning on yesterday's sales, the optimizer uses these statistics to generate an optimized query plan:

```sql
=> EXPLAIN SELECT COUNT(*) FROM public.store_orders_fact WHERE date_ordered = CURRENT_DATE-1;
EXPLAIN SELECT COUNT(*) FROM public.store_orders_fact WHERE date_ordered = CURRENT_DATE-1;

Access Path:
+GROUPBY NOTHING [Cost: 2, Rows: 1] (PATH ID: 1)
    | Aggregates: count(*)
    | Execute on: All Nodes
    | +----> STORAGE ACCESS for store_orders_fact [Cost: 1, Rows: 222(PARTITION-LEVEL STATISTICS)] (PATH ID: 2)
    |     | Projection: public.store_orders_fact_v1_b1
    |     | Filter: (store_orders_fact.date_ordered = '2019-04-01':date)
    |     | Execute on: All Nodes
```
Analyzing Row Counts

Vertica lets you obtain row counts for projections and for external tables, through `ANALYZE_ROW_COUNT` and `ANALYZE_EXTERNAL_ROW_COUNT`, respectively.

Projection Row Count

`ANALYZE_ROW_COUNT` is a lightweight operation that collects a minimal set of statistics and aggregate row counts for a projection, and saves it in the database catalog. In many cases, this data satisfies many optimizer requirements for producing optimal query plans. This operation is invoked on the following occasions:

- At the time intervals specified by configuration parameter `AnalyzeRowCountInterval`—by default, once a day.
- During loads. Vertica commits aggregate row count data to the catalog when the percentage of WOS to ROS equals the setting in configuration parameter `ARCCreditPercentage`.
- On calls to meta-functions `ANALYZE_STATISTICS` and `ANALYZE_STATISTICS_PARTITION`.

You can explicitly invoke `ANALYZE_ROW_COUNT` through calls to `DO_TM_TASK`. For example:

```sql
=> SELECT DO_TM_TASK('analyze_row_count', 'store_orders_fact_b0');
```

```
- Task: row count analyze
  (Table: public.store_orders_fact) (Projection: public.store_orders_fact_b0)
  (1 row)
```

You can change the intervals when Vertica regularly collects row-level statistics by setting configuration parameter `AnalyzeRowCountInterval`. For example, you can change the collection interval to 1 hour (3600 seconds):

```sql
=> ALTER DATABASE DEFAULT SET AnalyzeRowCountInterval = 3600;
=> ALTER DATABASE
```
External Table Row Count

`ANALYZE_EXTERNAL_ROW_COUNT` calculates the exact number of rows in an external table. The optimizer uses this count to optimize for queries that access external tables. This is especially useful when an external table participates in a join. This function enables the optimizer to identify the smaller table to use as the inner input to the join, and facilitate better query performance.

The following query calculates the exact number of rows in the external table `loader_rejects`:

```
=> SELECT ANALYZE_EXTERNAL_ROW_COUNT('loader_rejects');
ANALYZE_EXTERNAL_ROW_COUNT
-------------------------
 0
```

Canceling Statistics Collection

To cancel statistics collection mid analysis, execute CTRL-C on `vsql` or call the `INTERRUPT_STATEMENT()` function.

If you want to remove statistics for the specified table or type, call the `DROP_STATISTICS()` function.

**Caution:**

After you drop statistics, it can be time consuming to regenerate them.

Getting Data on Table Statistics

Vertica provides information about statistics for a given table and its columns and partitions in two ways:

- The query optimizer notifies you about the availability of statistics to process a given query.
- System table `PROJECTION_COLUMNS` shows what types of statistics are available for the table columns, and when they were last updated.
Query Evaluation

During predicate selectivity estimation, the query optimizer can identify when histograms are not available or are out of date. If the value in the predicate is outside the histogram's maximum range, the statistics are stale. If no histograms are available, then no statistics are available to the plan.

When the optimizer detects stale or no statistics, such as when it encounters a column predicate for which it has no histogram, the optimizer performs the following actions:

- Displays and logs a message that you should run ANALYZE_STATISTICS.
- Annotates EXPLAIN-generated query plans with a statistics entry.
- Ignores stale statistics when it generates a query plan. The optimizer uses other considerations to create a query plan, such as FK-PK constraints.

For example, the following query plan fragment shows no statistics (histograms unavailable):

```
| | +- Outer -> STORAGE ACCESS for fact [Cost: 604, Rows: 10K (NO STATISTICS)]
```

The following query plan fragment shows that the predicate falls outside the histogram range:

```
| | +- Outer -> STORAGE ACCESS for fact [Cost: 35, Rows: 1 (PREDICATE VALUE OUT-OF-RANGE)]
```

Statistics Data in PROJECTION_COLUMNS

Two columns in system table PROJECTION_COLUMNS show the status of each table column's statistics, as follows:

- STATISTICS_TYPE returns the type of statistics that are available for this column, one of the following: NONE, ROWCOUNT, or FULL.
- STATISTICS_UPDATED_TIMESTAMP returns the last time statistics were collected for this column.

For example, the following sample schema defines a table named trades, which groups the highly-correlated columns bid and ask and stores the stock column separately:

```
=> CREATE TABLE trades (stock CHAR(5), bid INT, ask INT);
=> CREATE PROJECTION trades_p (
set vertica

Now, collected statistics:

```
=> INSERT INTO trades VALUES('acme', 10, 20);
=> COMMIT;
```

Query the PROJECTION_COLUMNS table for table trades:

```
=> SELECT table_name AS table, projection_name AS projection, table_column_name AS column,
statistics_type, statistics_updated_timestamp AS last_updated
FROM projection_columns WHERE table_name = 'trades';
```

<table>
<thead>
<tr>
<th>table</th>
<th>projection</th>
<th>column</th>
<th>statistics_type</th>
<th>last_updated</th>
</tr>
</thead>
<tbody>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>stock</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>bid</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>ask</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>stock</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>bid</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>ask</td>
<td>NONE</td>
<td></td>
</tr>
</tbody>
</table>

(6 rows)

The statistics_type column returns NONE for all columns in the trades table, while statistics_updated_timestamp is empty because statistics have not yet been collected on this table.

Now, run **ANALYZE_STATISTICS** on the stock column:

```
=> SELECT ANALYZE_STATISTICS ('public.trades', 'stock');
```

```
ANALYZE_STATISTICS
---------------------
\n
0

(1 row)
```

Now, when you query **PROJECTION_COLUMNS**, it returns the following results:

```
=> SELECT table_name AS table, projection_name AS projection, table_column_name AS column,
statistics_type, statistics_updated_timestamp AS last_updated
FROM projection_columns WHERE table_name = 'trades';
```

<table>
<thead>
<tr>
<th>table</th>
<th>projection</th>
<th>column</th>
<th>statistics_type</th>
<th>last_updated</th>
</tr>
</thead>
<tbody>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>stock</td>
<td>FULL</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>bid</td>
<td>ROWCOUNT</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>ask</td>
<td>ROWCOUNT</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>stock</td>
<td>FULL</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>bid</td>
<td>ROWCOUNT</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>ask</td>
<td>ROWCOUNT</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
</tbody>
</table>

(6 rows)

This time, the query results contain several changes:

<table>
<thead>
<tr>
<th>statistics_type</th>
<th>• Set to FULL for the stock column, confirming that full statistics were run on</th>
</tr>
</thead>
</table>

Vertica Analytic Database (9.3.x)
| statistics_updated_timestamp | Set to the same timestamp for all columns, confirming that statistics (either full or row count) were updated on all. |

### Best Practices for Statistics Collection

You should call `ANALYZE_STATISTICS` or `ANALYZE_STATISTICS_PARTITION` when one or more of the following conditions are true:

- Data is bulk loaded for the first time.
- A new projection is refreshed.
- The number of rows changes significantly.
- A new column is added to the table.
- Column minimum/maximum values change significantly.
- New primary key values with referential integrity constraints are added. The primary key and foreign key tables should be re-analyzed.
- Table size notably changes relative to other tables it is joined to—for example, a table that was 50 times larger than another table is now only five times larger.
- A notable deviation in data distribution necessitates recalculating histograms—for example, an event causes abnormally high levels of trading for a particular stock.
- The database is inactive for an extended period of time.

### Overhead Considerations

Running `ANALYZE_STATISTICS` is an efficient but potentially long-running operation. You can run it concurrently with queries and loads in a production environment. However, the function can incur considerable overhead on system resources (CPU and memory), at the expense of queries and load operations. To minimize overhead, consider calling `ANALYZE_STATISTICS_PARTITIONS` on those partitions that are subject to significant activity—typically, the most recently loaded partitions, including the table's active partition. You can
further narrow the scope of both functions by specifying a subset of the table columns—generally, those that are queried most often.

**Related Tools**

You can diagnose and resolve many statistics-related issues by calling `ANALYZE_WORKLOAD`, which returns tuning recommendations. If you update statistics and find that a query still performs poorly, run it through the Database Designer and choose `incremental` as the design type.
Using Diagnostic Tools

Vertica provides several diagnostic tools. This section includes the following:

- Determining Your Version of Vertica
- Collecting Diagnostics: scrutinize Command
- Exporting a Catalog
- Exporting Profiling Data

Determining Your Version of Vertica

To determine which version of Vertica is installed on a host, log in to that host and type:

```
$ rpm -qa | grep vertica
```

The command returns the name of the installed package, which contains the version and build numbers. The following example indicates that both Vertica 9.3.x and Management Console 9.3.x are running on the targeted host:

```
$ rpm -qa | grep vertica
vertica-9.3.0-0
vertica-console-9.3.0-0.x86_64
```

When you are logged in to your Vertica Analytic Database database, you can also run a query for the version only, by running the following command:

```
=> SELECT version();
  version
--------------------------
  Vertica Analytic Database v9.3.0-0
```

Collecting Diagnostics: scrutinize Command

The diagnostics tool scrutinize collects a broad range of information from a Vertica cluster. It also supports a range of options that let you control the amount and type of data that is collected. Collected data can include but is not limited to:

- Host diagnostics and configuration data
- Run-time state (number of nodes up or down)
Log files from the installation process, the database, and the administration tools (such as, vertica.log, dbLog, /opt/vertica/log/adminTools.log)

- Error messages
- Database design
- System table information, such as system, resources, workload, and performance
- Catalog metadata, such as system configuration parameters
- Backup information

Requirements

scrutinize requires that a cluster be configured to support the Administration Tools utility. If Administration Tools cannot run on the initiating host, then scrutinize cannot run on that host.

Running scrutinize

You can run scrutinize with the following command:

```
$ /opt/vertica/bin/scrutinize
```

Unqualified, scrutinize collects a wide range of information from all cluster nodes. It stores the results in a .tar file (VerticaScrutinize. NumericID.tar), with minimal effect on database performance. scrutinize output can help diagnose most issues and yet reduces upload size by omitting fine-grained profiling data.

**Note:**

scrutinize is designed to collect information for troubleshooting your database and cluster. Depending on your system configuration, logs generated from running scrutinize might contain proprietary information. If you are concerned with sharing proprietary information, please remove it from the .tar file before you send it to Vertica Customer Support for assistance.
Command Options

scrutinize options support the following tasks:

- Obtain version information about scrutinize and Vertica, and online help.
- Redirect output.
- Access a password-protected database.
- Control the scope of data collection.
- Upload results to Vertica Customer Support.

Privileges

You must have database administrator (dbadmin) privileges to run scrutinize. If you run scrutinize as root when the dbadmin user exists, Vertica returns an error.

Disk Space Requirements

scrutinize requires temporary disk space where it can collect data before posting the final compressed (.tar) output. How much space depends on variables such as the size of the Vertica log and extracted system tables, as well as user-specified options that limit the scope of information collected. Before scrutinize runs, it verifies that the temporary directory contains at least 1 GB of space; however, the actual amount needed can be much higher.

You can redirect scrutinize output to another directory. For details, see Redirecting scrutinize Output.

Database Specification

If multiple databases are defined on the cluster and more than one is active, or none is active, you must run scrutinize with one of the following options:

$ /opt/vertica/bin/scrutinize {--database=database | -d database}

If you omit this option when these conditions are true, scrutinize returns with an error.
## Informational Options

`scrutinize` supports two informational options that cannot be combined with any other options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--version</code></td>
<td>Obtains the version number of the Vertica server and the <code>scrutinize</code> version number, and then exits. For example:</td>
</tr>
<tr>
<td></td>
<td>=&gt; <code>!/scrutinize --version</code></td>
</tr>
<tr>
<td></td>
<td>Scrutinize Version 9.3.1-20191208</td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Lists all <code>scrutinize</code> options to the console, and then exits:</td>
</tr>
<tr>
<td><code>-h</code></td>
<td>=&gt; <code>!/scrutinize -h</code></td>
</tr>
<tr>
<td></td>
<td>Usage: scrutinize [options]</td>
</tr>
<tr>
<td></td>
<td>Options:</td>
</tr>
<tr>
<td></td>
<td>--version show program's version number and exit</td>
</tr>
<tr>
<td></td>
<td>-h, --help show this help message and exit</td>
</tr>
<tr>
<td></td>
<td>-X LIST, --exclude-tasks=LIST Skip tasks of a particular type. Provide a comma-separated lists of types to skip. Types are case-sensitive. Possible types are: Command, File, VerticaLog, DC, SystemTable, CatalogObject, Query, all.</td>
</tr>
</tbody>
</table>

## Redirecting `scrutinize` Output

By default, `scrutinize` uses the temporary directory `/opt/vertica/tmp` execution to compile output while it executes. On completing its collection, it saves the collection to a tar file to the current directory. You can redirect `scrutinize` output with two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--tmpdir=path</code></td>
<td>Directs temporary output to the specified path, where the following requirements apply to <code>path</code>:</td>
</tr>
<tr>
<td></td>
<td>- The directory must have at least 1 GB of free space.</td>
</tr>
<tr>
<td></td>
<td>- You must have write permission to it.</td>
</tr>
<tr>
<td><code>--output_dir=path</code></td>
<td>Saves <code>scrutinize</code> results to a tar file in <code>path</code>. For example:</td>
</tr>
<tr>
<td><code>-o path</code></td>
<td>=&gt; <code>$/scrutinize --output_dir=&quot;/my_diagnostics/&quot;</code></td>
</tr>
</tbody>
</table>
scrutinize Security

scrutinize can specify user names and passwords as follows:

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--user=username</td>
<td>Specifies the dbadmin user name. By default, scrutinize uses the user name of the invoking user.</td>
</tr>
<tr>
<td>-U username</td>
<td></td>
</tr>
<tr>
<td>--password=password</td>
<td>Sets the database password as an argument to the scrutinize command. Use this option if the administrator account (default dbadmin) has password authentication. If you omit this option on a password-protected database, scrutinize returns a warning, unless the environment variable VSQL_PASSWORD is set. Passwords with special characters must be enclosed with single quotes. For example:</td>
</tr>
<tr>
<td>-P password</td>
<td></td>
</tr>
<tr>
<td>-prompt-password</td>
<td>Specifies to prompt users for their database password before scrutinize begins to collect data.</td>
</tr>
<tr>
<td>-W</td>
<td></td>
</tr>
</tbody>
</table>

Data Collection Scope

scrutinize options let you control the scope of the data collection. You can specify the scope of the data collection according to the following criteria:

- Time span
- Amount of data, including its level of granularity
- Specific nodes
- Types of data to include and exclude

You can use these options singly or in combination, to achieve the desired level of granularity.
**Time Span**

scrutinize --begin and --end options specify the time frame of diagnostic data that is collected from vertica.log and editor.log. You can use these options singly or together:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--begin=timestamp</td>
<td>Specifies to collect log data from timestamp.</td>
</tr>
<tr>
<td>--end=timestamp</td>
<td>Specifies to collect log data to timestamp or log end.</td>
</tr>
</tbody>
</table>

**Note:**
These options cannot be combined with --include_gzlogs.

*timestamp* can be an offset from the current time, or an absolute time, as follows:

- Absolute time: 'YYYY-MM-DD HH:MM:SS'
- Offset time (from current timestamp): DdHhMmSs

The --begin timestamp must precede the --end timestamp.

**Examples**

Collect 24 hours of data between 2017-11-19 and 2017-11-20:

```
$ scrutinize --begin='2017-11-19 00:00:00' --end='2017-11-20 00:00:00'
```
Using default temporary directory /tmp

Begin:

2017-11-19 00:00
0:00

End:

2017-11-20 00:00
0:00

Collect the last 2.5 hours of data:

$ date
Wed Nov 22 10:38:05 EST 2017
Collect data between the last 48 and 24 hours:

```
$ scrunтинизе -b begin=2h30m
Scru tínize Vers ion 9.0.1-1-20171119
Using default temporary directory /tmp
Begin:

2017-11-22 08:08:09

$ date
Wed Nov 22 10:36:17 EST 2017
$ 
```
scru
tini
ze -

2017- 11- 20
10:3
6:20
End:
2017- 11- 21
10:3
6:20
Collect data between 2017-11-19 and one day before the current time:

```
$ date
Wed Nov 22 10:36:05 EST 2017
$ scrutinize --begin='2017-11-19 00:00:00' --end=1d

Scrutinize Version 9.0.1-20171119

Using default temporary directory /tmp

Begin:

2017-11-19 00:00:00
```
### Amount of Collected Data

Several options let you limit how much data `scrutinize` collects:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--by-second</code></td>
<td>Specifies the granularity of information that is collected from Data Collector tables with one of the following options:</td>
</tr>
<tr>
<td><code>--by-minute=boolean-value</code></td>
<td>- <code>--by-second</code>: Highest level of granularity, specifies to collect data down to the second.</td>
</tr>
<tr>
<td></td>
<td>- <code>--by-minute=boolean-value</code> where <code>boolean-value</code> is set to one of the following:</td>
</tr>
<tr>
<td></td>
<td>- `{yes</td>
</tr>
<tr>
<td></td>
<td>- `{no</td>
</tr>
<tr>
<td><code>--get-files file-list</code></td>
<td>Specifies extra files to collect, including globs, where</td>
</tr>
</tbody>
</table>

For example, the following command collects the last five days of data down to the hour:

```bash
$ scrutinize --begin=5d --by-minute=no
```

This command collects the last hour's data down to the second:

```bash
$ scrutinize --begin=1h --by-second
```
**file-list** is a semicolon-delimited list of files.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `--include_gzlogs=num-files` | Specifies to include *num-files* rotated log files (vertica.log*.gz) in the scrutinize output, where *num-files* can be one of the following:  
  - An integer specifies the number of rotated log files to collect.  
  - `all` specifies to collect all rotated log files.  
  
  By default, *scrutinize* includes three rotated log files.  
  
  For example, the following command specifies to collect two rotated log files:  
  
  ```bash  
  $ scrutinize --include_gzlogs=2  
  ``` |
| `--log-limit=limit` | Specifies how much data to collect from Vertica logs, where *limit* specifies, in gigabytes, how much log data to collect, starting from the most recent log entry. By default, *scrutinize* collects 1 GB of log data.  
  
  For example, the following command specifies to collect 4 GB of log data:  
  
  ```bash  
  $ scrutinize --log-limit=4  
  ``` |

**Node-Specific Collection**

By default, *scrutinize* collects data from all cluster nodes. You can specify that *scrutinize* collect from individual nodes in two ways:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| `--local_diags`  | Specifies to collect diagnostics only from the host on which *scrutinize* was invoked.  
  
  **Tip:**  
  
  To collect data from multiple nodes in the cluster, use the `--hosts` option. |
| `--hosts=host-list` | Specifies to collect diagnostics only from the hosts specified in |
-n host-list  

*host-list*, where *host-list* is a comma-separated list of IP addresses or host names.

For example:

```
$ scrutinize --hosts=127.0.0.1,host_3,host_1
```

### Types of Data to Include

`scrutinize` provides several options that let you specify the type of data to collect:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--debug</strong></td>
<td>Collects debug information for the log.</td>
</tr>
<tr>
<td><strong>--diag-dump</strong></td>
<td>Limits the collection to database design, system tables, and Data Collector tables. Use this option to collect data to analyze system performance.</td>
</tr>
<tr>
<td><strong>--diagnostics</strong></td>
<td>Limits the collection to log file data and output from commands that are run against Vertica and its host system. Use this option to collect data to evaluate unexpected behavior in your Vertica system.</td>
</tr>
<tr>
<td><strong>--include-ros-info</strong></td>
<td>Includes ROS related information from system tables.</td>
</tr>
<tr>
<td><strong>--no-active-queries</strong></td>
<td>Specifies to exclude diagnostic information from system tables and Data Collector tables about currently running queries. By default, <code>scrutinize</code> collects this information (<strong>--with-active-queries</strong>).</td>
</tr>
<tr>
<td><strong>--with-active-queries</strong></td>
<td>Specifies that <code>scrutinize</code> gather diagnostics on one or more tasks, as specified in a file or JSON list. This option is typically used together with (<strong>--exclude</strong>).</td>
</tr>
<tr>
<td><strong>--tasks=</strong> tasks</td>
<td>Specifies the type of diagnostics collection to perform, where <em>type</em> can be one of the following arguments:</td>
</tr>
<tr>
<td><strong>-T</strong> tasks</td>
<td><strong>profiling</strong>: Gather profiling data.</td>
</tr>
</tbody>
</table>

**Note:**

Use this option only in consultation with Vertica Customer Support.
• context: Gather summary information.

--with-active-queries
The default setting, specifies to include diagnostic information from system tables and Data Collector tables about currently running queries. To omit this data, use --no-active-queries.

**Types of Data to Exclude**

scrutinize options also let you specify the types of data to exclude from its collection:

--exclude=tasks
-X tasks

Excludes one or more types of tasks from the diagnostics collection, where tasks is a comma-separated list of the tasks to exclude.

**Note:**
This option is typically used only in consultation with your Vertica Customer Support contact.

Specify the tasks to exclude with the following case-insensitive arguments:

- all: All default tasks
- DC: Data Collector tables
- File: Log files from the installation process, the database, and Administration Tools, such as vertica.log, dbLog, and adminTools.log
- VerticaLog: Vertica logs
- CatalogObject: Vertica catalog metadata, such as system configuration parameters
- SystemTable: Vertica system tables that contain information about system, resources, workload, and performance
- Query: Vertica metafunctions that use vsql to connect to the database, such as EXPORT_CATALOG()
- Command: Operating system information, such as the length of time that a node has been up
### --no-active-queries

Specifies to omit diagnostic information from system tables and Data Collector tables about currently running queries. By default, scrutinize always collects active query information (--with-active-queries).

### --vsql-off

Excludes Query and SystemTable tasks, which are used to connect to the database. This option can help you deal with problems that occur during an upgrade, and is typically used in the following cases:

- Vertica is running but is slow to respond.
- You haven't yet created a database but need help troubleshooting other cluster issues.

---

### Uploading scrutinize Results

scrutinize provides several options for uploading data to Vertica customer support.

#### Upload Packaging

When you use an upload option, scrutinize does not bundle all output in a single tar file. Instead, each node posts its output directly to the specified URL as follows:

1. Uploads a smaller, context file, enabling Customer Support to review high-level information.
2. On completion of scrutinize execution, uploads the complete diagnostics collection.

#### Upload Prerequisites

Before you run scrutinize with an upload option:
- Install the **cURL** program installed in the path for the database administrator user who is running **scrutinize**.
- Verify each node in the cluster can make an HTTP or FTP connection directly to the Internet.

## Upload Options

**Note:**
Two options upload **scrutinize** output to a Vertica support-provided URL or FTP address: **--auth-upload** and **--url**. Each option authenticates the upload differently, as noted below.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--auth-upload=url</strong></td>
<td>Uses your Vertica license to authenticate with the Vertica server, by uploading your customer name. Customer Support uses this information to verify your identity on receiving your uploaded file. This option requires a valid Vertica Premium Edition license.</td>
</tr>
<tr>
<td><strong>-A url</strong></td>
<td>For example:</td>
</tr>
<tr>
<td></td>
<td>$ scrutinize -U username -P 'password' --auth-upload=&quot;url&quot;</td>
</tr>
<tr>
<td><strong>--url=url</strong></td>
<td>Requires <strong>url</strong> to include a user name and password that is supplied by Vertica Customer Support.</td>
</tr>
<tr>
<td><strong>-u url</strong></td>
<td>For example:</td>
</tr>
<tr>
<td></td>
<td>$ scrutinize -U username -P 'password' --url='ftp://username/password@customers.vertica.com/'</td>
</tr>
<tr>
<td><strong>--message=message</strong></td>
<td>include a message with the <strong>scrutinize</strong> output, where <strong>message</strong> is one of the following:</td>
</tr>
<tr>
<td><strong>-m message</strong></td>
<td></td>
</tr>
</tbody>
</table>
|                         | • "**message** text"
  A message string. For example:                                                                                                                                                                         |
|                         | $ scrutinize --message="re: case number #ABC-12345"                                                                                                                                                         |
|                         | • "**file-path**"
  A path to a text file. For example:                                                                                                                                                                     |
$ scrutinize --message="/path/to/msg.txt"

- **PROMPT**
  Opens an input stream. `scrutinize` reads input until you type a period (.) on a new line. This closes the input stream, and `scrutinize` writes the message to the collected output.

  ```bash
  $ scrutinize --message=PROMPT
  Enter reason for collecting diagnostics; end with '.' on a line by itself:
  Query performance degradation noticed around 9AM EST on Saturday
  .
  Vertica Scrutinize Report
  --------------------------
  Result Dir: /home/dbadmin/VerticaScrutinize.20131126083311
  ...
  ```

  The message is set in the output directory, in `reason.txt`. If no message is specified, `scrutinize` generates the default message Unknown reason for collection. Messages typically include the following information:
  - Reason for gathering/submitting diagnostics.
  - Support-supplied case number and other issue-specific information, to help Vertica Customer Support identify your case and analyze the problem.

**Troubleshooting scrutinize**

The troubleshooting advice in this section can help you resolve common issues that you might encounter when using `scrutinize`.

**Collection Time Is Too Slow**

To speed up collection time, omit system tables when running an instance of `scrutinize`. Be aware that collecting from fewer nodes does not necessarily speed up the collection process.
Output Size Is Too Large

Output size depends on system table size and vertica log size.

To create a smaller scrutinize output, omit some system tables or truncate the vertica log. For more information, see Narrowing the Scope of scrutinize Data Collection.

System Tables Not Collected on Databases with Password

Running scrutinize on a password-protected database might require you to supply a user name and password:

```
$ scrutinize -U username -P 'password'
```

Exporting a Catalog

When you export a catalog you can quickly move a catalog to another cluster. Exporting a catalog transfers schemas, tables, constraints, projections, and views. System tables are not exported.

Exporting catalogs can also be useful for support purposes.

See the EXPORT_CATALOG function in the SQL Reference Manual for details.

Exporting Profiling Data

The diagnostics audit script gathers system table contents, design, and planning objects from a running database and exports the data into a file named ./diag_dump_<timestamp>.tar.gz, where <timestamp> denotes when you ran the script.

If you run the script without parameters, you will be prompted for a database password.
Syntax

/opt/vertica/scripts/collect_diag_dump.sh [ command... ]

Parameters

<table>
<thead>
<tr>
<th>command</th>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-U</td>
<td>User name, typically the database administrator account, dbadmin.</td>
</tr>
<tr>
<td></td>
<td>-W</td>
<td>Database password.</td>
</tr>
<tr>
<td></td>
<td>-C</td>
<td>Includes a compression analysis, resulting in a longer script execution time.</td>
</tr>
</tbody>
</table>

Example

The following command runs the audit script with all arguments:

```
$ /opt/vertica/scripts/collect_diag_dump.sh -U dbadmin -W password -C
```

Profiling Database Performance

You can profile database performance to evaluate query performance. Profiling can deliver information such as the following:
How much memory and how many threads each operator is allocated.
How data flows through each operator at different points in time during query execution.
Whether a query is network bound.

Profiling data can help provide valuable input into database design considerations, such as how best to segment and sort projections, or facilitate better distribution of data processing across the cluster.

For example, profiling can show data skew, where some nodes process more data than others. The rows produced counter in system table `EXECUTION_ENGINE_PROFILES` shows how many rows were processed by each operator. Comparing rows produced across all nodes for a given operator can reveal whether a data skew problem exists.

The topics in this section focus on obtaining profile data via vsql statements. The Vertica Management Console also provides an easy-to-read view of profiling data.

### Enabling Profiling

You can enable profiling at three scopes:

- **Globally across all database sessions**
- **The current session**
- **Individual SQL statements**

Vertica meta-function `SHOW_PROFILING_CONFIG` shows whether profiling is enabled at global and session scopes. In the following example, the function shows that profiling is disabled across all categories for the current session, and enabled globally across all categories:

```plaintext
=> SELECT SHOW_PROFILING_CONFIG();
SHOW_PROFILING_CONFIG
----------------------------------------
Session Profiling: Session off, Global on
EE Profiling:     Session off, Global on
Query Profiling:  Session off, Global on
(1 row)
```
Global Profiling

When global profiling is enabled or disabled for a given category, that setting persists across all database sessions. You set global profiling with `ALTER DATABASE`, as follows:

\[
\text{ALTER DATABASE } \text{db-spec} \text{ SET profiling-category = \{0 | 1\}}
\]

`profiling-category` specifies a profiling category with one of the following arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Data profiled</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlobalQueryProfiling</td>
<td>Query-specific information, such as query string and duration of execution, divided between two system tables:</td>
</tr>
<tr>
<td></td>
<td>• <code>QUERY_PLAN_PROFILES</code>: Real-time status for each query plan path.</td>
</tr>
<tr>
<td></td>
<td>• <code>QUERY_PROFILES</code>: Query information.</td>
</tr>
<tr>
<td>GlobalSessionProfiling</td>
<td>General information about query execution on each node during the current session, stored in system table <code>SESSION_PROFILES</code>.</td>
</tr>
<tr>
<td>GlobalEEProfiling</td>
<td>Execution engine data, saved in system tables <code>QUERY_CONSUMPTION</code> and <code>EXECUTION ENGINE_PROFILES</code>.</td>
</tr>
</tbody>
</table>

For example, the following statement globally enables query profiling on the current (DEFAULT) database:

\[
\Rightarrow \text{ALTER DATABASE DEFAULT SET GlobalQueryProfiling = 1;}
\]

Session Profiling

Session profiling can be enabled for the current session, and persists until you explicitly disable profiling, or the session ends. You set session profiling with the following Vertica meta-functions:

- `ENABLE_PROFILING (profiling-type)`
- `DISABLE_PROFILING (profiling-type)`
profiling-type specifies type of profiling data to enable or disable with one of the following arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Data profiled</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>Query-specific information, such as query string and duration of execution, divided between two system tables:</td>
</tr>
<tr>
<td></td>
<td>· QUERY_PLAN_PROFILES: Real-time status for each query plan path.</td>
</tr>
<tr>
<td></td>
<td>· QUERY_PROFILES: Query information.</td>
</tr>
<tr>
<td>session</td>
<td>General information about query execution on each node during the current session, stored in system table SESSION_PROFILES.</td>
</tr>
<tr>
<td>ee</td>
<td>Execution engine data, saved in system tables QUERY_CONSUMPTION and EXECUTION_ENGINE_PROFILES.</td>
</tr>
</tbody>
</table>

For example, the following statement enables session-scoped profiling for the execution run of each query:

```sql
=> SELECT ENABLE_PROFILING('ee');
  ENABLE_PROFILING
-----------------------
EE Profiling Enabled
(1 row)
```

**Statement Profiling**

You can enable profiling for individual SQL statements by prefixing them with the keyword PROFILE. You can profile a SELECT statement, or any DML statement such as INSERT, UPDATE, COPY, and MERGE. For detailed information, see Profiling Single Statements.

**Precedence of Profiling Scopes**

Vertica checks session and query profiling at the following scopes in descending order of precedence:

1. Statement profiling (highest)
2. Session profiling (ignored if global profiling is enabled)
3. Global profiling (lowest)
Regardless of query and session profiling settings, Vertica always saves a minimum amount of profiling data in the pertinent system tables: QUERY_PROFILES, QUERY_PLAN_PROFILES, and SESSION_PROFILES.

For execution engine profiling, Vertica first checks the setting of configuration parameter SaveDCEEProfileThresholdUS. If the query runs longer than the specified threshold (by default, 60 seconds), Vertica gathers execution engine data for that query and saves it to system tables QUERY_CONSUMPTION and EXECUTION_ENGINE_PROFILES. Vertica uses profiling settings of other scopes (statement, session, global) only if the query's duration is below the threshold.

Important:
To disable or minimize execution engine profiling:

- Set SaveDCEEProfileThresholdUS to a very high value, up to its maximum value of $2^{31}-1$.
- Disable profiling at session and global scopes.

### Profiling Single Statements

To profile a single statement, prefix it with `PROFILE`. You can profile a query (SELECT) statement, or any DML statement such as INSERT, UPDATE, COPY, and MERGE. The statement returns with a profile summary:

- Profile identifiers transaction_id and statement_id
- Initiator memory for the query
- Total memory required

For example:

```sql
=> PROFILE SELECT customer_name, annual_income FROM public.customer_dimension
    WHERE (customer_gender, annual_income) IN (SELECT customer_gender, MAX(annual_income)
    FROM public.customer_dimension GROUP BY customer_gender);NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996274760535 and statement_id=1;
NOTICE 3557: Initiator memory for query: [on pool general: 2783428 KB, minimum: 2312914 KB]
NOTICE 5077: Total memory required by query: [2783428 KB]
customer_name | annual_income
---------------|----------------
James M. McNulty | 999979
Emily G. Vogel  | 999998
(2 rows)
```
You can use the profile identifiers `transaction_id` and `statement_id` to obtain detailed profile information for this query from system tables `EXECUTIONENGINE_PROFILES` and `QUERY_PLAN_PROFILES`. You can also use these identifiers to obtain resource consumption data from system table `QUERY_CONSUMPTION`.

For example:

```sql
=> SELECT path_id, path_line::VARCHAR(68), running_time FROM v_monitor.query_plan_profiles
    WHERE transaction_id=45035996274760535 AND statement_id=1 ORDER BY path_id, path_line_index;
```

---

### Labeling Queries

To quickly identify queries for profiling and debugging purposes, include the `LABEL` hint.

`LABEL` hints are valid in the following statements:

- **DELETE**
- **INSERT**
- **MERGE**
- **SELECT**
- **UPDATE**
- **UNION**: Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

For example:

```sql
SELECT /*+label(myselectquery)*/ COUNT(*) FROM t;
INSERT /*+label(myinsertquery)*/ INTO t VALUES(1);
```
After you add a label to one or more queries, query the QUERY_PROFILES system table to see which queries ran with your supplied labels. The QUERY_PROFILES system table IDENTIFIER column returns the user-defined label that you previously assigned to a query. You can also obtain other query-specific data that can be useful for querying other system tables, such as transaction IDs.

For example:

```sql
=> SELECT identifier, query FROM query_profiles;

+----------------+------------------------------------------------------------------+
| identifier      | query                                                             |
|----------------+------------------------------------------------------------------|
| myselectquery   | SELECT /*+label(myselectquery)*/ COUNT(*) FROM t;                  |
| myinsertquery   | INSERT /*+label(myinsertquery)*/ INTO t VALUES(1);                 |
| myupdatequery   | UPDATE /*+label(myupdatequery)*/ t SET a = 2 WHERE a = 1;          |
| mydeletequery   | DELETE /*+label(mydeletequery)*/ FROM t WHERE a = 1;               |
|                | | SELECT identifier, query from query_profiles;                      |
(5 rows)
```

---

**Real-Time Profiling**

You can monitor long-running queries while they execute by querying system table EXECUTION_ENGINE_PROFILES. This table contains available profiling counters for internal operations and user statements. You can use the Linux `watch` command to query this table at frequent intervals.

Queries for real-time profiling data require a transaction ID. If the transaction executes multiple statements, the query also requires a statement ID to identify the desired statement. If you profile individual queries, the query returns with the statement's transaction and statement IDs. You can also obtain transaction and statement IDs from the SYSTEM_SESSIONS system table.

---

**Profiling Counters**

The EXECUTION_ENGINE_PROFILES system table contains available profiling counters for internal operations and user statements. Real-time profiling counters are available for all statements while they execute, including internal operations such as `mergeout`, `recovery`, and `refresh`. Unless you explicitly enable profiling using the keyword `PROFILE` on a specific SQL statement, or generally enable profiling for the database and/or the current session, profiling counters are unavailable after the statement completes.
Useful counters include:

- Execution time (µs)
- Rows produced
- Total merge phases
- Completed merge phases
- Current size of temp files (bytes)

You can view all available counters by querying `EXECUTION_ENGINE_PROFILES`:

```
=> SELECT DISTINCT(counter_name) FROM EXECUTION_ENGINE_PROFILES;
```

To monitor the profiling counters, you can run a command like the following using a retrieved transaction ID (a000000000027):

```
=> SELECT * FROM execution_engine_profiles
  WHERE TO_HEX(transaction_id)='a000000000027'
  AND counter_name = 'execution time (us)'
  ORDER BY node_name, counter_value DESC;
```

The following example finds operators with the largest execution time on each node:

```
=> SELECT node_name, operator_name, counter_value execution_time_us
  FROM V_MONITOR.EXECUTION_ENGINE_PROFILES
  WHERE counter_name='execution time (us)'
  LIMIT 1
  OVER(PARTITION BY node_name ORDER BY counter_value DESC);
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>operator_name</th>
<th>execution_time_us</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>Join</td>
<td>131906</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>Join</td>
<td>227778</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>NetworkSend</td>
<td>524080</td>
</tr>
</tbody>
</table>

(3 rows)

**Linux watch Command**

You can use the Linux `watch` command to monitor long-running queries at frequent intervals. Common use cases include:

- Observing executing operators within a query plan on each Vertica cluster node.
- Monitoring workloads that might be unbalanced among cluster nodes—for example, some nodes become idle while others are active. Such imbalances might be caused by data skews or by hardware issues.

In the following example, `watch` queries operators with the largest execution time on each node. The command specifies to re-execute the query each second:

```
watch -n 1 -d "vsql VMart -c"SELECT node_name, operator_name, counter_value execution_time_us
FROM v_monitor.execution_engine_profiles WHERE counter_name='execution time (us)'
```
Profiling Query Resource Consumption

Vertica collects data on resource usage of all queries—including those that fail—and summarizes this data in system table `QUERY_CONSUMPTION`. This data includes the following information about each query:

- Wall clock duration
- CPU cycles consumed
- Memory reserved and allocated
- Network bytes sent and received
- Disk bytes read and written
- Bytes spilled
- Threads allocated
- Rows output to client
- Rows read and written

You can obtain information about individual queries through their transaction and statement IDs. Columns `TRANSACTION_ID` and `STATEMENT_ID` provide a unique key to each query statement.

**Note:**
One exception applies: a query with multiple plans has a record for each plan.

For example, the following query is profiled:

```
=> PROFILE SELECT pd.category_description AS 'Category', SUM(sf.sales_quantity*sf.sales_dollar_amount) AS 'Total Sales'
   FROM store.store_sales_fact sf
   JOIN public.product_dimension pd ON pd.product_version=sf.product_version AND pd.product_key=sf.product_key
   GROUP BY pd.category_description;
NOTICE 4788: Statement is being profiled
```
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996274751822 and statement_id=1;

NOTICE 3557: Initiator memory for query: [on pool general: 256160 KB, minimum: 256160 KB]
NOTICE 5077: Total memory required by query: [256160 KB]

<table>
<thead>
<tr>
<th>Category</th>
<th>Total Sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-food</td>
<td>1147919813</td>
</tr>
<tr>
<td>Misc</td>
<td>1158328131</td>
</tr>
<tr>
<td>Medical</td>
<td>1155853990</td>
</tr>
<tr>
<td>Food</td>
<td>4038220327</td>
</tr>
</tbody>
</table>

(4 rows)

You can use the transaction and statement IDs that Vertica returns to get profiling data from QUERY_CONSUMPTION—for example, the total number of bytes sent over the network for a given query:

=> SELECT NETWORK_BYTES_SENT FROM query_consumption WHERE transaction_id=45035996274751822 AND statement_id=1;

<table>
<thead>
<tr>
<th>NETWORK_BYTES_SENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>757745</td>
</tr>
</tbody>
</table>

(1 row)

**Note:**

QUERY_CONSUMPTION saves data from all queries, whether explicitly profiled or not.

**QUERY_CONSUMPTION versus EXECUTION.Engine_PROFILES**

QUERY_CONSUMPTION includes data that it rolls up from counters in EXECUTION.Engine_PROFILES. In the previous example, NETWORK_BYTES_SENT rolls up data that is accessible through multiple counters in EXECUTION.Engine_PROFILES. The equivalent query on EXECUTION.Engine_PROFILES looks like this:

=> SELECT operator_name, counter_name, counter_tag, SUM(counter_value) FROM execution_engine_profiles
   WHERE transaction_id=45035996274751822 AND statement_id=1 AND counter_name='bytes sent'
   GROUP BY ROLLUP (operator_name, counter_name, counter_tag) ORDER BY 1,2,3, GROUPING_ID();

<table>
<thead>
<tr>
<th>operator_name</th>
<th>counter_name</th>
<th>counter_tag</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1000 - v_vmart_node0001</td>
<td>252471</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1000 - v_vmart_node0002</td>
<td>251076</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1000 - v_vmart_node0003</td>
<td>253717</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1001 - v_vmart_node0001</td>
<td>192</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1001 - v_vmart_node0002</td>
<td>192</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1001 - v_vmart_node0003</td>
<td>0</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1002 - v_vmart_node0001</td>
<td>97</td>
</tr>
</tbody>
</table>
QUERY_CONSUMPTION and EXECUTIONENGINE_PROFILES also differ as follows:

- QUERY_CONSUMPTION saves data from all queries, no matter their duration or whether they are explicitly profiled. It also includes data on unsuccessful queries.
- EXECUTIONENGINE_PROFILES only includes data from queries whose length of execution exceeds a set threshold, or that you explicitly profile. It also excludes data of unsuccessful queries.
Profiling Query Plans

To monitor real-time flow of data through a query plan and its individual paths, query the following system tables:

**EXECUTION_ENGINE_PROFILES** and **QUERY_PLAN_PROFILES**. These tables provide data on how Vertica executed a query plan and its individual paths:

- **EXECUTION_ENGINE_PROFILES** summarizes query execution runs.
- **QUERY_PLAN_PROFILES** shows the real-time flow of data, and the time and resources consumed for each query path.

Each query plan path has a unique ID, as shown in the following EXPLAIN output fragment.

![Query Plan Diagram]

Both tables provide path-specific data. For example, **QUERY_PLAN_PROFILES** provides high-level data for each path, which includes:

- Length of a query operation execution
- How much memory that path’s operation consumed
- Size of data sent/received over the network

For example, you might observe that a GROUP BY HASH operation executed in 0.2 seconds using 100MB of memory.

Requirements

Real-time profiling minimally requires the ID of the transaction to monitor. If the transaction includes multiple statements, you also need the statement ID. You can get statement and transaction IDs by issuing **PROFILE** on the query to profile. You can then use these identifiers to query system tables **EXECUTION_ENGINE_PROFILES** and **QUERY_PLAN_PROFILES**.

For more information, see Profiling Single Statements.
Getting Query Plan Status for Small Queries

Real-time profiling counters, stored in system table **EXECUTION_ENGINE_PROFILES**, are available for all currently executing statements, including internal operations, such as a `mergeout`.

Profiling counters are available after query execution completes, if any one of the following conditions is true:

- The query was run via the `PROFILE` command
- Systemwide profiling is enabled by Vertica meta-function `ENABLE_PROFILING`.
- The query ran more than two seconds.

Profiling counters are saved in system table **EXECUTION_ENGINE_PROFILES** until the storage quota is exceeded.

For example:

1. Profile the query to get `transaction_id` and `statement_id` from `EXECUTION_ENGINE_PROFILES`. For example:

   ```sql
   => PROFILE SELECT * FROM t1 JOIN t2 ON t1.x = t2.y;
   NOTICE 4788: Statement is being profiled
   HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996273955065 and statement_id=4;
   NOTICE 3557: Initiator memory for query: [on pool general: 248544 KB, minimum: 248544 KB]
   NOTICE 5077: Total memory required by query: [248544 KB]
   x | y | z
   --------
   3 | 3 | three
   (1 row)
   ```

2. Query system table **QUERY_PLAN_PROFILES**.

   ```sql
   => SELECT ... FROM query_plan_profiles
      WHERE transaction_id=45035996273955065 and statement_id=4;
      ORDER BY transaction_id, statement_id, path_id, path_line_index;
   ```

**Note:**

For best results, sort on columns `transaction_id`, `statement_id`, `path_id`, and `path_line_index`.
Getting Query Plan Status for Large Queries

Real-time profiling is designed to monitor large (long-running) queries. Take the following steps to monitor plans for large queries:

1. Get the statement and transaction IDs for the query plan you want to profile by querying system table `CURRENT_SESSION`:

```sql
=> SELECT transaction_id, statement_id from current_session;

transaction_id | statement_id
----------------|-------------
45035996273955001 | 4
(1 row)
```

2. Run the query:

```sql
=> SELECT * FROM t1 JOIN t2 ON x=y JOIN ext ON y=z;
```

3. Query system table `QUERY_PLAN_PROFILES`, and sort on the `transaction_id`, `statement_id`, `path_id`, and `path_line_index` columns.

```sql
=> SELECT ... FROM query_plan_profiles WHERE transaction_id=45035996273955001 and statement_id=4
   ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

You can also use the Linux `watch` command to monitor long-running queries (see Real-Time Profiling).

**Example**

The following series of commands creates a table for a long-running query and then queries system table `QUERY_PLAN_PROFILES`:

1. Create table `longq`:

```sql
=> CREATE TABLE longq(x int);
CREATE TABLE
=> COPY longq FROM STDIN;
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.

>> 1
>> 2
>> 3
>> 4
>> 5
```
2. Suppress query output on the terminal window by using the vsql \o command:

```sql
=> \o /home/dbadmin/longQprof
```

3. Query the new table:

```sql
=> SELECT * FROM longq;
```

4. Get the transaction and statement IDs:

```sql
=> SELECT transaction_id, statement_id from current_session;
```

```
transaction_id | statement_id
---------------|---------------
----------------|---------------
45035996273955021 | 4
(1 row)
```

5. Turn off the \o command so Vertica continues to save query plan information to the file you specified. Alternatively, leave it on and examine the file after you query system table QUERY_PLAN_PROFILES.

```sql
=> \o
```

6. Query system table QUERY_PLAN_PROFILES:

```sql
=> SELECT
transaction_id,
statement_id,
path_id,
path_line_index,
is_executing,
running_time,
path_line
FROM query_plan_profiles
```
WHERE transaction_id=45035996273955021 AND statement_id=4
ORDER BY transaction_id, statement_id, path_id, path_line_index;

## Improving Readability of QUERY_PLAN_PROFILES Output

Output from the QUERY_PLAN_PROFILES table can be very wide because of the path_line column. To facilitate readability, query QUERY_PLAN_PROFILES using one or more of the following options:

- **Sort output by transaction_id, statement_id, path_id, and path_line_index:**

  ```sql
  => SELECT ... FROM query_plan_profiles
  WHERE ...
  ORDER BY transaction_id, statement_id, path_id, path_line_index;
  ```

- **Use column aliases to decrease column width:**

  ```sql
  => SELECT statement_id AS sid, path_id AS id, path_line_index AS order,
  is_started AS start, is_completed AS end, isExecuting AS exe,
  running_time AS run, memory_allocated_bytes AS mem,
  read_from_disk_bytes AS read, received_bytes AS rec,
  sent_bytes AS sent, FROM query_plan_profiles
  WHERE transaction_id=45035996273910558 AND statement_id=3
  ORDER BY transaction_id, statement_id, path_id, path_line_index;
  ```

- **Use the vsql \o command to redirect EXPLAIN output to a file:**

  ```sql
  => \o /home/dbadmin/long-queries
  => EXPLAIN SELECT * FROM customer_dimension;
  => \o
  ```

## Managing Query Profile Data

Vertica retains data for queries until the storage quota for the table is exceeded, when it automatically purges the oldest queries to make room for new ones. You can also clear profiled data by calling one of the following functions:

- **CLEAR_PROFILING** clears profiled data from memory. For example, the following command clears profiling for general query-run information, such as the query strings
used and the duration of queries.

```sql
=> SELECT CLEAR_PROFILING('query');
```

- **CLEAR_DATA_COLLECTOR** clears all memory and disk records on the Data Collector tables and functions and resets collection statistics in system table **DATA_COLLECTOR**.
- **FLUSH_DATA_COLLECTOR** waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the DataCollector log with the disk storage.

**Configuring data retention policies**

Vertica retains the historical data it gathers as specified by the **configured** retention policies.

**Analyzing Suboptimal Query Plans**

If profiling uncovers a suboptimal query, invoking one of the following functions might help:

- **ANALYZE_WORKLOAD** analyzes system information held in system tables and provides tuning recommendations that are based on a combination of statistics, system and data collector events, and database-table-projection design.
- **ANALYZE_STATISTICS** collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table or column.

You can also run your query through the Database Designer. See Incremental Design.

**Sample Views for Counter Information**

The EXECUTION_ENGINE_PROFILES table contains the data for each profiling counter as a row within the table. For example, the execution time (us) counter is in one row, and the rows produced counter is in a second row. Since there are many different profiling counters, many rows of profiling data exist for each operator. Some sample views are installed by default to simplify the viewing of profiling counters.
Running scripts to create the sample views

The following script creates the v_demo schema and places the views in that schema.

```
/opt/vertica/scripts/demo_eeprof_view.sql
```

Viewing counter values using the sample views

There is one view for each of the profiling counters to simplify viewing of a single counter value. For example, to view the execution time for all operators, issue the following command from the database:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us;
```

To view all counter values available for all profiled queries:

```
=> SELECT * FROM v_demo.eeprof_counters;
```

To select all distinct operators available for all profiled queries:

```
=> SELECT * FROM v_demo.eeprof_operators;
```

Combining sample views

These views can be combined:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us
    NATURAL LEFT OUTER JOIN v_demo.eeprof_rows_produced;
```

To view the execution time and rows produced for a specific transaction and statement_id ranked by execution time on each node:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us_rank
    WHERE transaction_id=45035996273709699
    AND statement_id=1
    ORDER BY transaction_id, statement_id, node_name, rk;
```

To view the top five operators by execution time on each node:
About Locale

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate GROUP BY and ORDER BY clauses, joins, and the analytic ORDER BY clause.

The default locale for a Vertica database is en_US@collation=binary (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default en_US@collation=binary collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to en_US_POSIX. You can set the locale back to the default locale and collation by issuing the vsql meta-command \locale. For example:

```sql
=> set locale to '';
INFO 2567: Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET \locale en_US@collation=binary;
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> \locale en_US@collation=binary;
```

You can set locale through ODBC, JDBC, and ADO.net.

Vertica locale specifications follow a subset of the Unicode LDML standard as implemented by the ICU library.

Locale Handling in Vertica

The following sections describes how Vertica handles locale.
Session Locale

Locale is session-scoped and applies only to queries executed in that session. You cannot specify locale for individual queries. When you start a session it obtains its locale from the configuration parameter `DefaultSessionLocale`.

Query Restrictions

The following restrictions apply when queries are run with locale other than the default `en_US@collation=binary`:

- When one or more of the left-side `NOT IN` columns is CHAR or VARCHAR, multi-column `NOT IN` subqueries are not supported. For example:

```sql
=> CREATE TABLE test (x VARCHAR(10), y INT);
=> SELECT ... FROM test WHERE (x,y) NOT IN (SELECT ...);
    ERROR: Multi-expression NOT IN subquery is not supported because a left hand expression could be NULL
```

**Note:**

Even if columns `test.x` and `test.y` have a `NOT NULL` constraint, an error occurs.

- If the outer query contains a `GROUP BY` clause on a CHAR or VARCHAR column, correlated HAVING clause subqueries are not supported. In the following example, the `GROUP BY x` in the outer query causes the error:

```sql
=> DROP TABLE test CASCADE;
=> CREATE TABLE test (x VARCHAR(10));
=> SELECT COUNT(*) FROM test t GROUP BY x HAVING x
  IN (SELECT x FROM test WHERE t.x||'a' = test.x||'a');
    ERROR: subquery uses ungrouped column "t.x" from outer query
```

- Subqueries that use analytic functions in the HAVING clause are not supported. For example:

```sql
=> DROP TABLE test CASCADE;
=> CREATE TABLE test (x VARCHAR(10));
=> SELECT MAX(x)OVER(PARTITION BY 1 ORDER BY 1) FROM test
  GROUP BY x HAVING x IN (SELECT MAX(x) FROM test);
    ERROR: Analytics query with having clause expression that involves aggregates and subquery is not supported
```
Collation and Projections

Projection data is sorted according to the default en_US@collation=binary collation. Thus, regardless of the session setting, issuing the following command creates a projection sorted by col1 according to the binary collation:

```sql
=> CREATE PROJECTION p1 AS SELECT * FROM table1 ORDER BY col1;
```

In such cases, straße and strasse are not stored near each other on disk.

Sorting by binary collation also means that sort optimizations do not work in locales other than binary. Vertica returns the following warning if you create tables or projections in a non-binary locale:

```
WARNING: Projections are always created and persisted in the default Vertica locale. The current locale is de_DE
```

Non-Binary Locale Input Handling

When the locale is non-binary, Vertica uses the `COLLATION` function to transform input to a binary string that sorts in the proper order.

This transformation increases the number of bytes required for the input according to this formula:

```
result_column_width = input_octet_width * CollationExpansion + 4
```

The default value of configuration parameter `CollationExpansion` is 5.

Character Data Type Handling

- CHAR fields are displayed as fixed length, including any trailing spaces. When CHAR fields are processed internally, they are first stripped of trailing spaces. For VARCHAR fields, trailing spaces are usually treated as significant characters; however, trailing spaces are ignored when sorting or comparing either type of character string field using a non-binary locale.
- The maximum length parameter for VARCHAR and CHAR data type refers to the number of octets (bytes) that can be stored in that field and not number of
characters. When using multi-byte UTF-8 characters, the fields must be sized to accommodate from 1 to 4 bytes per character, depending on the data.

**Specifying Locale: Long Form**

Vertica supports long forms that specify the `collation` keyword. Vertica extends long-form processing to accept collation arguments.

**Syntax**

\[\text{[language]_[script]_[country]_[variant]@[collation-spec]}\]

**Note:**

The following syntax options apply:

- Locale specification strings are case insensitive. For example, `en_us` and `EN_US`, are equivalent.
- You can substitute underscores with hyphens. For example: `[script]`

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language</td>
<td>A two- or three-letter lowercase code for a particular language. For example, Spanish is <code>es</code> English is <code>en</code> and French is <code>fr</code>. The two-letter language code uses the ISO-639 standard.</td>
</tr>
<tr>
<td><em>script</em></td>
<td>An optional four-letter script code that follows the language code. If specified, it should be a valid script code as listed on the Unicode ISO 15924 Registry.</td>
</tr>
<tr>
<td><em>country</em></td>
<td>A specific language convention within a generic language for a specific country or region. For example, French is spoken in many countries, but the currencies are different in each country. To allow for these differences among specific geographical, political, or cultural regions, locales are specified by two-letter, uppercase codes. For example, FR represents France and CA represents Canada. The two letter country code uses the ISO-3166 standard.</td>
</tr>
</tbody>
</table>
| **_variant** | Differences may also appear in language conventions used within the same country. For example, the Euro currency is used in several European countries while the individual country's currency is still in circulation. To handle variations inside a language and country pair, add a third code, the variant code. The variant code is arbitrary and completely application-specific. ICU adds _EURO to its locale designations for locales that support the Euro currency. Variants can have any number of underscored keywords. For example, EURO_WIN is a variant for the Euro currency on a Windows computer.

Another use of the variant code is to designate the Collation (sorting order) of a locale. For instance, the es__TRADITIONAL locale uses the traditional sorting order which is different from the default modern sorting of Spanish. |
| **@collation-spec** | Vertica only supports the keyword collation, as follows:

@collation=collation-type[;arg]...

Collation can specify one or more semicolon-delimited arguments, described below.

**collation-type** is set to one of the following values:

- **big5han**: Pinyin ordering for Latin, big5 charset ordering for CJK characters (used in Chinese).
- **dict**: For a dictionary-style ordering (such as in Sinhala).
- **direct**: Hindi variant.
- **gb2312/gb2312han**: Pinyin ordering for Latin, gb2312han charset ordering for CJK characters (used in Chinese).
- **phonebook**: For a phonebook-style ordering (such as in German).
- **pinyin**: Pinyin ordering for Latin and for CJK characters; that is, an ordering for CJK characters based on a character-by-character transliteration into a pinyin (used in Chinese).
- **reformed**: Reformed collation (such as in Swedish).
- **standard**: The default ordering for each language. For root it is [UCA] order; for each other locale it is the same as UCA (Unicode Collation Algorithm) ordering except for appropriate modifications to certain characters for that language. The following are additional choices for certain locales; they have effect only in certain locales. |
stroke: Pinyin ordering for Latin, stroke order for CJK characters (used in Chinese) not supported.

traditional: For a traditional-style ordering (such as in Spanish).

unihan: Pinyin ordering for Latin, Unihan radical-stroke ordering for CJK characters (used in Chinese) not supported.

binary: Vertica default, providing UTF-8 octet ordering.

Notes:

- Collations might default to root, the ICU default collation.
- Invalid values of the collation keyword and its synonyms do not cause an error. For example, the following does not generate an error. It simply ignores the invalid value:

```plaintext
=> \locale en_GB@collation=xyz
INFO 2567: Canonical locale: 'en_GB@collation=xyz'
Standard collation: 'LEN'
English (United Kingdom, collation=xyz)
```

For more about collation options, see [Unicode Locale Data Markup Language (LDML)](https://unicode.org/reports/tr15/index.html).

### Collation Arguments

collation can specify one or more of the following arguments:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Short form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>colstrength</td>
<td>S</td>
<td>Sets the default strength for comparison. This feature is locale dependent. Set colstrength to one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 2</td>
</tr>
<tr>
<td>Parameter</td>
<td>Short form</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Only secondary and above differences are considered for comparison—for example, different accented forms of the same base letter such as a versus \u00E4.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 4</td>
</tr>
<tr>
<td>colAlternate</td>
<td>A</td>
<td>Sets alternate handling for variable weights, as described in UCA, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• non-ignorable</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• shifted</td>
</tr>
<tr>
<td>colBackwards</td>
<td>F</td>
<td>For Latin with accents, this parameter determines which accents are sorted. It sets the comparison for the second level to be backwards.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> colBackwards is automatically set for French accents.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set colBackwards to one of the following:</td>

</tr>
</tbody>
</table>
| colNormalization           | N          | Set to one of the following:  
  - **on** | 0: The normal UCA algorithm is used.  
  - **off** | X: All strings that are in Fast C or D normalization form (FCD) sort correctly, but others won't necessarily sort correctly. It should only be set off if the strings to be compared are in FCD. |
| colCaseLevel                | E          | Set to one of the following:  
  - **on** | 0: A level consisting only of case characteristics is inserted in front of tertiary level. To ignore accents but take cases into account, set strength to primary and case level to on.  
  - **off** | X: This level is omitted. |
| colCaseFirst                | C          | Set to one of the following:  
  - upper | U: Upper case sorts before lower case.  
  - lower | L: Lower case sorts before upper case. This is useful for locales that have already supported ordering but require different order of cases. It affects case and tertiary levels.  
  - off | short: Tertiary weights unaffected |
| colHiraganaQuarternary      | H          | Controls special treatment of Hiragana code points on quaternary level, one of the following:  
  - **on** | 0: Hiragana codepoints get lower values than all the other |
<table>

<td>non-variable code points. The strength must be greater or equal than quaternary for this attribute to take effect.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• off</td>
</tr>
<tr>
<td>colNumeric</td>
<td>D</td>
<td>If set to on, any sequence of Decimal Digits (\textit{General_Category} = Nd in the [UCD]) is sorted at a primary level with its numeric value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, A-21 A-123.</td>
</tr>
<tr>
<td>variableTop</td>
<td>B</td>
<td>Sets the default value for the variable top. All code points with primary weights less than or equal to the variable top will be considered variable, and are affected by the alternate handling.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, the following command sets variableTop to be HYPHEN (\texttt{u2010})</td>
</tr>
<tr>
<td></td>
<td></td>
<td>\texttt{=&gt; \locale en_US@colalternate=shifted;variabletop=u2010}</td>
</tr>
</tbody>
</table>

**Locale Processing Notes**

- Incorrect locale strings are accepted if the prefix can be resolved to a known locale version.

For example, the following works because the language can be resolved:

```plaintext
=> \locale en\_XX
INFO 2567: Canonical locale: 'en\_XX'
Standard collation: 'LEN'
English (XX)
```

The following does not work because the language cannot be resolved:
• POSIX-type locales such as en_US.UTF-8 work to some extent in that the encoding part "UTF-8" is ignored.
• Vertica uses the icu4c-4_2_1 library to support basic locale/collation processing with some extensions. This does not currently meet current standards for locale processing (https://tools.ietf.org/html/rfc5646).

Examples

Specify German locale as used in Germany (de), with phonebook-style collation:

```sql
=> \locale de_DE@collation=phonebook
INFO 2567: Canonical locale: 'de_DE@collation=phonebook'
Standard collation: 'KPHONEBOOK_LDE'
  German (Germany, collation=Phonebook Sort Order)
  Deutsch (Deutschland, Sortierung=Telefonbuch-Sortierregeln)
```

Specify German locale as used in Germany (de), with phonebook-style collation and strength set to secondary:

```sql
=> \locale de_DE@collation=phonebook;colStrength=secondary
INFO 2567: Canonical locale: 'de_DE@collation=phonebook'
Standard collation: 'KPHONEBOOK_LDE_S2'
  German (Germany, collation=Phonebook Sort Order)
  Deutsch (Deutschland, Sortierung=Telefonbuch-Sortierregeln)
```

Specifying Locale: Short Form

Vertica accepts locales in short form. You can use the short form to specify the locale and keyname pair/value names.

To determine the short form for a locale, type in the long form and view the last line of INFO, as follows:

```sql
\locale frINFO: Locale: 'fr'
INFO: French
INFO: franÃ§ais
INFO: Short form: 'LFR'
```
Examples

Specify en (English) locale:

```locale
LENINFO: Locale: 'en'
INFO: English
INFO: Short form: 'LEN'
```

Specify German locale as used in Germany (de), with phonebook-style collation:

```locale
LDE_KPHONEBOOKINFO: Locale: 'de@collation=phonebook'
INFO: German (collation=Phonebook Sort Order)
INFO: Deutsch (Sortierung=Telefonbuch-Sortierregeln)
INFO: Short form: 'KPHONEBOOK_LDE'
```

Specify German locale as used in Germany (de), with phonebook-style collation:

```locale
LDE_KPHONEBOOK_S2INFO: Locale: 'de@collation=phonebook'
INFO: German (collation=Phonebook Sort Order)
INFO: Deutsch (Sortierung=Telefonbuch-Sortierregeln)
INFO: Short form: 'KPHONEBOOK_LDE_S2'
```

Supported Locales

The following are the supported locale strings for Vertica. Each locale can optionally have a list of key/value pairs (see Specifying Locale: Long Form).

### Locale and UTF-8 Support

Vertica supports Unicode Transformation Format-8, or UTF8, where 8 equals 8-bit. UTF-8 is a variable-length character encoding for Unicode created by Ken Thompson and Rob Pike. UTF-8 can represent any universal character in the Unicode standard. Initial encoding of byte codes and character assignments for UTF-8 coincides with ASCII. Thus, UTF8 requires little or no change for software that handles ASCII but preserves other values.

Vertica database servers expect to receive all data in UTF-8, and Vertica outputs all data in UTF-8. The ODBC API operates on data in UCS-2 on Windows systems, and normally UTF-8 on Linux systems. JDBC and ADO.NET APIs operate on data in UTF-16. Client drivers automatically convert data to and from UTF-8 when sending to and receiving data from Vertica using API calls. The drivers do not transform data loaded by executing a `COPY` or `COPY LOCAL` statement.

### UTF-8 String Functions

The following string functions treat VARCHAR arguments as UTF-8 strings (when USING OCTETS is not specified) regardless of locale setting.
## Locale-Aware String Functions

Vertica provides string functions to support internationalization. Unless otherwise specified, these string functions can optionally specify whether VARCHAR arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of characters. Specify this information by adding the parameter `USING OCTETS` and `USING CHARACTERS` (default) to the function.

The following table lists all string functions that are locale-aware:

<table>
<thead>
<tr>
<th>String function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BTRIM</td>
<td>Removes the longest string consisting only of specified characters from the start and end of a string.</td>
</tr>
<tr>
<td>CHARACTER_LENGTH</td>
<td>Returns an integer value representing the number of characters or octets in a string.</td>
</tr>
<tr>
<td>String function</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>GREATEST</td>
<td>Returns the largest value in a list of expressions.</td>
</tr>
<tr>
<td>GREATESTB</td>
<td>Returns its greatest argument, using binary ordering, not UTF-8 character ordering.</td>
</tr>
<tr>
<td>INITCAP</td>
<td>Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.</td>
</tr>
<tr>
<td>INSTR</td>
<td>Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence.</td>
</tr>
<tr>
<td>LEAST</td>
<td>Returns the smallest value in a list of expressions.</td>
</tr>
<tr>
<td>LEASTB</td>
<td>Returns its least argument, using binary ordering, not UTF-8 character ordering.</td>
</tr>
<tr>
<td>LEFT</td>
<td>Returns the specified characters from the left side of a string.</td>
</tr>
<tr>
<td>LENGTH</td>
<td>Takes one argument as an input and returns an integer value representing the number of characters in a string.</td>
</tr>
<tr>
<td>LTRIM</td>
<td>Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning).</td>
</tr>
<tr>
<td>OVERLAY</td>
<td>Returns a VARCHAR value representing a string having had a substring replaced by another string.</td>
</tr>
<tr>
<td>OVERLAYB</td>
<td>Returns an octet value representing a string having had a substring replaced by another string.</td>
</tr>
<tr>
<td>REPLACE</td>
<td>Replaces all occurrences of characters in a string with another set of characters.</td>
</tr>
<tr>
<td>RIGHT</td>
<td>Returns the length right-most characters of string.</td>
</tr>
<tr>
<td>SUBSTR</td>
<td>Returns a VARCHAR value representing a substring of a specified string.</td>
</tr>
<tr>
<td>SUBSTRB</td>
<td>Returns a byte value representing a substring of a specified string.</td>
</tr>
<tr>
<td>SUBSTRING</td>
<td>Given a value, a position, and an optional length, returns a value representing a substring of the specified string at the given position.</td>
</tr>
<tr>
<td>TRANSLATE</td>
<td>Replaces individual characters in string_to_replace with other characters.</td>
</tr>
<tr>
<td>String function</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>UPPER</td>
<td>Returns a VARCHAR value containing the argument converted to uppercase letters.</td>
</tr>
</tbody>
</table>

### Appendix: Creating Native Binary Format Files

Using COPY to load data with the NATIVE parser requires that the input data files conform to the requirements described in this appendix. All NATIVE files must contain:

- File signature
- Column size definitions
- Rows of data

The subsection Loading a NATIVE File into a Table: Example describes an example of loading data with the NATIVE parser.

**Note:**
You cannot mix Binary and ASCII source files in the same COPY statement.

### File Signature

The first part of a NATIVE binary file consists of a file signature. The contents of the signature are fixed, and listed in the following table.

<table>
<thead>
<tr>
<th>Byte Offset</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hex Value</td>
<td>4E</td>
<td>41</td>
<td>54</td>
<td>49</td>
<td>56</td>
<td>45</td>
<td>0A</td>
<td>FF</td>
<td>0D</td>
<td>0A</td>
<td>00</td>
</tr>
<tr>
<td>Text Literals</td>
<td>NATIVE</td>
<td>E'\n'</td>
<td>E'\31'7'</td>
<td>E'\r'</td>
<td>E'\n'</td>
<td>E'\000'</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.3.x)
The signature ensures that the file has neither been corrupted by a non-8-bit file transfer, nor stripped of carriage returns, linefeeds, or null values. If the signature is intact, Vertica determines that the file has not been corrupted.

**Column Definitions**

Following the file signature, the file must define the widths of each column in the file as follows.

<table>
<thead>
<tr>
<th>Byte Offset</th>
<th>Length (bytes)</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>4</td>
<td>Header area length</td>
<td>32-bit integer in little-endian format that contains the length in bytes of remaining in the header, not including itself. This is the number of bytes from the end of this value to the start of the row data.</td>
</tr>
<tr>
<td>15</td>
<td>2</td>
<td>NATIVE file version</td>
<td>16-bit integer in little-endian format containing the version number of the NATIVE file format. The only valid value is currently 1. Future changes to the format could be assigned different version numbers to maintain backward compatibility.</td>
</tr>
<tr>
<td>17</td>
<td>1</td>
<td>Filler</td>
<td>Always 0.</td>
</tr>
<tr>
<td>18</td>
<td>2</td>
<td>Number of columns</td>
<td>16-bit integer in little-endian format that contains the number of columns in each row in the file.</td>
</tr>
<tr>
<td>20+</td>
<td>4 bytes for each column of data in the table</td>
<td>Column widths</td>
<td>Array of 32-bit integers in little-endian format that define the width of each column in the row. Variable-width columns have a value of -1 (0xFF 0xFF 0xFF 0xFF).</td>
</tr>
</tbody>
</table>

**Note:**

All integers in NATIVE files are in **little-endian format** (least significant byte first).

The width of each column is determined by the data type it contains. The following table explains the column width needed for each data type, along with the data encoding.
<table>
<thead>
<tr>
<th>Data Type</th>
<th>Length (bytes)</th>
<th>Column Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>1, 2, 4, 8</td>
<td>8-, 16-, 32-, and 64-bit integers are supported. All multi-byte values are stored in little-endian format. <strong>Note</strong>: All values for a column must be the width you specify here. If you set the length of an INTEGER column to be 4 bytes, then all of the values you supply for that column must be 32-bit integers.</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>1</td>
<td>0 for false, 1 for true.</td>
</tr>
<tr>
<td>FLOAT</td>
<td>8</td>
<td>Encoded in IEEE-754 format.</td>
</tr>
</tbody>
</table>
| CHAR      | User-specified| **•** Strings shorter than the specified length must be right-padded with spaces (E'\040').  
**•** Strings are not null-terminated.  
**•** Character encoding is UTF-8.  
**•** UTF-8 strings can contain multi-byte characters. Therefore, number of characters in the string may not equal the number of bytes. |
| VARCHAR   | 4-byte integer (length) + data | The column width for a VARCHAR column is always -1 to signal that it contains variable-length data.  
**•** Each VARCHAR column value starts with a 32-bit integer that contains the number of bytes in the string.  
**•** The string must not be null-terminated.  
**•** Character encoding must be UTF-8.  
**•** Remember that UTF-8 strings can contain multi-byte characters. Therefore, number of characters in the string may not equal the number of bytes. |
<p>| DATE      | 8              | 64-bit integer in little-endian format containing the Julian day since Jan 01 2000 (J2451545) |
| TIME      | 8              | 64-bit integer in little-endian format containing the number of microseconds since midnight in the UTC time zone. |
| TIMETZ    | 8              | 64-bit value where |</p>
<table>
<thead>
<tr>
<th>Data Type</th>
<th>Length (bytes)</th>
<th>Column Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIMESTAMP</td>
<td>8</td>
<td>64-bit integer in little-endian format containing the number of microseconds since Julian day: Jan 01 2000 00:00:00.</td>
</tr>
<tr>
<td>TIMESTAMPTZ</td>
<td>8</td>
<td>A 64-bit integer in little-endian format containing the number of microseconds since Julian day: Jan 01 2000 00:00:00 in the UTC timezone.</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>8</td>
<td>64-bit integer in little-endian format containing the number of microseconds in the interval.</td>
</tr>
<tr>
<td>BINARY</td>
<td>User-specified</td>
<td>Similar to CHAR. The length should be specified in the file header in the Field Lengths entry for the field. The field in the record must contain length number of bytes. If the value is smaller than the specified length, the remainder should be filled with nulls (E'\000').</td>
</tr>
<tr>
<td>VARBINARY</td>
<td>4-byte integer + data</td>
<td>Stored just like VARCHAR but data is interpreted as bytes rather than UTF-8 characters.</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>(precision, scale) (precision ÷ 19 + 1) × 8 rounded up</td>
<td>A constant-length data type. Length is determined by the precision, assuming that a 64-bit unsigned integer can store roughly 19 decimal digits. The data consists of a sequence of 64-bit integers, each stored in little-endian format, with the most significant integer first. Data in the integers is stored in base $2^{64}$. 2's complement is used for negative numbers.</td>
</tr>
</tbody>
</table>

- Upper 40 bits contain the number of microseconds since midnight.
- Lower 24 bits contain time zone as the UTC offset in microseconds calculated as follows: Time zone is logically from -24hrs to +24hrs from UTC. Instead it is represented here as a number between 0hrs to 48hrs. Therefore, 24hrs should be added to the actual time zone to calculate it.

Each portion is stored in little-endian format (5 bytes followed by 3 bytes).
If there is a scale, then the numeric is stored as numeric $\times 10^{\text{scale}}$, that is, all real numbers are stored as integers, ignoring the decimal point. It is required that the scale matches that of the target column in the data anchor table. Another option is to use FILLER columns to coerce the numeric to the scale of the target column.

### Row Data

Following the file header is a sequence of records that contain the data for each row of data. Each record starts with a header:

<table>
<thead>
<tr>
<th>Length (bytes)</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Row length</td>
<td>A 32-bit integer in little-endian format containing the length of the row's data in bytes. It includes the size of data only, not the header.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> The number of bytes in each row can vary not only because of variable-length data, but also because columns containing NULL values do not have any data in the row. If column 3 has a NULL value, then column 4's data immediately follows the end of column 2's data. See the next</td>
</tr>
</tbody>
</table>

Number of columns $\div 8$ rounded up (CEILING (NumFields / ( sizeof (uint8) * 8 ) ));)  | Null value bit field | A series of bytes whose bits indicate whether a column contains a NULL. The most significant bit of the first byte indicates whether the first column in this row contains a NULL, the next most significant bit indicates whether the next column contains a NULL, and so on. If a bit is 1 (true) then the column contains a NULL, and there is no value for the column in the data for the row. |

Following the record header is the column values for the row. There is no separator characters for these values. Their location in the row of data is calculated based on where
the previous column's data ended. Most data types have a fixed width, so their location is easy to determine. Variable-width values (such as VARCHAR and VARBINARY) start with a count of the number of bytes the value contains.

See the table in the previous section for details on how each data type's value is stored in the row's data.

## Loading a NATIVE File into a Table: Example

The example below demonstrates creating a table and loading a NATIVE file that contains a single row of data. The table contains all possible data types.

```sql
=> CREATE TABLE allTypes (INTCOL INTEGER,
                        FLOATCOL FLOAT,
                        CHARCOL CHAR(10),
                        VARCHARCOL VARCHAR,
                        BOOLCOL BOOLEAN,
                        DATECOL DATE,
                        TIMESTAMPCOL TIMESTAMP,
                        TIMESTAMPTZCOL TIMESTAMPTZ,
                        TIMECOL TIME,
                        TIMETZCOL TIMETZ,
                        VARBINCOL VARBINARY,
                        BINCOL BINARY,
                        NUMCOL NUMERIC(38,0),
                        INTERVALCOL INTERVAL);
=> COPY allTypes FROM '/home/dbadmin/allTypes.bin' NATIVE DIRECT;
=> \pset expanded
Expanded display is on.
=> SELECT * from allTypes;
-[ RECORD 1 ]------------------------
  INTCOL | 1
  FLOATCOL | -1.11
  CHARCOL | one
  VARCHARCOL | one
  BOOLCOL | t
  DATECOL | 1999-01-08
  TIMESTAMPCOL | 1999-02-23 03:11:52.35
  TIMESTAMPTZCOL | 1999-01-08 07:04:37-05
  TIMECOL | 07:09:23
  TIMETZCOL | 15:12:34-04
  VARBINCOL | \253\315
  BINCOL | \253
  NUMCOL | 1234532
  INTERVALCOL | 03:03:03
```

The content of the allTypes.bin file appears below as a raw hex dump:

```
4E 41 54 49 56 0A 0D 0A 00 3D 00 00 00 01 00 00 0E 00
08 00 00 00 08 00 00 00 0A 00 00 00 FF FF FF 01 00 00 00
```
The following table breaks this file down into each of its components, and describes the values it contains.

<table>
<thead>
<tr>
<th>Hex Values</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
</table>
| 4E 41 54 49 56 45 0A FF 0D 0A 00 | Signature | NATIVE
\n\n\n00 |
<p>| 3D 00 00 00 | Header area length | 61 bytes |
| 01 00 | Native file format version | Version 1 |
| 00 | Filler value | 0 |
| 0E 00 | Number of columns | 14 columns |
| 08 00 00 00 | Width of column 1 (INTEGER) | 8 bytes |
| 08 00 00 00 | Width of column 2 (FLOAT) | 8 bytes |
| 0A 00 00 00 | Width of column 3 (CHAR(10)) | 10 bytes |
| FF FF FF FF | Width of column 4 (VARCHAR) | -1 (variable width column) |
| 01 00 00 00 | Width of column 5 (BOOLEAN) | 1 bytes |
| 08 00 00 00 | Width of column 6 (DATE) | 8 bytes |</p>
<table>
<thead>
<tr>
<th>Hex Values</th>

</table>
Welcome to the Analyzing Data Guide. This guide explains how to query and analyze data in your Vertica database.

 Queries

Queries are database operations that retrieve data from one or more tables or views. In Vertica, the top-level SELECT statement is the query, and a query nested within another SQL statement is called a subquery.

Vertica is designed to run the same SQL standard queries that run on other databases. However, there are some differences between Vertica queries and queries used in other relational database management systems.

The Vertica transaction model is different from the SQL standard in a way that has a profound effect on query performance. You can:

- Run a query on a static backup of the database from any specific date and time. Doing so avoids holding locks or blocking other database operations.
- Use a subset of the standard SQL isolation levels and access modes (read/write or read-only) for a user session.

In Vertica, the primary structure of a SQL query is its statement. Each statement ends with a semicolon, and you can write multiple queries separated by semicolons; for example:
Historical Queries

Vertica can execute historical queries, which execute on a snapshot of the database taken at a specific timestamp or epoch. Historical queries can be used to evaluate and possibly recover data that was deleted but has not yet been purged.

You specify a historical query by qualifying the SELECT statement with an AT `epoch` clause, where `epoch` is one of the following:

- `EPOCH LATEST`: Return data up to but not including the current epoch. The result set includes data from the latest committed DML transaction.
- `EPOCH integer`: Return data up to and including the `integer`-specified epoch.
- `TIME 'timestamp'`: Return data from the `timestamp`-specified epoch.

**Note:**
These options are ignored if used to query temporary or external tables.

Historical queries return data only from the specified epoch. Because they do not return the latest data, historical queries hold no locks or blocking write operations.

Query results are private to the transaction and valid only for the length of the transaction. Query execution is the same regardless of the transaction isolation level.

Restrictions

- The specified epoch, or epoch of the specified timestamp, cannot be less than the Ancient History Mark epoch.
- Vertica does not support running historical queries on temporary tables.

**Important:**
Any changes to a table schema are reflected across all epochs. For example, if you add a column to a table and specify a default value for it, all historical queries on that table display the new column and its default value.
Temporary Tables

You can use the `CREATE TEMPORARY TABLE` statement to implement certain queries using multiple steps:

1. Create one or more temporary tables.
2. Execute queries and store the result sets in the temporary tables.
3. Execute the main query using the temporary tables as if they were a normal part of the logical schema.

See `CREATE TEMPORARY TABLE` in the SQL Reference Manual for details.

SQL Queries

All DML (Data Manipulation Language) statements can contain queries. This section introduces some of the query types in Vertica, with additional details in later sections.

**Note:**
Many of the examples in this chapter use the [VMart schema](https://example.com). For information about other Vertica-supplied queries, see the [Getting Started](https://example.com).

Simple Queries

Simple queries contain a query against one table. Minimal effort is required to process the following query, which looks for product keys and SKU numbers in the product table:

```sql
=> SELECT product_key, sku_number FROM public.product_dimension;

<table>
<thead>
<tr>
<th>product_key</th>
<th>sku_number</th>
</tr>
</thead>
<tbody>
<tr>
<td>43</td>
<td>SKU-#129</td>
</tr>
<tr>
<td>87</td>
<td>SKU-#250</td>
</tr>
<tr>
<td>42</td>
<td>SKU-#125</td>
</tr>
<tr>
<td>49</td>
<td>SKU-#154</td>
</tr>
<tr>
<td>37</td>
<td>SKU-#107</td>
</tr>
<tr>
<td>36</td>
<td>SKU-#106</td>
</tr>
<tr>
<td>86</td>
<td>SKU-#248</td>
</tr>
<tr>
<td>41</td>
<td>SKU-#121</td>
</tr>
<tr>
<td>88</td>
<td>SKU-#257</td>
</tr>
<tr>
<td>40</td>
<td>SKU-#120</td>
</tr>
</tbody>
</table>
```
Joins

Joins use a relational operator that combines information from two or more tables. The query's ON clause specifies how tables are combined, such as by matching foreign keys to primary keys. In the following example, the query requests the names of stores with transactions greater than 70 by joining the store key ID from the store schema's sales fact and sales tables:

```sql
=> SELECT store_name, COUNT(*) FROM store.store_sales_fact
    JOIN store.store_dimension ON store.store_sales_fact.store_key = store.store_dimension.store_key
    GROUP BY store_name HAVING COUNT(*) > 70 ORDER BY store_name;
```

<table>
<thead>
<tr>
<th>store_name</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Store49</td>
<td>72</td>
</tr>
<tr>
<td>Store83</td>
<td>78</td>
</tr>
</tbody>
</table>

(2 rows)

For more detailed information, see Joins. See also the Multicolumn subqueries section in Subquery Examples.

Cross Joins

Also known as the Cartesian product, a cross join is the result of joining every record in one table with every record in another table. A cross join occurs when there is no join key between tables to restrict records. The following query, for example, returns all instances of vendor and store names in the vendor and store tables:

```sql
=> SELECT vendor_name, store_name FROM public.vendor_dimension
    CROSS JOIN store.store_dimension;
```

<table>
<thead>
<tr>
<th>vendor_name</th>
<th>store_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deal Warehouse</td>
<td>Store41</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store12</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store46</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store50</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store15</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store48</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store39</td>
</tr>
<tr>
<td>Sundry Wholesale</td>
<td>Store41</td>
</tr>
<tr>
<td>Sundry Wholesale</td>
<td>Store12</td>
</tr>
<tr>
<td>Sundry Wholesale</td>
<td>Store46</td>
</tr>
<tr>
<td>Sundry Wholesale</td>
<td>Store50</td>
</tr>
</tbody>
</table>
This example's output is truncated because this particular cross join returned several thousand rows. See also Cross Joins.

**Subqueries**

A subquery is a query nested within another query. In the following example, we want a list of all products containing the highest fat content. The inner query (subquery) returns the product containing the highest fat content among all food products to the outer query block (containing query). The outer query then uses that information to return the names of the products containing the highest fat content.

```sql
=> SELECT product_description, fat_content FROM public.product_dimension
    WHERE fat_content IN
        (SELECT MAX(fat_content) FROM public.product_dimension
            WHERE category_description = 'Food' AND department_description = 'Bakery')
    LIMIT 10;
```

<table>
<thead>
<tr>
<th>product_description</th>
<th>fat_content</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brand #59110 hotdog buns</td>
<td>90</td>
</tr>
<tr>
<td>Brand #58107 english muffins</td>
<td>90</td>
</tr>
<tr>
<td>Brand #57135 english muffins</td>
<td>90</td>
</tr>
<tr>
<td>Brand #54870 cinnamon buns</td>
<td>90</td>
</tr>
<tr>
<td>Brand #53690 english muffins</td>
<td>90</td>
</tr>
<tr>
<td>Brand #53096 bagels</td>
<td>90</td>
</tr>
<tr>
<td>Brand #50678 chocolate chip cookies</td>
<td>90</td>
</tr>
<tr>
<td>Brand #49269 wheat bread</td>
<td>90</td>
</tr>
<tr>
<td>Brand #47156 coffee cake</td>
<td>90</td>
</tr>
<tr>
<td>Brand #43844 corn muffins</td>
<td>90</td>
</tr>
</tbody>
</table>

(10 rows)

For more information, see Subqueries.
Sorting Queries

Use the ORDER BY clause to order the rows that a query returns.

Special Note About Query Results

You could get different results running certain queries on one machine or another for the following reasons:

- **Partitioning** on a FLOAT type could return nondeterministic results because of the precision, especially when the numbers are close to one another, such as results from the RADIANS() function, which has a very small range of output.

  To get deterministic results, use NUMERIC if you must partition by data that is not an INTEGER type.

- Most analytics (with analytic aggregations, such as MIN()/MAX()/SUM()/COUNT() /AVG() as exceptions) rely on a unique order of input data to get deterministic result. If the analytic window-order clause cannot resolve ties in the data, results could be different each time you run the query.

For example, in the following query, the analytic ORDER BY does not include the first column in the query, promotion_key. So for a tie of AVG(RADIANS(cost_dollar_amount)), product_version, the same promotion_key could have different positions within the analytic partition, resulting in a different NTILE() number. Thus, DISTINCT could also have a different result:

```sql
=> SELECT COUNT(*) FROM
  (SELECT DISTINCT SIN(FLOOR(MAX(store.store_sales_fact.promotion_key))),
  NTILE(79) OVER(PARTITION BY AVG (RADIANS
  (store.store_sales_fact.cost_dollar_amount )))
  ORDER BY store.store_sales_fact.promotion_key)
FROM store.store_sales_fact
GROUP BY store.store_sales_fact.product_version,
  store.store_sales_fact.sales_dollar_amount ) AS store;

  count  
  -------
  1425
  (1 row)
```

If you add MAX(promotion_key) to analytic ORDER BY, the results are the same on any machine:
=> SELECT COUNT(*) FROM (SELECT DISTINCT MAX(store.store_sales_fact.promotion_key),
    NTILE(79) OVER(PARTITION BY MAX(store.store_sales_fact.cost_dollar_amount)
    ORDER BY store.store_sales_fact.product_version,
    MAX(store.store_sales_fact.promotion_key))
FROM store.store_sales_fact
GROUP BY store.store_sales_fact.product_version,
    store.store_sales_fact.sales_dollar_amount) AS store;
Subqueries

A subquery is a SELECT statement embedded within another SELECT statement. The embedded subquery is often referenced as the query's inner statement, while the containing query is typically referenced as the query's statement, or outer query block. A subquery returns data that the outer query uses as a condition to determine what data to retrieve. There is no limit to the number of nested subqueries you can create.

Like any query, a subquery returns records from a table that might consist of a single column and record, a single column with multiple records, or multiple columns and records. Queries can be noncorrelated or correlated. You can even use them to update or delete records in a table based on values that are stored in other database tables.

Note:
Many examples in this section use the VMart database.
Subqueries Used in Search Conditions

Subqueries are used as search conditions in order to filter results. They specify the conditions for the rows returned from the containing query's select-list, a query expression, or the subquery itself. The operation evaluates to TRUE, FALSE, or UNKNOWN (NULL).

Syntax

```
search-condition { 
    [ { AND | OR | NOT } { predicate | ( search-condition ) } ]
}[,...]

predicate 
    { expression comparison-operator expression 
        | string-expression [ NOT ] ( LIKE | ILIKE | LIKEB | ILIKEB ) string-expression 
        | expression IS [ NOT ] NULL 
        | expression [ NOT ] IN ( subquery | expression[,... ] ) 
        | expression comparison-operator [ ANY | SOME ] ( subquery ) 
        | expression comparison-operator ALL ( subquery ) 
        | expression OR ( subquery ) 
        | [ NOT ] EXISTS ( subquery ) 
        | [ NOT ] IN ( subquery )
    }
```

Parameters

<table>
<thead>
<tr>
<th>search-condition</th>
<th>Specifies the search conditions for the rows returned from one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Containing query's select-list</td>
</tr>
<tr>
<td></td>
<td>• Query expression</td>
</tr>
<tr>
<td></td>
<td>• Subquery</td>
</tr>
<tr>
<td></td>
<td>If the subquery is used with an UPDATE or DELETE statement, UPDATE specifies the rows to update and DELETE specifies the rows to delete.</td>
</tr>
</tbody>
</table>

| { AND | OR | NOT } | Keywords that specify the logical operators that combine conditions, or in the case of NOT, negate |
|-----------|------------------------------------------------------------------------------------------|
conditions.

- **AND**: Combines two conditions and evaluates to TRUE when both of the conditions are TRUE.
- **OR**: Combines two conditions and evaluates to TRUE when either condition is TRUE.
- **NOT**: Negates the Boolean expression specified by the predicate.

<table>
<thead>
<tr>
<th>predicate</th>
<th>An expression that returns TRUE, FALSE, or UNKNOWN (NULL).</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>A column name, constant, function, or scalar subquery, or combination of column names, constants, and functions connected by operators or subqueries.</td>
</tr>
<tr>
<td>comparison-operator</td>
<td>An operator that tests conditions between two expressions, one of the following:</td>
</tr>
<tr>
<td>This operator...</td>
<td>Tests whether...</td>
</tr>
<tr>
<td>&lt;</td>
<td>The first expression is less than the second.</td>
</tr>
<tr>
<td>&gt;</td>
<td>The first expression is greater than the second.</td>

<tr>
<td>&lt;=</td>
<td>The first expression is less than or equal to the second.</td>
</tr>
<tr>
<td>This operator...</td>
<td>Tests whether...</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------</td>
</tr>
<tr>
<td>&gt;=</td>
<td>The first expression is greater than or equal to the second expression.</td>
</tr>
<tr>
<td>=</td>
<td>Two expressions are equal.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Like the = operator, but returns TRUE (instead of UNKNOWN) if both expressions evaluate to UNKNOWN, and FALSE (instead of UNKNOWN) if one expression evaluates to UNKNOWN.</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>Two expressions are not equal.</td>
</tr>
<tr>
<td>!=</td>
<td>A character string with optional wildcard (*) characters.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>string-expression</th>
<th>A character string with optional wildcard (*) characters.</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ NOT ] { LIKE</td>
<td>ILIKE</td>
</tr>
<tr>
<td>Predicate</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>IS [ NOT ] NULL</strong></td>
<td>Searches for values that are null or are not null.</td>
</tr>
<tr>
<td><strong>ALL</strong></td>
<td>Used with a comparison operator and a subquery. Returns TRUE for the left-hand predicate if all values returned by the subquery satisfy the comparison operation, or FALSE if not all values satisfy the comparison or if the subquery returns no rows to the outer query block.</td>
</tr>
<tr>
<td>**ANY</td>
<td>SOME**</td>
</tr>
<tr>
<td><strong>[ NOT ] EXISTS</strong></td>
<td>Used with a subquery to test for the existence of records that the subquery returns.</td>
</tr>
<tr>
<td><strong>[ NOT ] IN</strong></td>
<td>Searches for an expression on the basis of an expression's exclusion or inclusion from a list. The list of values is enclosed in parentheses and can be a subquery or a set of constants.</td>
</tr>
</tbody>
</table>
**Logical Operators AND and OR**

The AND and OR logical operators combine two conditions. AND evaluates to TRUE when both of the conditions joined by the AND keyword are matched, and OR evaluates to TRUE when either condition joined by OR is matched.

**OR Subqueries (complex expressions)**

Vertica supports subqueries in more complex expressions using OR; for example:

- More than one subquery in the conjunct expression:
  
  $$(\text{SELECT MAX(b) FROM t1} + \text{SELECT MAX FROM t2}) \text{ a IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2)}$$

- An OR clause in the conjunct expression involves at least one subquery:

  $a \text{ IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2) a IN (SELECT a FROM t1) OR b = 5}$
  
  $a = (\text{SELECT MAX FROM t2}) \text{ OR b = 5}$

- One subquery is present but it is part of a another expression:

  $x \text{ IN (SELECT a FROM t1)} = (x = (\text{SELECT MAX FROM t2}) (x \text{ IN (SELECT a FROM t1)} \text{ IS NULL})$

**How AND Queries Are Evaluated**

Vertica treats expressions separated by AND (conjunctive) operators individually. For example if the WHERE clause were:

```
WHERE (a IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2)) AND (c IN (SELECT a FROM t1))
```

the query would be interpreted as two conjunct expressions:

1. $(a \text{ IN (SELECT a FROM t1)}) \text{ OR b IN (SELECT x FROM t2))}$
2. $(c \text{ IN (SELECT a FROM t1))}$

The first expression is considered a complex subquery, whereas the second expression is not.
Examples

The following list shows some of the ways you can filter complex conditions in the WHERE clause:

- **OR expression between a subquery and a non-subquery condition:**

  ```sql
  => SELECT x FROM t WHERE x > (SELECT SUM(DISTINCT x) FROM t GROUP BY y) OR x < 9;
  ```

- **OR expression between two subqueries:**

  ```sql
  => SELECT * FROM t WHERE x=(SELECT x FROM t) OR EXISTS(SELECT x FROM tt);
  ```

- **Subquery expression:**

  ```sql
  => SELECT * FROM t WHERE x=(SELECT x FROM t)+1 OR x>(SELECT x FROM t)+1;
  ```

- **OR expression with [NOT] IN subqueries:**

  ```sql
  => SELECT * FROM t WHERE NOT (EXISTS (SELECT x FROM t)) OR x >9;
  ```

- **OR expression with IS [NOT] NULL subqueries:**

  ```sql
  => SELECT * FROM t WHERE (SELECT * FROM t)IS NULL OR (SELECT * FROM tt)IS NULL;
  ```

- **OR expression with boolean column and subquery that returns Boolean data type:**

  ```sql
  => SELECT * FROM t2 WHERE x = (SELECT x FROM t2) OR x;
  ```

Note:
To return TRUE, the argument of OR must be a Boolean data type.

- **OR expression in the CASE statement:**

  ```sql
  => SELECT * FROM t WHERE CASE WHEN x=1 THEN x > (SELECT * FROM t)
  OR x < (SELECT * FROM t2) END;
  ```

- **Analytic function, NULL-handling function, string function, math function, and so on:**

  ```sql
  => SELECT x FROM t WHERE x > (SELECT COALESCE (x,y) FROM t GROUP BY x,y) OR
  x < 9;
  ```

- **In user-defined functions (assuming \( f() \) is one):**
Use of parentheses at different places to restructure the queries:

```sql
=> SELECT x FROM t WHERE (x = (SELECT x FROM t) AND y = (SELECT y FROM t))
    OR (SELECT x FROM t) = 1;
```

Multicolumn subqueries:

```sql
=> SELECT * FROM t WHERE (x,y) = (SELECT x,y FROM t) OR x > 5;
```

Constant/NULL on lefthand side of subquery:

```sql
=> SELECT * FROM t WHERE x > 5 OR 5 = (SELECT x FROM t);
```

See Also

- Subquery Restrictions

In Place of an Expression

Subqueries that return a single value (unlike a list of values returned by IN subqueries) can be used just about anywhere an expression is allowed in SQL. It can be a column name, a constant, a function, a scalar subquery, or a combination of column names, constants, and functions connected by operators or subqueries.

For example:

```sql
=> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
=> SELECT c1 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)), TRUE);
=> SELECT c1 FROM t1 GROUP BY c1 HAVING COALESCE((t1.c1 <> ALL (SELECT c1 FROM t2)), TRUE);
```

Multi-column expressions are also supported:

```sql
=> SELECT c1 FROM t1 WHERE (t1.c1, t1.c2) = ALL (SELECT c1, c2 FROM t2);
=> SELECT c1 FROM t1 WHERE (t1.c1, t1.c2) <> ANY (SELECT c1, c2 FROM t2);
```

Vertica returns an error on queries where more than one row would be returned by any subquery used as an expression:
See Also

- Subquery Restrictions

**Comparison Operators**

Vertica supports Boolean subquery expressions in the WHERE clause with any of the following operators:

- >
- <
- >=
- <=
- =
- <>
- <=>

WHERE clause subqueries filter results and take the following form:

```sql
SELECT <column, ...> FROM <table>
WHERE <condition> (SELECT <column, ...> FROM <table> WHERE <condition>);
```

These conditions are available for all data types where comparison makes sense. All *Comparison Operators* are binary operators that return values of TRUE, FALSE, or UNKNOWN (NULL).

Expressions that correlate to just one outer table in the outer query block are supported, and these correlated expressions can be comparison operators.

The following subquery scenarios are supported:

```sql
SELECT * FROM T1 WHERE T1.x = (SELECT MAX(c1) FROM T2);
SELECT * FROM T1 WHERE T1.x >= (SELECT MAX(c1) FROM T2 WHERE T1.y = T2.c2);
SELECT * FROM T1 WHERE T1.x <= (SELECT MAX(c1) FROM T2 WHERE T1.y = T2.c2);
```
**LIKE Pattern Matching**

Vertica supports LIKE pattern-matching conditions in subqueries and take the following form:

\[ \text{string-expression} \ [\ \text{NOT} \ ] \{ \ \text{LIKE} \ | \ \text{ILIKE} \ | \ \text{LIKEB} \ | \ \text{ILIKEB} \} \ \text{string-expression} \]

The following command searches for customers whose company name starts with "Ev" and returns the total count:

```sql
=> SELECT COUNT(*) FROM customer_dimension WHERE customer_name LIKE (SELECT 'Ev%' FROM customer_dimension LIMIT 1);
```

<table>
<thead>
<tr>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>153</td>
</tr>
</tbody>
</table>

(1 row)

Vertica also supports single-row subqueries as the pattern argument for LIKEB and ILIKEB predicates; for example:

```sql
=> SELECT * FROM t1 WHERE t1.x LIKEB (SELECT t2.x FROM t2);
```

The following symbols are substitutes for the LIKE keywords:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>~~</td>
<td>LIKE</td>
</tr>
<tr>
<td>~#</td>
<td>LIKEB</td>
</tr>
<tr>
<td>~~*</td>
<td>LIKE</td>
</tr>
<tr>
<td>~#*</td>
<td>ILIKEB</td>
</tr>
<tr>
<td>!~~</td>
<td>NOT LIKE</td>
</tr>
<tr>
<td>!~#</td>
<td>NOT LIKEB</td>
</tr>
<tr>
<td>!~~*</td>
<td>NOT ILIKE</td>
</tr>
<tr>
<td>!~#*</td>
<td>NOT IILIKEB</td>
</tr>
</tbody>
</table>

**Note:**
The ESCAPE keyword is not valid for the above symbols.

See **LIKE predicate** in the SQL Reference Manual for additional examples.

**ANY and ALL**

You typically use comparison operators (=, >, <, etc.) only on subqueries that return one row. With ANY and ALL operators, you can make comparisons on subqueries that return multiple rows.

These subqueries take the following form:
expression comparison-operator { ANY | ALL } (subquery)

ANY and ALL evaluate whether any or all of the values returned by a subquery match the left-hand expression.

**Equivalent Operators**

You can use following operators instead of ANY or ALL:

<table>
<thead>
<tr>
<th>This operator...</th>
<th>Is equivalent to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOME</td>
<td>ANY</td>
</tr>
<tr>
<td>IN</td>
<td>= ANY</td>
</tr>
<tr>
<td>NOT IN</td>
<td>&lt;&gt; ALL</td>
</tr>
</tbody>
</table>

**Example Data**

Examples below use the following tables and data:

\[
\begin{array}{ll}
\text{CREATE TABLE t1 (c1 int, c2 VARCHAR(8));} & \text{CREATE TABLE t2 (c1 int, c2 VARCHAR(8));} \\

\text{=> SELECT * FROM t1 ORDER BY c1; } \\
\text{c1 | c2} \\
\text{---------} \\
\text{1 | cab} \\
\text{1 | abc} \\
\text{2 | fed} \\
\text{2 | def} \\
\text{3 | ihg} \\
\text{3 | ghi} \\
\text{4 | jkl} \\
\text{5 | mno} \\
\text{(8 rows)} \\

\text{=> SELECT * FROM t2 ORDER BY c1; } \\
\text{c1 | c2} \\
\text{---------} \\
\text{1 | abc} \\
\text{2 | fed} \\
\text{3 | jkl} \\
\text{3 | stu} \\
\text{3 | zzz} \\
\text{(5 rows)}
\end{array}
\]

**ANY Subqueries**

Subqueries that use the ANY keyword return true when any value retrieved in the subquery matches the value of the left-hand expression.

**Examples**
An ANY subquery within an expression:

```sql
=> SELECT c1, c2 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)));
c1  |  c2  
-----+-----
 2  |  fed 
 2  |  def 
 3  |  ihg 
 3  |  ghi 
 4  |  jkl 
 5  |  mno 
(6 rows)
```

ANY noncorrelated subqueries without aggregates:

```sql
=> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
c1  
----
 1
 1
 2
 2
 3
 3 
(6 rows)
```

ANY noncorrelated subqueries with aggregates:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
c1  |  c2  
-----+-----
 1  |  cab 
 1  |  abc 
 2  |  fed 
 2  |  def 
 4  |  jkl 
 5  |  mno 
(6 rows)

=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
c1  
----
 1
 2
 4
 5 
(4 rows)
```

ANY noncorrelated subqueries with aggregates and a GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
c1  |  c2  
-----+-----
 1  |  cab 
 1  |  abc 
 2  |  fed 
```
ANY noncorrelated subqueries with a GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <= ANY (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
  c1 | c2
-----+-----
  1 | cab
  1 | abc
  2 | fed
  2 | def
  3 | ihg
  3 | ghi
(6 rows)
```

ANY correlated subqueries with no aggregates or GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 >= ANY (SELECT c1 FROM t2 WHERE t2.c2 = t1.c2) ORDER BY c1;
  c1 | c2
-----+-----
  1 | abc
  2 | fed
  4 | jkl
(3 rows)
```

ALL Subqueries

A subquery that uses the ALL keyword returns true when all values retrieved by the subquery match the left-hand expression, otherwise it returns false.

Examples

ALL noncorrelated subqueries without aggregates:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 >= ALL (SELECT c1 FROM t2) ORDER BY c1;
  c1 | c2
-----+-----
  3 | ihg
  3 | ghi
  4 | jkl
  5 | mno
(4 rows)
```

ALL noncorrelated subqueries with aggregates:
ALL noncorrelated subqueries with aggregates and a GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 = ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
   c1 | c2
-------
   3 | ihg
   3 | ghi
(2 rows)
```

```sql
=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
   c1
----
   1
   2
   4
   5
(4 rows)
```

ALL noncorrelated subqueries with a GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <= ALL (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
   c1 | c2
-------
   1 | cab
   1 | abc
(2 rows)
```

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <> ALL (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
   c1 | c2
-------
   4 | jkl
   5 | mno
(2 rows)
```

**NULL Handling**

Vertica supports multicolumn <> ALL subqueries where the columns are not marked NOT NULL. If any column contains a NULL value, Vertica returns a run-time error.

Vertica does not support = ANY subqueries that are nested within another expression if any column values are NULL.

**See Also**

*Subquery Restrictions*
**EXISTS and NOT EXISTS**

The EXISTS predicate is one of the most common predicates used to build conditions that use noncorrelated and correlated subqueries. Use EXISTS to identify the existence of a relationship without regard for the quantity. For example, EXISTS returns true if the subquery returns any rows, and [NOT] EXISTS returns true if the subquery returns no rows.

[NOT] EXISTS subqueries take the following form:

```
expression [ NOT ] EXISTS ( subquery )
```

The EXISTS condition is considered to be met if the subquery returns at least one row. Since the result depends only on whether any records are returned, and not on the contents of those records, the output list of the subquery is normally uninteresting. A common coding convention is to write all EXISTS tests as follows:

```
EXISTS (SELECT 1 WHERE ...)
```

In the above fragment, SELECT 1 returns the value 1 for every record in the query. If the query returns, for example, five records, it returns 5 ones. The system doesn't care about the real values in those records; it just wants to know if a row is returned.

Alternatively, a subquery’s select list that uses EXISTS might consist of the asterisk (*). You do not need to specify column names, because the query tests for the existence or nonexistence of records that meet the conditions specified in the subquery.

```
EXISTS (SELECT * WHERE ...)
```

**Notes**

- If EXISTS (subquery) returns at least 1 row, the result is TRUE.
- If EXISTS (subquery) returns no rows, the result is FALSE.
- If NOT EXISTS (subquery) returns at least 1 row, the result is FALSE.
- If NOT EXISTS (subquery) returns no rows, the result is TRUE.

**Examples**

The following query retrieves the list of all the customers who purchased anything from any of the stores amounting to more than 550 dollars:
Whether you use EXISTS or IN subqueries depends on which predicates you select in outer and inner query blocks. For example, to get a list of all the orders placed by all stores on January 2, 2003 for vendors with records in the vendor table:

```sql
=> SELECT store_key, order_number, date_ordered
   FROM store.store_orders_fact WHERE EXISTS
     (SELECT 1 FROM public.vendor_dimension v
      WHERE v.vendor_key = store.store_orders_fact.vendor_key
     )
     AND date_ordered = '2012-01-02';
```

The above query looks for existence of the vendor and date ordered. To return a particular value, rather than simple existence, the query looks for orders placed by the vendor who got the best deal on January 4, 2004:

```sql
=> SELECT store_key, order_number, date_ordered
   FROM store.store_orders_fact ord, public.vendor_dimension vd
     WHERE ord.vendor_key = vd.vendor_key AND vd.deal_size IN
       (SELECT MAX(deal_size) FROM public.vendor_dimension
        )
     AND date_ordered = '2013-01-04';
```
**IN and NOT IN**

While you cannot equate a single value to a set of values, you can check to see if a single value is found within that set of values. Use the IN clause for multiple-record, single-column subqueries. After the subquery returns results introduced by IN or NOT IN, the outer query uses them to return the final result.

[NOT] IN subqueries take the following form:

\[
\{ \text{expression} \ [\text{NOT}] \ \text{IN} ( \text{subquery} ) | \text{expression} \ [\text{NOT}] \ \text{IN} ( \text{expression} ) \}\n\]

There is no limit to the number of parameters passed to the IN clause of the SELECT statement; for example:

```sql
=> SELECT * FROM tablename WHERE column IN (a, b, c, d, e, ...);```

Vertica also supports queries where two or more outer expressions refer to different inner expressions:

```sql
=> SELECT * FROM A WHERE (A.x,A.x) IN (SELECT B.x, B.y FROM B);
```

**Examples**

The following query uses the VMart schema to illustrate the use of outer expressions referring to different inner expressions:

```sql
=> SELECT product_description, product_price FROM product_dimension
    WHERE (product_dimension.product_key, product_dimension.product_key) IN
    (SELECT store.store_orders_fact.order_number,
     store.store_orders_fact.quantity_ordered
    FROM store.store_orders_fact);
```

<table>
<thead>
<tr>
<th>product_description</th>
<th>product_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brand #72 box of candy</td>
<td>326</td>
</tr>
<tr>
<td>Brand #71 vanilla ice cream</td>
<td>270</td>
</tr>
</tbody>
</table>
To find all products supplied by stores in MA, first create the inner query and run it to ensure that it works as desired. The following query returns all stores located in MA:

```sql
=> SELECT store_key FROM store.store_dimension WHERE store_state = 'MA';
store_key
----------
 13
 31
(2 rows)
```

Then create the outer or main query that specifies all distinct products that were sold in stores located in MA. This statement combines the inner and outer queries using the IN predicate:

```sql
=> SELECT DISTINCT s.product_key, p.product_description
  FROM store.store_sales_fact s, public.product_dimension p
  WHERE s.product_key = p.product_key
    AND s.product_version = p.product_version
    AND s.store_key IN
        (SELECT store_key
         FROM store.store_dimension
         WHERE store_state = 'MA')
  ORDER BY s.product_key;
```

<table>
<thead>
<tr>
<th>product_key</th>
<th>product_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Brand #1 white bread</td>
</tr>
<tr>
<td>1</td>
<td>Brand #4 vegetable soup</td>
</tr>
<tr>
<td>3</td>
<td>Brand #9 wheelchair</td>
</tr>
<tr>
<td>5</td>
<td>Brand #15 cheddar cheese</td>
</tr>
<tr>
<td>5</td>
<td>Brand #19 bleach</td>
</tr>
<tr>
<td>7</td>
<td>Brand #22 canned green beans</td>
</tr>
<tr>
<td>7</td>
<td>Brand #23 canned tomatoes</td>
</tr>
<tr>
<td>8</td>
<td>Brand #24 champagne</td>
</tr>
<tr>
<td>8</td>
<td>Brand #25 chicken nuggets</td>
</tr>
<tr>
<td>11</td>
<td>Brand #32 sausage</td>
</tr>
</tbody>
</table>

(281 rows) ... ...

When using NOT IN, the subquery returns a list of zero or more values in the outer query where the comparison column does not match any of the values returned from the subquery. Using the previous example, NOT IN returns all the products that are not supplied from MA.

**Notes**

Vertica supports multicolour NOT IN subqueries in which the columns are not marked NOT NULL. If one of the columns is found to contain a NULL value during query execution, Vertica returns a run-time error.
Similarly, IN subqueries nested within another expression are not supported if any of the column values are NULL. For example, if in the following statement column x from either table contained a NULL value, Vertica returns a run-time error:

```
=> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;
ERROR: NULL value found in a column used by a subquery
```

### Subqueries in the SELECT List

Subqueries can occur in the select list of the containing query. The results from the following statement are ordered by the first column (customer_name). You could also write ORDER BY 2 and specify that the results be ordered by the select-list subquery.

```
=> SELECT c.customer_name, (SELECT AVG(annual_income) FROM customer_dimension WHERE deal_size = c.deal_size) AS AVG_SAL DEAL FROM customer_dimension c ORDER BY 1;
```

<table>
<thead>
<tr>
<th>customer_name</th>
<th>AVG_SAL DEAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Goldstar</td>
<td>683429</td>
</tr>
<tr>
<td>Metatech</td>
<td>628086</td>
</tr>
<tr>
<td>Metadata</td>
<td>666728</td>
</tr>
<tr>
<td>Foodstar</td>
<td>695962</td>
</tr>
<tr>
<td>Verihope</td>
<td>715683</td>
</tr>
<tr>
<td>Veridata</td>
<td>868252</td>
</tr>
<tr>
<td>Bettercare</td>
<td>879156</td>
</tr>
<tr>
<td>Foodgen</td>
<td>958954</td>
</tr>
<tr>
<td>Virtacom</td>
<td>991551</td>
</tr>
<tr>
<td>Inicorp</td>
<td>1098835</td>
</tr>
</tbody>
</table>

### Notes

- Scalar subqueries in the select-list return a single row/column value. These subqueries use Boolean comparison operators: =, >, <, <=, >=.

  If the query is correlated, it returns NULL if the correlation results in 0 rows. If the query returns more than one row, the query errors out at run time and Vertica displays an error message that the scalar subquery must only return 1 row.
Subquery expressions such as [NOT] IN, [NOT] EXISTS, ANY/SOME, or ALL always return a single Boolean value that evaluates to TRUE, FALSE, or UNKNOWN; the subquery itself can have many rows. Most of these queries can be correlated or noncorrelated.

**Note:**
ALL subqueries cannot be correlated.

Subqueries in the ORDER BY and GROUP BY clauses are supported; for example, the following statement says to order by the first column, which is the select-list subquery:

```sql
=> SELECT (SELECT MAX(x) FROM t2 WHERE y=t1.b) FROM t1 ORDER BY 1;
```

- Subquery Restrictions

**WITH Clauses**

WITH clauses are concomitant queries within a larger, primary query. Vertica can evaluate WITH clauses in two ways:

- **Inline expansion** (default): Vertica evaluates each WITH clause every time it is referenced by the primary query.
- **Materialization**: Vertica evaluates each WITH clause once, stores results in a temporary table, and references this table as often as the query requires.

See [WITH Clause](#) for details on syntax options and requirements.

**Inline Expansion of WITH Clause**

By default, Vertica uses inline expansion to evaluate WITH clauses. Vertica evaluates each WITH clause every time it is referenced by the primary query. Inline expansion often works best if the query does not reference the same WITH clause multiple times, or if some local optimizations are possible after inline expansion.
Example

The following example shows a WITH clause that is a good candidate for inline expansion. The WITH clause is used in a query that obtains order information for all 2018 orders shipped between December 01-07:

```
-- Enable materialization
ALTER SESSION SET PARAMETER WithClauseMaterialization=1;

-- Begin WITH
WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION */
    store_orders_fact_new AS(
        SELECT * FROM store.store_orders_fact WHERE date_shipped between '2018-12-01' and '2018-12-07')

-- End WITH
-- Begin primary query
SELECT store_key, product_key, product_version, SUM(quantity_ordered*unit_price) AS total_price
FROM store_orders_fact_new
GROUP BY store_key, product_key, product_version
ORDER BY total_price DESC;
```

<table>
<thead>
<tr>
<th>store_key</th>
<th>product_key</th>
<th>product_version</th>
<th>total_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>135</td>
<td>14015</td>
<td>2</td>
<td>30000</td>
</tr>
<tr>
<td>154</td>
<td>19202</td>
<td>1</td>
<td>29186</td>
</tr>
<tr>
<td>232</td>
<td>1855</td>
<td>2</td>
<td>29000</td>
</tr>
<tr>

<td>25026</td>
</tr>
<tr>
<td>97</td>
<td>16324</td>
<td>2</td>
<td>24864</td>
</tr>
<tr>
<td>234</td>
<td>17681</td>
<td>1</td>
<td>24795</td>
</tr>
<tr>
<td>195</td>
<td>16532</td>
<td>1</td>
<td>24794</td>
</tr>
<tr>
<td>83</td>
<td>9597</td>
<td>2</td>
<td>24661</td>
</tr>
<tr>
<td>149</td>
<td>7164</td>
<td>5</td>
<td>24518</td>
</tr>
<tr>
<td>142</td>
<td>11022</td>
<td>4</td>
<td>24400</td>
</tr>
<tr>
<td>282</td>
<td>12712</td>
<td>1</td>
<td>24380</td>
</tr>
<tr>
<td>13</td>
<td>18154</td>
<td>1</td>
<td>24273</td>
</tr>
<tr>
<td>7</td>
<td>3793</td>
<td>3</td>
<td>24250</td>
</tr>
</tbody>
</table>

Vertica processes the query as follows:
1. Expands the WITH clause reference to store_orders_fact_new within the primary query.
2. After expanding the WITH clause, evaluates the primary query.

**Materialization of WITH Clause**

When materialization is enabled, Vertica evaluates each WITH clause once, stores results in a temporary table, and references this table as often as the query requires. Vertica drops the temporary table after primary query execution completes.

**Note:**
If the primary query returns with an error, temporary tables might be dropped only after the client’s session ends.

Materialization can facilitate better performance when WITH clauses are complex—for example, when the WITH clauses contain JOIN and GROUP BY clauses, and are referenced multiple times in the primary query.

If materialization is enabled, WITH statements perform an auto-commit of the user transaction. This occurs even when using EXPLAIN with the WITH statement.

**Enabling Materialization**

WITH materialization is set by configuration parameter WithClauseMaterialization, by default set to 0 (disabled). You can enable and disable materialization by setting WithClauseMaterialization at database and session levels, with ALTER DATABASE and ALTER SESSION, respectively:

- **Database:**
  
  ```sql
  ALTER DATABASE db-spec SET PARAMETER WithClauseMaterialization={ 0 | 1 };
  ALTER DATABASE db-spec CLEAR PARAMETER WithClauseMaterialization;
  ```

- **Session:** Parameter setting remains in effect until you explicitly clear it, or the session ends.

  ```sql
  ALTER SESSION SET PARAMETER WithClauseMaterialization={ 0 | 1 };
  ALTER SESSION CLEAR PARAMETER WithClauseMaterialization;
  ```

You can also enable WITH materialization for individual queries with the hint `ENABLE_WITH_CLAUSE_MATERIALIZATION`. Materialization is automatically cleared when the query
returns. For example:

```sql
=> WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION */ revenue AS
  (SELECT vendor_key, SUM(total_order_cost) AS total_revenue
  FROM store.store_orders_fact
  GROUP BY vendor_key ORDER BY 1)
...```

### Example

The following example shows a WITH clause that is a good candidate for materialization. The query obtains data for the vendor who has the highest combined order cost for all orders:

```sql
-- Enable materialization
ALTER SESSION SET PARAMETER WithClauseMaterialization=1;

-- Define WITH clause
WITH revenue AS (SELECT vendor_key, SUM(total_order_cost) AS total_revenue
  FROM store.store_orders_fact
  GROUP BY vendor_key ORDER BY 1)
-- End WITH clause

-- Primary query
SELECT vendor_name, vendor_address, vendor_city, total_revenue
FROM vendor_dimension v, revenue r
WHERE v.vendor_key = r.vendor_key AND total_revenue = (SELECT MAX(total_revenue) FROM revenue )
ORDER BY vendor_name;

+-----------------+--------------------+-----------------+-------------+
<table>
<thead>
<tr>
<th>vendor_name</th>
<th>vendor_address</th>
<th>vendor_city</th>
<th>total_revenue</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frozen Suppliers</td>
<td>471 Mission St</td>
<td>Peoria</td>
<td>49877044</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(1 row)</td>
</tr>
</tbody>
</table>
```

Vertica processes this query as follows:

1. **WITH clause revenue** evaluates its SELECT statement from table store.store_orders_fact.
2. Results of the revenue clause are stored in a local temporary table.
3. Whenever the revenue clause statement is referenced, the results stored in the table are used.
4. The temporary table is dropped when query execution is complete.

### Noncorrelated and Correlated Subqueries

Subqueries can be categorized into two types:
A noncorrelated (simple) subquery obtains its results independently of its containing (outer) statement.
A correlated subquery requires values from its outer query in order to execute.

## Noncorrelated Subqueries

A noncorrelated subquery executes independently of the outer query. The subquery executes first, and then passes its results to the outer query. For example:

```sql
=> SELECT name, street, city, state FROM addresses WHERE state IN (SELECT state FROM states);
```

Vertica executes this query as follows:

1. Executes the subquery `SELECT state FROM states` (in bold).
2. Passes the subquery results to the outer query.

A query's WHERE and HAVING clauses can specify noncorrelated subqueries if the subquery resolves to a single row, as shown below:

**In WHERE clause**

```sql
=> SELECT COUNT(*) FROM SubQ1 WHERE SubQ1.a = (SELECT y FROM SubQ2);
```

**In HAVING clause**

```sql
=> SELECT COUNT(*) FROM SubQ1 GROUP BY SubQ1.a HAVING SubQ1.a = (SubQ1.a & (SELECT y FROM SubQ2))
```

## Correlated Subqueries

A correlated subquery typically obtains values from its outer query before it executes. When the subquery returns, it passes its results to the outer query.

**Note:**

You can use an outer join to obtain the same effect as a correlated subquery.

In the following example, the subquery needs values from the `addresses.state` column in the outer query:

```sql
=> SELECT name, street, city, state FROM addresses
WHERE EXISTS (SELECT * FROM states WHERE states.state = addresses.state);
```

Vertica executes this query as follows:
1. The query extracts and evaluates each addresses.state value in the outer subquery records.
2. Then the query—using the EXISTS predicate—checks the addresses in the inner (correlated) subquery.
3. Because it uses the EXISTS predicate, the query stops processing when it finds the first match.

When Vertica executes this query, it translates the full query into a JOIN WITH SIPS.

**Flattening FROM Clause Subqueries**

FROM clause subqueries are always evaluated before their containing query. In some cases, the optimizer flattens FROM clause subqueries so the query can execute more efficiently.

For example, in order to create a query plan for the following statement, the Vertica query optimizer evaluates all records in table t1 before it evaluates the records in table t0:

```sql
=> SELECT * FROM (SELECT a, MAX(a) AS max FROM (SELECT * FROM t1) AS t0 GROUP BY a);
```

Given the previous query, the optimizer can internally flatten it as follows:

```sql
=> SELECT * FROM (SELECT a, MAX(a) FROM t1 GROUP BY a) AS t0;
```

Both queries return the same results, but the flattened query runs more quickly.

**Flattening Views**

When a query’s FROM clause specifies a view, the optimizer expands the view by replacing it with the query that the view encapsulates. If the view contains subqueries that are eligible for flattening, the optimizer produces a query plan that flattens those subqueries.

**Flattening Restrictions**

The optimizer cannot create a flattened query plan if a subquery or view contains one of the following elements:

- Aggregate function
- Analytic function
- Outer join (left, right or full)
- GROUP BY, ORDER BY, or HAVING clause
- DISTINCT keyword
- LIMIT or OFFSET clause
- UNION, EXCEPT, or INTERSECT clause
- EXISTS subquery

**Examples**

If a predicate applies to a view or subquery, the flattening operation can allow for optimizations by evaluating the predicates before the flattening takes place. Two examples follow.

**View flattening**

In this example, view v1 is defined as follows:

```sql
=> CREATE VIEW v1 AS SELECT * FROM a;
```

The following query specifies this view:

```sql
=> SELECT * FROM v1 JOIN b ON x=y WHERE x > 10;
```

Without flattening, the optimizer evaluates the query as follows:

1. Evaluates the subquery.
2. Applies the predicate WHERE x > 10.

In contrast, the optimizer can create a flattened query plan by applying the predicate before evaluating the subquery. This reduces the optimizer's work because it returns only the records WHERE x > 10 to the containing query.

Vertica internally transforms the previous query as follows:

```sql
=> SELECT * FROM (SELECT * FROM a) AS t1 JOIN b ON x=y WHERE x > 10;
```

The optimizer then flattens the query:

```sql
=> SELECT * FROM a JOIN b ON x=y WHERE x > 10;
```

**Subquery flattening**

The following example shows how Vertica transforms FROM clause subqueries within a WHERE clause IN subquery. Given the following query:
The optimizer flattens it as follows:

```sql
=> SELECT * FROM a
WHERE b IN (SELECT b FROM t2) AS D WHERE x=1;
```

**See Also**

Subquery Restrictions

Subqueries in UPDATE and DELETE Statements

You can nest subqueries within UPDATE and DELETE statements.

**UPDATE Subqueries**

You can update records in one table according to values in others, by nesting a subquery within an UPDATE statement. The example below illustrates this through a couple of noncorrelated subqueries. You can reproduce this example with the following tables:

```sql
CREATE TABLE addresses(cust_id INTEGER, address VARCHAR(2000));
CREATE TABLE new_addresses(new_cust_id integer, new_address Boolean DEFAULT 'T');
```

```sql
INSERT INTO addresses VALUES(20,'Lincoln Street');
INSERT INTO addresses VALUES(30,'Booth Hill Road');
INSERT INTO addresses VALUES(30,'Beach Avenue');
INSERT INTO addresses VALUES(40,'Mt. Vernon Street');
INSERT INTO addresses VALUES(50,'Hillside Avenue');
INSERT INTO new_addresses VALUES(20);
INSERT INTO new_addresses VALUES(30);
INSERT INTO new_addresses VALUES(60,'F');
INSERT INTO new_addresses VALUES(80,'T');
COMMIT;
```

Queries on these tables return the following results:

```sql
=> SELECT * FROM addresses;
  cust_id | address
-----------
   50 | Hillside Avenue
   30 | Booth Hill Road
   40 | Mt. Vernon Street
```
The following UPDATE statement uses a noncorrelated subquery to join new_addresses and addresses records on customer IDs. UPDATE sets the value 'New Address' in the joined addresses records. The statement output indicates that three rows were updated:

```sql
=> UPDATE addresses SET address='New Address'
   WHERE cust_id IN (SELECT new_cust_id FROM new_addresses WHERE new_address='T');
OUTPUT
-------
3
(1 row)
```

Query the addresses table to see the changes for matching customer ID 20 and 30. Addresses for customer ID 40 and 50 are not updated:

```sql
=> SELECT * FROM addresses;
cust_id | address
---------
20 | New Address
30 | New Address
30 | New Address
40 | Mt. Vernon Street
50 | Hillside Avenue
(5 rows)
=>COMMIT;
COMMIT
```

**DELETE Subqueries**

You can delete records in one table based according to values in others by nesting a subquery within a DELETE statement.

For example, you want to remove records from new_addresses that were used earlier to update records in addresses. The following DELETE statement uses a noncorrelated subquery to join new_addresses and addresses records on customer IDs. It then deletes the joined records from table new_addresses:
DELETE FROM new_addresses
WHERE new_cust_id IN (SELECT cust_id FROM addresses WHERE address='New Address');

QUERYING NEW_ADDRESSES CONFIRMS THAT THE RECORDS WERE DELETED:

SELECT * FROM new_addresses;

<table>
<thead>
<tr>
<th>new_cust_id</th>
<th>new_address</th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>f</td>
</tr>
<tr>
<td>80</td>
<td>t</td>
</tr>
</tbody>
</table>

(2 rows)

**Subquery Examples**

This topic illustrates some of the subqueries you can write. The examples use the VMart example database.

**Single-Row Subqueries**

Single-row subqueries are used with single-row comparison operators (=, >=, <=, <>, and <=>) and return exactly one row.

For example, the following query retrieves the name and hire date of the oldest employee in the Vmart database:

SELECT employee_key, employee_first_name, employee_last_name, hire_date
FROM employee_dimension
WHERE hire_date = (SELECT MIN(hire_date) FROM employee_dimension);

<table>
<thead>
<tr>
<th>employee_key</th>
<th>employee_first_name</th>
<th>employee_last_name</th>
<th>hire_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>2292</td>
<td>Mary</td>
<td>Bauer</td>
<td>1956-01-11</td>
</tr>
</tbody>
</table>

(1 row)

**Multiple-Row Subqueries**

Multiple-row subqueries return multiple records.
For example, the following IN clause subquery returns the names of the employees making the highest salary in each of the six regions:

```
=> SELECT employee_first_name, employee_last_name, annual_salary, employee_region
    FROM employee_dimension WHERE annual_salary IN
        (SELECT MAX(annual_salary) FROM employee_dimension GROUP BY employee_region)
    ORDER BY annual_salary DESC;
```

<table>
<thead>
<tr>
<th>employee_first_name</th>
<th>employee_last_name</th>
<th>annual_salary</th>
<th>employee_region</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alexandra</td>
<td>Sanchez</td>
<td>992363</td>
<td>West</td>
</tr>
<tr>
<td>Mark</td>
<td>Vogel</td>
<td>983634</td>
<td>South</td>
</tr>
<tr>
<td>Tiffany</td>
<td>Vu</td>
<td>977716</td>
<td>SouthWest</td>
</tr>
<tr>
<td>Barbara</td>
<td>Lewis</td>
<td>957949</td>
<td>MidWest</td>
</tr>
<tr>
<td>Sally</td>
<td>Gauthier</td>
<td>927335</td>
<td>East</td>
</tr>
<tr>
<td>Wendy</td>
<td>Nielson</td>
<td>777037</td>
<td>NorthWest</td>
</tr>
</tbody>
</table>

(6 rows)

### Multicolumn Subqueries

Multicolumn subqueries return one or more columns. Sometimes a subquery's result set is evaluated in the containing query in column-to-column and row-to-row comparisons.

**Note:**

Multicolumn subqueries can use the <>, !=, and = operators but not the <, >, <=, => operators.

You can substitute some multicolumn subqueries with a join, with the reverse being true as well. For example, the following two queries ask for the sales transactions of all products sold online to customers located in Massachusetts and return the same result set. The only difference is the first query is written as a join and the second is written as a subquery.

**Join query:**

```
=> SELECT *
    FROM online_sales.online_sales_fact
    INNER JOIN public.customer_dimension
    USING (customer_key)
    WHERE customer_state = 'MA';
```

**Subquery:**

```
=> SELECT *
    FROM online_sales.online_sales_fact
    WHERE customer_key IN
    (SELECT customer_key
     FROM public.customer_dimenion
     WHERE customer_state = 'MA');
```

The following query returns all employees in each region whose salary is above the average:

```
=> SELECT e.employee_first_name, e.employee_last_name, e.annual_salary,
    e.employee_region, s.average
    FROM employee_dimension e,
    (SELECT employee_region, AVG(annual_salary) AS average
    FROM employee_dimension
    GROUP BY employee_region) s
    WHERE e.annual_salary > s.average;
```
FROM employee_dimension GROUP BY employee_region) AS s
WHERE e.employee_region = s.employee_region AND e.annual_salary > s.average
ORDER BY annual_salary DESC;

You can also use the **EXCEPT**, **INTERSECT**, and **UNION** [ALL] keywords in FROM, WHERE, and HAVING clauses.

The following subquery returns information about all Connecticut-based customers who bought items through either stores or online sales channel and whose purchases amounted to more than 500 dollars:

=> SELECT DISTINCT customer_key, customer_name FROM public.customer_dimension
WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact
WHERE sales_dollar_amount > 500
UNION ALL
SELECT customer_key FROM online_sales.online_sales_fact
WHERE sales_dollar_amount > 500)
AND customer_state = 'CT';

customer_key | customer_name
------------------------
200 | Carla Y. Kramer
733 | Mary Z. Vogel
931 | Lauren X. Roy
1533 | James C. Vu
2948 | Infocare
4999 | Matt Z. Winkler
5311 | John Z. Goldberg
5520 | Laura M. Martin
5623 | Daniel R. Kramer
6759 | Daniel Q. Nguyen
...
**HAVING Clause Subqueries**

A HAVING clause is used in conjunction with the GROUP BY clause to filter the select-list records that a GROUP BY returns. HAVING clause subqueries must use Boolean comparison operators: =, >, <, <=, >= and take the following form:

```
SELECT <column, ...>
FROM <table>
GROUP BY <expression>
HAVING <expression>
(SELECT <column, ...>
FROM <table>
HAVING <expression>);
```

For example, the following statement uses the **VMart** database and returns the number of customers who purchased lowfat products. Note that the GROUP BY clause is required because the query uses an aggregate (COUNT).

```
=> SELECT s.product_key, COUNT(s.customer_key) FROM store.store_sales_fact s
    GROUP BY s.product_key HAVING s.product_key IN
    (SELECT product_key FROM product_dimension WHERE diet_type = 'Low Fat');
```

The subquery first returns the product keys for all low-fat products, and the outer query then counts the total number of customers who purchased those products.

<table>
<thead>
<tr>
<th>product_key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>2</td>
</tr>
<tr>
<td>41</td>
<td>1</td>
</tr>
<tr>
<td>66</td>
<td>1</td>
</tr>
<tr>
<td>106</td>
<td>1</td>
</tr>
<tr>
<td>118</td>
<td>1</td>
</tr>
<tr>
<td>169</td>
<td>1</td>
</tr>
<tr>
<td>181</td>
<td>2</td>
</tr>
<tr>
<td>184</td>
<td>2</td>

**Subquery Restrictions**

The following restrictions apply to Vertica subqueries:
• Subqueries are not allowed in the defining query of a `CREATE PROJECTION` statement.
• Subqueries can be used in the `SELECT` list, but GROUP BY or aggregate functions are not allowed in the query if the subquery is not part of the GROUP BY clause in the containing query. For example, the following two statement returns an error message:

```sql
=> SELECT y, (SELECT MAX(a) FROM t1) FROM t2 GROUP BY y;
ERROR: subqueries in the SELECT or ORDER BY are not supported if the subquery is not part of the GROUP BY
=> SELECT MAX(y), (SELECT MAX(a) FROM t1) FROM t2;
ERROR: subqueries in the SELECT or ORDER BY are not supported if the query has aggregates and the subquery is not part of the GROUP BY
```

• Subqueries are supported within UPDATE statements with the following exceptions:
  • You cannot use `SET column = {expression}` to specify a subquery.
  • The table specified in the UPDATE list cannot also appear in the FROM clause (no self joins).
  • FROM clause subqueries require an alias but tables do not. If the table has no alias, the query must refer its columns as `table-name.column-name`. However, column names that are unique among all tables in the query do not need to be qualified by their table name.
  • If the ORDER BY clause is inside a FROM clause subquery, rather than in the containing query, the query is liable to return unexpected sort results. This occurs because Vertica data comes from multiple nodes, so sort order cannot be guaranteed unless the outer query block specifies an ORDER BY clause. This behavior complies with the SQL standard, but it might differ from other databases.
  • Multicolumn subqueries cannot use the `<, >, <=, >=` comparison operators. They can use `<, >, !=, and = operators.
  • WHERE and HAVING clause subqueries must use Boolean comparison operators: `=, >, <, <=, >=`. Those subqueries can be noncorrelated and correlated.
  • `[NOT] IN and ANY subqueries nested in another expression are not supported if any of the column values are NULL. In the following statement, for example, if column `x` from either table `t1` or `t2` contains a NULL value, Vertica returns a run-time error:

```sql
=> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;
ERROR: NULL value found in a column used by a subquery
```

• Vertica returns an error message during subquery run time on scalar subqueries that return more than one row.
• Aggregates and GROUP BY clauses are allowed in subqueries, as long as those subqueries are not correlated.
• Correlated expressions under ALL and `[NOT] IN are not supported.
• Correlated expressions under OR are not supported.
Multiple correlations are allowed only for subqueries that are joined with an equality (=) predicate. However, IN/NOT IN, EXISTS/NOT EXISTS predicates within correlated subqueries are not allowed:

```sql
=> SELECT t2.x, t2.y, t2.z FROM t2 WHERE t2.z NOT IN
   (SELECT t1.z FROM t1 WHERE t1.x = t2.x);
ERROR: Correlated subquery with NOT IN is not supported
```

Up to one level of correlated subqueries is allowed in the WHERE clause if the subquery references columns in the immediate outer query block. For example, the following query is not supported because the \( t2.x = t3.x \) subquery can only refer to table \( t1 \) in the outer query, making it a correlated expression because \( t3.x \) is two levels out:

```sql
=> SELECT t3.x, t3.y, t3.z FROM t3 WHERE t3.z IN (
     SELECT t1.z FROM t1 WHERE EXISTS (
         SELECT 'x' FROM t2 WHERE t2.x = t3.x AND t1.x = t3.x);
ERROR: More than one level correlated subqueries are not supported
```

The query is supported if it is rewritten as follows:

```sql
=> SELECT t3.x, t3.y, t3.z FROM t3 WHERE t3.z IN
   (SELECT t1.z FROM t1 WHERE EXISTS
     (SELECT 'x' FROM t2 WHERE t2.x = t1.x)
    AND t1.x = t3.x);
```
Joins

Queries can combine records from multiple tables, or multiple instances of the same table. A query that combines records from one or more tables is called a join. Joins are allowed in SELECT statements and subqueries.

Supported Join Types

Vertica supports the following join types:

- Inner (including natural, cross) joins
- Left, right, and full outer joins
- Optimizations for equality and range joins predicates

Vertica does not support nested loop joins.

Join Algorithms

Vertica's query optimizer implements joins with either the hash join or merge join algorithm. For details, see Hash Joins Versus Merge Joins.

Join Syntax

Vertica supports the ANSI SQL-92 standard for joining tables, as follows:

```
table-reference [join-type] JOIN table-reference [ ON join-predicate ]
```

where `join-type` can be one of the following:

- **INNER** (default)
- **LEFT** [ OUTER ]
- **RIGHT** [ OUTER ]
- **FULL** [ OUTER ]
- **NATURAL**
- **CROSS**
For example:

```sql
=> SELECT * FROM T1 INNER JOIN T2 ON T1.id = T2.id;
```

**Note:**
The ON join-predicate clause is invalid for NATURAL and CROSS joins, required for all other join types.

### Alternative Syntax Options

Vertica also supports two older join syntax conventions:

**Join specified by WHERE clause join predicate**

INNER JOIN is equivalent to a query that specifies its join predicate in a WHERE clause. For example, this example and the previous one return equivalent results. They both specify an inner join between tables T1 and T2 on columns T1.id and T2.id, respectively.

```sql
=> SELECT * FROM T1, T2 WHERE T1.id = T2.id;
```

**Join specified by USING clause**

You can join two tables on identically named columns in a USING clause. For example:

```sql
=> SELECT * FROM T1 INNER JOIN T2 USING(id);
```

The INNER keyword is optional; a join that is specified by a USING clause is always an inner join. Thus, this example and the previous ones return equivalent results.

### Benefits of SQL-92 Join Syntax

Vertica recommends that you use SQL-92 join syntax for several reasons:

- SQL-92 outer join syntax is portable across databases; the older syntax was not consistent between databases.
- SQL-92 syntax provides greater control over whether predicates are evaluated during or after outer joins. This was also not consistent between databases when using the older syntax.
- SQL-92 syntax eliminates ambiguity in the order of evaluating the joins, in cases where more than two tables are joined with outer joins.
Join Conditions vs. Filter Conditions

If you do not use the SQL-92 syntax, join conditions (predicates that are evaluated during the join) are difficult to distinguish from filter conditions (predicates that are evaluated after the join), and in some cases cannot be expressed at all. With SQL-92, join conditions and filter conditions are separated into two different clauses, the ON clause and the WHERE clause, respectively, making queries easier to understand.

- **The ON clause** contains relational operators (for example, <, <=, >, >=, <>, =, <=>) or other predicates that specify which records from the left and right input relations to combine, such as by matching foreign keys to primary keys. ON can be used with inner, left outer, right outer, and full outer joins. Cross joins and union joins do not use an ON clause.

  Inner joins return all pairings of rows from the left and right relations for which the ON clause evaluates to TRUE. In a left join, all rows from the left relation in the join are present in the result; any row of the left relation that does not match any rows in the right relation is still present in the result but with nulls in any columns taken from the right relation. Similarly, a right join preserves all rows from the right relation, and a full join retains all rows from both relations.

- **The WHERE clause** is evaluated after the join is performed. It filters records returned by the FROM clause, eliminating any records that do not satisfy the WHERE clause condition.

Vertica automatically converts outer joins to inner joins in cases where it is correct to do so, allowing the optimizer to choose among a wider set of query plans and leading to better performance.
**Inner Joins**

An inner join combines records from two tables based on a join predicate and requires that each record in the first table has a matching record in the second table. Thus, inner joins return only records from both joined tables that satisfy the join condition. Records that contain no matches are excluded from the result set.

Inner joins take the following form:

```sql
SELECT column-list FROM left-join-table
[INNER] JOIN right-join-table ON join-predicate
```

If you omit the INNER keyword, Vertica assumes an inner join. Inner joins are commutative and associative. You can specify tables in any order without changing the results.

**Example**

The following example specifies an inner join between tables `store.store_dimension` and `public.employee_dimension` whose records have matching values in columns `store_region` and `employee_region`, respectively:

```sql
=> SELECT s.store_region, SUM(e.vacation_days) TotalVacationDays
FROM public.employee_dimension e, store.store_dimension s
WHERE s.store_region=e.employee_region
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

This join can also be expressed as follows:

```sql
=> SELECT s.store_region, SUM(e.vacation_days) TotalVacationDays
FROM public.employee_dimension e, store.store_dimension s
WHERE s.store_region=e.employee_region
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

Both queries return the same result set:

<table>
<thead>
<tr>
<th>store_region</th>
<th>TotalVacationDays</th>
</tr>
</thead>
<tbody>
<tr>
<td>NorthWest</td>
<td>23280</td>
</tr>
<tr>
<td>Southwest</td>
<td>367250</td>
</tr>
<tr>
<td>Midwest</td>
<td>925938</td>
</tr>
<tr>
<td>South</td>
<td>1288468</td>
</tr>
<tr>
<td>East</td>
<td>1952854</td>
</tr>
<tr>
<td>West</td>
<td>2849976</td>
</tr>
</tbody>
</table>

(6 rows)
If the join's inner table store.store_dimension has any rows with store_region values that do not match employee_region values in table public.employee_dimension, those rows are excluded from the result set. To include that row, you can specify an outer join.

**Equi-Joins and Non Equi-Joins**

Vertica supports any arbitrary join expression with both matching and non-matching column values. For example:

```sql
SELECT * FROM Fact JOIN dim ON fact.x = dim.x;
SELECT * FROM Fact JOIN dim ON fact.x > dim.y;
SELECT * FROM Fact JOIN dim ON fact.x <= dim.y;
SELECT * FROM Fact JOIN dim ON fact.x <> dim.y;
SELECT * FROM Fact JOIN dim ON fact.x <=> dim.y;
```

**Note:**
Operators = and <=> generally run the fastest.

Equi-joins are based on equality (matching column values). This equality is indicated with an equal sign (=), which functions as the comparison operator in the ON clause using SQL-92 syntax or the WHERE clause using older join syntax.

The first example below uses SQL-92 syntax and the ON clause to join the online sales table with the call center table using the call center key; the query then returns the sale date key that equals the value 156:

```sql
=> SELECT sale_date_key, cc_open_date FROM online_sales.online_sales_fact
   INNER JOIN online_sales.call_center_dimension
   ON online_sales.online_sales_fact.call_center_key =
   online_sales.call_center_dimension.call_center_key
   AND sale_date_key = 156);
sale_date_key | cc_open_date
--------------+------------------
156 | 2005-08-12
(1 row)
```

The second example uses older join syntax and the WHERE clause to join the same tables to get the same results:

```sql
=> SELECT sale_date_key, cc_open_date
   FROM online_sales.online_sales_fact, online_sales.call_center_dimension
   WHERE online_sales.online_sales_fact.call_center_key =
   online_sales.call_center_dimension.call_center_key
   AND sale_date_key = 156;
sale_date_key | cc_open_date
--------------+------------------
156 | 2005-08-12
```
Vertica also permits tables with compound (multiple-column) primary and foreign keys. For example, to create a pair of tables with multi-column keys:

```sql
cREATE TABLE dimension(pk1 INTEGER NOT NULL, pk2 INTEGER NOT NULL);
ALTER TABLE dimension ADD PRIMARY KEY (pk1, pk2);
cREATE TABLE fact (fk1 INTEGER NOT NULL, fk2 INTEGER NOT NULL);
ALTER TABLE fact ADD FOREIGN KEY (fk1, fk2) REFERENCES dimension (pk1, pk2);
```

To join tables using compound keys, you must connect two join predicates with a Boolean AND operator. For example:

```sql
SELECT * FROM fact f JOIN dimension d ON f.fk1 = d.pk1 AND f.fk2 = d.pk2;
```

You can write queries with expressions that contain the `<=>` operator for NULL=NULL joins.

```sql
SELECT * FROM fact JOIN dim ON fact.x <=> dim.y;
```

The `<=>` operator performs an equality comparison like the `=` operator, but it returns true, instead of NULL, if both operands are NULL, and false, instead of NULL, if one operand is NULL.

```sql
SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
```

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>t</td>
<td>f</td>
</tr>
</tbody>
</table>

(1 row)

Compare the `<=>` operator to the `=` operator:

```sql
SELECT 1 = 1, NULL = NULL, 1 = NULL;
```

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>t</td>
<td></td>
</tr>
</tbody>
</table>

(1 row)

**Note:**

Writing NULL=NULL joins on primary key/foreign key combinations is not an optimal choice because PK/FK columns are usually defined as NOT NULL.

When composing joins, it helps to know in advance which columns contain null values. An employee's hire date, for example, would not be a good choice because it is unlikely hire date would be omitted. An hourly rate column, however, might work if some employees are paid hourly and some are salaried. If you are unsure about the value of columns in a given table and want to check, type the command:
Natural Joins

A natural join is just a join with an implicit join predicate. Natural joins can be inner, left outer, right outer, or full outer joins and take the following form:

```
SELECT column-list FROM left-join-table
NATURAL [ INNER | LEFT OUTER | RIGHT OUTER | FULL OUTER ] JOIN right-join-table
```

Natural joins are, by default, natural inner joins; however, there can also be natural left/right/full outer joins. The primary difference between an inner and natural join is that inner joins have an explicit join condition, whereas the natural join’s conditions are formed by matching all pairs of columns in the tables that have the same name and compatible data types, making natural joins equi-joins because join condition are equal between common columns. (If the data types are incompatible, Vertica returns an error.)

**Note:**
The Data Type Coercion Chart lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

The following query is a simple natural join between tables T1 and T2 when the T2 column `val` is greater than 5:

```
=> SELECT * FROM T1 NATURAL JOIN T2 WHERE T2.val > 5;
```

The `store_sales_fact` table and the `product_dimension` table have two columns that share the same name and data type: `product_key` and `product_version`. The following example creates a natural join between those two tables at their shared columns:

```
=> SELECT product_description, sales_quantity FROM store.store_sales_fact
   NATURAL JOIN public.product_dimension;
```

The following three queries return the same result expressed as a basic query, an inner join, and a natural join. At the table expressions are equivalent only if the common attribute in the `store_sales_fact` table and the `store_dimension` table is `store_key`. If both tables have a column named `store_key`, then the natural join would also have a `store_sales_fact.store_key = store_dimension.store_key` join condition. Since the results are the same in all three instances, they are shown in the first (basic) query only:
The query written as an inner join:

```sql
=> SELECT store_name FROM store.store_sales_fact
    INNER JOIN store.store_dimension
    ON (store.store_sales_fact.store_key = store.store_dimension.store_key)
    WHERE store.store_dimension.store_state = 'MA' ORDER BY store_name;
```

In the case of the natural join, the join predicate appears implicitly by comparing all of the columns in both tables that are joined by the same column name. The result set contains only one column representing the pair of equally-named columns.

```sql
=> SELECT store_name FROM store.store_sales_fact
    NATURAL JOIN store.store_dimension
    WHERE store.store_dimension.store_state = 'MA' ORDER BY store_name;
```

### Cross Joins

Cross joins are the simplest joins to write, but they are not usually the fastest to run because they consist of all possible combinations of two tables' records. Cross joins contain no join condition and return what is known as a Cartesian product, where the number of rows in the result set is equal to the number of rows in the first table multiplied by the number of rows in the second table.

The following query returns all possible combinations from the promotion table and the store sales table:

```sql
=> SELECT * FROM promotion_dimension CROSS JOIN store.store_sales_fact;
```

Because this example returns over 600 million records, many cross join results can be extremely large and difficult to manage. Cross joins can be useful, however, such as when you want to return a single-row result set.
**Tip:**
Filter out unwanted records in a cross with `WHERE` clause join predicates:

```sql
=> SELECT * FROM promotion_dimension p  CROSS JOIN store.store_sales_fact f
    WHERE p.promotion_key LIKE f.promotion_key;
```

**Implicit versus Explicit Joins**

Vertica recommends that you do not write implicit cross joins (comma-separated tables in the `FROM` clause). These queries can imply accidental omission of a join predicate.

The following query implicitly cross joins tables `promotion_dimension` and `store.store_sales_fact`:

```sql
=> SELECT * FROM promotion_dimension, store.store_sales_fact;
```

It is better practice to express this cross join explicitly, as follows:

```sql
=> SELECT * FROM promotion_dimension CROSS JOIN store.store_sales_fact;
```

**Examples**

The following example creates two small tables and their superprojections and then runs a cross join on the tables:

```sql
=> CREATE TABLE employee(employee_id INT, employee_f_name VARCHAR(50));
=> CREATE TABLE department(dept_id INT, dept_name VARCHAR(50));
=> INSERT INTO employee VALUES (1, 'Andrew');
=> INSERT INTO employee VALUES (2, 'Priya');
=> INSERT INTO employee VALUES (3, 'Michelle');
=> INSERT INTO department VALUES (1, 'Engineering');
=> INSERT INTO department VALUES (2, 'QA');
=> SELECT * FROM employee CROSS JOIN department;
```

In the result set, the cross join retrieves records from the first table and then creates a new row for every row in the 2nd table. It then does the same for the next record in the first table, and so on.

<table>
<thead>
<tr>
<th>employee_id</th>
<th>employee_name</th>
<th>dept_id</th>
<th>dept_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andrew</td>
<td>1</td>
<td>Engineering</td>
</tr>
<tr>
<td>2</td>
<td>Priya</td>
<td>1</td>
<td>Engineering</td>
</tr>
<tr>
<td>3</td>
<td>Michelle</td>
<td>1</td>
<td>Engineering</td>
</tr>
<tr>
<td>1</td>
<td>Andrew</td>
<td>2</td>
<td>QA</td>
</tr>
<tr>
<td>2</td>
<td>Priya</td>
<td>2</td>
<td>QA</td>
</tr>
</tbody>
</table>
Outer Joins

Outer joins extend the functionality of inner joins by letting you preserve rows of one or both tables that do not have matching rows in the non-preserved table. Outer joins take the following form:

\[
\text{SELECT column-list FROM left-join-table} \\
[ \text{LEFT | RIGHT | FULL } ] \text{ OUTER JOIN right-join-table ON join-predicate}
\]

**Note:**
Omitting the keyword OUTER from your statements does not affect results of left and right joins. LEFT OUTER JOIN and LEFT JOIN perform the same operation and return the same results.

**Left Outer Joins**

A left outer join returns a complete set of records from the left-joined (preserved) table T1, with matched records, where available, in the right-joined (non-preserved) table T2. Where Vertica finds no match, it extends the right side column (T2) with null values.

\[
\text{=> SELECT * FROM T1 LEFT OUTER JOIN T2 ON T1.x = T2.x;}
\]

To exclude the non-matched values from T2, write the same left outer join, but filter out the records you don't want from the right side by using a WHERE clause:

\[
\text{=> SELECT * FROM T1 LEFT OUTER JOIN T2} \\
\text{ ON T1.x = T2.x WHERE T2.x IS NOT NULL;}
\]

The following example uses a left outer join to enrich telephone call detail records with an incomplete numbers dimension. It then filters out results that are known not to be from Massachusetts:

\[
\text{=> SELECT COUNT(*) FROM calls LEFT OUTER JOIN numbers} \\
\text{ ON calls.to_phone = numbers.phone WHERE NVL(numbers.state, '') <> 'MA';}
\]
**Right Outer Joins**

A right outer join returns a complete set of records from the right-joined (preserved) table, as well as matched values from the left-joined (non-preserved) table. If Vertica finds no matching records from the left-joined table (T1), NULL values appear in the T1 column for any records with no matching values in T1. A right join is, therefore, similar to a left join, except that the treatment of the tables is reversed.

=> SELECT * FROM T1 RIGHT OUTER JOIN T2 ON T1.x = T2.x;

The above query is equivalent to the following query, where T1 RIGHT OUTER JOIN T2 = T2 LEFT OUTER JOIN T1.

=> SELECT * FROM T2 LEFT OUTER JOIN T1 ON T2.x = T1.x;

The following example identifies customers who have *not* placed an order:

=> SELECT customers.customer_id FROM orders RIGHT OUTER JOIN customers ON orders.customer_id = customers.customer_id GROUP BY customers.customer_id HAVING COUNT(orders.customer_id) = 0;

**Full Outer Joins**

A full outer join returns results for both left and right outer joins. The joined table contains all records from both tables, including nulls (missing matches) from either side of the join. This is useful if you want to see, for example, each employee who is assigned to a particular department and each department that has an employee, but you also want to see all the employees who are not assigned to a particular department, as well as any department that has no employees:

=> SELECT employee_last_name, hire_date FROM employee_dimension emp
   FULL OUTER JOIN department dept ON emp.employee_key = dept.department_key;

**Notes**

Vertica also supports joins where the outer (preserved) table or subquery is replicated on more than one node and the inner (non-preserved) table or subquery is segmented across
more than one node. For example, in the following query, the fact table, which is almost always segmented, appears on the non-preserved side of the join, and it is allowed:

```sql
=> SELECT sales_dollar_amount, transaction_type, customer_name
    FROM store.store_sales_fact f RIGHT JOIN customer_dimension d
    ON f.customer_key = d.customer_key;

<table>
<thead>
<tr>
<th>sales_dollar_amount</th>
<th>transaction_type</th>
<th>customer_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>252</td>
<td>purchase</td>
<td>Inistar</td>
</tr>
<tr>
<td>363</td>
<td>purchase</td>
<td>Inistar</td>
</tr>
<tr>
<td>510</td>
<td>purchase</td>
<td>Inistar</td>
</tr>
<tr>
<td>-276</td>
<td>return</td>
<td>Foodcorp</td>
</tr>
<tr>
<td>252</td>
<td>purchase</td>
<td>Foodcorp</td>
</tr>
<tr>
<td>195</td>
<td>purchase</td>
<td>Foodcorp</td>
</tr>
<tr>
<td>290</td>
<td>purchase</td>
<td>Foodcorp</td>
</tr>
<tr>
<td>222</td>
<td>purchase</td>
<td>Foodcorp</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Foodgen</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Goldcare</td>
</tr>
</tbody>
</table>

(10 rows)
```

**Controlling Join Inputs**

By default, the optimizer uses its own internal logic to determine whether to join one table to another as an inner or outer input. Occasionally, the optimizer might choose the larger table as the inner input to a join. Doing so can incur performance and concurrency issues.

If the configuration parameter `EnableForceOuter` is set to 1, you can control join inputs for specific tables through `ALTER_TABLE..FORCE_OUTER`. The `FORCE OUTER` option modifies a table's `force_outer` setting in the system table `TABLES`. When implementing a join, Vertica compares the `force_outer` settings of the participating tables:

- If table settings are unequal, Vertica uses them to set the join inputs:
  - A table with a low `force_outer` setting relative to other tables is joined to them as an inner input.
  - A table with a high `force_outer` setting relative to other tables is joined to them as an outer input.
- If all table settings are equal, Vertica ignores them and assembles the join on its own.

The `force_outer` column is initially set to 5 for all newly-defined tables. You can use `ALTER_TABLE..FORCE_OUTER` to reset `force_outer` to a value equal to or greater than 0. For example, you might change the `force_outer` settings of tables `abc` and `xyz` to 3 and 8, respectively:

```sql
=> ALTER TABLE abc FORCE OUTER 3;
=> ALTER TABLE xyz FORCE OUTER 8;
```
Given these settings, the optimizer joins abc as the inner input to any table with a force_outer value greater than 3. The optimizer joins xyz as the outer input to any table with a force_outer value less than 8.

Projection Inheritance

When you query a projection directly, it inherits the force_outer setting of its anchor table. The query then uses this setting when joined to another projection.

Enabling Forced Join Inputs

The configuration parameter EnableForceOuter determines whether Vertica uses a table's force_outer value to implement a join. By default, this parameter is set to 0, and forced join inputs are disabled. You can enable forced join inputs at session and database scopes, through ALTER SESSION and ALTER DATABASE, respectively:

```sql
=> ALTER SESSION SET EnableForceOuter = { 0 | 1 };
=> ALTER DATABASE db-name SET EnableForceOuter = { 0 | 1 };
```

If EnableForceOuter is set to 0, ALTER TABLE..FORCE OUTER statements return with this warning:

```
WARNING 0: Set configuration parameter EnableForceOuter for the current session or the database in order to use force_outer value
```

Viewing Forced Join Inputs

EXPLAIN-generated query plans indicate whether the configuration parameter EnableForceOuter is on. A join query might include tables whose force_outer settings are less or greater than the default value of 5. In this case, the query plan includes a Force outer level field for the relevant join inputs.

For example, the following query joins tables store.store_sales and public.products, where both tables have the same force_outer setting (5). EnableForceOuter is on, as indicated in the generated query plan:

```sql
=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
   FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
```
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;

EnableForceOuter is on
Access Path:
+--> OUTER -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
    |    Order: sales.store_key ASC, sales.sale_date ASC
    |    Execute on: All Nodes
    |    Inner to Outer Join Cond: (sales.product_key = products.product_key)
    |    Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
    |    Filter: (sales.sale_date = '2014-12-01'::date)
    |    Execute on: All Nodes

The following ALTER TABLE statement resets the force_outer setting of public.products to 1:

=> ALTER TABLE public.products FORCE OUTER 1;
ALTER TABLE

The regenerated query plan for the same join now includes a Force outer level field and specifies public.products as the inner input:

=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
    FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
    WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;

EnableForceOuter is on
Access Path:
+--> OUTER -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
    |    Order: sales.store_key ASC, sales.sale_date ASC
    |    Execute on: All Nodes
    |    Inner to Outer Join Cond: (sales.product_key = products.product_key)
    |    Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
    |    Filter: (sales.sale_date = '2014-12-01'::date)
    |    Execute on: All Nodes
    |    Force outer level: 1
    |    Materialize: products.product_key, products.product_description
    |    Execute on: All Nodes

If you change the force_outer setting of public.products to 8, Vertica creates a different query plan that specifies public.products as the outer input:
ALTER TABLE public.products FORCE OUTER 8;

EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;

Restrictions

Vertica ignores force_outer settings when it performs the following operations:

- Outer joins: Vertica generally respects OUTER JOIN clauses regardless of the force_outer settings of the joined tables.
- **MERGE** statement joins.
- Queries that include the **SYNTACTIC JOIN** hint.
- Half-join queries such as **SEMI JOIN**.
- Joins to subqueries, where the subquery is always processed as having a force_outer setting of 5 regardless of the force_outer settings of the tables that are joined in the subquery. This setting determines a subquery's designation as inner or outer input relative to other join inputs. If two subqueries are joined, the optimizer determines which one is the inner input, and which one the outer.

Range Joins

Vertica provides performance optimizations for <, <=, >, >=, and BETWEEN predicates in join ON clauses. These optimizations are particularly useful when a column from one table is
restricted to be in a range specified by two columns of another table.

**Key Ranges**

Multiple, consecutive key values can map to the same dimension values. Consider, for example, a table of IPv4 addresses and their owners. Because large subnets (ranges) of IP addresses can belong to the same owner, this dimension can be represented as:

```sql
=> CREATE TABLE ip_owners(
    ip_start INTEGER,
    ip_end INTEGER,
    owner_id INTEGER);
=> CREATE TABLE clicks(
    ip_owners INTEGER,
    dest_ip INTEGER);
```

A query that associates a click stream with its destination can use a join similar to the following, which takes advantage of range optimization:

```sql
=> SELECT owner_id, COUNT(*) FROM clicks JOIN ip_owners
    ON clicks.dest_ip BETWEEN ip_start AND ip_end
    GROUP BY owner_id;
```

**Requirements**

Operators <, <=, >, >=, or BETWEEN must appear as top-level conjunctive predicates for range join optimization to be effective, as shown in the following examples:

**BETWEEN as the only predicate:**

```sql
=> SELECT COUNT(*) FROM fact JOIN dim
    ON fact.point BETWEEN dim.start AND dim.end;
```

**Comparison operators as top-level predicates (within AND):**

```sql
=> SELECT COUNT(*) FROM fact JOIN dim
    ON fact.point > dim.start AND fact.point < dim.end;
```

**BETWEEN as a top-level predicate (within AND):**

```sql
=> SELECT COUNT(*) FROM fact JOIN dim
    ON (fact.point BETWEEN dim.start AND dim.end) AND fact.c <> dim.c;
```

Query not optimized because OR is top-level predicate (disjunctive):
```
SELECT COUNT(*) FROM fact JOIN dim 
ON (fact.point BETWEEN dim.start AND dim.end) OR dim.end IS NULL;
```

**Notes**

- Expressions are optimized in range join queries in many cases.
- If range columns can have NULL values indicating that they are open-ended, it is possible to use range join optimizations by replacing nulls with very large or very small values:

  ```
  SELECT COUNT(*) FROM fact JOIN dim 
  ON fact.point BETWEEN NVL(dim.start, -1) AND NVL(dim.end, 1000000000000);
  ```

- If there is more than one set of ranging predicates in the same `ON` clause, the order in which the predicates are specified might impact the effectiveness of the optimization:

  ```
  SELECT COUNT(*) FROM fact JOIN dim ON fact.point1 BETWEEN dim.start1 AND dim.end1 
  AND fact.point2 BETWEEN dim.start2 AND dim.end2;
  ```

  The optimizer chooses the first range to optimize, so write your queries so that the range you most want optimized appears first in the statement.

- The use of the range join optimization is not directly affected by any characteristics of the physical schema; no schema tuning is required to benefit from the optimization.
- The range join optimization can be applied to joins without any other predicates, and to `HASH` or `MERGE` joins.

  - To determine if an optimization is in use, search for `RANGE` in the `EXPLAIN` plan.

**Event Series Joins**

An **event series** join is a Vertica SQL extension that enables the analysis of two series when their measurement intervals don’t align precisely, such as with mismatched timestamps. You can compare values from the two series directly, rather than having to normalize the series to the same measurement interval.

Event series joins are an extension of **Outer Joins**, but instead of padding the non-preserved side with NULL values when there is no match, the event series join pads the non-preserved side values that it interpolates from the previous value.
The difference in how you write a regular join versus an event series join is the INTERPOLATE predicate, which is used in the ON clause. For example, the following two statements show the differences, which are shown in greater detail in Writing Event Series Joins.

<table>
<thead>
<tr>
<th>Regular full outer join</th>
<th>Event series join</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time = a.time);</td>
<td>SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time INTERPOLATE PREVIOUS VALUE a.time);</td>
</tr>
</tbody>
</table>

Similar to regular joins, an event series join has inner and outer join modes, which are described in the topics that follow.

For full syntax, including notes and restrictions, see INTERPOLATE in the SQL Reference Manual

**Sample Schema for Event Series Joins Examples**

If you don't plan to run the queries and just want to look at the examples, you can skip this topic and move straight to Writing Event Series Joins.

**Schema of hTicks and aTicks Tables**

The examples that follow use the following hTicks and aTicks tables schemas:

```sql
CREATE TABLE hTicks (  
    stock VARCHAR(20),  
    time TIME,  
    price NUMERIC(8,2)  
);  
CREATE TABLE aTicks (  
    stock VARCHAR(20),  
    time TIME,  
    price NUMERIC(8,2)  
);  
```

Although TIMESTAMP is more commonly used for the event series column, the examples in this topic use TIME to keep the output simple.

```sql
INSERT INTO hTicks VALUES ('HPQ', '12:00', 50.00);  
INSERT INTO hTicks VALUES ('HPQ', '12:01', 51.00);  
INSERT INTO hTicks VALUES ('HPQ', '12:05', 51.00);  
INSERT INTO hTicks VALUES ('HPQ', '12:06', 52.00);  
INSERT INTO aTicks VALUES ('ACME', '12:00', 340.00);  
```
Output of the two tables:

**hTicks**

```
=> SELECT * FROM hTicks;

There are no entry records between 12:02–12:04:

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>50.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>51.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
<td>51.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:06:00</td>
<td>52.00</td>
</tr>
</tbody>
</table>
(4 rows)
```

**aTicks**

```
=> SELECT * FROM aTicks;

There are no entry records at 12:01, 12:02 and at 12:04:

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>340.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:03:00</td>
<td>340.10</td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>340.20</td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>333.80</td>
</tr>
</tbody>
</table>
(4 rows)
```

**Example Query Showing Gaps**

A full outer join shows the gaps in the timestamps:

```
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON h.time = a.time;

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>50.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>51.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
<td>51.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:06:00</td>
<td>52.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>340.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:03:00</td>
<td>340.10</td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>340.20</td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>333.80</td>
</tr>
</tbody>
</table>
(6 rows)
```

**Schema of Bid and Asks Tables**

The examples that follow use the following hTicks and aTicks tables.

```sql
CREATE TABLE bid(stock VARCHAR(20), time TIME, price NUMERIC(8,2));
CREATE TABLE ask(stock VARCHAR(20), time TIME, price NUMERIC(8,2));
INSERT INTO bid VALUES ('HPQ', '12:00', 100.10);
INSERT INTO bid VALUES ('HPQ', '12:01', 100.00);
INSERT INTO bid VALUES ('ACME', '12:00', 80.00);
INSERT INTO bid VALUES ('ACME', '12:03', 79.80);
```
Output of the two tables:

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>100.10</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>100.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:03:00</td>
<td>79.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>79.90</td>
</tr>
</tbody>
</table>
(5 rows)

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>101.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
</tbody>
</table>
(3 rows)

Example Query Showing Gaps

A full outer join shows the gaps in the timestamps:

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>100.10</td>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>100.00</td>
<td>HPQ</td>
<td>12:01:00</td>
<td>101.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:03:00</td>
<td>79.80</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>79.90</td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
</tbody>
</table>
(6 rows)

Writing Event Series Joins

The examples in this topic contain mismatches between timestamps—just as you’d find in real life situations; for example, there could be a period of inactivity on stocks where no trade occurs, which can present challenges when you want to compare two stocks whose timestamps don’t match.
The hTicks and aTicks Tables

As described in the example ticks schema, tables hTicks is missing input rows for 12:02, 12:03, and 12:04, and aTicks is missing inputs at 12:01, 12:02, and 12:04.

<table>
<thead>
<tr>
<th>hTicks</th>
<th>aTicks</th>
</tr>
</thead>
<tbody>
<tr>
<td>=&gt; SELECT * FROM hTicks;</td>
<td>=&gt; SELECT * FROM aTicks;</td>
</tr>
<tr>
<td>stock</td>
<td>time</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:06:00</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>(4 rows)</td>
<td></td>
</tr>
</tbody>
</table>

Querying Event Series Data with Full Outer Joins

Using a traditional full outer join, this query finds a match between tables hTicks and aTicks at 12:00 and 12:05 and pads the missing data points with NULL values.

```sql
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time = a.time);
stock | time | price     | stock | time | price     |
HPQ   | 12:00:00 | 50.00   | ACME  | 12:00:00 | 340.00   |
HPQ   | 12:01:00 | 51.00   | ACME  | 12:03:00 | 340.10   |
HPQ   | 12:05:00 | 51.00   | ACME  | 12:05:00 | 340.20   |
HPQ   | 12:06:00 | 52.00   | ACME  | 12:05:00 | 333.80   |
|       |          |         |       |          |          |
(6 rows)
```

To replace the gaps with interpolated values for those missing data points, use the INTERPOLATE predicate to create an event series join. The join condition is restricted to the ON clause, which evaluates the equality predicate on the timestamp columns from the two input tables. In other words, for each row in outer table hTicks, the ON clause predicates are evaluated for each combination of each row in the inner table aTicks.

Simply rewrite the full outer join query to use the INTERPOLATE predicate with the required PREVIOUS VALUE keywords. Note that a full outer join on event series data is the most common scenario for event series data, where you keep all rows from both tables

```sql
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
```
Vertica interpolates the missing values (which appear as NULL in the full outer join) using that table's previous value:

![Table diagram](image)

**Note:**
The output ordering above is different from the regular full outer join because in the event series join, interpolation occurs independently for each stock (hTicks and aTicks), where the data is partitioned and sorted based on the equality predicate. This means that interpolation occurs within, not across, partitions.

If you review the regular full outer join output, you can see that both tables have a match in the time column at 12:00 and 12:05, but at 12:01, there is no entry record for ACME. So the operation interpolates a value for ACME (ACME, 12:00, 340) based on the previous value in the aTicks table.

### Querying Event Series Data with Left Outer Joins

You can also use left and right outer joins. You might, for example, decide you want to preserve only hTicks values. So you'd write a left outer join:

```sql
=> SELECT * FROM hTicks h LEFT OUTER JOIN aTicks a
   ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
```

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>50.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>340.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>51.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>340.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
<td>51.00</td>
<td>ACME</td>
<td>12:05:00</td>
<td>333.80</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
<td>51.00</td>
<td>ACME</td>
<td>12:05:00</td>
<td>340.20</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:06:00</td>
<td>52.00</td>
<td>ACME</td>
<td>12:05:00</td>
<td>340.20</td>
</tr>
</tbody>
</table>

(5 rows)

Here's what the same data looks like using a traditional left outer join:
Note that a right outer join has the same behavior with the preserved table reversed.

**Querying Event Series Data with Inner Joins**

Note that INNER event series joins behave the same way as normal ANSI SQL-99 joins, where all gaps are omitted. Thus, there is nothing to interpolate, and the following two queries are equivalent and return the same result set:

A regular inner join:

```sql
=> SELECT * FROM hTicks h LEFT OUTER JOIN aTicks a ON h.time = a.time;
stock | time | price | stock | time | price
-------+-------+-------+-------+-------+-------
HPQ   | 12:00:00 | 50.00 | ACME  | 12:00:00 | 340.00
HPQ   | 12:01:00 | 51.00 |       |         |       
HPQ   | 12:05:00 | 51.00 | ACME  | 12:05:00 | 333.80
HPQ   | 12:05:00 | 51.00 | ACME  | 12:05:00 | 340.20
HPQ   | 12:06:00 | 52.00 |       |         |       
(5 rows)
```

An event series inner join:

```sql
=> SELECT * FROM hTicks h INNER JOIN aTicks a ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
stock | time | price | stock | time | price
-------+-------+-------+-------+-------+-------
HPQ   | 12:00:00 | 50.00 | ACME  | 12:00:00 | 340.00
HPQ   | 12:05:00 | 51.00 | ACME  | 12:05:00 | 333.80
HPQ   | 12:05:00 | 51.00 | ACME  | 12:05:00 | 340.20
(3 rows)
```

**The Bid and Ask Tables**

Using the example schema for the bid and ask tables, write a full outer join to interpolate the missing data points:

```sql
=> SELECT * FROM bid b FULL OUTER JOIN ask a
 ON (b.stock = a.stock AND b.time INTERPOLATE PREVIOUS VALUE a.time);
```
In the below output, the first row for stock HPQ shows nulls because there is no entry record for HPQ before 12:01.

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:03:00</td>
<td>79.80</td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>79.90</td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>100.10</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>100.00</td>
<td>HPQ</td>
<td>12:01:00</td>
<td>101.00</td>
</tr>
</tbody>
</table>

(6 rows)

Note also that the same row (ACME, 12:02, 75) from the ask table appears three times. The first appearance is because no matching rows are present in the bid table for the row in ask, so Vertica interpolates the missing value using the ACME value at 12:02 (75.00). The second appearance occurs because the row in bid (ACME, 12:05, 79.9) has no matches in ask. The row from ask that contains (ACME, 12:02, 75) is the closest row; thus, it is used to interpolate the values.

If you write a regular full outer join, you can see where the mismatched timestamps occur:

```sql
=> SELECT * FROM bid b FULL OUTER JOIN ask a ON (b.time = a.time);
```

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:03:00</td>
<td>79.80</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>79.90</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>100.10</td>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>100.00</td>
<td>HPQ</td>
<td>12:01:00</td>
<td>101.00</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
</tbody>
</table>

(6 rows)

**Query Optimization**

When you submit a query to Vertica for processing, the Vertica query optimizer automatically chooses a set of operations to compute the requested result. These operations together are called a *query plan*. The choice of operations can significantly affect how many resources are needed to compute query results, and overall run-time performance. Optimal performance depends in great part on the projections that are available for a given query.

This section describes the different operations that the optimizer uses and how you can facilitate optimizer performance.

**Note:**

Database response time depends on many factors. These include type and...
size of the application query, database design, data size and data types
stored, available computational power, and network bandwidth. Adding
nodes to a database cluster does not necessarily improve the system
response time for every query, especially if response times are already
short, or are not hardware bound.
Initial Process for Improving Query Performance

To optimize query performance, begin by performing the following tasks:

1. Run Database Designer.
2. Check query events proactively.
3. Review the query plan.

Run Database Designer

Database Designer creates a physical schema for your database that provides optimal query performance. The first time you run Database Designer, you should create a comprehensive design that includes relevant sample queries and data on which to base the design. If you develop performance issues later, consider loading additional queries that you run frequently and then rerunning Database Designer to create an incremental design.

When you run Database Designer, choose the option, Update Statistics. The Vertica query optimizer uses statistics about the data to create a query plan. Statistics help the optimizer determine:

- Multiple eligible projections to answer the query
- The best order in which to perform joins
- Data distribution algorithms, such as broadcast and resegmentation

If your statistics become out of date, run the Vertica function `ANALYZE_STATISTICS` function to update statistics for a schema, table, or columns. For more information, see Collecting Database Statistics.

Check Query Events Proactively

The `QUERY_EVENTS` system table returns information on query planning, optimization, and execution events.

The `EVENT_TYPE` column provides various event types:
• Some event types are informational.
• Others you should review for possible corrective action.
• Several are most important to address.

Review the Query Plan

A query plan is a sequence of step-like paths that the Vertica query optimizer selects to access or alter information in your Vertica database. There are two ways to get information about the query plan:

• Run the EXPLAIN command. Each step (path) represents a single operation that the optimizer uses for its execution strategy.
• Query the QUERY_PLAN_PROFILES system table. This table provides detailed execution status for currently running queries. Output from the QUERY_PLAN_PROFILES table shows the real-time flow of data and the time and resources consumed for each path in each query plan.

• QUERY_EVENTS
Column Encoding

You can potentially make queries faster by changing column encoding. Encoding reduces the on-disk size of your data so the amount of I/O required for queries is reduced, resulting in faster execution times. Make sure all columns and projections included in the query use the correct data encoding. To do this, take the following steps:

1. Run Database Designer to create an incremental design. Database Designer implements the optimum encoding and projection design.
2. After creating the incremental design, update statistics using the `ANALYZE_STATISTICS` function.
3. Run `EXPLAIN` with one or more of the queries you submitted to the design to make sure it is using the new projections.

Alternatively, run `DESIGNER_DESIGN_PROJECTION_ENCODINGS` to re-evaluate the current encoding and update it if necessary.

Improving Column Compression

If you see slow performance or a large storage footprint with your `FLOAT` data, evaluate the data and your business needs to see if it can be contained in a `NUMERIC` column with a precision of 18 digits or less. Converting a `FLOAT` column to a `NUMERIC` column can improve data compression, reduce the on-disk size of your database, and improve performance of queries on that column.

When you define a `NUMERIC` data type, you specify the precision and the scale; `NUMERIC` data are exact representations of data. `FLOAT` data types represent variable precision and approximate values; they take up more space in the database.

Converting `FLOAT` columns to `NUMERIC` columns is most effective when:

- **NUMERIC precision is 18 digits or less.** Performance of `NUMERIC` data is fine-tuned for the common case of 18 digits of precision. Vertica recommends converting `FLOAT` columns to `NUMERIC` columns only if they require precision of 18 digits or less.
- **FLOAT precision is bounded, and the values will all fall within a specified precision for a `NUMERIC` column.** One example is monetary values like product prices or financial transaction amounts. For example, a column defined as `NUMERIC(11,2)` can
accommodate prices from 0 to a few million dollars and can store cents, and compresses more efficiently than a FLOAT column.

If you try to load a value into a NUMERIC column that exceeds the specified precision, Vertica returns an error and does not load the data. If you assign a value with more decimal digits than the specified scale, the value is rounded to match the specified scale and stored in that column.

Numeric Data Types

Using Run Length Encoding

When you run Database Designer, you can choose to optimize for loads, which minimizes database footprint. In this case, Database Designer applies encodings to columns to maximize query performance. Encoding options include run length encoding (RLE), which replaces sequences (runs) of identical values in a column with a set of pairs, where each pair represents the number of contiguous occurrences for a given value: (occurrences, value).

RLE is generally applicable to a column with low-cardinality, and where identical values are contiguous—typically, because table data is sorted on that column. For example, a customer profile table typically includes a gender column that contains values of F and M only. Sorting on gender ensures runs of F or M values that can be expressed as a set of two pairs: (occurrences, F) and (occurrences, M). So, given 8,147 occurrences of F and 7,956 occurrences of M, and a projection that is sorted primarily on gender, Vertica can apply RLE and store these values as a single set of two pairs: (8147, F) and (7956, M). Doing so reduces this projection’s footprint and improves query performance.

Projections for Queries with Predicates

If your query contains one or more predicates, you can modify the projections to improve the query's performance, as described in the following two examples.
Queries That Use Date Ranges

This example shows how to encode data using RLE and change the projection sort order to improve the performance of a query that retrieves all data within a given date range.

Suppose you have a query that looks like this:

```sql
=> SELECT * FROM trades
   WHERE trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

To optimize this query, determine whether all of the projections can perform the SELECT operation in a timely manner. Run SELECT COUNT(*) statement for each projection, specifying the date range, and note the response time. For example:

```sql
=> SELECT COUNT(*) FROM [projection_name]
   WHERE trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

If one or more of the queries is slow, check the uniqueness of the trade_date column and determine if it needs to be in the projection’s ORDER BY clause and/or can be encoded using RLE. RLE replaces sequences of the same data values within a column by a pair that represents the value and a count. For best results, order the columns in the projection from lowest cardinality to highest cardinality, and use RLE to encode the data in low-cardinality columns.

**Note:**
For an example of using sorting and RLE, see [Combine RLE and Sort Order](#).

If the number of unique columns is unsorted, or if the average number of repeated rows is less than 10, trade_date is too close to being unique and cannot be encoded using RLE. In this case, add a new column to minimize the search scope.

The following example adds a new column trade_year:

1. Determine if the new column trade_year returns a manageable result set. The following query returns the data grouped by trade_year:

   ```sql
   => SELECT DATE_TRUNC('trade_year', trade_date), COUNT(*)
      FROM trades
      GROUP BY DATE_TRUNC('trade_year', trade_date);
   ```

2. Assuming that trade_year = 2007 is near 8k, add a column for trade_year to the trades table. The SELECT statement then becomes:
As a result, you have a projection that is sorted on trade_year, which can be encoded using RLE.

**Queries for Tables with a High-Cardinality Primary Key**

This example demonstrates how you can modify the projection to improve the performance of queries that select data from a table with a high-cardinality primary key.

Suppose you have the following query:

```sql
SELECT * FROM trades
WHERE trade_year = 2007
AND trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

Creating a lower cardinality column and adding it to the query limits the search scope and improves the query performance. In addition, if you create a projection where buckets is first in the sort order, the query may run even faster.
GROUP BY Queries

The following sections include several examples that show how you can design your projections to optimize the performance of your GROUP BY queries.

GROUP BY Implementation Options

Vertica implements a query GROUP BY clause with one of these algorithms: GROUPBY PIPELINED or GROUPBY HASH. Both algorithms return the same results. Performance of both is generally similar for queries that return a small number of distinct groups—typically a thousand per node.

You can use EXPLAIN to determine which algorithm the query optimizer chooses for a given query. The following conditions generally determine which algorithm is chosen:

- GROUPBY PIPELINED requires all GROUP BY data to be specified in the projection's ORDER BY clause. For details, see GROUPBY PIPELINED Requirements below.

  Because GROUPBY PIPELINED only needs to retain in memory the current group data, this algorithm generally requires less memory and executes faster than GROUPBY HASH. Performance improvements are especially notable for queries that aggregate large numbers of distinct groups.

- GROUPBY HASH is used for any query that does not comply with GROUP BY PIPELINED sort order requirements. In this case, Vertica must build a hash table on GROUP BY columns before it can start grouping the data.

GROUPBY PIPELINED Requirements

You can enable use of the GROUP BY PIPELINED algorithm by ensuring that the query and one of its projections comply with GROUP BY PIPELINED requirements. The following conditions apply to GROUPBY PIPELINED. If none of them is true for the query, then Vertica uses GROUPBY HASH.

All examples that follow assume this schema:
CREATE TABLE sortopt(
    a INT NOT NULL,
    b INT NOT NULL,
    c INT,
    d INT
);
CREATE PROJECTION sortopt_p(
    a_proj,
    b_proj,
    c_proj,
    d_proj)
AS SELECT * FROM sortopt
ORDER BY a,b,c
UNSEGMENTED ALL NODES;
INSERT INTO sortopt VALUES(5,2,13,84);
INSERT INTO sortopt VALUES(14,22,8,115);
INSERT INTO sortopt VALUES(79,9,401,33);

**Condition 1**

All GROUP BY columns are also included in the projection ORDER BY clause.

For example:

<table>
<thead>
<tr>
<th>GROUP BY columns</th>
<th>GROUPBY algorithm</th>
<th>Reason chosen</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td></td>
<td></td>
</tr>
<tr>
<td>a,b</td>
<td>GROUPBY PIPELINED</td>
<td>Columns a, b, and c are included in the projection sort columns.</td>
</tr>
<tr>
<td>b,a</td>
<td></td>
<td></td>
</tr>
<tr>
<td>a,b,c</td>
<td>GROUPBY PIPELINED</td>
<td></td>
</tr>
<tr>
<td>c,a,b</td>
<td>GROUPBY PIPELINED</td>
<td></td>
</tr>
<tr>
<td>a,b,c,d</td>
<td>GROUPBY HASH</td>
<td>Column d is not part of the projection sort columns.</td>
</tr>
</tbody>
</table>

**Condition 2**

If the query's GROUP BY clause has fewer columns than the projection's ORDER BY clause, the GROUP BY columns must:

- Be a subset of ORDER BY columns that are contiguous.
- Include the first ORDER BY column.

For example:

<table>
<thead>
<tr>
<th>GROUP BY columns</th>
<th>GROUPBY algorithm</th>
<th>Reason chosen</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>GROUPBY PIPELINED</td>
<td>All GROUP BY columns are a subset of contiguous columns in the projection's</td>
</tr>
<tr>
<td>a,b</td>
<td>GROUPBY PIPELINED</td>
<td></td>
</tr>
<tr>
<td>GROUP BY columns</td>
<td>GROUPBY algorithm</td>
<td>Reason chosen</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>b, a</td>
<td></td>
<td>ORDER BY clause {a, b, c}, and include column a.</td>
</tr>
<tr>
<td>a, c</td>
<td>GROUPBY HASH</td>
<td>GROUP BY columns {a, c} are not contiguous in the projection ORDER BY clause {a, b, c}.</td>
</tr>
<tr>
<td>b, c</td>
<td>GROUPBY HASH</td>
<td>GROUP BY columns {b, c} do not include the projection's first ORDER BY column a.</td>
</tr>
</tbody>
</table>

**Condition 3**

If a query's GROUP BY columns do not appear first in the projection's ORDER BY clause, then any early-appearing projection sort columns that are missing in the query's GROUP BY clause must be present as single-column constant equality predicates in the query's WHERE clause.

For example:

<table>
<thead>
<tr>
<th>Query</th>
<th>GROUPBY algorithm</th>
<th>Reason chosen</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY b</td>
<td>GROUPBY PIPELINED</td>
<td>All columns preceding b in the projection sort order appear as constant equality predicates.</td>
</tr>
<tr>
<td>SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY a, b</td>
<td>GROUPBY PIPELINED</td>
<td>Grouping column a is redundant but has no effect on algorithm selection.</td>
</tr>
<tr>
<td>SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY b, c</td>
<td>GROUPBY PIPELINED</td>
<td>All columns preceding b and c in the projection sort order appear as constant equality predicates.</td>
</tr>
<tr>
<td>SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY c, b</td>
<td>GROUPBY PIPELINED</td>
<td>All columns preceding b and c in the projection sort order appear as constant equality predicates.</td>
</tr>
<tr>
<td>SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY c</td>
<td>GROUPBY HASH</td>
<td>All columns preceding c in the projection sort order do not appear as constant equality predicates.</td>
</tr>
</tbody>
</table>
Controlling GROUPBY Algorithm Choice

It is generally best to allow Vertica to determine which GROUP BY algorithm is best suited for a given query. Occasionally, you might want to use one algorithm over another. In such cases, you can qualify the GROUP BY clause with a GBYTYPE hint:

GROUP BY /*+ GBYTYPE( HASH | PIPE ) */

For example, given the following query, the query optimizer uses the GROUPBY PIPELINED algorithm:

```sql
=> EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY a,b;
QUERY PLAN DESCRIPTION:
EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY a,b;
Access Path:
  +--GROUPBY PIPELINED [Cost: 11, Rows: 3 (NO STATISTICS)] (PATH ID: 1)
    | Aggregates: sum(sortopt.a)
    | Group By: sortopt.a, sortopt.b
...```

You can use the GBYTYPE hint to force the query optimizer to use the GROUPBY HASH algorithm instead:

```sql
=> EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(HASH) */ a,b;
QUERY PLAN DESCRIPTION:
EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(HASH) */ a,b;
Access Path:
  +--GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 11, Rows: 3 (NO STATISTICS)] (PATH ID: 1)
    | Aggregates: sum(sortopt.a)
    | Group By: sortopt.a, sortopt.b
...```

The GBYTYPE hint can specify a PIPE (GROUPBY PIPELINED algorithm) argument only if the query and one of its projections comply with GROUP BY PIPELINED requirements. Otherwise, Vertica issues a warning and uses GROUPBY HASH.

For example, the following query cannot use the GROUPBY PIPELINED algorithm, as the GROUP BY columns \{b, c\} do not include the projection's first ORDER BY column a:
Avoiding Resegmentation During GROUP BY Optimization with Projection Design

To compute the correct result of a query that contains a GROUP BY clause, Vertica must ensure that all rows with the same value in the GROUP BY expressions end up at the same node for final computation. If the projection design already guarantees the data is segmented by the GROUP BY columns, no resegmentation is required at run time.

To avoid resegmentation, the GROUP BY clause must contain all the segmentation columns of the projection, but it can also contain other columns.

When your query includes a GROUP BY clause and joins, if the join depends on the results of the GROUP BY, as in the following example, Vertica performs the GROUP BY first:

```sql
=> EXPLAIN SELECT * FROM (SELECT b FROM foo GROUP BY b) AS F, foo WHERE foo.a = F.b;
Access Path:
+JOIN MERGEJOIN(inputs presorted) [Cost: 649, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Join Cond: (foo.a = F.b)
| Materialize at Output: foo.b
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for foo [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
| | Projection: public.foo_super
| | Materialize: foo.a
| | Execute on: All Nodes
| | Runtime Filter: (SIPI(MergeJoin): foo.a)
| +- Inner -> SELECT [Cost: 245, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
| | Execute on: All Nodes
| | +- GROUPBY HASH (SORT OUTPUT) (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 245, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
| | | Group By: foo.b
| | | Execute on: All Nodes
| | | +- STORAGE ACCESS for foo [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 5)
| | | | Projection: public.foo_super
| | | | Materialize: foo.b
| | | | Execute on: All Nodes
```

If the result of the join operation is the input to the GROUP BY clause, Vertica performs the join first, as in the following example. The segmentation of those intermediate results may
not be consistent with the GROUP BY clause in your query, resulted in resegmentation at run time.

```sql
=> EXPLAIN SELECT * FROM foo AS F, foo WHERE foo.a = F.b GROUP BY 1,2,3,4;
```

Access Path:
+-GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 869, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
 | Group By: F.a, F.b, foo.a, foo.b
 | Execute on: All Nodes
 | +-- JOIN HASH [Cost: 853, Rows: 10K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND ROBIN)
 | | Join Cond: (foo.a = F.b)
 | | Execute on: All Nodes
 | | +-- Outer -> STORAGE ACCESS for F [Cost: 403, Rows: 10K (NO STATISTICS)] (PUSHED GROUPING) (PATH ID: 3)
 | | | Projection: public.foo_super
 | | | Materialize: F.a, F.b
 | | | Execute on: All Nodes
 | | +-- Inner -> STORAGE ACCESS for Foo [Cost: 403, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
 | | | Projection: public.foo_super
 | | | Materialize: foo.a, foo.b
 | | | Execute on: All Nodes

If your query does not include joins, the GROUP BY clauses are processed using the existing database projections.

**Examples**

Assume the following projection:

```sql
CREATE PROJECTION ... SEGMENTED BY HASH(a,b) ALL NODES
```

The following table explains whether or not resegmentation occurs at run time and why.

| GROUP BY a | Requires resegmentation at run time. The query does not contain all the projection segmentation columns. |
| GROUP BY a, b | Does not require resegmentation at run time. The GROUP BY clause contains all the projection segmentation columns. |
| GROUP BY a, b, c | Does not require resegmentation at run time. The GROUP BY clause contains all the projection segmentation columns. |
| GROUP BY a+1, b | Requires resegmentation at run time because of the expression on column a. |

To determine if resegmentation will occur during your GROUP BY query, look at the **EXPLAIN**-generated query plan.
For example, the following plan uses GROUPBY PIPELINED sort optimization and requires resegmentation to perform the GROUP BY calculation:

```
+-GROUPBY PIPELINED (RESEGMENT GROUPS) [Cost: 194, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
```

The following plan uses GROUPBY PIPELINED sort optimization, but does not require resegmentation:

```
+-GROUPBY PIPELINED [Cost: 459, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
```

**DISTINCT in a SELECT Query List**

This section describes how to optimize queries that have the DISTINCT keyword in their SELECT list. The techniques for optimizing DISTINCT queries are similar to the techniques for optimizing GROUP BY queries because when processing queries that use DISTINCT, the Vertica optimizer rewrites the query as a GROUP BY query.

The following sections below this page describe specific situations:

- Query Has No Aggregates in SELECT List
- COUNT (DISTINCT) and Other DISTINCT Aggregates
- Approximate Count Distinct Functions
- Single DISTINCT Aggregates
- Multiple DISTINCT Aggregates

Examples in these sections use the following table:

```sql
=> CREATE TABLE table1 (a INT, b INT, c INT);
```

**Query Has No Aggregates in SELECT List**

If your query has no aggregates in the SELECT list, internally, Vertica treats the query as if it uses GROUP BY instead.

For example, you can rewrite the following query:
SELECT DISTINCT a, b, c FROM table1;

as:

SELECT a, b, c FROM table1 GROUP BY a, b, c;

For fastest execution, apply the optimization techniques for GROUP BY queries described in GROUP BY Queries.

**COUNT (DISTINCT) and Other DISTINCT Aggregates**

Computing a DISTINCT aggregate generally requires more work than other aggregates. Also, a query that uses a single DISTINCT aggregate consumes fewer resources than a query with multiple DISTINCT aggregates.

**Tip:**
Vertica executes queries with multiple distinct aggregates more efficiently when all distinct aggregate columns have a similar number of distinct values.

**Examples**

The following query returns the number of distinct values in the primary_key column of the date_dimension table:

```sql
=> SELECT COUNT (DISTINCT date_key) FROM date_dimension;
COUNT
------
1826
(1 row)
```

This example returns all distinct values of evaluating the expression $x+y$ for all inventory_fact records.

```sql
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
COUNT
------
21560
(1 row)
```

You can create an equivalent query using the LIMIT keyword to restrict the number of rows returned:
SELECT COUNT(date_key + product_key) FROM inventory_fact GROUP BY date_key LIMIT 10;

<table>
<thead>
<tr>
<th>COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>173</td>
</tr>
<tr>
<td>31</td>
</tr>
<tr>
<td>321</td>
</tr>
<tr>
<td>113</td>
</tr>
<tr>
<td>286</td>
</tr>
<tr>
<td>84</td>
</tr>
<tr>
<td>244</td>
</tr>
<tr>
<td>238</td>
</tr>
<tr>
<td>145</td>
</tr>
<tr>
<td>202</td>
</tr>
</tbody>
</table>

(10 rows)

This query returns the number of distinct values of date_key in all records with the specific distinct product_key value.

=> SELECT product_key, COUNT (DISTINCT date_key) FROM inventory_fact GROUP BY product_key LIMIT 10;

<table>
<thead>
<tr>
<th>product_key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>12</td>
</tr>
<tr>
<td>2</td>
<td>18</td>
</tr>
<tr>
<td>3</td>
<td>13</td>
</tr>
<tr>
<td>4</td>
<td>17</td>
</tr>
<tr>

(15 rows)

The following example returns the number of warehouses from the warehouse dimension table:

=> SELECT COUNT(warehouse_name) FROM warehouse_dimension;

COUNT
-----
100
(1 row)

This next example returns the total number of vendors:

=> SELECT COUNT(*) FROM vendor_dimension;

COUNT
-----
50
(1 row)

**Approximate Count Distinct Functions**

Vertica provides the COUNT(DISTINCT) function to compute the exact number of distinct values in a data set. If projections are available that allow COUNT(DISTINCT) to execute using the GROUPBY PIPELINED algorithm, COUNT(DISTINCT) performs well. In some situations, however, using APPROXIMATE_COUNT_DISTINCT performs better than COUNT(DISTINCT).

A **COUNT [Aggregate]** operation performs well when:
One of the sorted projections delivers an order that enables sorted aggregation to be performed.
- The number of distinct values is fairly small.
- Hashed aggregation is required to execute the query.

When an approximate value will suffice or the values need to be rolled up, consider using the APPROXIMATE_COUNT_DISTINCT* functions.

**Note:**
The APPROXIMATE_COUNT_DISTINCT* functions cannot appear in the same query block as DISTINCT aggregates.

**Use Cases**

Use APPROXIMATE_COUNT_DISTINCT as a direct replacement for COUNT (DISTINCT) when:
- You have a large data set and you do not require an exact count of distinct values.
- The performance of COUNT(DISTINCT) on a given data set is insufficient.
- You calculate several distinct counts in the same query.
- The plan for COUNT(DISTINCT) uses hashed aggregation.

Most of the time, APPROXIMATE_COUNT_DISTINCT executes faster than a comparable COUNT(DISTINCT) operation when hashed.

The expected value that APPROXIMATE_COUNT_DISTINCT returns is equal to COUNT (DISTINCT), with an error that is lognormally distributed with standard deviation \( s \). You can control the standard deviation directly by setting the `error_tolerance`.

Use APPROXIMATE_COUNT_DISTINCT_SYNOPSIS and APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS together when:
- You have a large data set and you don't require an exact count of distinct values.
- The performance of COUNT(DISTINCT) on a given data set is insufficient.

\[ \text{and} \]
- You want to pre-compute the distinct counts and later combine them in different ways.

Pass APPROXIMATE_COUNT_DISTINCT_SYNOPSIS the data set and a normally distributed confidence interval. The function returns a subset of the data, as a binary object called a synopsis.
Pass the synopsis to the APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS function, which then performs an approximate count distinct on the synopsis.

COUNT (DISTINCT) performs better on small groups of data. APPROXIMATE_COUNT_DISTINCT performs better on larger groups of data.

Use APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE to merge multiple synopses into one synopsis. This allows you to continually update a "master" synopsis by merging in one or more synopses that cover more recent, shorter periods of time.

**Example**

This example shows how you can use Approximate Count Distinct functions, along with GROUP BY, as an efficient way to keep a running approximate count of how many separate users have clicked a given web page in a given period of time.

First, we create a distributed table called **pviews** to store data about visits to a website. The columns in the table record time of visit, the web page visited, and the user who visited it:

```
visit_time | page_id | user_id
```

The table is segmented by the hash of the **user_id** column. This ensures that all the visits by a given user will be stored on the same segment, on the same node. This prevents inefficient cross-node transfer of data, when later we do a COUNT (DISTINCT user_id).

The table also uses hierarchical partitioning by time of visit to optimize the ROS storage to improve performance when we filter data by time.

We use the APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE function to merge the daily synopses into monthly synopses.

```sql
DROP TABLE IF EXISTS pviews;
DROP TABLE
CREATE TABLE pviews(
    visit_time TIMESTAMP NOT NULL,
    page_id INTEGER NOT NULL,
    user_id INTEGER NOT NULL)
ORDER BY page_id, visit_time
SEGMENTED BY HASH(user_id) ALL NODES KSAFE
PARTITION BY visit_time::DATE
GROUP BY CALENDAR_HIERARCHY_DAY(visit_time::DATE, 2, 2);
-- HINT: Use mark_design_ksafe() to set system KSAFE level
CREATE TABLE
-- Load some data to pviews
```

Vertica Analytic Database (9.3.x)
-- Now create a summary table, **pview_summary**, where each row summarizes activities for one date.

-- The first column is the **date** to summarize.

-- The second column, **partial_visit_count**, stores the number of rows in the **pviews** table

```sql
COPY pviews FROM STDIN DELIMITER '|' DIRECT;

• COUNT [Aggregate]

Single DISTINCT Aggregates

Vertica computes a DISTINCT aggregate by first removing all duplicate values of the aggregate's argument to find the distinct values. Then it computes the aggregate.

For example, you can rewrite the following query:

```
SELECT a, b, COUNT(DISTINCT c) AS dcnt FROM table1 GROUP BY a, b;
```

as:

```
SELECT a, b, COUNT(dcnt) FROM  
  (SELECT a, b, c AS dcnt FROM table1 GROUP BY a, b, c)  
GROUP BY a, b;
```

For fastest execution, apply the optimization techniques for GROUP BY queries.

Multiple DISTINCT Aggregates

If your query has multiple DISTINCT aggregates, there is no straightforward SQL rewrite that can compute them. The following query cannot easily be rewritten for improved performance:

```
SELECT a, COUNT(DISTINCT b), COUNT(DISTINCT c) AS dcnt FROM table1 GROUP BY a;
```

For a query with multiple DISTINCT aggregates, there is no projection design that can avoid using GROUPBY HASH and resegmenting the data. To improve performance of this query, make sure that it has large amounts of memory available. For more information about memory allocation for queries, see Resource Manager.
JOIN Queries

In general, you can optimize execution of queries that join multiple tables in several ways:

- **Create projections for the joined tables that are sorted on join predicate columns.** This facilitates use of the merge join algorithm, which generally joins tables more efficiently than the hash join algorithm.
- **Create projections that are identically segmented on the join keys.**

Other Best Practices

Vertica also executes joins more efficiently if the following conditions are true:

- Query construction enables the query optimizer to create a plan where the larger table is defined as the outer input.
- The columns on each side of the equality predicate are from the same table. For example in the following query, the left and right sides of the equality predicate include only columns from tables T and X, respectively:

  ```
  => SELECT * FROM T JOIN X ON T.a + T.b = X.x1 - X.x2;
  ```

  Conversely, the following query incurs more work to process, because the right side of the predicate includes columns from both tables T and X:

  ```
  => SELECT * FROM T JOIN X WHERE T.a = X.x1 + T.b
  ```

Hash Joins Versus Merge Joins

The Vertica optimizer implements a join with one of the following algorithms:

- **Merge join** is used when projections of the joined tables are sorted on the join columns. Merge joins are faster and uses less memory than hash joins.
- **Hash join** is used when projections of the joined tables are not already sorted on the join columns. In this case, the optimizer builds an in-memory hash table on the inner table’s join column. The optimizer then scans the outer table for matches to the hash table, and joins data from the two tables accordingly. The cost of performing a hash
join is low if the entire hash table can fit in memory. Cost rises significantly if the hash table must be written to disk.

The optimizer automatically chooses the most appropriate algorithm to execute a query, given the projections that are available.

**Facilitating Merge Joins**

To facilitate a merge join, create projections for the joined tables that are sorted on the join predicate columns. The join predicate columns should be the first columns in the ORDER BY clause.

For example, tables `first` and `second` are defined as follows, with projections `first_p1` and `second_p1`, respectively. The projections are sorted on `data_first` and `data_second`:

```sql
CREATE TABLE first ( id INT, data_first INT );
CREATE PROJECTION first_p1 AS SELECT * FROM first ORDER BY data_first;

CREATE TABLE second ( id INT, data_second INT );
CREATE PROJECTION second_p1 AS SELECT * FROM first ORDER BY data_second;
```

When you join these tables on unsorted columns `first.id` and `second.id`, Vertica uses the hash join algorithm:

```sql
EXPLAIN SELECT first.data_first, second.data_second FROM first JOIN second ON first.id = second.id;
```

Access Path:

```
+JOIN HASH [Cost: 752, Rows: 300K] (PATH ID: 1) Inner (BROADCAST)
```

You can facilitate execution of this query with the merge join algorithm by creating projections `first_p2` and `second_p2`, which are sorted on join columns `first_p2.id` and `second_p2.id`, respectively:

```sql
CREATE PROJECTION first_p2 AS SELECT id, data_first FROM first ORDER BY id SEGMENTED BY hash(id, data_first) ALL NODES;
CREATE PROJECTION second_p2 AS SELECT id, data_second FROM second ORDER BY id SEGMENTED BY hash(id, data_second) ALL NODES;
```

If the query joins significant amounts of data, the query optimizer uses the merge algorithm:

```sql
EXPLAIN SELECT first.data_first, second.data_second FROM first JOIN second ON first.id = second.id;
```

Access Path:
You can also facilitate a merge join by using subqueries to pre-sort the join predicate columns. For example:

```sql
SELECT first.id, first.data_first, second.data_second FROM
(SELECT * FROM first ORDER BY id ) first JOIN
(SELECT * FROM second ORDER BY id) second ON first.id = second.id;
```

### Identical Segmentation

To improve query performance when you join multiple tables, create projections that are identically segmented on the join keys. Identically-segmented projections allow the joins to occur locally on each node, thereby helping to reduce data movement across the network during query processing.

To determine if projections are identically-segmented on the query join keys, create a query plan with `EXPLAIN`. If the query plan contains `RESEGMENT` or `BROADCAST`, the projections are not identically segmented.

The Vertica optimizer chooses a projection to supply rows for each table in a query. If the projections to be joined are segmented, the optimizer evaluates their segmentation against the query join expressions. It thereby determines whether the rows are placed on each node so it can join them without fetching data from another node.

### Join Conditions for Identically Segmented Projections

A projection $p$ is segmented on join columns if all column references in $p$’s segmentation expression are a subset of the columns in the join expression.

The following conditions must be true for two segmented projections $p_1$ of table $t_1$ and $p_2$ of table $t_2$ to participate in a join of $t_1$ to $t_2$:

- The join condition must have the following form:
  ```sql
t1.j1 = t2.j1 AND t1.j2 = t2.j2 AND ... t1.jN = t2.jN
  ```

- The join columns must share the same base data type. For example:
• If \( t_1.j_1 \) is an INTEGER, \( t_2.j_1 \) can be an INTEGER but it cannot be a FLOAT.
• If \( t_1.j_1 \) is a CHAR(10), \( t_2.j_1 \) can be any CHAR or VARCHAR (for example, CHAR(10), VARCHAR(10), VARCHAR(20)), but \( t_2.j_1 \) cannot be an INTEGER.
• If \( p_1 \) is segmented by an expression on columns \( \{t_1.s_1, t_1.s_2, \ldots t_1.s_N\} \), each segmentation column \( t_1.s_X \) must be in the join column set \( \{t_1.j_X\} \).
• If \( p_2 \) is segmented by an expression on columns \( \{t_2.s_1, t_2.s_2, \ldots t_2.s_N\} \), each segmentation column \( t_2.s_X \) must be in the join column set \( \{t_2.j_X\} \).
• The segmentation expressions of \( p_1 \) and \( p_2 \) must be structurally equivalent. For example:
  • If \( p_1 \) is SEGMENTED BY hash(\( t_1.x \)) and \( p_2 \) is SEGMENTED BY hash(\( t_2.x \)), \( p_1 \) and \( p_2 \) are identically segmented.
  • If \( p_1 \) is SEGMENTED BY hash(\( t_1.x \)) and \( p_2 \) is SEGMENTED BY hash(\( t_2.x + 1 \)), \( p_1 \) and \( p_2 \) are not identically segmented.
• \( p_1 \) and \( p_2 \) must have the same segment count.
• The assignment of segments to nodes must match. For example, if \( p_1 \) and \( p_2 \) use an OFFSET clause, their offsets must match.
• If Vertica finds projections for \( t_1 \) and \( t_2 \) that are not identically segmented, the data is redistributed across the network during query run time, as necessary.

Tip:
If you create custom designs, try to use segmented projections for joins whenever possible.

Examples

The following statements create two tables and specify to create identical segments:

\[
\text{=> CREATE TABLE } t1 \text{ (id INT, x1 INT, y1 INT) SEGMENTED BY HASH(id, x1) ALL NODES;}
\text{=> CREATE TABLE } t2 \text{ (id INT, x1 INT, y1 INT) SEGMENTED BY HASH(id, x1) ALL NODES;}
\]

Given this design, the join conditions in the following queries can leverage identical segmentation:

\[
\text{=> SELECT * FROM } t1 \text{ JOIN } t2 \text{ ON } t1.id = t2.id;
\text{=> SELECT * FROM } t1 \text{ JOIN } t2 \text{ ON } t1.id = t2.id \text{ AND } t1.x1 = t2.x1;
\]

Conversely, the join conditions in the following queries require resegmentation:

\[
\text{=> SELECT * FROM } t1 \text{ JOIN } t2 \text{ ON } t1.x1 = t2.x1;
\text{=> SELECT * FROM } t1 \text{ JOIN } t2 \text{ ON } t1.id = t2.x1;
\]
Joining Variable Length String Data

When you join tables on VARCHAR columns, Vertica calculates how much storage space it requires to buffer join column data. It does so by formatting the column data in one of two ways:

- Uses the join column metadata to size column data to a fixed length and buffer accordingly. For example, given a column that is defined as VARCHAR(1000), Vertica always buffers 1000 characters.
- Uses the actual length of join column data, so buffer size varies for each join. For example, given a join on strings Xi, John, and Amrita, Vertica buffers only as much storage as it needs for each join—in this case, 2, 4, and 6 bytes, respectively.

The second approach can improve join query performance. It can also reduce memory consumption, which helps prevent join spills and minimize how often memory is borrowed from the resource manager. In general, these benefits are especially marked in cases where the defined size of a join column significantly exceeds the average length of its data.

Setting and Verifying Variable Length Formatting

You can control how Vertica implements joins at the session or database levels, through configuration parameter `JoinDefaultTupleFormat`, or for individual queries, through the `JFMT` hint. Vertica supports variable length formatting for all joins except `merge` and `event_series` joins.

Use `EXPLAIN VERBOSE` to verify whether a given query uses variable character formatting, by checking for these flags:

- `JF_EE_VARIABLE_FORMAT`
- `JF_EE_FIXED_FORMAT`
ORDER BY Queries

You can improve the performance of queries that contain only ORDER BY clauses if the columns in a projection's ORDER BY clause are the same as the columns in the query.

If you define the projection sort order in the CREATE PROJECTION statement, the Vertica query optimizer does not have to sort projection data before performing certain ORDER BY queries.

The following table, sortopt, contains the columns a, b, c, and d. Projection sortopt_p specifies to order on columns a, b, and c.

```sql
CREATE TABLE sortopt (  
a INT NOT NULL,  
b INT NOT NULL,  
c INT,  
d INT  
);  
CREATE PROJECTION sortopt_p (  
a_proj,  
b_proj,  
c_proj,  
d_proj  
) AS SELECT * FROM sortopt  
ORDER BY a,b,c  
UNSEGMENTED ALL NODES;  
INSERT INTO sortopt VALUES(5,2,13,84);  
INSERT INTO sortopt VALUES(14,22,8,115);  
INSERT INTO sortopt VALUES(79,9,401,33);  
```

Based on this sort order, if a SELECT * FROM sortopt query contains one of the following ORDER BY clauses, the query does not have to resort the projection:

- ORDER BY a
- ORDER BY a, b
- ORDER BY a, b, c

For example, Vertica does not have to resort the projection in the following query because the sort order includes columns specified in the CREATE PROJECTION..ORDER BY a, b, c clause, which mirrors the query's ORDER BY a, b, c clause:

```sql
=> SELECT * FROM sortopt ORDER BY a, b, c;  
  a | b | c | d  
---+---+---+---  
  5 | 2 | 13 | 84  
 14 | 22 | 8 | 115  
 79 | 9 | 401 | 33
```
If you include column d in the query, Vertica must re-sort the projection data because column d was not defined in the CREATE PROJECTION . ORDER BY clause. Therefore, the ORDER BY d query won't benefit from any sort optimization.

You cannot specify an ASC or DESC clause in the CREATE PROJECTION statement's ORDER BY clause. Vertica always uses an ascending sort order in physical storage, so if your query specifies descending order for any of its columns, the query still causes Vertica to re-sort the projection data. For example, the following query requires Vertica to sort the results:

```
=> SELECT * FROM sortopt ORDER BY a DESC, b, c;

 a  |  b  |  c  |  d
-----+-----+-----+-----
 79  |  9  |401  |  33
 14  | 22  |  8  |115
  5  |  2  | 13  | 84
```

CREATE PROJECTION
Analytic Functions

The following sections describe how to optimize SQL-99 analytic functions that Vertica supports.

Empty OVER Clauses

The OVER() clause does not require a windowing clause. If your query uses an analytic function like SUM(x) and you specify an empty OVER() clause, the analytic function is used as a reporting function, where the entire input is treated as a single partition; the aggregate returns the same aggregated value for each row of the result set. The query executes on a single node, potentially resulting in poor performance.

If you add a PARTITION BY clause to the OVER() clause, the query executes on multiple nodes, improving its performance.

NULL Sort Order

By default, projection column values are stored in ascending order, but placement of NULL values depends on a column's data type.

NULL Placement Differences With ORDER BY Clauses

The analytic OVER(\textit{window-order-clause}) and the SQL ORDER BY clause have slightly different semantics:

\textbf{OVER(ORDER BY ...)}

The analytic window order clause uses the ASC or DESC sort order to determine NULLS FIRST or NULLS LAST placement for analytic function results. NULL values are placed as follows:

- ASC, NULLS LAST — NULL values appear at the end of the sorted result.
- DESC, NULLS FIRST — NULL values appear at the beginning of the sorted result.

\textbf{(SQL) ORDER BY}
The SQL and Vertica ORDER BY clauses produce different results. The SQL ORDER BY clause specifies only ascending or descending sort order. The Vertica ORDER BY clause determines NULL placement based on the column data type:

- NUMERIC, INTEGER, DATE, TIME, TIMESTAMP, and INTERVAL columns: NULLS FIRST (NULL values appear at the beginning of a sorted projection.)
- FLOAT, STRING, and BOOLEAN columns: NULLS LAST (NULL values appear at the end of a sorted projection.)

### NULL Sort Options

If you do not care about NULL placement in queries that involve analytic computations, or if you know that columns do not contain any NULL values, specify NULLS AUTO—irrespective of data type. Vertica chooses the placement that gives the fastest performance, as in the following query. Otherwise, specify NULLS FIRST or NULLS LAST.

```sql
=> SELECT x, RANK() OVER (ORDER BY x NULLS AUTO) FROM t;
```

You can carefully formulate queries so Vertica can avoid sorting the data and increase query performance, as illustrated by the following example. Vertica sorts inputs from table `t` on column `x`, as specified in the `OVER(ORDER BY)` clause, and then evaluates `RANK()`:

```sql
=> CREATE TABLE t (x FLOAT,
y FLOAT);
=> CREATE PROJECTION t_p (x, y) AS SELECT * FROM t ORDER BY x, y UNSEGMENTED ALL NODES;
=> SELECT x, RANK() OVER (ORDER BY x) FROM t;
```

In the preceding SELECT statement, Vertica eliminates the ORDER BY clause and executes the query quickly because column `x` is a FLOAT data type. As a result, the projection sort order matches the analytic default ordering (ASC + NULLS LAST). Vertica can also avoid having to sort the data when the underlying projection is already sorted.

However, if column `x` is an INTEGER data type, Vertica must sort the data because the projection sort order for INTEGER data types (ASC + NULLS FIRST) does not match the default analytic ordering (ASC + NULLS LAST). To help Vertica eliminate the sort, specify the placement of NULLs to match the default ordering:

```sql
=> SELECT x, RANK() OVER (ORDER BY x NULLS FIRST) FROM t;
```

If column `x` is a STRING, the following query eliminates the sort:

```sql
=> SELECT x, RANK() OVER (ORDER BY x NULLS LAST) FROM t;
```
If you omit NULLS LAST in the preceding query, Ver eliminates the sort because ASC + NULLS LAST is the default sort specification for both the analytic ORDER BY clause and for string-related columns in Vertica.

### Runtime Sorting of NULL Values in Analytic Functions

By carefully writing queries or creating your design (or both), you can help the Vertica query optimizer skip sorting all columns in a table when performing an analytic function, which can improve query performance.

To minimize Vertica’s need to sort projections during query execution, redefine the employee table and specify that NULL values are not allowed in the sort fields:

```sql
=> DROP TABLE employee CASCADE;
=> CREATE TABLE employee
  (empno INT,
   deptno INT NOT NULL,
   sal INT NOT NULL);
CREATE TABLE
=> CREATE PROJECTION employee_p AS
  SELECT * FROM employee
  ORDER BY deptno, sal;
CREATE PROJECTION
=> INSERT INTO employee VALUES(101,10,50000);
=> INSERT INTO employee VALUES(103,10,43000);
=> INSERT INTO employee VALUES(104,10,45000);
=> INSERT INTO employee VALUES(105,20,97000);
=> INSERT INTO employee VALUES(108,20,33000);
=> INSERT INTO employee VALUES(109,20,51000);
=> COMMIT;
COMMIT
```

```sql
=> SELECT * FROM employee;
empno | deptno | sal
-------+--------+-----
101    | 10     | 50000
103    | 10     | 43000
104    | 10     | 45000
105    | 20     | 97000
108    | 20     | 33000
109    | 20     | 51000
(6 rows)
=) SELECT deptno, sal, empno, RANK() OVER
```
(PARTITION BY deptno ORDER BY sal)
FROM employee;

| deptno | sal   | empno | ?column?
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>43000</td>
<td>103</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>45000</td>
<td>104</td>
<td>2</td>
</tr>
<tr>
<td>10</td>
<td>50000</td>
<td>101</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>33000</td>
<td>108</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>51000</td>
<td>109</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>97000</td>
<td>105</td>
<td>3</td>
</tr>
</tbody>
</table>

(6 rows)

**Tip:**
If you do not care about NULL placement in queries that involve analytic computations, or if you know that columns contain no NULL values, specify NULLS AUTO in your queries. Vertica attempts to choose the placement that gives the fastest performance. Otherwise, specify NULLS FIRST or NULLS LAST.

**LIMIT Queries with ROW_NUMBER Predicates**

Queries that use the LIMIT clause with ORDER BY or analytic function ROW_NUMBER() return a specific subset of rows in the query result. Vertica processes these queries efficiently using Top-K Optimization, which is a database query ranking process. Top-K optimization avoids sorting (and potentially writing to disk) an entire data set to find a small number of rows. This can significantly improve query performance.

For example, in the following query, Vertica extracts only the three smallest rows from column x:

```sql
=> SELECT * FROM t1 ORDER BY x LIMIT 3;
```

If table t1 contains millions of rows, it is time consuming to sort all the x values. Instead, Vertica keeps track of the smallest three values in x.

**Note:**
If you omit the ORDER BY clause, when using the LIMIT clause, the results can be nondeterministic.

Sort operations that precede a SQL analytics computation benefit from Top-K optimization if the query contains an OVER (ORDER BY) clause and a predicate on the ROW_NUMBER function, as in the following example:
The preceding query has the same behavior as the following query, which uses a LIMIT clause:

```
=> SELECT x FROM
    (SELECT *, ROW_NUMBER() OVER (ORDER BY x) AS row
    FROM t1) t2 WHERE row <= 3;
```

You can use \( \text{ROW\_NUMBER()} \) with the analytic window partition clause, something you cannot do if you use LIMIT:

```
=> SELECT x, y FROM
    (SELECT *, ROW_NUMBER() OVER (PARTITION BY x ORDER BY y)
    AS row FROM t1) t2 WHERE row <= 3;
```

**Note:**

When the `OVER()` clause includes the `window-partition-clause`, Top-K optimization occurs only when the analytic sort matches the input's sort, for example, if the projection is sorted on columns \( x \) and \( y \) in table \( t1 \).

If you still want to improve the performance of your query, consider using the optimization techniques described in ORDER BY Queries.
**INSERT-SELECT Operations**

There are several ways to optimize an INSERT-SELECT query that has the following format:

```sql
INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

**Matching Sort Orders**

When performing INSERT-SELECT operations, to avoid the sort phase of the INSERT, make sure that the sort order for the SELECT query matches the projection sort order of the target table.

For example, on a single-node database:

```sql
=> CREATE TABLE source (col1 INT, col2 INT, col3 INT);
=> CREATE PROJECTION source_p (col1, col2, col3)
    AS SELECT col1, col2, col3 FROM source
    ORDER BY col1, col2, col3
    SEGMENTED BY HASH(col3)
    ALL NODES;
=> CREATE TABLE destination (col1 INT, col2 INT, col3 INT);
=> CREATE PROJECTION destination_p (col1, col2, col3)
    AS SELECT col1, col2, col3 FROM destination
    ORDER BY col1, col2, col3
    SEGMENTED BY HASH(col3)
    ALL NODES;
```

The following INSERT does not require a sort because the query result has the column order of the projection:

```sql
=> INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

The following INSERT requires a sort because the order of the columns in the SELECT statement does not match the projection order:

```sql
=> INSERT /*+direct*/ INTO destination SELECT col1, col3, col2 FROM source;
```

The following INSERT does not require a sort. The order of the columns doesn't match, but the explicit ORDER BY causes the output to be sorted by c1, c3, c2 in Vertica:
Identical Segmentation

When performing an INSERT-SELECT operation from a segmented source table to a segmented destination table, segment both projections on the same column to avoid resegmenting the data, as in the following example:

```sql
CREATE TABLE source (col1 INT, col2 INT, col3 INT);
CREATE PROJECTION source_p (col1, col2, col3) AS
    SELECT col1, col2, col3 FROM source
    SEGMENTED BY HASH(col3) ALL NODES;
CREATE TABLE destination (col1 INT, col2 INT, col3 INT);
CREATE PROJECTION destination_p (col1, col2, col3) AS
    SELECT col1, col2, col3 FROM destination
    SEGMENTED BY HASH(col3) ALL NODES;
INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

=> INSERT /*+direct*/ INTO destination SELECT col1, col13, col2 FROM source
    GROUP BY col1, col13, col2
    ORDER BY col1, col2, col13 ;
DELETE and UPDATE Queries

Vertica is optimized for query-intensive workloads, so DELETE and UPDATE queries might not achieve the same level of performance as other queries. A DELETE and UPDATE operation has to update all projections, so the operation is as slow as the slowest projection. For additional information, see Using INSERT, UPDATE, and DELETE.

The topics that follow discuss best practices for optimizing DELETE and UPDATE queries in Vertica.

DELETE and UPDATE Performance Considerations

To improve the performance of your DELETE and UPDATE queries, consider the following issues:

- **Query performance after large deletes**—A large number of (unpurged) deleted rows can negatively affect query performance.

  To eliminate rows that have been deleted from the result, a query must do extra processing. If 10% or more of the total rows in a table have been deleted, the performance of a query on the table degrades. However, your experience may vary depending on the size of the table, the table definition, and the query. If a table has a large number of deleted rows, consider purging those rows to improve performance. For more information on purging, see Purging Deleted Data.

- **Recovery performance**—Recovery is the action required for a cluster to restore K-safety after a crash. Large numbers of deleted records can degrade the performance of a recovery. To improve recovery performance, purge the deleted rows. For more information on purging, see Purging Deleted Data.

- **Concurrency**—DELETE and UPDATE take exclusive locks on the table. Only one DELETE or UPDATE transaction on a table can be in progress at a time and only when no loads (or INSERTs) are in progress. DELETEs and UPDATEs on different tables can be run concurrently.

For detailed tips about improving DELETE and UPDATE performance, see DELETE and UPDATE Optimization.
Caution:
Vertica does not remove deleted data immediately but keeps it as history for the purposes of historical query. A large amount of history can result in slower query performance. For information about how to configure the appropriate amount of history to retain, see Purging Deleted Data.

DELETE and UPDATE Optimization

The process of optimizing DELETE and UPDATE queries is the same for both operations. Some simple steps can increase the query performance by tens to hundreds of times. The following sections describe several ways to improve projection design and improve DELETE and UPDATE queries to significantly increase DELETE and UPDATE performance.

Tip:
To optimize large bulk deletion, consider dropping partitions where possible.

Projection Column Requirements for Optimized Deletes

A projection is optimized for delete and update operations if it contains all columns required by the query predicate. In general, DML operations are significantly faster when performed on optimized projections than on non-optimized projections.

For example, consider the following table and projections:

```sql
=> CREATE TABLE t (a INTEGER, b INTEGER, c INTEGER);
=> CREATE PROJECTION p1 (a, b, c) AS SELECT * FROM t ORDER BY a;
=> CREATE PROJECTION p2 (a, c) AS SELECT a, c FROM t ORDER BY c, a;
```

In the following query, both p1 and p2 are eligible for DELETE and UPDATE optimization because column a is available:

```sql
=> DELETE from t WHERE a = 1;
```

In the following example, only projection p1 is eligible for DELETE and UPDATE optimization because the b column is not available in p2:

```sql
=> DELETE from t WHERE b = 1;
```
**Optimized Deletes in Subqueries**

To be eligible for DELETE optimization, all target table columns referenced in a DELETE or UPDATE statement's WHERE clause must be in the projection definition.

For example, the following simple schema has two tables and three projections:

```sql
CREATE TABLE tb1 (a INT, b INT, c INT, d INT);
CREATE TABLE tb2 (g INT, h INT, i INT, j INT);
```

The first projection references all columns in `tb1` and sorts on column `a`:

```sql
CREATE PROJECTION tb1_p AS SELECT a, b, c, d FROM tb1 ORDER BY a;
```

The buddy projection references and sorts on column `a` in `tb1`:

```sql
CREATE PROJECTION tb1_p_2 AS SELECT a FROM tb1 ORDER BY a;
```

This projection references all columns in `tb2` and sorts on column `i`:

```sql
CREATE PROJECTION tb2_p AS SELECT g, h, i, j FROM tb2 ORDER BY i;
```

Consider the following DML statement, which references `tb1.a` in its WHERE clause. Since both projections on `tb1` contain column `a`, both are eligible for the optimized DELETE:

```sql
DELETE FROM tb1 WHERE tb1.a IN (SELECT tb2.i FROM tb2);
```

**Restrictions**

Optimized DELETES are not supported under the following conditions:

- With replicated projections if subqueries reference the target table. For example, the following syntax is not supported:

  ```sql
  DELETE FROM tb1 WHERE tb1.a IN (SELECT e FROM tb2, tb2 WHERE tb2.e = tb1.e);
  ```

- With subqueries that do not return multiple rows. For example, the following syntax is not supported:

  ```sql
  DELETE FROM tb1 WHERE tb1.a = (SELECT k FROM tb2);
  ```
**Projection Sort Order for Optimizing Deletes**

Design your projections so that frequently-used DELETE or UPDATE predicate columns appear in the sort order of all projections for large DELETES and UPDATEs.

For example, suppose most of the DELETE queries you perform on a projection look like the following:

```sql
=> DELETE from t where time_key < '1-1-2007'
```

To optimize the delete operations, make `time_key` appear in the `ORDER BY` clause of all projections. This schema design results in better performance of the delete operation.

In addition, add sort columns to the sort order such that each combination of the sort key values uniquely identifies a row or a small set of rows. For more information, see Combine RLE and Sort Order. To analyze projections for sort order issues, use the `EVALUATE_DELETE_PERFORMANCE` function.

**Data Collector Table Queries**

The Vertica Data Collector extends system table functionality by gathering and retaining information about your database cluster. The Data Collector makes this information available in system tables.

Vertica Analytic Database stores Data Collection data in the Data Collector directory under the Vertica or catalog path. Use Data Collector information to query the past state of system tables and extract aggregate information.

In general, queries on Data Collector tables are more efficient when they include only the columns that contain the desired data. Queries are also more efficient when they:

- Avoid resegmentation
- Use time predicates

**Avoiding Resegmentation**

You can avoid resegmentation when you join the following DC tables on `session_id` or `transaction_id`, because all data is local:
• dc_session_starts
• dc_session_ends
• dc_requests_issued
• dc_requests_completed

Resegmentation is not required when a query includes the node_name column. For example:

```sql
=> SELECT dri.transaction_id, dri.request, drc.processed_row_count
   FROM dc_requests_issued dri
   JOIN dc_requests_completed drc
   USING (node_name, session_id, request_id)
   WHERE dri.time between 'April 7,2015'::timestamptz and 'April 8,2015'::timestamptz
   AND drc.time between 'April 7,2015'::timestamptz and 'April 8,2015'::timestamptz;
```

This query runs efficiently because:

• The **initiator node** writes only to dc_requests_issued and dc_requests_completed.
• Columns session_id and node_name are correlated.

## Using Time Predicates

Use non-volatile functions and **TIMESTAMP** for the time range predicates. Vertica Analytic Database optimizes SQL performance for DC tables that use the time predicate.

Each DC table has a time column. Use this column to enter the time range as the query predicate.

For example, this query returns data for dates between September 1 and September 10:

```sql
SELECT * from dc_foo where time > 'Sept 1, 2015::timestamptz and time < 'Sept 10 2015'::timestamptz;
```

You can change the minimum and maximum time values to adjust the time for which you want to retrieve data.

You must use non-volatile functions as time predicates. **Volatile functions** cause queries to run inefficiently. This example returns all queries that started and ended on April 7, 2015. However, the query runs at less than optimal performance because trunc and timestamp are volatile:

```sql
=> SELECT dri.transaction_id, dri.request, drc.processed_row_count
   FROM dc_requests_issued dri
   LEFT JOIN dc_requests_completed drc
```
Using (session_id, request_id)
WHERE trunc(dri.time, 'DD') > 'April 7, 2015'::timestamp
AND trunc(drc.time, 'DD') < 'April 8, 2015'::timestamp;

Views

A view is a stored query that encapsulates one or more SELECT statements. Views dynamically access and compute data from the database at execution time. A view is read-only, and can reference any combination of tables, temporary tables, and other views.

You can use views to achieve the following goals:

- Hide the complexity of SELECT statements from users for support or security purposes. For example, you can create a view that exposes only the data users need from various tables, while withholding sensitive data from the same tables.
- Encapsulate details about table structures, which might change over time, behind a consistent user interface.

Unlike projections, views are not materialized—that is, they do not store data on disk. Thus, the following restrictions apply:

- Vertica does not need to refresh view data when the underlying table data changes. However, a view does incur overhead to access and compute data.
- Views do not support inserts, deletes, or updates.

Creating Views

You can create two types of views:

- **CREATE VIEW** creates a view that persists across all sessions until it is explicitly dropped with **DROP VIEW**
- **CREATE LOCAL TEMPORARY VIEW** creates a view that is accessible only during the current Vertica session, and only to its creator. The view is automatically dropped when the current session ends.

After you create a view, you cannot change its definition. You can replace it with another view of the same name; or you can delete and redefine it.
Permissions

To create a view, you must be a superuser or have the following privileges:

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Objects</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE</td>
<td>Schema where the view is created</td>
</tr>
<tr>
<td>DROP</td>
<td>The view (only required if you specify an existing view in CREATE OR REPLACE VIEW)</td>
</tr>
<tr>
<td>SELECT</td>
<td>Tables and views referenced by the view query</td>
</tr>
<tr>
<td>USAGE</td>
<td>All schemas that contain tables and views referenced by the view query</td>
</tr>
</tbody>
</table>

For information about enabling users to access views, see Enabling View Access.

Using Views

Views can be used in the FROM clause of any SQL query or subquery. At execution, Vertica internally substitutes the name of the view used in the query with the actual query used in the view definition.

CREATE VIEW Example

The following CREATE VIEW statement creates the view myview, which sums all individual incomes of customers listed in the store.store_sales_fact table, and groups results by state:

```
=> CREATE VIEW myview AS
    SELECT SUM(annual_income), customer_state FROM public.customer_dimension
    WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact)
    GROUP BY customer_state
    ORDER BY customer_state ASC;
```

You can use this view to find all combined salaries greater than $2 billion:
-> SELECT * FROM myview where sum > 2000000000 ORDER BY sum DESC;

<table>
<thead>
<tr>
<th>SUM</th>
<th>customer_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>29253817091</td>
<td>CA</td>
</tr>
<tr>
<td>14215397659</td>
<td>TX</td>
</tr>
<tr>
<td>522533668</td>
<td>MI</td>
</tr>
<tr>
<td>4907216137</td>
<td>CO</td>
</tr>
<tr>
<td>4581840709</td>
<td>IL</td>
</tr>
<tr>
<td>3769455689</td>
<td>CT</td>
</tr>
<tr>
<td>3330524215</td>
<td>FL</td>
</tr>
<tr>
<td>331067307</td>
<td>IN</td>
</tr>
<tr>
<td>2832710696</td>
<td>TN</td>
</tr>
<tr>
<td>2806150503</td>
<td>PA</td>
</tr>
<tr>
<td>2793284639</td>
<td>MA</td>
</tr>
<tr>
<td>272341590</td>
<td>AZ</td>
</tr>
<tr>
<td>2642551509</td>
<td>UT</td>
</tr>
<tr>
<td>2128169759</td>
<td>NV</td>
</tr>
</tbody>
</table>

(14 rows)

### Enabling View Access

You can query any view that you create. To enable other non-superusers to access a view, you must:

- Have `SELECT...WITH GRANT OPTION` privileges on the view's base table
- Grant users `USAGE` privileges on the view schema
- Grant users `SELECT` privileges to the view itself

The following example grants `user2` access to view `schema1.view1`:

```sql
=> GRANT USAGE ON schema schema1 TO user2;
=> GRANT SELECT ON schema1.view1 TO user2;
```

**Important:**

If the view references an external table, you must also grant `USAGE` privileges to the external table's schema. So, if `schema1.view1` references external table `schema2.extTable1`, you must also grant `user2` `USAGE` privileges to `schema2`:

```sql
=> GRANT USAGE on schema schema2 to user2;
```

For more information see [GRANT (View)](https://www.vertica.com/docs/9.3.x/EN-466753_1.html).
View Execution

When Vertica processes a query that contains a view, it treats the view as a subquery. Vertica executes the query by expanding it to include the query in the view definition. For example, Vertica expands the query on the view myview shown in CREATE VIEW Example, to include the query that the view encapsulates, as follows:

```sql
=> SELECT *
    FROM (SELECT SUM(annual_income), customer_state FROM public.customer_dimension
          WHERE customer_key IN
          (SELECT customer_key FROM store.store_sales_fact)
          GROUP BY customer_state
          ORDER BY customer_state ASC)
     AS ship where sum > 200000000;
```

View Optimization

If you query a view and your query only includes columns from a subset of the tables that are joined in that view, Vertica executes that query by expanding it to include only those tables. This optimization requires one of the following conditions to be true:

- Join columns are foreign and primary keys.
- The join is a left or right outer join on columns with unique values.

View Sort Order

When processing a query on a view, Vertica considers the ORDER BY clause only in the outermost query. If the view definition includes an ORDER BY clause, Vertica ignores it. Thus, in order to sort the results returned by a view, you must specify the ORDER BY clause in the outermost query:

```sql
=> SELECT * FROM view-name ORDER BY view-column;
```

Note:
One exception applies: Vertica sorts view data when the view includes a LIMIT clause. In this case, Vertica must sort the data before it can process the LIMIT clause.
For example, the following view definition contains an ORDER BY clause inside a FROM subquery:

```sql
=> CREATE VIEW myview AS
   SELECT SUM(annual_income),
          customer_state
   FROM public.customer_dimension
   WHERE customer_key IN
     (SELECT customer_key FROM store.store_sales_fact)
   GROUP BY customer_state
   ORDER BY customer_state ASC;
```

When you query the view, Vertica does not sort the data:

```sql
=> SELECT * FROM myview WHERE SUM > 2000000000;
SUM | customer_state
----------
5225333668 | MI
2832710696 | TN
14215397659 | TX
4907216137 | CO
2793284639 | MA
3769455689 | CT
3310667307 | IN
2723441590 | AZ
2642551509 | UT
3330524215 | FL
2128169759 | NV
29253817091 | CA
4581840709 | IL
2806150503 | PA
(14 rows)
```

To return sorted results, the outer query must include an ORDER BY clause:

```sql
=> SELECT * FROM myview WHERE SUM > 2000000000 ORDER BY customer_state ASC;
SUM | customer_state
----------
2723441590 | AZ
29253817091 | CA
4907216137 | CO
3769455689 | CT
3330524215 | FL
4581840709 | IL
3310667307 | IN
2793284639 | MA
5225333668 | MI
2128169759 | NV
2806150503 | PA
2832710696 | TN
14215397659 | TX
2642551509 | UT
(14 rows)
```
Run-Time Errors

If Vertica does not have to evaluate an expression that would generate a run-time error in order to answer a query, the run-time error might not occur.

For example, the following query returns an error, because TO_DATE cannot convert the string F to the specified date format:

```sql
=> SELECT TO_DATE('F','dd mm yyyy') FROM customer_dimension;
ERROR: Invalid input for DD: "F"
```

Now create a view using the same query:

```sql
=> CREATE VIEW temp AS SELECT TO_DATE('F','dd mm yyyy') FROM customer_dimension;
CREATE VIEW
```

In many cases, this view generates the same error message. For example:

```sql
=> SELECT * FROM temp;
ERROR: Invalid input for DD: "F"
```

However, if you query that view with the COUNT function, Vertica returns with the desired results:

```sql
=> SELECT COUNT(*) FROM temp;
COUNT
-------
100
(1 row)
```

This behavior works as intended. You can create views that contain subqueries, where not every row is intended to pass the predicate.

Managing Views

Obtaining View Information

You can query system tables VIEWS and VIEW_COLUMNS to obtain information about existing views—for example, a view's definition and the attributes of columns that comprise
that view. You can also query system table `VIEW_TABLES` to examine view-related dependencies—for example, to determine how many views reference a table before you drop it.

**Renaming a View**

Use `ALTER VIEW` to rename a view.

**Dropping a View**

Use `DROP VIEW` to drop a view. Only the specified view is dropped. Vertica does not support `CASCADE` functionality for views, and does not check for dependencies. Dropping a view causes any view that references it to fail.

**Disabling and Re-enabling Views**

If you drop a table that is referenced by a view, Vertica does not drop the view. However, attempts to use that view or access information about it from system table `VIEW_COLUMNS` return an error that the referenced table does not exist. If you restore that table, Vertica also re-enables usage of the view.

**Flattened Tables**

Highly normalized database design often uses a star or snowflake schema model, comprising multiple large fact tables and many smaller dimension tables. Queries typically involve joins between a large fact table and multiple dimension tables. Depending on the number of tables and quantity of data that are joined, these queries can incur significant overhead.

To avoid this problem, some users create wide tables that combine all fact and dimension table columns that their queries require. These tables can dramatically speed up query execution. However, maintaining redundant sets of normalized and denormalized data has its own administrative costs.

Denormalized, or flattened, tables, can minimize these problems. Flattened tables can include columns that get their values by querying other tables. Operations on the source
tables and flattened table are decoupled; changes in one are not automatically propagated to the other. This minimizes the overhead that is otherwise typical of denormalized tables.

A flattened table defines derived columns with one of the following column constraint clauses:

- **DEFAULT query-expression** sets the column value when the column is created with CREATE TABLE or ALTER TABLE...ADD COLUMN.
- **SET USING query-expression** sets the column value when the function REFRESH_COLUMNS is invoked.

In both cases, *query-expression* must return only one row and column value, or none. If the query returns no rows, the column value is set to NULL.

Like other tables defined in Vertica, you can add and remove DEFAULT and SET USING columns from a flattened table at any time. Vertica enforces dependencies between a flattened table and the tables that it queries. For details, see Modifying SET USING and DEFAULT Columns.

### Flattened Table Example

In the following example, columns `orderFact.cust_name` and `orderFact.cust_gender` are defined as SET USING and DEFAULT columns, respectively. Both columns obtain their values by querying table `custDim`:

```sql
=> CREATE TABLE public.custDim(
    cid int PRIMARY KEY NOT NULL,
    name varchar(20),
    age int,
    gender varchar(1)
);
=> CREATE TABLE public.orderFact(
    order_id int PRIMARY KEY NOT NULL,
    order_date timestamp DEFAULT CURRENT_TIMESTAMP NOT NULL,
    cid int REFERENCES public.custDim(cid),
    cust_name varchar(20) SET USING (SELECT name FROM public.custDim WHERE (custDim.cid = orderFact.cid)),
    cust_gender varchar(1) DEFAULT (SELECT gender FROM public.custDim WHERE (custDim.cid = orderFact.cid)),
    amount numeric(12,2)
) PARTITION BY order_date::DATE GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 2, 2);
```

The following INSERT commands load data into both tables:
When you query the tables, Vertica returns the following result sets:

```sql
=> SELECT * FROM custDim;
    cid | name  | age | gender
    ---+-------+-----+------
      1 | Alice | 25  | F
      2 | Boz   | 30  | M
      3 | Eva   | 32  | F
(3 rows)

=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
    order_id | order_date | cid | cust_name | cust_gender | amount
    --------+-----------+-----+-----------+------------+-------
        100 | 2018-12-31| 1   | F         |            | 15.00
        200 | 2018-12-31| 1   | F         |            | 1000.00
        300 | 2018-12-31| 2   | M         |            | -50.00
        500 | 2018-12-31| 2   | M         |            | 200.00
        400 | 2018-12-31| 3   | F         |            | 100.00
(5 rows)
```

Vertica automatically populates the DEFAULT column `orderFact.cust_gender`, but the SET USING column `orderFact.cust_name` remains NULL. You can automatically populate this column by calling the function `REFRESH_COLUMNS` on flattened table `orderFact`. This function invokes the SET USING query for column `orderFact.cust_name` and populates the column from the result set:

```sql
=> SELECT REFRESH_COLUMNS('orderFact', 'cust_name', 'REBUILD');

              REFRESH_COLUMNS
---------------------------------------------
refresh_columns completed
(1 row)

=> COMMIT;
COMMIT
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
    order_id | order_date | cid | cust_name | cust_gender | amount
    --------+-----------+-----+-----------+------------+-------
        100 | 2018-12-31| 1   | Alice     | F          | 15.00
        200 | 2018-12-31| 1   | Alice     | F          | 1000.00
```

=> INSERT INTO custDim VALUES(1, 'Alice', 25, 'F');
=> INSERT INTO custDim VALUES(2, 'Boz', 30, 'M');
=> INSERT INTO custDim VALUES(3, 'Eva', 32, 'F');
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(100, 1, 15);
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(200, 1, 1000);
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(300, 2, -50);
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(400, 3, 100);
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(500, 2, 200);
=> COMMIT;
Sometimes, it can be useful to set an entire column to NULL or some other value.

=> ALTER TABLE orderFact ALTER COLUMN cust_name SET USING NULL;
=> ALTER TABLE

=> SELECT REFRESH_COLUMNS('orderFact', 'cust_name', 'REBUILD');
REFRESH_COLUMNS
refresh_columns completed
(1 row)

=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;

<table>
<thead>
<tr>
<th>order_id</th>
<th>order_date</th>
<th>cid</th>
<th>cust_name</th>
<th>cust_gender</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2018-12-31</td>
<td>1</td>
<td>F</td>
<td></td>
<td>15.00</td>
</tr>
<tr>
<td>200</td>
<td>2018-12-31</td>
<td>1</td>
<td>F</td>
<td></td>
<td>1000.00</td>
</tr>
<tr>
<td>300</td>
<td>2018-12-31</td>
<td>2</td>
<td>M</td>
<td></td>
<td>-50.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>2</td>
<td>M</td>
<td></td>

</tr>
<tr>
<td>400</td>
<td>2018-12-31</td>
<td>3</td>
<td>F</td>
<td></td>
<td>100.00</td>
</tr>
</tbody>
</table>

(5 rows)

You can also remove the SET USING expression from the column, but retain the column's data.

=> ALTER TABLE orderFact ALTER COLUMN cust_name DROP SET USING;
=> ALTER TABLE

Creating Flattened Tables

A flattened table is typically a fact table where one or more columns query other tables for their values, through DEFAULT or SET USING constraints. Like other columns, you can set these constraints when you create the flattened table, or any time thereafter by modifying the table schema:

CREATE TABLE ...(..., column-name data-type { DEFAULT | SET USING } expression,...)
ALTER TABLE ... ADD COLUMN column-name { DEFAULT | SET USING } expression
ALTER TABLE ... ALTER COLUMN column-name { SET DEFAULT | SET USING } expression

DEFAULT and SET USING constraints can be used for columns of all data types. The expressions that you set for these constraints are stored in the system table COLUMNS, in columns COLUMN_DEFAULT and COLUMN_SET_USING. Both constraints support the same
expressions. For detailed information, including restrictions, see Defining Column Values in the Administrator's Guide.

**Supported Expressions**

DEFAULT and SET USING generally support the same expressions. These include:

- Queries (see Flattened Tables)
- Other columns in the same table
- Literals (constants)
- All operators supported by Vertica
- The following categories of functions:
  - Null-handling
  - User-defined scalar
  - System information
  - String
  - Mathematical
  - Formatting

**Disambiguating Predicate Columns**

If a SET USING or DEFAULT query expression joins two columns with the same name, the column names must include their table names. Otherwise, Vertica assumes that both columns reference the dimension table, and the predicate always evaluates to true.

For example, tables orderFact and custDim both include column cid. Flattened table orderFact defines column cust_name with a SET USING query expression. Because the query predicate references columns cid from both tables, the column names are fully qualified:

```sql
=> CREATE TABLE public.orderFact
 ( ...
   cid int REFERENCES public.custDim(cid),
   cust_name varchar(20) SET USING (  
     SELECT name FROM public.custDim WHERE (custDIM.cid = orderFact.cid)),
   ...  
 )
```
Requirements and Restrictions

Required Privileges

<table>
<thead>
<tr>
<th>Operation</th>
<th>Required Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retrieve data from a flattened table</td>
<td>Schema: USAGE</td>
</tr>
<tr>
<td></td>
<td>Flattened table: SELECT</td>
</tr>

<tr>
<td>Run REFRESH_COLUMNS</td>
<td>Schema: USAGE</td>
</tr>
<tr>
<td></td>
<td>Queried table: SELECT</td>
</tr>
<tr>
<td></td>
<td>Flattened table: SELECT, UPDATE</td>
</tr>
</tbody>
</table>

Restrictions

If you call REFRESH_COLUMNS on a SET USING column and specify the refresh mode as REBUILD, Vertica returns an error if any of the following conditions is true for that column:

- Specified as a table partition key.
- Included in an unsegmented projection of the target table.
- Included in a projection with expressions, or any live aggregate projection that invokes a user-defined transform function (UDTF).
- Included in a projection's sort order or segmentation.
- Included in a projection, and the projection omits an anchor table column that is referenced in the column's SET USING expression.
- Included in a projection's GROUPED clause.

**SET USING versus DEFAULT**

Columns in a flattened table can query other tables with constraints SET USING and DEFAULT. In both cases, changes in the queried tables are not automatically propagated to the flattened table. The two constraints differ as described below.

**DEFAULT Columns**

Vertica executes DEFAULT queries only on new rows when they are added to the flattened table, through load operations such as INSERT and COPY. Thereafter, changes in the original data sources have no effect on the flattened table.

**SET USING Columns**

Vertica executes SET USING queries only when you invoke the function `REFRESH_COLUMNS`. Load operations set SET USING columns in new rows to NULL. After the load, you must call `REFRESH_COLUMNS` to populate these columns from the queried tables. This can be useful in two ways: you can defer the overhead of updating the flattened table to any time that is convenient; and you can repeatedly query source tables for new data.

**Tip:**

It might be more efficient to drop the column and add a new one. `ALTER TABLE...ADD COLUMN` does not call `REFRESH_COLUMNS` when you add a SET USING column to a table.

SET USING is especially useful for large flattened tables that reference data from multiple dimension tables. Often, only a small subset of SET USING columns are subject to change, and queries on the flattened table do not always require up-to-the-minute data. Given this scenario, you can refresh table content at regular intervals, or only during off-peak hours.
One or both of these strategies can minimize overhead, and facilitate performance when querying large data sets.

**Partition-based Rebuild Operations**

If a flattened table is partitioned, you can reduce the overhead of calling REFRESH_COLUMNS in REBUILD mode, by specifying one or more partition keys. Doing so limits the rebuild operation to the specified partitions. For example, table public.orderFact is defined with SET USING column cust_name. This table is partitioned on column order_date, where the partition clause invokes Vertica function CALENDAR_HIERARCHY_DAY. Thus, you can call REFRESH_COLUMNS on specific time-delimited partitions of this table—in this case, on orders over the last two months:

```sql
=> SELECT REFRESH_COLUMNS ('public.orderFact',
    'cust_name',
    'REBUILD',
    TO_CHAR(ADD_MONTHS(current_date, -2), 'YYYY-MM')||'-01',
    TO_CHAR(LAST_DAY(ADD_MONTHS(current_date, -1))));

refresh_columns completed
(1 row)
```

**Combining DEFAULT and SET USING Constraints**

A column can specify both DEFAULT and SET USING constraints, as follows:

```
column-name data-type DEFAULT default-expr SET USING using-expr
```

Typically, both constraints specify the same expression. In this case, you can define the column as follows:

```
column-name data-type DEFAULT USING expression
```

DEFAULT USING columns support the same expressions as SET USING columns, and are subject to the same restrictions.

**Example**

The following SQL illustrates differences between SET USING and DEFAULT constraints. The examples use the custDim and orderFact tables described in Flattened Table Example.
The following **UPDATE** statement updates the `custDim` table:

```sql
=> UPDATE custDim SET name='Roz', gender='F' WHERE cid=2;
   OUTPUT
   -----------
      1
(1 row)
=> COMMIT;
   COMMIT
```

Changes are not propagated to flattened table `orderFact`, which includes SET USING and DEFAULT columns `cust_name` and `cust_gender`, respectively:

```sql
=> SELECT * FROM custDim ORDER BY cid;
   cid  | name  | age | gender
        +--------+-----+-----+-------
        | 1      | Alice| 25  | F     |
        | 2      | Roz  | 30  | F     |
        | 3      | Eva  | 32  | F     |
(3 rows)
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
   order_id | order_date | cid | cust_name | cust_gender | amount
            +--------+-----+--------+-----------+--------+-----
            | 100   | 2018-12-31 | 1 | Alice  | F     | 15.00
            | 200   | 2018-12-31 | 1 | Alice  | F     | 1000.00
            | 300   | 2018-12-31 | 2 | Boz    | M     | -50.00
            | 500   | 2018-12-31 | 2 | Boz    | M     | 200.00
            | 400   | 2018-12-31 | 3 | Eva    | F     | 100.00
(5 rows)
```

The following **INSERT** statement invokes the `cust_gender` column's DEFAULT query and sets that column to F. The load operation does not invoke the `cust_name` column's SET USING query, so `cust_name` is set to null:

```sql
=> INSERT INTO orderFact(order_id, cid, amount) VALUES(500, 3, 750);
   OUTPUT
   -----------
      1
(1 row)
=> COMMIT;
   COMMIT
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
   order_id | order_date | cid | cust_name | cust_gender | amount
            +--------+-----+--------+-----------+--------+-----
            | 100   | 2018-12-31 | 1 | Alice  | F     | 15.00
            | 200   | 2018-12-31 | 1 | Alice  | F     | 1000.00
            | 300   | 2018-12-31 | 2 | Boz    | M     | -50.00
            | 500   | 2018-12-31 | 2 | Boz    | M     | 200.00
            | 400   | 2018-12-31 | 3 | Eva    | F     | 100.00
            | 500   | 2018-12-31 | 3 |         | F     | 750.00
(6 rows)
```
To set a value in cust_name, invoke its SET USING query by calling REFRESH_COLUMNS:

```sql
=> SELECT REFRESH_COLUMNS ('orderFact', '');

refresh_columns completed
(1 row)
=> COMMIT;

=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;

<table>
<thead>
<tr>
<th>order_id</th>
<th>order_date</th>
<th>cid</th>
<th>cust_name</th>
<th>cust_gender</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>15.00</td>
</tr>
<tr>
<td>200</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>1000.00</td>
</tr>
<tr>
<td>300</td>
<td>2018-12-31</td>
<td>2</td>
<td>Roz</td>
<td>M</td>
<td>-50.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>2</td>
<td>Roz</td>
<td>M</td>
<td>200.00</td>
</tr>
<tr>
<td>400</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>100.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>750.00</td>
</tr>
</tbody>
</table>

(6 rows)
```

REFRESH_COLUMNS executes cust_name's SET USING query: it queries the name column in table custDim and updates cust_name with the following values:

- Sets cust_name in the new row to Eva.
- Returns updated values for cid=2, and changes Boz to Roz.

REFRESH_COLUMNS only affects the values in column cust_name. Values in column gender are unchanged, so settings for rows where cid=2 (Roz) remain set to M. To repopulate orderFact.cust_gender with default values from custDim.gender, call UPDATE on orderFact:

```sql
=> UPDATE orderFact SET cust_gender=DEFAULT WHERE cust_name='Roz';

OUTPUT
----------
2
(1 row)
=> COMMIT;

=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;

<table>
<thead>
<tr>
<th>order_id</th>
<th>order_date</th>
<th>cid</th>
<th>cust_name</th>
<th>cust_gender</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>15.00</td>
</tr>
<tr>
<td>200</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>1000.00</td>
</tr>
<tr>
<td>300</td>
<td>2018-12-31</td>
<td>2</td>
<td>Roz</td>
<td>F</td>
<td>-50.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>2</td>
<td>Roz</td>
<td>F</td>
<td>200.00</td>
</tr>
<tr>
<td>400</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>100.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>750.00</td>
</tr>
</tbody>
</table>

(6 rows)
```
Modifying SET USING and DEFAULT Columns

Removing SET USING and DEFAULT Constraints

You remove a column's SET USING or DEFAULT constraint with `ALTER TABLE...ALTER COLUMN`, as follows:

```
ALTER TABLE table-name ALTER COLUMN column-name DROP { SET USING | DEFAULT };
```

Vertica removes the constraint from the specified column, but the column and its data are otherwise unaffected.

```
=> ALTER TABLE table1 ALTER COLUMN column1 DROP SET USING;
```

Modifying a SET USING and DEFAULT Expression

`ALTER TABLE...ALTER COLUMN` can set an existing column to SET USING or DEFAULT, or change the query expression of an existing SET USING or DEFAULT column. In both cases, existing values remain unchanged. Vertica refreshes column values only in the following cases:

- DEFAULT column: Refreshed only when you load new rows, or when you invoke `UPDATE` to set column values to DEFAULT.
- SET USING column: Refreshed only when you call `REFRESH_COLUMNS` on the table.

For details, see Defining Column Values

Dropping Columns Queried by SET USING or DEFAULT

Vertica enforces dependencies between a flattened table and the tables that it queries. Attempts to drop a queried column or its table return an error unless the drop operation, such as `DROP TABLE`, also includes CASCADE. Vertica implements CASCADE by removing the SET USING or DEFAULT constraint from the flattened table. The table column and its data are otherwise unaffected.
For example, attempts to drop column name in table custDim returns a rollback error, as this column is referenced by SET USING column cust_name in orderFact:

```
=> ALTER TABLE custDim DROP COLUMN name;
ROLLBACK 7302: Cannot drop column "name" since it is referenced in the set using expression of table "public.orderFact", column "cust_name"
```

To drop this column, use the CASCADE option:

```
=> ALTER TABLE custDim DROP COLUMN name CASCADE;
ALTER TABLE
```

Vertica removes the SET USING constraint from orderFact.cust_name as part of the drop operation. However, cust_name retains the data that it derived from dropped column custDim.name:

```
=> SELECT EXPORT_TABLES('', 'orderFact');

CREATE TABLE public.orderFact
(
    order_id int NOT NULL,
    cid int,
    cust_name varchar(20)
    cust_gender varchar(1) DEFAULT ( SELECT custDim.gender
    FROM public.custDim
    WHERE (custDim.cid = orderFact.cid),
    amount numeric(12,2)
);
ALTER TABLE public.orderFact ADD CONSTRAINT C_PRIMARY PRIMARY KEY (order_id) ENABLED;
ALTER TABLE public.orderFact ADD CONSTRAINT C_FOREIGN FOREIGN KEY (cid) references public.custDim (cid);
(1 row)
```

```
=> SELECT * FROM orderFact;

<table>
<thead>
<tr>
<th>order_id</th>
<th>cid</th>
<th>cust_name</th>
<th>cust_gender</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>300</td>
<td>2</td>
<td>Roz</td>
<td>F</td>
<td>-50.00</td>
</tr>
<tr>
<td>400</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>100.00</td>
</tr>
<tr>
<td>100</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>15.00</td>
</tr>
<tr>
<td>500</td>
<td>2</td>
<td>Roz</td>
<td>F</td>
<td>200.00</td>
</tr>
<tr>
<td>200</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>1000.00</td>
</tr>
</tbody>
</table>
(5 rows)
```
Impact of SET USING Columns on License Limits

Vertica does not count the data in denormalized columns towards your raw data license limit. SET USING columns obtain their data by querying columns in other tables. Only data from the source tables counts against your raw data license limit.

For a list of SET USING restrictions, see Defining Column Values.

You can remove a SET USING column so it counts toward your license limit with the following command:

```sql
=> ALTER TABLE table1 ALTER COLUMN column1 DROP SET USING;
```

SQL Analytics

Vertica analytics are SQL functions based on the ANSI 99 standard. These functions handle complex analysis and reporting tasks—for example:

- Rank the longest-standing customers in a particular state.
- Calculate the moving average of retail volume over a specified time.
- Find the highest score among all students in the same grade.
- Compare the current sales bonus that salespersons received against their previous bonus.

Analytic functions return aggregate results but they do not group the result set. They return the group value multiple times, once per record. You can sort group values, or partitions, using a window ORDER BY clause, but the order affects only the function result set, not the entire query result set.

For details about supported functions, see Analytic Functions in the SQL Reference Manual.

Invoking Analytic Functions

You invoke analytic functions as follows:
analytic-function (arguments) OVER(
    [ window-partition-clause ]
    [ window-order-clause [ window-frame-clause ] ]
)

An analytic function's OVER clause can contain up to three sub-clauses, which specify how to partition and sort function input, and how to frame input with respect to the current row. Function input is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses.

Each function has its own OVER clause requirements. For example, some analytic functions do not support window order and window frame clauses.

Function Execution

An analytic function executes as follows:

1. Takes the input rows that the query returns after it performs all joins, and evaluates FROM, WHERE, GROUP BY, and HAVING clauses.

2. Groups input rows according to the window partition (PARTITION BY) clause. If this clause is omitted, all input rows are treated as a single partition.

3. Sorts rows within each partition according to window order (ORDER BY) clause.

4. If the OVER clause includes a window order clause, the function checks for a window frame clause and executes it as it processes each input row. If the OVER clause omits a window frame clause, the function treats the entire partition as a window frame.

Restrictions

- Analytic functions are allowed only in a query's SELECT and ORDER BY clauses.
- Analytic functions cannot be nested. For example, the following query throws an error:

  => SELECT MEDIAN(RANK() OVER(ORDER BY sal)) OVER().

Analytic Functions Versus Aggregate Functions

Like aggregate functions, analytic functions return aggregate results, but analytics do not group the result set. Instead, they return the group value multiple times with each record,
allowing further analysis.

Analytic queries generally run faster and use fewer resources than aggregate queries.

<table>
<thead>
<tr>
<th>Aggregate functions</th>
<th>Analytic functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return a single summary value.</td>
<td>Return the same number of rows as the input.</td>
</tr>
<tr>
<td>Define the groups of rows on which they operate through the SQL GROUP BY clause.</td>
<td>Define the groups of rows on which they operate through window partition and window frame clauses.</td>
</tr>
</tbody>
</table>

**Examples**

The examples below contrast the aggregate function **COUNT** with its analytic counterpart **COUNT**. The examples use the employees table as defined below:

```sql
CREATE TABLE employees(emp_no INT, dept_no INT);
INSERT INTO employees VALUES(1, 10);
INSERT INTO employees VALUES(2, 30);
INSERT INTO employees VALUES(3, 30);
INSERT INTO employees VALUES(4, 10);
INSERT INTO employees VALUES(5, 30);
INSERT INTO employees VALUES(6, 20);
INSERT INTO employees VALUES(7, 20);
INSERT INTO employees VALUES(8, 20);
INSERT INTO employees VALUES(9, 20);
INSERT INTO employees VALUES(10, 20);
INSERT INTO employees VALUES(11, 20);
COMMIT;
```

When you query this table, the following result set returns:

```sql
=> SELECT * FROM employees ORDER BY emp_no;
emp_no | dept_no
---------+
     1 |     10
     2 |     30
     3 |     30
     4 |     10
     5 |     30
     6 |     20
     7 |     20
     8 |     20
     9 |     20
    10 |     20
    11 |     20
(11 rows)
```
Below, two queries use the `COUNT` function to count the number of employees in each department. The query on the left uses aggregate function `COUNT`; the query on the right uses analytic function `COUNT`:

<table>
<thead>
<tr>
<th>Aggregate COUNT</th>
<th>Analytics COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>=&gt; SELECT dept_no, COUNT(*) AS emp_count FROM employees GROUP BY dept_no;</td>
<td>=&gt; SELECT emp_no, dept_no, COUNT(*) OVER(PARTITION BY dept_no ORDER BY emp_no) AS emp_count FROM employees;</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>dept_no</th>
<th>emp_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>6</td>
</tr>
<tr>
<td>30</td>
<td>3</td>
</tr>
<tr>
<td>(3 rows)</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>emp_no</th>
<th>dept_no</th>
<th>emp_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>10</td>
<td>2</td>
</tr>
<tr>
<td>6</td>
<td>20</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>20</td>
<td>2</td>
</tr>
<tr>
<td>8</td>
<td>20</td>
<td>3</td>
</tr>
<tr>
<td>9</td>
<td>20</td>
<td>4</td>
</tr>
<tr>
<td>10</td>
<td>20</td>
<td>5</td>
</tr>
<tr>
<td>11</td>
<td>20</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>30</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>30</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>30</td>
<td>3</td>
</tr>
<tr>
<td>(11 rows)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Aggregate function `COUNT` returns one row per department for the number of employees in that department. Within each `dept_no` partition analytic function `COUNT` returns a cumulative count of employees. The count is ordered by `emp_no`, as specified by the `ORDER BY` clause.

- Analytic Query Examples

### Window Partitioning

Optionally specified in an analytic function's `OVER` clause, a partition (`PARTITION BY`) clause groups input rows before the function processes them. Window partitioning is similar to an aggregate function's `GROUP BY` clause, except it returns exactly one result row per input row. If you omit the window partition clause, the function treats all input rows as a single partition.
Specifying Window Partitioning

You specify window partitioning in the analytic function's OVER clause, as shown below. The window partition clause is set off in bold:

\[
\text{OVER( } \{ \text{PARTITION BY expression} | \text{PARTITION BEST} | \text{PARTITION NODES} \} \\
\text{window-order-clause} \\
\text{window-frame-clause} \text{ )}
\]

For syntax details, see Window Partition Clause in the SQL Reference Manual.

Examples

The examples in this topic use the allsales schema defined in Invoking Analytic Functions.

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Median of sales within each state

The following query uses the analytic window-partition-clause to calculate the median of sales within each state. The analytic function is computed per partition and starts over again at the beginning of the next partition.

```sql
=> SELECT state, name, sales, MEDIAN(sales) OVER (PARTITION BY state) AS median from allsales;
```

Results are grouped into partitions for MA (35) and NY (20) under the median column.

```
<table>
<thead>
<tr>
<th>state</th>
<th>name</th>
<th>sales</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>NY</td>
<td>C</td>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>NY</td>
<td>B</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>NY</td>
<td>F</td>
<td>40</td>
<td>20</td>
</tr>
<tr>
<td>MA</td>
<td>G</td>
<td>10</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>D</td>
<td>20</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>E</td>
<td>50</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>A</td>
<td>60</td>
<td>35</td>
</tr>
</tbody>
</table>
```

(7 rows)
Median of sales among all states

The following query calculates the median of total sales among states. When you use OVER () with no parameters, there is one partition—the entire input:

```sql
=> SELECT state, sum(sales), median(SUM(sales))
   OVER () AS median
FROM allsales GROUP BY state;
```

<table>
<thead>
<tr>
<th>state</th>
<th>sum</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>NY</td>
<td>75</td>
<td>107.5</td>
</tr>
<tr>
<td>MA</td>
<td>140</td>
<td>107.5</td>
</tr>
</tbody>
</table>

(2 rows)

Sales larger than median (evaluation order)

Analytic functions are evaluated after all other clauses except the query's final SQL ORDER BY clause. So a query that asks for all rows with sales larger than the median returns an error because the WHERE clause is applied before the analytic function and column m does not yet exist:

```sql
=> SELECT name, sales, MEDIAN(sales) OVER () AS m
   FROM allsales WHERE sales > m;
ERROR 2624: Column "m" does not exist
```

You can work around this by placing in a subquery the predicate WHERE sales > m:

```sql
=> SELECT * FROM
   (SELECT name, sales, MEDIAN(sales) OVER () AS m FROM allsales) sq
   WHERE sales > m;
```

<table>
<thead>
<tr>
<th>name</th>
<th>sales</th>
<th>m</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>40</td>
<td>20</td>
</tr>
<tr>
<td>E</td>
<td>50</td>
<td>20</td>
</tr>
<tr>
<td>A</td>
<td>60</td>
<td>20</td>
</tr>
</tbody>
</table>

(3 rows)

For more examples, see Analytic Query Examples.

Window Ordering

Window ordering specifies how to sort rows that are supplied to the analytic function. You specify window ordering through an ORDER BY clause in the function's OVER clause, as shown below. If the OVER clause includes a window partition clause, rows are sorted within each partition. An window order clause also creates a default window frame if none is explicitly specified.
The window order clause only specifies order within a window result set. The query can have its own \texttt{ORDER BY} clause outside the \texttt{OVER} clause. This has precedence over the window order clause and orders the final result set.

### Specifying Window Order

You specify a window frame in the analytic function's \texttt{OVER} clause, as shown below. The window order clause is set off in bold:

\begin{verbatim}
OVER(
    [ window-partition-clause ]
    ORDER BY { expression[ sort-qualifiers ] } [, ...]
    [ window-frame-clause ]
)
\end{verbatim}

\texttt{sort-qualifiers} =

[ ASC | DESC ]
[ NULLS { FIRST | LAST | AUTO} ]

For syntax details, see \texttt{Window Order Cause} in the SQL Reference Manual.

### Analytic Function Usage

Analytic aggregation functions such as \texttt{SUM} support window order clauses.

#### Required Usage

The following functions require a window order clause:

- \texttt{RANK}
- \texttt{DENSE_RANK}
- \texttt{LEAD}
- \texttt{LAG}
- \texttt{PERCENT_RANK}
- \texttt{CUME_DIST}
- \texttt{NTILE}

#### Invalid Usage

You cannot use a window order clause with the following functions:

- \texttt{PERCENTILE_CONT}
- \texttt{PERCENTILE_DISC}
- \texttt{MEDIAN}
Examples

The examples below use the allsales table schema:

```sql
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

**Example 1**

The following query orders sales inside each state partition:

```sql
=> SELECT state, sales, name, RANK() OVER(PARTITION BY state
ORDER BY sales) AS RANK
FROM allsales;
```

<table>
<thead>
<tr>
<th>state</th>
<th>sales</th>
<th>name</th>
<th>RANK</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>10</td>
<td>G</td>
<td>1</td>
</tr>
<tr>
<td>MA</td>
<td>20</td>
<td>D</td>
<td>2</td>
</tr>
<tr>
<td>MA</td>
<td>50</td>
<td>E</td>
<td>3</td>
</tr>
<tr>
<td>MA</td>
<td>60</td>
<td>A</td>
<td>4</td>
</tr>
<tr>
<td>NY</td>
<td>15</td>
<td>C</td>
<td>1</td>
</tr>
<tr>
<td>NY</td>
<td>20</td>
<td>B</td>
<td>2</td>
</tr>
<tr>
<td>NY</td>
<td>40</td>
<td>F</td>
<td>3</td>
</tr>
</tbody>
</table>

(7 rows)

**Example 2**

The following query's final ORDER BY clause sorts results by name:

```sql
=> SELECT state, sales, name, RANK() OVER(PARTITION BY state
ORDER BY sales) AS RANK
FROM allsales ORDER BY name;
```

<table>
<thead>
<tr>
<th>state</th>
<th>sales</th>
<th>name</th>
<th>RANK</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>60</td>
<td>A</td>
<td>4</td>
</tr>
<tr>
<td>NY</td>
<td>20</td>
<td>B</td>
<td>2</td>
</tr>
<tr>
<td>NY</td>
<td>15</td>
<td>C</td>
<td>1</td>
</tr>
<tr>
<td>MA</td>
<td>20</td>
<td>D</td>
<td>2</td>
</tr>
<tr>
<td>MA</td>
<td>50</td>
<td>E</td>
<td>3</td>
</tr>
<tr>
<td>NY</td>
<td>40</td>
<td>F</td>
<td>3</td>
</tr>
<tr>
<td>MA</td>
<td>10</td>
<td>G</td>
<td>1</td>
</tr>
</tbody>
</table>

(7 rows)
Window Framing

The window frame of an analytic function comprises a set of rows relative to the row that is currently being evaluated by the function. After the analytic function processes that row and its window frame, Vertica advances the current row and adjusts the frame boundaries accordingly. If the OVER clause also specifies a partition, Vertica also checks that frame boundaries do not cross partition boundaries. This process repeats until the function evaluates the last row of the last partition.

Specifying a Window Frame

You specify a window frame in the analytic function's OVER clause, as shown below. The window frame clause is set off in bold:

```
OVER(
    [ window-partition-clause ]
    window-order-clause
    { ROWS | RANGE } { BETWEEN start-point AND end-point } | start-point
)
```

`start-point` and `end-point` specify the window frame's offset from the current row, as follows:

```
{ UNBOUNDED { PRECEDING | FOLLOWING } |
  CURRENT ROW |
  constant-value { PRECEDING | FOLLOWING } }
```

The keywords `ROWS` and `RANGE` specify whether the offset is physical or logical. If you specify only a start point, Vertica creates a window from that point to the current row.

For syntax details, see `window-frame-clause` in the SQL Reference Manual.

Requirements

In order to specify a window frame, the OVER must also specify a `window order` (ORDER BY) clause. If the OVER clause includes a window order clause but omits specifying a window frame, the function creates a default frame that extends from the first row in the current partition to the current row. This is equivalent to the following clause:

```
RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
```
Window Aggregate Functions

Analytic functions that support window frames are called window aggregates. They return information such as moving averages and cumulative results. To use the following functions as window (analytic) aggregates, instead of basic aggregates, the OVER clause must specify a window order clause and, optionally, a window frame clause. If the OVER clause omits specifying a window frame, the function creates a default window frame as described earlier.

The following analytic functions support window frames:

- AVG
- COUNT
- MAX / MIN
- SUM
- STDDEV / STDDEV_POP / STDDEV_SAMP
- VARIANCE / VAR_POP / VAR_SAMP

**Note:**
Functions FIRST_VALUE and LAST_VALUE also support window frames, but they are only analytic functions with no aggregate counterpart. EXPONENTIAL_MOVING_AVERAGE, LAG, and LEAD analytic functions do not support window frames.

A window aggregate with an empty OVER clause creates no window frame. The function is used as a reporting function, where all input is treated as a single partition.

Windows with a Physical Offset (ROWS)

The keyword ROWS in a window frame clause specifies window dimensions as the number of rows relative to the current row. The value can be INTEGER data type only.

**Note:**
The value returned by an analytic function with a physical offset is liable to produce nondeterministic results unless the ordering expression results in a unique ordering. To achieve unique ordering, the window order clause might need to specify multiple columns.
**Examples**

The examples on this page use the `emp` table schema:

```sql
CREATE TABLE emp (deptno INT, sal INT, empno INT);
INSERT INTO emp VALUES(10,101,1);
INSERT INTO emp VALUES(10,104,4);
INSERT INTO emp VALUES(20,100,11);
INSERT INTO emp VALUES(20,109,7);
INSERT INTO emp VALUES(20,109,6);
INSERT INTO emp VALUES(20,109,8);
INSERT INTO emp VALUES(20,110,10);
INSERT INTO emp VALUES(20,110,9);
INSERT INTO emp VALUES(30,102,2);
INSERT INTO emp VALUES(30,103,3);
INSERT INTO emp VALUES(30,105,5);
COMMIT;
```

The following query invokes `COUNT` to count the current row and the rows preceding it, up to two rows:

```sql
SELECT deptno, sal, empno, COUNT(*) OVER (PARTITION BY deptno ORDER BY sal ROWS BETWEEN 2 PRECEDING AND CURRENT ROW) AS count FROM emp;
```

The `OVER` clause contains three components:

- Window partition clause `PARTITION BY deptno`
- Order by clause `ORDER BY sal`
- Window frame clause `ROWS BETWEEN 2 PRECEDING AND CURRENT ROW`. This clause defines window dimensions as extending from the current row through the two rows that precede it.

The query returns results that are divided into three partitions, indicated below as red lines. Within the second partition (deptno=20), `COUNT` processes the window frame clause as follows:

1. Creates the first window (green box). This window comprises a single row, as the current row (blue box) is also the the partition's first row. Thus, the value in the `count` column shows the number of rows in the current window, which is 1:
2. After COUNT processes the partition's first row, it resets the current row to the partition's second row. The window now spans the current row and the row above it, so COUNT returns a value of 2:

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td></td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>

3. After COUNT processes the partition's second row, it resets the current row to the partition's third row. The window now spans the current row and the two rows above.
it, so COUNT returns a value of 3:

```
<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>
```

4. Thereafter, COUNT continues to process the remaining partition rows and moves the window accordingly, but the window dimensions (ROWS BETWEEN 2 PRECEDING AND CURRENT ROW) remain unchanged as three rows. Accordingly, the value in the count column also remains unchanged (3):

```
<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td></td>
</tr>
<tr>
<td>20</td>
<td>110</td>

</table>

**Windows with a Logical Offset (RANGE)**

The RANGE keyword defines an analytic window frame as a logical offset from the current row.

**Note:**
The value returned by an analytic function with a logical offset is always deterministic.
For each row, an analytic function uses the `window order clause` (ORDER_BY) column or expression to calculate window frame dimensions as follows:

1. Within the current partition, evaluates the ORDER_BY value of the current row against the ORDER_BY values of contiguous rows.
2. Determines which of these rows satisfy the specified range requirements relative to the current row.
3. Creates a window frame that includes only those rows.
4. Executes on the current window.

**Example**

This example uses the table `property_sales`, which contains data about neighborhood home sales:

```sql
=> SELECT property_key, neighborhood, sell_price FROM property_sales ORDER BY neighborhood, sell_price;

<table>
<thead>
<tr>
<th>property_key</th>
<th>neighborhood</th>
<th>sell_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>10918</td>
<td>Jamaica Plain</td>
<td>353000</td>
</tr>
<tr>
<td>10921</td>
<td>Jamaica Plain</td>
<td>450000</td>
</tr>
<tr>
<td>10927</td>
<td>Jamaica Plain</td>
<td>450000</td>
</tr>
<tr>
<td>10922</td>
<td>Jamaica Plain</td>
<td>474000</td>
</tr>
<tr>
<td>10919</td>
<td>Jamaica Plain</td>
<td>515000</td>
</tr>
<tr>
<td>10917</td>
<td>Jamaica Plain</td>
<td>675000</td>
</tr>
<tr>
<td>10924</td>
<td>Jamaica Plain</td>
<td>675000</td>
</tr>
<tr>
<td>10920</td>
<td>Jamaica Plain</td>
<td>705000</td>
</tr>
<tr>
<td>10923</td>
<td>Jamaica Plain</td>
<td>710000</td>
</tr>
<tr>
<td>10926</td>
<td>Jamaica Plain</td>
<td>875000</td>
</tr>
<tr>
<td>10925</td>
<td>Jamaica Plain</td>
<td>900000</td>
</tr>
<tr>
<td>10930</td>
<td>Roslindale</td>
<td>300000</td>
</tr>
<tr>
<td>10928</td>
<td>Roslindale</td>
<td>422000</td>
</tr>
<tr>
<td>10932</td>
<td>Roslindale</td>
<td>450000</td>
</tr>
<tr>
<td>10929</td>
<td>Roslindale</td>
<td>485000</td>
</tr>
<tr>
<td>10931</td>
<td>Roslindale</td>
<td>519000</td>
</tr>
<tr>
<td>10938</td>
<td>West Roxbury</td>
<td>479000</td>
</tr>
<tr>
<td>10933</td>
<td>West Roxbury</td>
<td>550000</td>
</tr>
<tr>
<td>10937</td>
<td>West Roxbury</td>
<td>550000</td>
</tr>
<tr>
<td>10934</td>
<td>West Roxbury</td>
<td>574000</td>
</tr>
<tr>
<td>10935</td>
<td>West Roxbury</td>
<td>598000</td>
</tr>
<tr>
<td>10936</td>
<td>West Roxbury</td>
<td>615000</td>
</tr>
<tr>
<td>10939</td>
<td>West Roxbury</td>
<td>720000</td>
</tr>
</tbody>
</table>

(23 rows)

The analytic function `AVG` can obtain the average of proximate selling prices within each neighborhood. The following query calculates for each home the average sale for all other neighborhood homes whose selling price was $50k higher or lower:

```sql
=> SELECT property_key, neighborhood, sell_price, AVG(sell_price) OVER(PARTITION BY neighborhood ORDER BY sell_price) FROM property_sales;
```
AVG processes this query as follows:

1. AVG evaluates row 1 of the first partition (Jamaica Plain), but finds no sales within $50k of this row's sell_price, ($353k). AVG creates a window that includes this row only, and returns an average of 353k for row 1:

2. AVG evaluates row 2 and finds three sell_price values within $50k of the current row. AVG creates a window that includes these three rows, and returns an average of
3. AVG evaluates row 3 and finds the same three `sell_price` values within $50k of the current row. AVG creates a window identical to the one before, and returns the same average of 458k for row 3:

4. AVG evaluates row 4 and finds four `sell_price` values within $50k of the current row. AVG expands its window to include rows 2 through 5, and returns an average of $472.25k for row 4:

5. In similar fashion, AVG evaluates the remaining rows in this partition. When the function evaluates the first row of the second partition (Roslindale), it resets the
window as follows:

<table>
<thead>
<tr>
<th>property_key</th>

</tbody>
</table>

**Restrictions**

If RANGE specifies a constant value, that value's data type and the window's ORDER BY data type must be the same. The following exceptions apply:

- RANGE can specify INTERVAL Year to Month if the window order clause data type is one of following: TIMESTAMP, TIMESTAMP WITH TIMEZONE, or DATE. TIME and TIME WITH TIMEZONE are not supported.
- RANGE can specify INTERVAL Day to Second if the window order clause data is one of following: TIMESTAMP, TIMESTAMP WITH TIMEZONE, DATE, TIME, or TIME WITH TIMEZONE.

The window order clause must specify one of the following data types: NUMERIC, DATE/TIME, FLOAT or INTEGER. This requirement is ignored if the window specifies one of following frames:

- RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
- RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING
- RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING
Reporting Aggregates

Some of the analytic functions that take the window-frame-clause are the reporting aggregates. These functions let you compare a partition's aggregate values with detail rows, taking the place of correlated subqueries or joins.

- \( \text{AVG()} \)
- \( \text{COUNT()} \)
- \( \text{MAX()} \) and \( \text{MIN()} \)
- \( \text{SUM()} \)
- \( \text{STDDEV()}, \text{STDDEV\_POP()}, \) and \( \text{STDDEV\_SAMP()} \)
- \( \text{VARIANCE()}, \text{VAR\_POP()}, \) and \( \text{VAR\_SAMP()} \)

If you use a window aggregate with an empty OVER() clause, the analytic function is used as a reporting function, where the entire input is treated as a single partition.

About Standard Deviation and Variance Functions

With standard deviation functions, a low standard deviation indicates that the data points tend to be very close to the mean, whereas high standard deviation indicates that the data points are spread out over a large range of values.

Standard deviation is often graphed and a distributed standard deviation creates the classic bell curve.

Variance functions measure how far a set of numbers is spread out.

Examples

Think of the window for reporting aggregates as a window defined as UNBOUNDED PRECEDING and UNBOUNDED FOLLOWING. The omission of a window-order-clause makes all rows in the partition also the window (reporting aggregates).

```sql
=> SELECT deptno, sal, empno, COUNT(sal)
    OVER (PARTITION BY deptno) AS COUNT FROM emp;

deptno | sal  | empno | count
--------+------+-------+------
    10 | 101  |   1   |   2  
    10 | 104  |   4   |   2  
--------+------+-------+------
    20 | 110  |   10  |   6  
```
If the OVER() clause in the above query contained a window-order-clause (for example, ORDER BY sal), it would become a moving window (window aggregate) query with a default window of RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW:

```sql
=> SELECT deptno, sal, empno, COUNT(sal) OVER (PARTITION BY deptno ORDER BY sal) AS COUNT FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>6</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>

(11 rows)

What About LAST_VALUE?

You might wonder why you couldn't just use the LAST_VALUE() analytic function.

For example, for each employee, get the highest salary in the department:

```sql
=> SELECT deptno, sal, empno, LAST_VALUE(empno) OVER (PARTITION BY deptno ORDER BY sal) AS lv FROM emp;
```
Due to default window semantics, LAST_VALUE does not always return the last value of a partition. If you omit the window-frame-clause from the analytic clause, LAST_VALUE operates on this default window. Results, therefore, can seem non-intuitive because the function does not return the bottom of the current partition. It returns the bottom of the window, which continues to change along with the current input row being processed.

Remember the default window:

```
OVER (PARTITION BY deptno ORDER BY sal)
```

is the same as:

```
OVER(PARTITION BY deptno ORDER BY salROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
```
If you want to return the last value of a partition, use UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING.

```sql
=> SELECT deptno, sal, empno, LAST_VALUE(empno)
   OVER (PARTITION BY deptno ORDER BY sal
         ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM emp;
```
Vertica recommends that you use LAST_VALUE with the window-order-clause to produce deterministic results.

In the following example, empno 6, 7, and 8 have the same salary, so they are in adjacent rows. empno 8 appears first in this case but the order is not guaranteed.

Notice in the output above, the last value is 7, which is the last row from the partition deptno = 20. If the rows have a different order, then the function returns a different value:
Now the last value is 6, which is the last row from the partition deptno = 20. The solution is to add a unique key to the sort order. Even if the order of the query changes, the result will always be the same, and so deterministic.

```
=> SELECT deptno, sal, empno, LAST_VALUE(empno)
OVER (PARTITION BY deptno ORDER BY sal, empno
ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) as lv
FROM emp;
```

Notice how the rows are now ordered by empno, the last value stays at 8, and it does not matter the order of the query.

### Named Windows

An analytic function's OVER clause can reference a named window, which encapsulates one or more window clauses: a window partition (PARTITION BY) clause and (optionally) a
window order (ORDER BY) clause. Named windows can be useful when you write queries that invoke multiple analytic functions with similar OVER clause syntax—for example, they use the same partition clauses.

A query names a window as follows:

```
WINDOW window-name AS ( window-partition-clause [window-order-clause] );
```

The same query can name and reference multiple windows. All window names must be unique within the same query.

## Examples

The following query invokes two analytic functions, `RANK` and `DENSE_RANK`. Because the two functions use the same partition and order clauses, the query names a window `w` that specifies both clauses. The two functions reference this window as follows:

```
=> SELECT employee_region region, employee_key, annual_salary, 
    RANK() OVER w Rank, 
    DENSE_RANK() OVER w "Dense Rank" 
FROM employee_dimension WINDOW w AS (PARTITION BY employee_region ORDER BY annual_salary);
```

<table>
<thead>
<tr>
<th>region</th>
<th>employee_key</th>
<th>annual_salary</th>
<th>Rank</th>
<th>Dense Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>West</td>
<td>5248</td>
<td>1200</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>West</td>
<td>6880</td>
<td>1204</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>West</td>
<td>5700</td>
<td>1214</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>West</td>
<td>9857</td>
<td>1218</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>West</td>
<td>6014</td>
<td>1218</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>West</td>
<td>9221</td>
<td>1220</td>
<td>6</td>
<td>5</td>
</tr>
<tr>
<td>West</td>
<td>7646</td>
<td>1222</td>
<td>7</td>
<td>6</td>
</tr>
<tr>
<td>West</td>
<td>6621</td>
<td>1222</td>
<td>7</td>
<td>6</td>
</tr>
<tr>
<td>West</td>
<td>6488</td>
<td>1224</td>
<td>9</td>
<td>7</td>
</tr>
<tr>
<td>West</td>
<td>7659</td>
<td>1226</td>
<td>10</td>
<td>8</td>
</tr>
<tr>
<td>West</td>
<td>7432</td>
<td>1226</td>
<td>10</td>
<td>8</td>
</tr>
<tr>
<td>West</td>
<td>9905</td>
<td>1226</td>
<td>10</td>
<td>8</td>
</tr>
<tr>
<td>West</td>
<td>9021</td>
<td>1228</td>
<td>13</td>
<td>9</td>
</tr>
<tr>
<td>West</td>
<td>7855</td>
<td>1228</td>
<td>13</td>
<td>9</td>
</tr>
<tr>
<td>West</td>
<td>7119</td>
<td>1230</td>
<td>15</td>
<td>10</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

If the named window omits an order clause, the query's OVER clauses can specify their own order clauses. For example, you can modify the previous query so each function uses a different order clause. The named window is defined so it includes only a partition clause:

```
=> SELECT employee_region region, employee_key, annual_salary, 
    RANK() OVER (w ORDER BY annual_salary DESC) Rank, 
    DENSE_RANK() OVER (w ORDER BY annual_salary ASC) "Dense Rank" 
FROM employee_dimension WINDOW w AS (PARTITION BY employee_region);
```

<table>
<thead>
<tr>
<th>region</th>
<th>employee_key</th>
<th>annual_salary</th>
<th>Rank</th>
<th>Dense Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>West</td>
<td>5248</td>
<td>1200</td>
<td>2795</td>
<td>1</td>
</tr>
<tr>
<td>West</td>
<td>6880</td>
<td>1204</td>
<td>2794</td>
<td>2</td>
</tr>
</tbody>
</table>
Similarly, an OVER clause specifies a named window can also specify a window frame clause, provided the named window includes an order clause. This can be useful inasmuch as you cannot define a named windows to include a window frame clause.

For example, the following query defines a window that encapsulates partitioning and order clauses. The OVER clause invokes this window and also includes a window frame clause:

```sql
=> SELECT deptno, sal, empno, COUNT(*) OVER (w ROWS BETWEEN 2 PRECEDING AND CURRENT ROW) AS count
    FROM emp WINDOW w AS (PARTITION BY deptno ORDER BY sal);
```
Restrictions

- An OVER clause can reference only one named window.
- Each WINDOW clause within the same query must have a unique name.
Analytic Query Examples

The topics in this section show how to use analytic queries for calculations.

Calculating a Median Value

A median is a numerical value that separates the higher half of a sample from the lower half. For example, you can retrieve the median of a finite list of numbers by arranging all observations from lowest value to highest value and then picking the middle one.

If the number of observations is even, then there is no single middle value; the median is the mean (average) of the two middle values.

The following example uses this table:

```sql
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

You can use the analytic function `MEDIAN` to calculate the median of all sales in this table. In the following query, the function's `OVER` clause is empty, so the query returns the same aggregated value for each row of the result set:

```sql
=> SELECT name, sales, MEDIAN(sales) OVER() AS median FROM allsales;
```

<table>
<thead>
<tr>
<th>name</th>
<th>sales</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>G</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>D</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>F</td>
<td>40</td>
<td>20</td>
</tr>
<tr>
<td>E</td>
<td>50</td>
<td>20</td>
</tr>
<tr>
<td>A</td>
<td>60</td>
<td>20</td>
</tr>
</tbody>
</table>

(7 rows)

You can modify this query to group sales by state and obtain the median for each one. To do so, include a window partition clause in the `OVER` clause:
\[
\text{SELECT state, name, sales, MEDIAN(sales) OVER(partition by state) AS median FROM allsales;}
\]

<table>
<thead>
<tr>
<th>state</th>
<th>name</th>
<th>sales</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>G</td>
<td>10</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>D</td>
<td>20</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>E</td>
<td>50</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>A</td>
<td>60</td>
<td>35</td>
</tr>
<tr>
<td>NY</td>
<td>C</td>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>NY</td>
<td>B</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>NY</td>
<td>F</td>
<td>40</td>
<td>20</td>
</tr>
</tbody>
</table>

(7 rows)

**Getting Price Differential for Two Stocks**

The following subquery selects out two stocks of interest. The outer query uses the \text{LAST\_VALUE()} and \text{OVER()} components of analytics, with \text{IGNORE NULLS}.

**Schema**

\[
\text{DROP TABLE Ticks CASCADE;}
\]

\[
\text{CREATE TABLE Ticks (ts TIMESTAMP, Stock varchar(10), Bid float);}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:23:54', 'abc', 10.12);}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:23:58', 'abc', 10.34);}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:23:59', 'abc', 10.75);}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:25:15', 'abc', 11.98);}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:25:16', 'abc');}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:25:22', 'xyz', 45.16);}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:25:27', 'xyz', 49.33);}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:31:12', 'xyz', 65.25);}\]

\[
\text{INSERT INTO Ticks VALUES('2011-07-12 10:31:15', 'xyz');}\]

\[
\text{COMMIT;}\]

**ticks Table**

\[
\text{SELECT * FROM ticks;}
\]

<table>
<thead>
<tr>
<th>ts</th>
<th>stock</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2011-07-12 10:23:59</td>
<td>abc</td>
<td>10.75</td>
</tr>
<tr>
<td>2011-07-12 10:25:22</td>
<td>xyz</td>
<td>45.16</td>
</tr>
<tr>
<td>2011-07-12 10:23:58</td>
<td>abc</td>
<td>10.34</td>
</tr>
<tr>
<td>2011-07-12 10:25:27</td>
<td>xyz</td>
<td>49.33</td>
</tr>
<tr>
<td>2011-07-12 10:31:15</td>
<td>xyz</td>
<td></td>
</tr>
<tr>
<td>2011-07-12 10:25:15</td>
<td>abc</td>
<td>11.98</td>
</tr>
<tr>
<td>2011-07-12 10:25:16</td>
<td>abc</td>
<td></td>
</tr>
</tbody>
</table>
Calculating the Moving Average

Calculating the moving average is useful to get an estimate about the trends in a data set. The moving average is the average of any subset of numbers over a period of time. For example, if you have retail data that spans over ten years, you could calculate a three year moving average, a four year moving average, and so on. This example calculates a 40-second moving average of bids for one stock. This examples uses the `ticks` table schema.

Query

```sql
=> SELECT ts, bid, AVG(bid) 
    OVER(ORDER BY ts 
        RANGE BETWEEN INTERVAL '40 seconds' 
        PRECEDING AND CURRENT ROW) 
FROM ticks 
WHERE stock = 'abc'
```
GROUP BY bid, ts
ORDER BY ts;

<table>
<thead>
<tr>
<th>ts</th>
<th>bid</th>
<th>?column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>2011-07-12 10:23:58</td>
<td>10.34</td>
<td>10.23</td>
</tr>
<tr>
<td>2011-07-12 10:23:59</td>
<td>10.75</td>
<td>10.4033333333333</td>
</tr>
<tr>
<td>2011-07-12 10:25:15</td>
<td>11.98</td>
<td>11.98</td>
</tr>
<tr>
<td>2011-07-12 10:25:16</td>
<td></td>
<td>11.98</td>
</tr>
</tbody>
</table>

(Drop 5 rows)

CREATE TABLE Ticks (ts TIMESTAMP, Stock varchar(10), Bid float);
INSERT INTO Ticks VALUES('2011-07-12 10:23:54', 'abc', 10.12);
INSERT INTO Ticks VALUES('2011-07-12 10:23:58', 'abc', 10.34);
INSERT INTO Ticks VALUES('2011-07-12 10:23:59', 'abc', 10.75);
INSERT INTO Ticks VALUES('2011-07-12 10:25:15', 'abc', 11.98);
INSERT INTO Ticks VALUES('2011-07-12 10:25:16', 'abc');
INSERT INTO Ticks VALUES('2011-07-12 10:25:22', 'xyz', 45.16);
INSERT INTO Ticks VALUES('2011-07-12 10:25:27', 'xyz', 49.33);
INSERT INTO Ticks VALUES('2011-07-12 10:31:12', 'xyz', 65.25);
INSERT INTO Ticks VALUES('2011-07-12 10:31:15', 'xyz');

COMMIT;

**Getting Latest Bid and Ask Results**

The following query fills in missing NULL values to create a full book order showing latest bid and ask price and size, by vendor id. Original rows have values for (typically) one price and one size, so use last_value with "ignore nulls" to find the most recent non-null value for the other pair each time there is an entry for the ID. Sequenceno provides a unique total ordering.

**Schema:**

```sql
=> CREATE TABLE bookorders(
    vendorid VARCHAR(100),
    date TIMESTAMP,
    sequenceno INT,
    askprice FLOAT,
    asksize INT,
    bidprice FLOAT,
    bidsize INT);
=> INSERT INTO bookorders VALUES('3325XPK', '2011-07-12 10:23:54', 1, 10.12, 55, 10.23, 59);
=> INSERT INTO bookorders VALUES('3345XPZ', '2011-07-12 10:23:55', 2, 10.55, 58, 10.75, 57);
=> INSERT INTO bookorders VALUES('445XPKF', '2011-07-12 10:23:56', 3, 10.22, 43, 10.25, 61);
```
Query:

```sql
=> SELECT
    sequenceno Seq,
    date "Time",
    vendorID ID,
    LAST_VALUE (bidprice IGNORE NULLS)
        OVER (PARTITION BY vendorID ORDER BY sequenceno
               ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
    AS "Bid Price",
    LAST_VALUE (bidsize IGNORE NULLS)
        OVER (PARTITION BY vendorID ORDER BY sequenceno
               ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
    AS "Bid Size",
    LAST_VALUE (askprice IGNORE NULLS)
        OVER (PARTITION BY vendorID ORDER BY sequenceno
               ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
    AS "Ask Price",
    LAST_VALUE (asksize IGNORE NULLS)
        OVER (PARTITION BY vendorID ORDER BY sequenceno
               ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
    AS "Ask Size"
FROM bookorders
ORDER BY sequenceno;
```

Event-Based Windows

Event-based windows let you break time series data into windows that border on significant events within the data. This is especially relevant in financial data where analysis often focuses on specific events as triggers to other activity.
Vertica provides two event-based window functions that are not part of the SQL-99 standard:

- **CONDITIONAL_CHANGE_EVENT** assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row. This function is similar to the analytic function **ROW_NUMBER**, which assigns a unique number, sequentially, starting from 1, to each row within a partition.
- **CONDITIONAL_TRUE_EVENT** assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true.

Both functions are described in greater detail below.

**Note:** CONDITIONAL_CHANGE_EVENT and CONDITIONAL_TRUE_EVENT do not support window framing.

### Example schema

The examples on this page use the following schema:

```sql
CREATE TABLETickStore3 (ts TIMESTAMP, symbol VARCHAR(8), bid FLOAT);
CREATE PROJECTION TickStore3_p (ts, symbol, bid) AS SELECT * FROM TickStore3 ORDER BY ts, symbol, bid UNSEGMENTED ALL NODES;
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:00', 'XYZ', 10.0);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:03', 'XYZ', 11.0);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:06', 'XYZ', 10.5);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:09', 'XYZ', 11.0);
COMMIT;
```

### Using CONDITIONAL_CHANGE_EVENT

The analytical function CONDITIONAL_CHANGE_EVENT returns a sequence of integers indicating event window numbers, starting from 0. The function increments the event window number when the result of evaluating the function expression on the current row differs from the previous value.

In the following example, the first query returns all records from the TickStore3 table. The second query uses the CONDITIONAL_CHANGE_EVENT function on the bid column. Since each bid row value is different from the previous value, the function increments the window ID from 0 to 3:

```
SELECT ts, symbol, bid FROM Tickstore3 ORDER BY
SELECT CONDITIONAL_CHANGE_EVENT(bid)
```
The following figure is a graphical illustration of the change in the bid price. Each value is different from its previous one, so the window ID increments for each time slice:

So the window ID starts at 0 and increments at every change in from the previous value.

In this example, the bid price changes from $10 to $11 in the second row, but then stays the same. CONDITIONAL_CHANGE_EVENT increments the event window ID in row 2, but not subsequently:
The following figure is a graphical illustration of the change in the bid price at 3:00:03 only. The price stays the same at 3:00:06 and 3:00:09, so the window ID remains at 1 for each time slice after the change:

Using **CONDITIONAL_TRUE_EVENT**

Like **CONDITIONAL_CHANGE_EVENT**, the analytic function **CONDITIONAL_TRUE_EVENT** also returns a sequence of integers indicating event window numbers, starting from 0. The two functions differ as follows:

- **CONDITIONAL_TRUE_EVENT** increments the window ID each time its expression evaluates to true.
- **CONDITIONALCHANGE_EVENT** increments on a comparison expression with the previous value.

In the following example, the first query returns all records from the TickStore3 table. The second query uses **CONDITIONAL_TRUE_EVENT** to test whether the current bid is greater than a given value (10.6). Each time the expression tests true, the function increments the window ID. The first time the function increments the window ID is on row 2, when the value is 11. The expression tests false for the next row (value is not greater than 10.6), so the function does not increment the event window ID. In the final row, the expression is true for the given condition, and the function increments the window:
The following figure is a graphical illustration that shows the bid values and window ID changes. Because the bid value is greater than $10.6 on only the second and fourth time slices (3:00:03 and 3:00:09), the window ID returns <0,1,1,2>: 

In the following example, the first query returns all records from the TickStore3 table, ordered by the tickstore values (ts). The second query uses CONDITIONAL_TRUE_EVENT to increment the window ID each time the bid value is greater than 10.6. The first time the function increments the event window ID is on row 2, where the value is 11. The window ID then increments each time after that, because the expression (bid > 10.6) tests true for each time slice:
The following figure is a graphical illustration that shows the bid values and window ID changes. The bid value is greater than 10.6 on the second time slice (3:00:03) and remains for the remaining two time slices. The function increments the event window ID each time because the expression tests true:

![Graphical illustration of bid values and window ID changes]

### Advanced Use of Event-Based Windows

In event-based window functions, the condition expression accesses values from the current row only. To access a previous value, you can use a more powerful event-based window that allows the window event condition to include previous data points. For example, analytic function `LAG(x, n)` retrieves the value of column x in the nth to last input record. In this case, `LAG` shares the `OVER` specifications of the `CONDITIONAL_CHANGE_EVENT` or `CONDITIONAL_TRUE_EVENT` function expression.

In the following example, the first query returns all records from the TickStore3 table. The second query uses `CONDITIONAL_TRUE_EVENT` with the `LAG` function in its boolean expression. In this case, `CONDITIONAL_TRUE_EVENT` increments the event window ID each time the bid value on the current row is less than the previous value. The first time
CONDITIONAL_TRUE_EVENT increments the window ID starts on the third time slice, when the expression tests true. The current value (10.5) is less than the previous value. The window ID is not incremented in the last row because the final value is greater than the previous row:

<table>
<thead>
<tr>
<th>ts</th>
<th>symbol</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:03</td>
<td>XYZ</td>
<td>11</td>
</tr>
<tr>
<td>2009-01-01 03:00:06</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
<tr>
<td>2009-01-01 03:00:09</td>
<td>XYZ</td>
<td>11</td>
</tr>
</tbody>
</table>

The following figure illustrates the second query above. When the bid price is less than the previous value, the window ID gets incremented, which occurs only in the third time slice (3:00:06):

Sessionization with Event-Based Windows

Sessionization, a special case of event-based windows, is a feature often used to analyze click streams, such as identifying web browsing sessions from recorded web clicks.

In Vertica, given an input clickstream table, where each row records a Web page click made by a particular user (or IP address), the sessionization computation attempts to identify Web browsing sessions from the recorded clicks by grouping the clicks from each user based on the time-intervals between the clicks. If two clicks from the same user are made too far apart in time, as defined by a time-out threshold, the clicks are treated as though they are from two different browsing sessions.

Example Schema

The examples in this topic use the following WebClicks schema to represent a simple clickstream table:

```sql
CREATE TABLE WebClicks(userId INT, timestamp TIMESTAMP);
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:00 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:25 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:45 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:01:45 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:02:45 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:02:55 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:03:55 pm');
COMMIT;
```

The input table `WebClicks` contains the following rows:

```sql
=> SELECT * FROM WebClicks;

<table>
<thead>
<tr>
<th>userId</th>
<th>timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2009-12-08 15:00:00</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:25</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:45</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:01:45</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:45</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:55</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:03:55</td>
</tr>
</tbody>
</table>

(7 rows)
```

In the following query, sessionization performs computation on the SELECT list columns, showing the difference between the current and previous timestamp value using `LAG()`. It evaluates to true and increments the window ID when the difference is greater than 30 seconds.
=> SELECT userId, timestamp, 
    CONDITIONAL_TRUE_EVENT(timestamp - LAG(timestamp) > '30 seconds')
    OVER(PARTITION BY userId ORDER BY timestamp) AS session 
FROM WebClicks;

<table>
<thead>
<tr>
<th>userId</th>
<th>timestamp</th>
<th>session</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2009-12-08 15:00:00</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:25</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:45</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:01:45</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:45</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:55</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:03:55</td>
<td>1</td>
</tr>
</tbody>
</table>

(7 rows)

In the output, the session column contains the window ID from the CONDITIONAL_TRUE_EVENT function. The window ID evaluates to true on row 4 (timestamp 15:01:45), and the ID that follows row 4 is zero because it is the start of a new partition (for user ID 2), and that row does not evaluate to true until the last line in the output.

You might want to give users different time-out thresholds. For example, one user might have a slower network connection or be multi-tasking, while another user might have a faster connection and be focused on a single Web site, doing a single task.

To compute an adaptive time-out threshold based on the last 2 clicks, use CONDITIONAL_TRUE_EVENT with LAG to return the average time between the last 2 clicks with a grace period of 3 seconds:

=> SELECT userId, timestamp, 
    CONDITIONAL_TRUE_EVENT(timestamp - LAG(timestamp) > 
    (LAG(timestamp, 1) - LAG(timestamp, 3)) / 2 + '3 seconds')
    OVER(PARTITION BY userId ORDER BY timestamp) AS session 
FROM WebClicks;

<table>
<thead>
<tr>
<th>userId</th>
<th>timestamp</th>
<th>session</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2009-12-08 15:02:45</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:55</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:03:55</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:00</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:25</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:45</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:01:45</td>
<td>1</td>
</tr>
</tbody>
</table>

(7 rows)

Note:
You cannot define a moving window in time series data. For example, if the query is evaluating the first row and there’s no data, it will be the current row. If you have a lag of 2, no results are returned until the third row.

Machine Learning for Predictive Analytics

Vertica provides a number of machine learning functions for performing in-database analysis. These functions can perform a number of data preparation and predictive tasks.

For more information about specific machine learning functions see Machine Learning Functions.

Downloading the Machine Learning Example Data

You need several data sets to run the machine learning examples. You can download these data sets from the Vertica Github repository.

Important: The Github examples are based on the latest Vertica version. If you note differences, please upgrade to the latest version.

You can download the example data in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the Vertica Machine Learning Github repository. Using a terminal window, run the following command:

  $ git clone https://github.com/vertica/Machine-Learning-Examples
Loading the Example Data

You can load the example data by doing one of the following. Note that models are not automatically dropped. You must either rerun the load_ml_data.sql script to drop models or manually drop them.

- Copying and pasting the DDL and DML operations in load_ml_data.sql in a vsql prompt or another Vertica client.
- Running the following command from a terminal window in the Machine-Learning-Examples directory:

  ```
  $ /opt/vertica/bin/vsql -d <name of your database> -f load_ml_data.sql
  ```

You must also load the naive_bayes_data_preparation.sql script:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f naive_bayes_data_preparation.sql
```

Example Data Descriptions

The repository contains the following data sets.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agar_dish</td>
<td>Synthetic data set meant to represent clustering of bacteria on an agar dish. Contains the following columns: id, x-coordinate, and y-coordinate.</td>
</tr>
<tr>
<td>agar_dish_2</td>
<td>125 rows sampled randomly from the original 500 rows of the agar_dish data set.</td>
</tr>
<tr>
<td>agar_dish_1</td>
<td>375 rows sampled randomly from the original 500 rows of the agar_dish data set.</td>
</tr>
<tr>
<td>baseball</td>
<td>Contains statistics from a fictional baseball league. The statistics included are: first name, last name, date of birth, team name, homeruns, hits, batting average, and salary.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>faithful</td>
<td>Wait times between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA.</td>
</tr>
<tr>
<td></td>
<td><strong>Reference</strong></td>
</tr>
<tr>
<td>faithful_testing</td>
<td>Roughly 60% of the original 272 rows of the faithful data set.</td>
</tr>
<tr>
<td>faithful_training</td>
<td>Roughly 40% of the original 272 rows of the faithful data set.</td>
</tr>
<tr>
<td>house84</td>
<td>The house84 data set includes votes for each of the U.S. House of Representatives Congress members on 16 votes. Contains the following columns: id, party, vote1, vote2, vote3, vote4, vote5, vote6, vote7, vote8, vote9, vote10, vote11, vote12, vote13, vote14, vote15, vote16.</td>
</tr>
<tr>
<td></td>
<td><strong>Reference</strong></td>
</tr>
<tr>
<td>iris</td>
<td>The iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are Iris setosa, versicolor, and virginica.</td>
</tr>
<tr>
<td></td>
<td><strong>Reference</strong></td>
</tr>
<tr>
<td>iris1</td>
<td>90 rows sampled randomly from the original 150 rows in the iris data set.</td>
</tr>
<tr>
<td>iris2</td>
<td>60 rows sampled randomly from the original 150 rows in the iris data set.</td>
</tr>
<tr>
<td>mtcars</td>
<td>The data was extracted from the 1974 Motor Trend US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>salary_data</td>
<td>Contains fictional employee data. The data included are: employee id, first name, last name, years worked, and current salary.</td>
</tr>
<tr>
<td>transaction_data</td>
<td>Contains fictional credit card transactions with a BOOLEAN column indicating whether there was fraud associated with the transaction. The data included are: first name, last name, store, cost, and fraud.</td>
</tr>
<tr>
<td>titanic_testing</td>
<td>Contains passenger information from the Titanic ship including sex, age, passenger class, and whether or not they survived.</td>
</tr>
<tr>
<td>titanic_training</td>
<td>Contains passenger information from the Titanic ship including sex, age, passenger class, and whether or not they survived.</td>
</tr>
<tr>
<td>world</td>
<td>Contains country-specific information about human development using HDI, GDP, and CO2 emissions.</td>
</tr>
</tbody>
</table>

**Data Preparation**

Before you can analyze your data, you must prepare it. You can do the following data preparation tasks in Vertica:

**Balancing Imbalanced Data**

Imbalanced data occurs when an uneven distribution of classes occurs in the data. Building a predictive model on the imbalanced data set would cause a model that appears to yield high accuracy but does not generalize well to the new data in the minority class. To prevent creating models with false levels of accuracy, you should rebalance your imbalanced data before creating a predictive model.

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).
You see imbalanced data a lot in financial transaction data where the majority of the transactions are not fraudulent and a small number of the transactions are fraudulent, as shown in the following example.

1. View the distribution of the classes.

```
=> SELECT fraud, COUNT(fraud) FROM transaction_data GROUP BY fraud;

<table>
<thead>
<tr>
<th>fraud</th>
<th>COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE</td>
<td>19</td>
</tr>
<tr>
<td>FALSE</td>
<td>981</td>
</tr>
</tbody>
</table>
```

2. Use the BALANCE function to create a more balanced data set.

```
=> SELECT BALANCE('balance_fin_data', 'transaction_data', 'fraud', 'under_sampling' USING PARAMETERS sampling_ratio = 0.2);

BALANCE

Finished in 1 iteration

(1 row)
```

3. View the new distribution of the classifiers.

```
=> SELECT fraud, COUNT(fraud) FROM balance_fin_data GROUP BY fraud;

<table>
<thead>
<tr>
<th>fraud</th>
<th>COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>19</td>
</tr>
<tr>
<td>f</td>
<td>236</td>
</tr>
</tbody>
</table>
```

- BALANCE

Detecting Outliers

Before you perform an in-depth analysis of your data, you should first remove the outliers from the data. Outliers are data points that greatly differ from other similar data points. If you leave outliers in your data, you risk misclassifying data, introducing bias, or incorrect calculations.

This example uses the baseball data set found on the Vertica GitHub page.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.
1. Detect the outliers based on the hr, hits, and salary columns. The DETECT_OUTLIERS function creates a table containing the outliers with the input and key columns. Before you use the DETECT_OUTLIERS function, make sure that you are a superuser or have CREATE privileges for the schema and SELECT privileges for the table.

```sql
=> SELECT DETECT_OUTLIERS('baseball_hr_hits_salary_outliers', 'baseball', 'hr, hits, salary', 'robust_zscore'
   USING PARAMETERS outlier_threshold=3.0);
```

Detected 5 outliers

(1 row)

2. Query the output table containing the outliers.

```sql
=> SELECT * FROM baseball_hr_hits_salary_outliers;
```

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>dob</th>
<th>team</th>
<th>hr</th>
<th>hits</th>
<th>avg</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>73</td>
<td>Marie</td>
<td>Fields</td>
<td>1985-11-23</td>
<td>Mauv</td>
<td>8888</td>
<td>34</td>
<td>0.283</td>
<td>9.99999999341471e+16</td>
</tr>
<tr>
<td>89</td>
<td>Jacqueline</td>
<td>Richards</td>
<td>1975-10-06</td>
<td>Pink</td>
<td>273333</td>
<td>4490260</td>
<td>0.324</td>
<td>4.4444444444828e+17</td>
</tr>
<tr>
<td>87</td>
<td>Jose</td>
<td>Stephens</td>
<td>1991-07-20</td>
<td>Green</td>
<td>80</td>
<td>64253</td>
<td>0.69</td>
<td>16032567.12</td>
</tr>
<tr>
<td>222</td>
<td>Gerald</td>
<td>Fuller</td>
<td>1991-02-13</td>
<td>Goldenrod</td>
<td>3200000</td>
<td>216</td>
<td>0.299</td>
<td>37008899.76</td>
</tr>
<tr>
<td>147</td>
<td>Debra</td>
<td>Hall</td>
<td>1980-12-31</td>
<td>Maroon</td>
<td>230</td>
<td>0.431</td>
<td>9000101403</td>
<td>(5 rows)</td>
</tr>
</tbody>
</table>

3. Create a view omitting the outliers from the table.

```sql
=> CREATE VIEW clean_baseball AS
   SELECT * FROM baseball WHERE id NOT IN (SELECT id FROM baseball_hr_hits_salary_outliers);
```

CREATE VIEW

4. Perform your analysis using the view that omits the outliers.

Encoding Categorical Columns

Many machine learning algorithms cannot work with categorical data. To accommodate such algorithms, categorical data must be converted to numerical data before training. Directly mapping the categorical values into indices is not enough. For example, if your categorical feature has three distinct values "red", "green" and "blue", replacing them with 1, 2 and 3 may have a negative impact on the training process because algorithms usually rely on some kind of numerical distances between values to discriminate between them. In this case, the Euclidean distance from 1 to 3 is twice the distance from 1 to 2, which means the training process will think that "red" is much more different than "blue", while it is more similar to "green". Alternatively, one hot encoding maps each categorical value to a binary vector to avoid this problem. For example, "red" can be mapped to [1,0,0], "green" to [0,1,0] and "blue" to [0,0,1]. Now, the pair-wise distances between the three categories are all the same. One hot encoding allows you to convert categorical variables to binary values so that you can use different machine learning algorithms to evaluate your data.

The following example shows how you can apply one hot encoding to the Titanic data set. If you would like to read more about this data set, see the Kaggle site.

Suppose you want to use a logistic regression classifier to predict which passengers survived the sinking of the Titanic. You cannot use categorical features for logistic regression without one hot encoding. This data set has two categorical features that you can use. The "sex" feature can be either male or female. The "embarkation_point" feature can be one of the following:

- S for Southampton
- Q for Queenstown
- C for Cherbourg

Before you begin the example, make sure that you have loaded the Machine Learning sample data.

1. Run the ONE_HOT_ENCODER_FIT function on the training data:

```sql
=> SELECT ONE_HOT_ENCODER_FIT('titanic_encoder', 'titanic_training', 'sex, embarkation_point');
ONE_HOT_ENCODER_FIT
----------------------
Success

(1 row)
```

2. View a summary of the titanic_encoder model:
3. Run the **GET_MODEL_ATTRIBUTE** function. This function returns the categorical levels in their native data types, so they can be compared easily with the original table:

```sql
=> SELECT * FROM (SELECT GET_MODEL_ATTRIBUTE(USING PARAMETERS model_name='titanic_encoder',
attr_name='varchar_categories')) AS attrs INNER JOIN (SELECT passenger_id, name, sex, age,
embarkation_point FROM titanic_training) AS original_data ON attrs.category_level
LIKE original_data.embarkation_point ORDER BY original_data.passenger_id LIMIT 10;
```

```
category_name | category_level | category_level_index | passenger_id | name                   
-------------------------------------+---------------------+---------------------+---------------+------------------
embarkation_point | S               | 2                   | 1 | Braund, Mr. Owen Harris
| male | 22 | S
embarkation_point | C               | 0                   | 2 | Cumings, Mrs. John Bradley
| (Florence Briggs Thayer | female | 38 | C
embarkation_point | S               | 2                   | 3 | Heikkinen, Miss. Laina
| female | 26 | S
embarkation_point | S               | 2                   | 4 | Futrelle, Mrs. Jacques
Heath
| (Lily May Peel) | female | 35 | S
embarkation_point | S               | 2                   | 5 | Allen, Mr. William Henry
| male | 35 | S
embarkation_point | Q               | 1                   | 6 | Moran, Mr. James
| male | Q
embarkation_point | S               | 2                   | 7 | McCarthy, Mr. Timothy J
| male | 54 | S
embarkation_point | S               | 2                   | 8 | Palsson, Master. Gosta
Leonard
| male | 2 | S
embarkation_point | S               | 2                   | 9 | Johnson, Mrs. Oscar W
| (Elisabeth Wilhelmina Berg) | female | 27 | S
embarkation_point | C               | 0                   | 10 | Nasser, Mrs. Nicholas
| (Adèle Achem) | female | 14 | C
(10 rows)
```

4. Run the **APPLY_ONE_HOT_ENCODER** function on both the training and testing data:
5. Then, train a logistic regression classifier on the training data, and execute the model on the testing data:

```sql
=> SELECT LOGISTIC_REG('titanic_log_reg', 'titanic_training_encoded', 'survived', '*'
  USING PARAMETERS exclude_columns='passenger_id, survived');
LOGISTIC_REG
--------------------------
Finished in 5 iterations
(1 row)
```

```sql
=> SELECT passenger_id, name, PREDICT_LOGISTIC_REG(pclass, sex_1, age, sibling_and_spouse_count, parent_and_child_count, fare, embarkation_point_1, embarkation_point_2 USING PARAMETERS model_name='titanic_log_reg') FROM titanic_testing_encoded ORDER BY passenger_id LIMIT 10;
```

<table>
<thead>
<tr>
<th>passenger_id</th>
<th>name</th>
<th>PREDICT_LOGISTIC_REG</th>
</tr>
</thead>
<tbody>
<tr>
<td>893</td>
<td>Wilkes, Mrs. James (Ellen Needs)</td>
<td>0</td>
</tr>
<tr>
<td>894</td>
<td>Myles, Mr. Thomas Francis</td>
<td>0</td>

### Imputing Missing Values

You can use the `IMPUTE` function to replace missing data with the most frequent value or with the average value in the same column. This impute example uses the `small_input_impute` table. Using the function, you can specify either the mean or mode method.

These examples show how you can use the `IMPUTE` function on the `small_input_impute` table.
Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

First, query the table so you can see the missing values:

```sql
=> SELECT * FROM small_input_impute;
pid | pclass | gender | x1  | x2  | x3  | x4  | x5  | x6  
---+--------+--------+-----+-----+-----+-----+-----+-----
 5 |   0    |   1    | -2.590837 | -2.892819 | -2.70296 |   2 |   t |   C
 7 |   1    |   1    | 3.829239  | 3.08765   | Infinity |   | f   |   C
13 |   0    |   0    | -9.060605 | -9.390844 | -9.559848 |   6 |   t |   C
15 |   0    |   1    | -2.590837 | -2.892819 | -2.70296 |   2 |   f |   A
16 |   0    |   1    | -2.264599 | -2.615146 | -2.10729 |   11|   f |   A
19 |   1    |   1    | 3.841606  | 3.754375  |   |   t   |     
 1 |   0    |   0    | -9.445818 | -9.740541 | -9.786974 |   3 |   t |   A
 1 |   0    |   0    | -9.445818 | -9.740541 | -9.786974 |   3 |   t |   A
 2 |   0    |   0    | -9.618292 | -9.308881 | -9.562255 |   4 |   t |   A
 3 |   0    |   0    | -9.060605 | -9.390844 | -9.559848 |   6 |   t |   B
 4 |   0    |   0    | -2.264599 | -2.615146 | -2.10729 |   15|   t |   B
 6 |   0    |   1    | -2.264599 | -2.615146 | -2.10729 |   11|   t |   C
 8 |   1    |   1    | 3.273592  | 3.477332  |   |   f   |     
10 |   1    |   1    | 3.841606  | 3.754375  |   |   t   |     
18 |   1    |   1    | 3.273592  | 3.477332  |   |   t |   B
20 |   1    |   1    | 3.841606  | 3.754375  |   |   C   |     
 9 |   1    |   1    | 3.841606  | 3.754375  |   |   f |   B
11 |   0    |   0    | -9.445818 | -9.740541 | -9.786974 |   3 |   t |   B
12 |   0    |   0    | -9.618292 | -9.308881 | -9.562255 |   4 |   t |   C
14 |   0    |   0    | -2.264599 | -2.615146 | -2.10729 |   15|   f |   A
17 |   1    |   1    | 3.829239  | 3.08765   | Infinity |   | f   |   B

(21 rows)
```

**Specify the Mean Method**

Execute the IMPUTE function, specifying the mean method:

```sql
=> SELECT IMPUTE('output_view','small_input_impute', 'pid, x1,x2,x3,x4','mean'
                 USING PARAMETERS exclude_columns='pid');

IMPUTE
--------------------------
Finished in 1 iteration
(1 row)
```

View output_view to see the imputed values:

```sql
=> SELECT * FROM output_view;
pid | pclass | gender | x1 | x2 | x3 | x4 | x5 | x6  
---+--------+--------+-----+-----+-----+-----+-----+-----
 5 |   0    |   1    | -2.590837 | -2.892819 | -2.70296 |   2 |   t |   C
 7 |   1    |   1    | 3.829239  | 3.08765   |   |   f |   C
13 |   0    |   0    | -9.060605 | -9.390844 | -9.559848 |   6 |   t |   C
15 |   0    |   1    | -2.590837 | -2.892819 | -2.70296 |   2 |   f |   A
```
You can also execute the `IMPUTE` function, specifying the mean method and using the `partition_columns` parameter. This parameter works similarly to the `GROUP_BY` clause:

```sql
=> SELECT IMPUTE('output_view_group','small_input_impute', 'pid, x1,x2,x3,x4','mean'
  USING PARAMETERS exclude_columns='pid', partition_columns='pclass,gender');

Finished in 1 iteration
(1 row)
```

View `output_view_group` to see the imputed values:

```sql
=> SELECT * FROM output_view_group;
pid | pclass | gender | x1    | x2    | x3    | x4    | x5    | x6
-----+--------+--------+-------+-------+-------+-------+-------+-------
  5   |   0    |   1    | -2.590837 | -2.892819 | -2.702968 | 2    |   t   |   C
  7   |   1    |   1    | 3.829239  | 3.08765  | 3.66202733333333  | 19   |   f   |   C
 13   |   0    |   0    | -9.060606  | -9.390844 | -9.559848  | 6    |   t   |   C
 15   |   0    |   1    | -2.590837 | -2.892819 | -2.702968 | 2    |   f   |   A
 16   |   0    |   1    | -2.264599 | -2.615146 | -2.107294 | 11   |   t   |   A
 19   |   1    |   1    | 3.5514155 | 3.841606  | 3.754375  | 20   |   t   |   A
  1   |   0    |   0    | -9.445818 | -9.740541 | -9.786974 | 3    |   t   |   A
  3   |   0    |   0    | -9.618292 | -9.308881 | -9.562255 | 4    |   t   |   C
  4   |   0    |   0    | -2.264599 | -2.615146 | -2.107294 | 15   |   f   |   A
  6   |   0    |   1    | -2.264599 | -2.615146 | -2.107294 | 11   |   t   |   C
  8   |   1    |   1    | 3.273592  | -3.22766163157895 | 3.477332  | 18   |   f   |   B
 10   |   1    |   1    | -3.86645035294118 | 3.841606  | 3.754375  | 20   |   t   |   A
 18   |   1    |   1    | 3.273592  | -3.22766163157895 | 3.477332  | 18   |   t   |   B
20   |   1    |   1    | -3.86645035294118 | 3.841606  | 3.754375  | 20   |   t   |   C
```

(21 rows)
**Specify the Mode Method**

Execute the IMPUTE function, specifying the mode method:

```sql
=> SELECT impute('output_view_mode','small_input_impute', 'pid, x5,x6','mode'
    USING PARAMETERS exclude_columns='pid');
```

impute
--------------------------------------
Finished in 1 iteration
(1 row)

View output_view_mode to see the imputed values:

```sql
=> SELECT * FROM output_view_mode;
pid | pclass | gender | x1    | x2       | x3    | x4 | x5 | x6
-----+--------+--------+-------+----------+-------+----+----+----
 5   | 0      | 1      | -2.590837 | -2.892819 | -2.70296 | 2   | t  | C
 7   | 1      | 1      | 3.829239  | 3.08765   | Infinity | f   | C
 13  | 0      | 0      | -9.060605 | -9.390844 | -9.559848 | 6   | t  | C
 15  | 0      | 1      | -2.590837 | -2.892819 | -2.70296 | 2   | f  | A
 16  | 0      | 1      | -2.264599 | -2.615146 | -2.10729 | 11  | f  | A

Normalize Data

The purpose of normalization is, primarily, to scale numeric data from different columns down to an equivalent scale. For example, suppose you execute the LINEAR_REG function on a data set with two feature columns, current_salary and years_worked. The output value you are trying to predict is a worker's future salary. The values in the current_salary column are likely to have a far wider range, and much larger values, than the values in the years_worked column. Therefore, the values in the current_salary column can overshadow the values in the years_worked column, thus skewing your model.
Vertica offers the following data preparation methods which use normalization. These methods are:

- **MinMax**
  Using the MinMax normalization method, you can normalize the values in both of these columns to be within a distribution of values between 0 and 1. Doing so allows you to compare values on very different scales to one another by reducing the dominance of one column over the other.

- **Z-score**
  Using the Z-score normalization method, you can normalize the values in both of these columns to be the number of standard deviations an observation is from the mean of each column. This allows you to compare your data to a normally distributed random variable.

- **Robust Z-score**
  Using the Robust Z-score normalization method, you can lessen the influence of outliers on Z-score calculations. Robust Z-score normalization uses the median value as opposed to the mean value used in Z-score. By using the median instead of the mean, it helps remove some of the influence of outliers in the data.

Normalizing data results in the creation of a view where the normalized data is saved. The `output_view` option in the `NORMALIZE` function determines name of the view.

### Normalizing Salary Data Using MinMax

The following example shows how you can normalize the `salary_data` table using the MinMax normalization method.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.

```sql
=> SELECT NORMALIZE('normalized_salary_data', 'salary_data', 'current_salary, years_worked', 'minmax');
NORMALIZE
Finished in 1 iteration
```

```sql
(1 row)
=> SELECT * FROM normalized_salary_data;
```

<table>

PCA (Principal Component Analysis)

Principal Component Analysis (PCA) is a technique that reduces the dimensionality of data while retaining the variation present in the data. In essence, a new coordinate system is constructed so that data variation is strongest along the first axis, less strong along the second axis, and so on. Then, the data points are transformed into this new coordinate system. The directions of the axes are called principal components.

If the input data is a table with p columns, there could be maximum p principal components. However, it's usually the case that the data variation along the direction of some k-th principal component becomes almost negligible, which allows us to keep only the first k components. As a result, the new coordinate system has fewer axes. Hence, the transformed data table has only k columns instead of p. It is important to remember that the k output columns are not simply a subset of p input columns. Instead, each of the k output columns is a combination of all p input columns.

You can use the following functions to train and apply the PCA model:

- APPLY_INVERSE_PCA
- APPLY_PCA
- PCA

For a complete example, see Dimension Reduction Using PCA.

**Dimension Reduction Using PCA**

This PCA example uses a data set with a large number of columns named world. The example shows how you can apply PCA to all columns in the data set (except HDI) and reduce them into two dimensions.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.

1. Create the PCA model, named pcamodel.

```sql
=> SELECT PCA ('pcamodel',
                   'world',
```
Analyzing Vertica 4.3.2.96 state.

Then, apply PCA to a select few columns, with the exception of HDI and country.

```
   exclude_columns='HDI,country', key_columns='HDI,country',cutoff=.3) OVER () FROM world;
```

<table>
<thead>
<tr>
<th>HDI</th>
<th>country</th>
<th>col1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.886</td>
<td>Belgium</td>
<td>-36288.1191849017</td>
</tr>
<tr>
<td>0.699</td>
<td>Belize</td>
<td>-81740.32711562</td>
</tr>
<tr>
<td>0.427</td>
<td>Benin</td>
<td>-122666.882708325</td>
</tr>
<tr>
<td>0.805</td>
<td>Chile</td>
<td>-161356.484748602</td>
</tr>
<tr>
<td>0.687</td>
<td>China</td>
<td>-202634.254216416</td>
</tr>
<tr>
<td>0.744</td>
<td>Costa Rica</td>
<td>-242043.080125449</td>
</tr>
<tr>
<td>0.4</td>
<td>Cote d'Ivoire</td>
<td>-283330.394428932</td>
</tr>
<tr>
<td>0.776</td>
<td>Cuba</td>
<td>-322625.857541772</td>
</tr>
<tr>
<td>0.895</td>
<td>Denmark</td>
<td>-356086.311721071</td>
</tr>
<tr>
<td>0.644</td>
<td>Egypt</td>
<td>-403634.743992772</td>
</tr>
</tbody>
</table>

(96 rows)

4. Then, optionally apply the inverse function to transform the data back to its original state. This example shows an abbreviated output, only for the first record. There are 96 records in total.

```
   exclude_columns='HDI,country', key_columns='HDI,country') OVER () FROM world limit 1;
```
<table>
<thead>
<tr>
<th>HDI</th>
<th>0.886</th>
</tr>
</thead>
<tbody>
<tr>
<td>country</td>

**Sampling Data**

The goal of data sampling is to take a smaller, more manageable sample of a much larger data set. With a sample data set, you can produce predictive models or use it to help you tune your database. The following example shows how you can use the `TABLESAMPLE` clause to create a sample of your data.

**Sampling Data from a Table**

Before you begin the example, make sure that you have loaded the Machine Learning sample data.
Using the baseball table, create a new table named baseball_sample containing a 25% sample of baseball. Remember, TABLESAMPLE does not guarantee that the exact percentage of records defined in the clause are returned.

```sql
=> CREATE TABLE baseball_sample AS SELECT * FROM baseball TABLESAMPLE(25);
CREATE TABLE
=> SELECT * FROM baseball_sample;
```

- FROM Clause (for more information about the TABLESAMPLE clause)

SVD (Singular Value Decomposition)

Singular Value Decomposition (SVD) is a matrix decomposition method that allows you to approximate matrix X with dimensions n-by-p as a product of 3 matrices: X(n-by-p) = U(n-by-k).S(k-by-k).VT(k-by-p) where k is an integer from 1 to p, and S is a diagonal matrix. Its diagonal has non-negative values, called singular values, sorted from the largest, at the top left, to the smallest, at the bottom right. All other elements of S are zero.

In practice, the matrix V(p-by-k), which is the transposed version of VT, is more preferred.

If k (an input parameter to the decomposition algorithm, also known as the number of components to keep in the output) is equal to p, the decomposition is exact. If k is less than p, the decomposition becomes an approximation.

An application of SVD is lossy data compression. For example, storing X required n.p elements, while storing the three matrices U, S, and VT requires storing n.k + k + k.p
If \( n=1000 \), \( p=10 \), and \( k=2 \), storing \( X \) would require 10,000 elements while storing the approximation would require 2,000+4+20 = 2,024 elements. A smaller value of \( k \) increases the savings in storage space, while a larger value of \( k \) gives a more accurate approximation.

Depending on your data, the singular values may decrease rapidly, which allows you to choose a value of \( k \) that is much smaller than the value of \( p \).

Another common application of SVD is to perform the principal component analysis.

You can use the following functions to train and apply the SVD model:

- \texttt{APPLY\_INVERSE\_SVD}
- \texttt{APPLY\_SVD}
- \texttt{SVD}

For a complete example, see \texttt{Computing SVD}.

**Computing SVD**

This SVD example uses a small data set named \texttt{small\_svd}. The example shows you how to compute SVD using the given data set. The table is a matrix of numbers. The singular value decomposition is computed using the SVD function. This example computes the SVD of the table matrix and assigns it to a new object, which contains one vector, and two matrices, \( U \) and \( V \). The vector contains the singular values. The first matrix, \( U \) contains the left singular vectors and \( V \) contains the right singular vectors.

Before you begin the example, make sure that you have \texttt{loaded the Machine Learning sample data}.

1. Create the SVD model, named \texttt{svdmodel}.

```sql
=> SELECT SVD ('svdmodel', 'small\_svd', 'x1,x2,x3,x4');
SV
-----------------------------------------------
Finished in 1 iterations.
Accepted Rows: 8  Rejected Rows: 0
(1 row)
```

2. View the summary output of \texttt{svdmodel}.
```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svdmodel');

-- columns

<table>

</table>
3. Create a new table, named Umat to obtain the values for U.

```sql
=> CREATE TABLE Umat AS SELECT APPLY_SVD(id, x1, x2, x3, x4 USING PARAMETERS model_name='svdmodel', exclude_columns='id', key_columns='id') OVER() FROM small_svd;
```

4. View the results in the Umat table. This table transforms the matrix into a new coordinates system.

```sql
=> SELECT * FROM Umat ORDER BY id;
```

Regression Algorithms

Regression is an important and popular machine learning tool that makes predictions from data by learning the relationship between some features of the data and an observed value response. Regression is used to make predictions about profits, sales, temperature, stocks, and more. For example, you could use regression to predict the price of a house based on the location, the square footage, the size of the lot, and so on. In this example, the house's value is the response, and the other factors, such as location, are the features.

The optimal set of coefficients found for the regression's equation is known as the model. The relationship between the outcome and the features is summarized in the model, which can then be applied to different data sets, where the outcome value is unknown.

Linear Regression

Using linear regression, you can model the linear relationship between independent variables, or features, and a dependent variable, or outcome. You can build linear regression models to:

- Fit a predictive model to a training data set of independent variables and some dependent variable. Doing so allows you to use feature variable values to make predictions on outcomes. For example, you can predict the amount of rain that will fall on a particular day of the year.
- Determine the strength of the relationship between an independent variable and some outcome variable. For example, suppose you want to determine the importance of various weather variables on the outcome of how much rain will fall. You can build a linear regression model based on observations of weather patterns and rainfall to find the answer.
Unlike Logistic Regression, which you use to determine a binary classification outcome, linear regression is primarily used to predict continuous numerical outcomes in linear relationships.

You can use the following functions to build a linear regression model, view the model, and use the model to make predictions on a set of test data:

- `LINEAR_REG`
- `PREDICT_LINEAR_REG`
- `GET_MODEL_SUMMARY`

For a complete example of how to use linear regression on a table in Vertica, see Building a Linear Regression Model.

**Building a Linear Regression Model**

This linear regression example uses a small data set named faithful. The data set gives the waiting time between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park. The duration of each eruption can last anywhere between 1.5 and 5 minutes. The time between eruptions and the length of each eruption varies. However, you can estimate the time of the next eruption based on the duration of the previous eruption. The example shows how you can build a model to predict the value of eruptions, given the value of the waiting feature.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.

1. Create the linear regression model, named `linear_reg_faithful`, using the `faithful_training` training data:

   ```sql
   => SELECT LINEAR_REG('linear_reg_faithful', 'faithful_training', 'eruptions', 'waiting'
                        USING PARAMETERS optimizer='BFGS');

   LINEAR_REG
   -----------------------------
   Finished in 6 iterations
   (1 row)
   ```

2. View the summary output of `linear_reg_faithful`:

   ```sql
   => SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='linear_reg_faithful');
   ```
predictor|coefficient|std_err |t_value |p_value
--------------------------------------------------------------------------------
Intercept| -2.06795 | 0.21063| -9.81782| 0.00000
waiting | 0.07876 | 0.00292| 26.96925| 0.00000

---------------------

Random Forest for Regression

The Random Forest for regression algorithm creates an ensemble model of regression trees. Each tree is trained on a randomly selected subset of the training data. The algorithm predicts the value that is the mean prediction of the individual trees.

You can use the following functions to train the Random Forest model, and use the model to make predictions on a set of test data:

- GET_MODEL_SUMMARY
- PREDICT_RF_REGRESSOR
- RF_REGRESSOR

For a complete example of how to use the Random Forest for regression algorithm in Vertica, see Building a Random Forest for Regression Model.
Building a Random Forest for Regression Model

This random forest example uses a small data set named mtcars. The example shows you how to build a model to predict the value of carb (the number of carburetors). It uses the given values of all the other features in the data set.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.

1. Create the random forest model, named myRFRegressorModel, using the mtcars_train training data. View the summary output of the model.

```sql
=> SELECT RF_REGRESSOR ('myRFRegressorModel', 'mtcars', 'carb', 'mpg, cyl, hp, drat, wt' USING PARAMETERS ntree=100, sampling_size=0.3);
RF_REGRESSOR
----------
Finished
(1 row)

=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='myRFRegressorModel');

=========
call_string

**SVM (Support Vector Machine) for Regression**

Support Vector Machine (SVM) for regression predicts continuous ordered variables based on the training data.
Unlike Logistic Regression, which you use to determine a binary classification outcome, SVM for regression is primarily used to predict continuous numerical outcomes.

You can use the following functions to build an SVM for regression model, view the model, and use the model to make predictions on a set of test data:

- `SVM_REGRESSOR`
- `PREDICT_SVM_REGRESSOR`
- `GET_MODEL_SUMMARY`

For a complete example of how to use the SVM algorithm in Vertica, see Building an SVM for Regression Model.

### Building an SVM for Regression Model

This SVM for regression example uses a small data set named faithful, based on the Old Faithful geyser in Yellowstone National Park. The data set contains values about the waiting time between eruptions and the duration of eruptions of the geyser. The example shows how you can build a model to predict the value of eruptions, given the value of the waiting feature.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.

1. Create the SVM model, named `svm Faithful`, using the faithful_training training data:

```sql
=> SELECT SVM_REGRESSOR('svm_faithful', 'faithful_training', 'eruptions', 'waiting' USING PARAMETERS error_tolerance=0.1, max_iterations=100);
```

---

SVM_REGRESSOR

Finished in 5 iterations

Accepted Rows: 162 Rejected Rows: 0

(1 row)

2. View the summary output of `svm faithful`:

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svm Faithful');
```

Classification Algorithms

Classification is an important and popular machine learning tool that assigns items in a data set to different categories. Classification is used to predict risk over time, in fraud detection, text categorization, and more. Classification functions begin with a data set where the different categories are known. For example, suppose you want to classify students based on how likely they are to get into graduate school. In addition to factors like admission score exams and grades, you could also track work experience.

Binary classification means the outcome, in this case, admission, only has two possible values: admit or do not admit. Multiclass outcomes have more than two values. For example, low, medium, or high chance of admission. During the training process, classification algorithms find the relationship between the outcome and the features. This relationship is summarized in the model, which can then be applied to different data sets, where the categories are unknown.
Logistic Regression

Using logistic regression, you can model the relationship between independent variables, or features, and some dependent variable, or outcome. The outcome of logistic regression is always a binary value.

You can build logistic regression models to:

- Fit a predictive model to a training data set of independent variables and some binary dependent variable. Doing so allows you to make predictions on outcomes, such as whether a piece of email is spam mail or not.
- Determine the strength of the relationship between an independent variable and some binary outcome variable. For example, suppose you want to determine whether an email is spam or not. You can build a logistic regression model, based on observations of the properties of email messages. Then, you can determine the importance of various properties of an email message on that outcome.

You can use the following functions to build a logistic regression model, view the model, and use the model to make predictions on a set of test data:

- `LOGISTIC_REG`
- `PREDICT_LOGISTIC_REG`
- `GET_MODEL_SUMMARY`

For a complete programming example of how to use logistic regression on a table in Vertica, see Building a Logistic Regression Model.

Building a Logistic Regression Model

This logistic regression example uses a small data set named mtcars. The example shows you how to build a model to predict the value of `am` (whether the car has an automatic or a manual transmission). It uses the given values of all the other features in the data set.

In this example, roughly 60% of the data is used as training data to create a model. The remaining 40% of the data is used as testing data against which you can test your logistic regression model.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.
1. Create the logistic regression model, named `logistic_reg_mtcars`, using the `mtcars_train` training data.

```sql
=> SELECT LOGISTIC_REG('logistic_reg_mtcars', 'mtcars_train', 'am', 'cyl, wt'
USING PARAMETERS exclude_columns='hp');

LOGISTIC_REG--------------------------------
Finished in 15 iterations
(1 row)
```

2. View the summary output of `logistic_reg_mtcars`.

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='logistic_reg_mtcars');

=======
details
=======
predictor|coefficient| std_err | z_value | p_value

Naive Bayes

You can use the Naive Bayes algorithm to classify your data when features can be assumed independent. The algorithm uses independent features to calculate the probability of a specific class. For example, you might want to predict the probability that an email is spam. In that case, you would use a corpus of words associated with spam to calculate the probability the email's content is spam.

You can use the following functions to build a Naive Bayes model, view the model, and use the model to make predictions on a set of test data:

- `NAIVE_BAYES`
- `PREDICT_NAIVE_BAYES`
- `PREDICT_NAIVE_BAYES_CLASSES`
- `GET_MODEL_SUMMARY`

For a complete example of how to use the Naive Bayes algorithm in Vertica, see Classifying Data Using Naive Bayes.

Classifying Data Using Naive Bayes

This Naive Bayes example uses the HouseVotes84 data set to show you how to build a model. With this model, you can predict which party the member of the United States Congress is affiliated based on their voting record. To aid in classifying the data it has been cleaned, and any missed votes have been replaced. The cleaned data replaces missed votes with the voter's party majority vote. For example, suppose a member of the Democrats had a missing value for vote1 and majority of the Democrats voted in favor. This example replaces all missing Democrats' votes for vote1 with a vote in favor.

In this example, approximately 75% of the cleaned HouseVotes84 data is randomly selected and copied to a training table. The remaining cleaned HouseVotes84 data is used as a testing table.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.

You must also load the `naive_bayes_data_preparation.sql` script:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f naive_bayes_data_preparation.sql
```
1. Create the Naive Bayes model, named naive_house84_model, using the house84_train training data.

=> SELECT NAIVE_BAYES('naive_house84_model', 'house84_train', 'party', '**' USING PARAMETERS exclude_columns='party, id');

Finished. Accepted Rows: 315 Rejected Rows: 0
(1 row)

2. Create a new table, named predicted_party_naive. Populate this table with the prediction outputs you obtain from the PREDICT_NAIVE_BAYES function on your test data.

=> CREATE TABLE predicted_party_naive
AS SELECT party,
   PREDICT_NAIVE_BAYES (vote1, vote2, vote3, vote4, vote5, vote6, vote7, vote8, vote9, vote10, vote11, vote12, vote13, vote14, vote15, vote16
   USING PARAMETERS model_name = 'naive_house84_model',
   type = 'response') AS Predicted_Party
FROM house84_test;

CREATE TABLE

3. Calculate the accuracy of the model's predictions.

=> SELECT (Predictions.Num_Correct_Predictions / Count.Total_Count) AS Percent_Accuracy
   FROM ( SELECT COUNT(Predicted_Party) AS Num_Correct_Predictions
         FROM predicted_party_naive
         WHERE party = Predicted_Party
      ) AS Predictions,
     ( SELECT COUNT(party) AS Total_Count
         FROM predicted_party_naive
     ) AS Count;

Percent_Accuracy
0.9333333333333333
(1 row)

The model correctly predicted the party of the members of Congress based on their voting patterns with 93% accuracy.

**Viewing the Probability of Each Class**

You can also view the probability of each class. Use PREDICT_NAIVE_BAYES_CLASSES to see the probability of each class.
```sql
=> SELECT PREDICT_NAIVE_BAYES_CLASSES (id, vote1, vote2, vote3, vote4, vote5, vote6, vote7, vote8, vote9, vote10, vote11, vote12, vote13, vote14, vote15, vote16
   USING PARAMETERS
     model_name = 'naive_house84_model',
     key_columns = 'id', exclude_columns = 'id',
     classes = 'democrat, republican')
OVER() FROM house84_test;
```

Random Forest for Classification

The Random Forest algorithm creates an ensemble model of decision trees. Each tree is trained on a randomly selected subset of the training data.

You can use the following functions to train the Random Forest model, and use the model to make predictions on a set of test data:

- RF_CLASSIFIER
- PREDICT_RF_CLASSIFIER
- PREDICT_RF_CLASSIFIER_CLASSES
- GET_MODEL_SUMMARY

For a complete example of how to use the Random Forest algorithm in Vertica, see Classifying Data Using Random Forest.
Classifying Data Using Random Forest

This random forest example uses a data set named iris. The example contains four variables that measure various parts of the iris flower to predict its species.

Before you begin the example, make sure that you have followed the steps in Downloading the Machine Learning Example Data.

1. Create the random forest model, named rf_iris, using the iris data. View the summary output of the model.

```sql
=> SELECT RF_CLASSIFIER ('rf_iris', 'iris', 'Species', 'Sepal_Length, Sepal_Width, Petal_Length, Petal_Width'
USING PARAMETERS ntree=100, sampling_size=0.5);  
  RF_CLASSIFIER
  ---------------
  Finished training
  (1 row)

=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='rf_iris');
  --------------
  call_string
  ============
  SELECT rf_classifier('public.rf_iris', 'iris', '"species", 'Sepal_Length, Sepal_Width, Petal_Length, Petal_Width' USING PARAMETERS exclude_columns='', ntree=100, mtry=2, sampling_size=0.5, max_depth=5, max_breadth=32, min_leaf_size=1, min_info_gain=0, nbins=32);

  details
  =========
  predictor | type
  ===========

SVM (Support Vector Machine) for Classification

Support Vector Machine (SVM) is a classification algorithm that assigns data to one category or the other based on the training data. This algorithm implements linear SVM, which is highly scalable.

You can use the following functions to train the SVM model, and use the model to make predictions on a set of test data:

- SVM_CLASSIFIER
- PREDICT_SVM_CLASSIFIER
- GET_MODEL_SUMMARY

You can also use the following evaluation functions to gain further insights:

- CONFUSION_MATRIX
- DETECT_OUTLIERS
- ERROR_RATE
- ROC

For a complete example of how to use the SVM algorithm in Vertica, see Classifying Data Using SVM (Support Vector Machine).

The implementation of the SVM algorithm in Vertica is based on the paper Distributed Newton Methods for Regularized Logistic Regression.

Classifying Data Using SVM (Support Vector Machine)

This SVM example uses a small data set named mtcars. The example shows how you can use the SVM_CLASSIFIER function to train the model to predict the value of am (the transmission type, where 0 = automatic and 1 = manual) using the PREDICT_SVM_CLASSIFIER function.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.

1. Create the SVM model, named svm_class, using the mtcars_train training data.

```sql
=> SELECT SVM_CLASSIFIER('svm_class', 'mtcars_train', 'am', 'cyl, mpg, wt, hp, gear'
                         USING PARAMETERS exclude_columns='gear');
```
SVM_CLASSIFIER

----------------------------------------
Finished in 12 iterations.
Accepted Rows: 20 Rejected Rows: 0
(1 row)

2. View the summary output of svm_class.

=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svm_class');

--------
details
--------
predictor|coefficient
---------+----------
Intercept| -0.02006
  cyl   | 0.15367
  mpg   | 0.15698
  wt    | -1.78157
  hp    | 0.00957

--------
call_string
--------
SELECT svm_classifier('public.svm_class', 'mtcars_train', "'am'", 'cyl', mpg, wt, hp, gear'
USING PARAMETERS exclude_columns='gear', C=1, max_iterations=100, epsilon=0.001);

--------
Additional Info
--------
Name     |Value
---------+----------
accepted_row_count| 20
rejected_row_count| 0
iteration_count   | 12
(1 row)

3. Create a new table, named svm_mtcars_predict. Populate this table with the prediction outputs you obtain from running the PREDICT_SVM_CLASSIFIER function on your test data.

=> CREATE TABLE svm_mtcars_predict AS
  (SELECT car_model, am, PREDICT_SVM_CLASSIFIER(cyl, mpg, wt, hp
    USING PARAMETERS model_name='svm_class')
 AS Prediction FROM mtcars_test);

CREATE TABLE

4. View the results in the svm_mtcars_predict table.

=> SELECT * FROM svm_mtcars_predict;
car_model | am | Prediction
5. Evaluate the accuracy of the PREDICT_SVM_CLASSIFIER function, using the CONFUSION_MATRIX evaluation function.

```sql
=> SELECT CONFUSION_MATRIX(obs::int, pred::int USING PARAMETERS num_classes=2) OVER()
FROM (SELECT am AS obs, Prediction AS pred FROM svm_mtcars_predict) AS prediction_output;
```

<table>
<thead>
<tr>
<th>class</th>
<th>0</th>
<th>1</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>1</td>
<td>Of 12 rows, 12 were used and 0 were ignored</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>5</td>
<td>(2 rows)</td>
</tr>
</tbody>
</table>

In this case, PREDICT_SVM_CLASSIFIER correctly predicted that the cars with a value of 1 in the am column have a value of 1. No cars were incorrectly classified. Out of the seven cars which had a value of 0 in the am column, six were correctly predicted to have the value 0. One car was incorrectly classified as having the value 1.

Clustering Algorithms

Clustering is an important and popular machine learning tool used to find clusters of items in a data set that are similar to one another. The goal of clustering is to create clusters with a high number of objects that are similar. Similar to classification, clustering segments the data. However, in clustering, the categorical groups are not defined.
Clustering data into related groupings has many useful applications. If you already know how many clusters your data contains, the k-means algorithm may be sufficient to train your model and use that model to predict cluster membership for new data points.

However, in the more common case, you do not know before analyzing the data how many clusters it contains. In these cases, the bisecting k-means algorithm is much more effective at finding the correct clusters in your data.

Both k-means and bisecting k-means predict the clusters for a given data set. A model trained using either algorithm can then be used to predict the cluster to which new data points are assigned.

Clustering can be used to find anomalies in data and find natural groups of data. For example, you can use clustering to analyze a geographical region and determine which areas of that region are most likely to be hit by an earthquake. For a complete example, see Earthquake Cluster Analysis Using the KMeans Approach.

In Vertica, clustering is computed based on Euclidean distance. Through this computation, data points are assigned to the cluster with the nearest center.

**k-means**

You can use the clustering algorithm, *k-means clustering*, to cluster data points into $k$ different groups based on similarities between the data points.

The purpose of k-means is to partition $n$ observations into $k$ clusters. Through this partitioning, k-means assigns each observation to the cluster with the nearest mean. That nearest mean is also known as the *cluster center*.

For a complete example of how to use k-means on a table in Vertica, see Clustering Data Using k-means.

**Clustering Data Using k-means**

This k-means example uses two small data sets named agar_dish_1 and agar_dish_2. Using the numeric data in the agar_dish_1 data set, you can cluster the data into $k$ clusters. Then, using the created k-means model, you can run APPLY_KMEANS on agar_dish_2 and assign them to the clusters created in your original model.

Before you begin the example, make sure that you have loaded the Machine Learning sample data.
Clustering Training Data into $k$ Clusters

1. Create the $k$-means model, named $\text{agar\_dish\_kmeans}$ using the $\text{agar\_dish\_1\ table}$ data.

```sql
=> SELECT KMEANS('agar\_dish\_kmeans', 'agar\_dish\_1', '*', 5
    USING PARAMETERS exclude_columns = 'id', max_iterations=20, output_
    view='agar\_1\_view',
    key_columns='id');

KMEANS

Finished in 7 iterations
(1 row)
```

The example creates a model named $\text{agar\_dish\_kmeans}$ and a view containing the results of the model named $\text{agar\_1\_view}$. You might get different results when you run the clustering algorithm. This is because KMEANS randomly picks initial centers by default.

2. View the output of $\text{agar\_1\_view}$.

```sql
=> SELECT * FROM agar\_1\_view;

<table>
<thead>
<tr>
<th>id</th>
<th>cluster_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>4</td>
</tr>
<tr>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>9</td>
<td>4</td>
</tr>
<tr>
<td>13</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(375 rows)</td>
</tr>
</tbody>
</table>
```

3. Because you specified the number of clusters as 5, verify that the function created five clusters. Count the number of data points within each cluster.

```sql
=> SELECT cluster_id, COUNT(cluster_id) as Total_count
    FROM agar\_1\_view
    GROUP BY cluster_id;

<table>
<thead>
<tr>
<th>cluster_id</th>
<th>Total_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>76</td>
</tr>
<tr>
<td>2</td>
<td>80</td>
</tr>
<tr>
<td>1</td>
<td>74</td>
</tr>
<tr>
<td>3</td>
<td>73</td>
</tr>
<tr>
<td>4</td>
<td>72</td>
</tr>
</tbody>
</table>

(5 rows)
```

From the output, you can see that five clusters were created: 0, 1, 2, 3, and 4.
You have now successfully clustered the data from agar_dish_1.csv into five distinct clusters.

**Summarizing Your Model**

View the summary output of agar_dish_means using the `GET_MODEL_SUMMARY` function.

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='agar_dish_kmeans');
```

<table>
<thead>
<tr>
<th>centers</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>0.49708</td>
</tr>
<tr>
<td>-7.48119</td>
</tr>
<tr>
<td>-1.56238</td>
</tr>
<tr>
<td>-3.50616</td>
</tr>
<tr>
<td>-5.52057</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Evaluation metrics:</td>
</tr>
<tr>
<td>Total Sum of Squares: 6008.4619</td>
</tr>
<tr>
<td>Within-Cluster Sum of Squares:</td>
</tr>
<tr>
<td>Cluster 0: 12.003548</td>
</tr>
<tr>
<td>Cluster 1: 12.389038</td>
</tr>
<tr>
<td>Cluster 2: 12.639238</td>
</tr>
<tr>
<td>Cluster 3: 11.210146</td>
</tr>
<tr>
<td>Cluster 4: 12.994356</td>
</tr>
<tr>
<td>Total Within-Cluster Sum of Squares: 61.316326</td>
</tr>
<tr>
<td>Between-Cluster Sum of Squares: 5947.1456</td>
</tr>
<tr>
<td>Between-Cluster SS / Total SS: 98.98%</td>
</tr>
<tr>
<td>Number of iterations performed: 2</td>
</tr>
<tr>
<td>Converged: True</td>
</tr>
</tbody>
</table>

Call:

```
kmeans('public.agar_dish_kmeans', 'agar_dish_1', '*', 5 
USING PARAMETERS exclude_columns='id', max_iterations=20, epsilon=0.0001, init_method='kmeanspp', 
distance_method='euclidean', output_view='agar_view_1', key_columns='id')
```

(1 row)

**Clustering Data Using a k-means Model**

Using agar_dish_kmeans, the k-means model you just created, you can assign the points in agar_dish_2 to cluster centers.

Create a table named kmeans_results, using the agar_dish_2 table as your input table and the agar_dish_kmeans model for your initial cluster centers.

Add only the relevant feature columns to the arguments in the `APPLY_KMEANS` function.
CREATE TABLE kmeans_results AS
  (SELECT id,
   APPLY_KMEANS(x, y
   USING PARAMETERS model_name='agar_dish_kmeans') AS cluster_id
   FROM agar_dish_2);

The kmeans_results table shows that the agar_dish_kmeans model correctly clustered the agar_dish_2 data.

- APPLY_KMEANS
- KMEANS
- GET_MODEL_SUMMARY

bisecting k-means

The *bisecting k-means* clustering algorithm combines k-means clustering with divisive hierarchy clustering. With bisecting k-means, you get not only the clusters but also the hierarchical structure of the clusters of data points.

This hierarchy is more informative than the unstructured set of flat clusters returned by k-means. The hierarchy shows how the clustering results would look at every step of the process of bisecting clusters to find new clusters. The hierarchy of clusters makes it easier to decide the number of clusters in the data set.

Given a hierarchy of $k$ clusters produced by bisecting k-means, you can easily calculate any prediction of the form: Assume the data contain only $k'$ clusters, where $k'$ is a number that is smaller than or equal to the $k$ used to train the model.

For a complete example of how to use bisecting k-means to analyze a table in Vertica, see Clustering Data Hierarchically Using bisecting k-means.

Model Management

The topics in this section describe how to manage models.
Altering Models

You can modify a model using ALTER MODEL, in response to your model's needs. You can alter a model by renaming the model, changing the owner, and changing the schema.

You can drop or alter any model that you create.

Changing Model Ownership

As a superuser or model owner, you can reassign model ownership with ALTER MODEL as follows:

ALTER MODEL model-name OWNER TO owner-name

Changing model ownership is useful when a model owner leaves or changes responsibilities. Because you can change the owner, the models do not need to be rewritten.

Example

The following example shows how you can use ALTER_MODEL to change the model owner:

1. Find the model you want to alter. As the dbadmin, you own the model.

   ```SQL
   => SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
   ------------------------------------------------------------------------------------------------
   model_id | 45035996273816618
   model_name | mykmeansmodel
   schema_id | 45035996273704978
   schema_name | public
   owner_id | 45035996273704962
   owner_name | dbadmin
   category | VERTICA_MODELS
   model_type | kmeans
   is_complete | t
   create_time | 2017-03-02 11:16:04.990626-05
   size | 964
   ```

2. Change the model owner from dbadmin to user1.

   ```SQL
   => ALTER MODEL mykmeansmodel OWNER TO user1;
   ALTER MODEL
   ```
3. **Review V_CATALOG.MODELS to verify that the owner was changed.**

```sql
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
-| RECORD 1 |--------------------------------------------------------|
| model_id | 45035996273816618 |
| model_name | mykmeansmodel |
| schema_id | 45035996273704978 |
| schema_name | public |
| owner_id | 45035996273704962 |
| owner_name | user1 |
| category | VERTICA_MODELS |
| model_type | kmeans |
| is_complete | t |
| create_time | 2017-03-02 11:16:04.990626-05 |
| size | 964 |
```

**Moving Models to Another Schema**

You can move a model from one schema to another with `ALTER MODEL`. You can move the model as a superuser or user with `USAGE` privileges on the current schema and `CREATE` privileges on the destination schema.

**Example**

The following example shows how you can use `ALTER MODEL` to change the model schema:

1. **Find the model you want to alter.**

```sql
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
-| RECORD 1 |--------------------------------------------------------|
| model_id | 45035996273816618 |
| model_name | mykmeansmodel |
| schema_id | 45035996273704978 |
| schema_name | public |
| owner_id | 45035996273704962 |
| owner_name | user1 |
| category | VERTICA_MODELS |
| model_type | kmeans |
| is_complete | t |
| create_time | 2017-03-02 11:16:04.990626-05 |
| size | 964 |
```

2. **Change the model schema.**

```sql
=> ALTER MODEL mykmeansmodel SET SCHEMA test;
ALTER MODEL
```

3. **Review V_CATALOG.MODELS to verify that the owner was changed.**
## Renaming a Model

**ALTER MODEL** lets you rename models. For example:

1. Find the model you want to alter.

   ```sql
   => SELECT * FROM V_CATALOG.MODELS WHERE model_name='mymodel';
   -[ RECORD 1 ]-----------------------------------------------
     model_id | 45035996273816618
     model_name | mymymodel
     schema_id | 45035996273704978
     schema_name | test
     owner_id | 45035996273704962
     owner_name | dbadmin
     category | VERTICA_MODELS
     model_type | kmeans
     is_complete | t
     create_time | 2017-03-02 11:16:04.990626-05
     size | 964
   ```

2. Rename the model.

   ```sql
   => ALTER MODEL mymymodel RENAME TO mykmeansmodel;
   ALTER MODEL
   ```

3. Review **V_CATALOG.MODELS** to verify that the model name was changed.

   ```sql
   => SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
   -[ RECORD 1 ]-----------------------------------------------
     model_id | 45035996273816618
     model_name | mykmeansmodel
     schema_id | 45035996273704978
     schema_name | public
     owner_id | 45035996273704962
     owner_name | dbadmin
     category | VERTICA_MODELS
     model_type | kmeans
     is_complete | t
   ```
Dropping Models

DROP MODEL removes one or more models from the database. For example:

1. Find the model you want to drop.

```sql
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mySvmClassModel';
```

```plaintext
model_id | 45035996273765414
model_name | mySvmClassModel
schema_id | 45035996273704978
schema_name | public
owner_id | 45035996273704962
owner_name | dbadmin
category | VERTICA_MODELS
model_type | SVM_CLASSIFIER
is_complete | t
create_time | 2017-02-14 10:30:44.903946-05
size | 525
```

2. Drop the model.

```sql
=> DROP MODEL mySvmClassModel;
DROP MODEL
```

3. Review V_CATALOG.MODELS to verify that the model was dropped.

```sql
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mySvmClassModel';
(0 rows)
```

Managing Model Security

You can manage the security privileges on your models by using the GRANT and REVOKE statements. The following examples show how you can change privileges on user1 and user2 using the faithful table and the linearReg model.

- In the following example, the dbadmin grants the SELECT privilege to user1:

```sql
=> GRANT SELECT ON TABLE faithful TO user1;
GRANT PRIVILEGE
```

- Then, the dbadmin grants the CREATE privilege on the public schema to user1:
GRANT CREATE ON SCHEMA public TO user1;
GRANT PRIVILEGE

- Connect to the database as user1:

  => \c user1

- As user1, build the linearReg model:

  => SELECT LINEAR_REG('linearReg', 'faithful', 'waiting', 'eruptions');

  LINEAR_REG
  ----------------------------
  Finished in 1 iterations
  (1 row)

- As user1, grant USAGE privileges to user2:

  => GRANT USAGE ON MODEL linearReg TO user2;
  GRANT PRIVILEGE

- Connect to the database as user2:

  => \c - user2

- To confirm privileges were granted to user2, run the GET_MODEL_SUMMARY function. A user with the USAGE privilege on a model can run GET_MODEL_SUMMARY on that model:

  => SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='linearReg');

  =========
  details

Viewing model attributes

The following topics explain the model attributes for the Vertica machine learning algorithms. These attributes describe the internal structure of a particular model:

- Cross validation model attributes
- K-means model attributes
- Naive Bayes model attributes
- Normalization model attributes
- One Hot Encoder model attributes
Summarizing Models

1. Find the model you want to summarize.

```sql
--> SELECT * FROM v_catalog.models WHERE model_name='svm_class';
```

<table>
<thead>
<tr>
<th>model_id</th>
<th>model_name</th>
<th>schema_id</th>
<th>schema_name</th>
<th>owner_id</th>
<th>owner_name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
45035996273715226 | svm_class | 45035996273704980 | public | 45035996273704962 | dbadmin | VERTICA_MODELS |
| SVM_CLASSIFIER | t | 2017-08-28 09:49:00.082166-04 | 1427 |
```

1 row

2. View the model summary.

```sql
--> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svm_class');
```

```
details

predictor|coefficient
----------|-----------
Intercept | -0.02006 |
cyl | 0.15367 |
mpg | 0.15698 |
wt | -1.78157 |
hp | 0.00957 |

SELECT svm_classifier('public.svm_class', 'mtcars_train', "am", "cyl, mpg, wt, hp, gear" USING PARAMETERS exclude_columns='gear', C=1, max_iterations=100, epsilon=0.001);
```

```

Viewing Models

Vertica stores the models you create in the V_CATALOG.MODELS system table.

You can query V_CATALOG.MODELS to view information about the models you have created:

```sql
=> SELECT * FROM V_CATALOG.MODELS;
- [ RECORD 1 ]-+---------------------------------------------
  model_id      | 45035996273765414
  model_name    | mySvmClassModel
  schema_id     | 45035996273704978
  schema_name   | public
  owner_id      | 45035996273704962
  owner_name    | dbadmin
  category      | VERTICA_MODELS

Geospatial Analytics

Vertica provides functions that allows you to manipulate complex two- and three-dimensional spatial objects. These functions follow the Open Geospatial Consortium (OGC) standards. Vertica also provides data types and SQL functions that allow you to specify and store spatial objects in a database according to OGC standards.

Convert Well-Known Text (WKT) and Well-Known Binary (WKB)

Convert WKT and WKB.

Optimized Spatial Joins

Perform fast spatial joins using ST_Intersects and STV_Intersects.

Load and Export Spatial Data From Shapefiles

Easily load and export shapefiles.

Store and Retrieve Objects

Determine if:

- An object contains self-intersection or self-tangency points.
- One object is entirely within another object, such as a point within a polygon.

Test the relationships between objects

For example, if they intersect or touch:

- Identify the boundary of an object.
- Identify vertices of an object.
Calculate

- Shortest distance between two objects.
- Size of an object (length, area).
- Centroid for one or more objects.
- Buffer around one or more objects.

Best Practices for Geospatial Analytics

Vertica recommends the following best practices when performing geospatial analytics in Vertica.

Performance Optimization

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use the minimum column size for spatial data.</td>
<td>Performance degrades as column widths increase. When creating columns for your spatial data, use the smallest size column that can accommodate your data. For example, use GEOMETRY(85) for point data.</td>
</tr>
<tr>
<td>Use GEOMETRY types where possible.</td>
<td>Performance of functions on GEOGRAPHY types is slower than functions that support GEOMETRY types. Use GEOMETRY types where possible.</td>
</tr>
<tr>
<td>To improve the performance of the following functions, sort projections on spatial columns:</td>
<td>You may improve the pruning efficiency of these functions by sorting the projection on the GEOMETRY column. However, sorting on a large GEOMETRY column may slow down data load.</td>
</tr>
<tr>
<td>STV_Intersect scalar function</td>
<td></td>
</tr>
<tr>
<td>ST_Distance</td>
<td></td>
</tr>
<tr>
<td>ST_Area</td>
<td></td>
</tr>
<tr>
<td>ST_Length</td>
<td></td>
</tr>
</tbody>
</table>
Spatial Joins with Points and Polygons

Vertica provides two ways to identify whether a set of points intersect with a set of polygons. Depending on the size of your data set, choose the approach that gives the best performance.

For a detailed example of best practices with spatial joins, see Best Practices for Spatial Joins.

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a spatial index only when performing spatial joins with STV_Intersect.</td>
<td>Spatial indexes should only be used with STV_Intersect. Creating a spatial index and then performing spatial joins with ST_Intersects will not improve performance.</td>
</tr>
<tr>
<td>Use the STV_Intersect function when you intersect a set of points with a set of polygons.</td>
<td>Determine if a set of points intersects with a set of polygons in a medium to large data set. First, create a spatial index using STV_Create_Index. Then, use one of the STV_Intersect functions to return the set of pairs that intersect. Spatial indexes provide the best performance for accessing a large number of polygons.</td>
</tr>
<tr>
<td>When using the STV_Intersect transform function, partition the data and use an OVER(PARTITION BEST) clause.</td>
<td>The STV_Intersect Transform Function does not require that you partition the data. However, you may improve performance by partitioning the data and using an OVER(PARTITION BEST) clause.</td>
</tr>
</tbody>
</table>

Spatial Indexes

The STV_Create_Index function can consume large amounts of processing time and memory. When you index new data for the first time, monitor memory usage to be sure it stays within safe limits. Memory usage depends on:

- Number of polygons
- Number of vertices
- Amount of overlap among polygons
<table>
<thead>
<tr>
<th><strong>Recommendation</strong></th>
<th><strong>Details</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Segment polygon data when a table contains a large number of polygons.</td>
<td>Segmenting the data allows the index creation process to run in parallel. This is advantageous because sometimes STV_C...be completed when large tables that are not segmented prior to index creation.</td>
</tr>
<tr>
<td>Adjust STV_Create_Index parameters as needed for memory allocation and CPU usage.</td>
<td>The <code>max_mem_mb</code> parameter can affect the resource usage of STV_Create_Index. <code>max_mem_mb</code> assigns a limit to the amount of memory that STV_Create_Index can allocate. Default value: 256 Valid values: Any value less than or equal to the amount of memory in the GENERAL resource pool. Assigning a higher value results in an error.</td>
</tr>
</tbody>
</table>
| Make changes if STV_Create_Index cannot allocate 300 MB memory. | Before STV_Create_Index starts creating the index, it tries to allocate about 300 MB of memory. If that much memory is not available, the function fails. If you get a failure message, try these solutions:  
  - Create the index at a time of less load on the system.  
  - Avoid concurrent index creation.  
  - Add more memory to your system. |
| Create misplaced indexes again, if needed. | When you back up your Vertica database, spatial index files are not included. If you misplace an index, use STV_Create_Index to re-create it. |
| Use STV_Refresh_Index to add new or updated polygons to an existing index. | Instead of rebuilding your spatial index each time you add new or updated polygons to a table, you can use STV_Refresh_Index to append the polygons to your existing spatial index. |
Checking Polygon Validity

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>Details</th>
</tr>
</thead>
</table>
| Run ST_IsValid to check if polygons are valid. | Many spatial functions do not check the validity of polygons.  
  - Run ST_IsValid on all polygons to determine if they are valid.  
  - If your object is not valid, run STV_IsValidReason to get information about the location of the invalid polygon.  
  For more information, see Ensuring Polygon Validity Before Creating or Refreshing an Index. |

Spatial Objects

Vertica implements several data types for storing spatial objects, Well-Known Text (WKT) strings, and Well-Known Binary (WKB) representations. These data types include:

- Supported Spatial Objects
- Spatial Reference Identifiers (SRIDs)

Supported Spatial Objects

Vertica supports two spatial data types. These data types store two- and three-dimensional spatial objects in a table column:

- **GEOMETRY**: Spatial object with coordinates expressed as \((x,y)\) pairs, defined in the Cartesian plane. All calculations use Cartesian coordinates.

- **GEOGRAPHY**: Spatial object defined as on the surface of a perfect sphere, or a spatial object in the WGS84 coordinate system. Coordinates are expressed in longitude/latitude angular values, measured in degrees. All calculations are in meters. For perfect sphere calculations, the sphere has a radius of 6371 kilometers, which approximates the shape of the earth.
Some spatial programs use an ellipsoid to model the earth, resulting in slightly different data.

The maximum size of a GEOMETRY or GEOGRAPHY data type is 10,000,000 bytes (10 MB). You cannot use either data type as a table's primary key.

For details, see Geospatial Analytics in Analyzing Data.

**Spatial Reference Identifiers (SRIDs)**

A *spatial reference identifier* (SRID) is an integer value that represents a method for projecting coordinates on the plane. A SRID is metadata that indicates the coordinate system in which a spatial object is defined.

Geospatial functions using Geometry arguments must contain the same SRID. If the functions do not contain the same SRID, then the query returns an error.

For example, in this query the two points have different SRIDs. As a result the query returns an error:

```sql
=> SELECT ST_Distance(ST_GeomFromText('POINT(34 9)', 2749), ST_GeomFromText('POINT(70 12)', 3359));
ERROR 5861: Error calling processBlock() in User Function ST_Distance at [src/Distance.cpp:65], error code: 0, message: Geometries with different SRIDs found: 2749, 3359
```

**Supported SRIDs**

Vertica supports SRIDs derived from the EPSG standards. Geospatial functions using Geometry arguments must use supported SRIDs when performing calculations. SRID values of 0 to \(2^{32}-1\) are valid. Queries with SRID values outside of this range will return an error.

**Working with Spatial Objects in Tables**

- Defining Table Columns for Spatial Data
- Exporting Spatial Data from a Table
Defining Table Columns for Spatial Data

To define columns to contain GEOMETRY and GEOGRAPHY data, use this command:

```
=> CREATE TABLE [[db-name.]schema.]table-name ( 
  column-name GEOMETRY[(length)],
  column-name GEOGRAPHY[(length)];
```

If you omit the length specification, the default column size is 1 MB. The maximum column size is 10 MB. The upper limit is not enforced, but the geospatial functions can only accept or return spatial data up to 10 MB.

You cannot modify the size or data type of a GEOMETRY or GEOGRAPHY column after creation. If the column size you created is not sufficient, create a new column with the desired size. Then copy the data from the old column, and drop the old column from the table.

You cannot import data to or export data from tables that contain spatial data from another Vertica database.

**Important:**

A column width that is too large could impact performance. Use a column width that fits the data without being excessively large. See `STV_MemSize`.

Exporting Spatial Data from a Table

You can export spatial data from a table in your Vertica database to a shapefile.

To export spatial data from a table to a shapefile:

1. As the superuser, set the shapefile export directory.

```
=> SELECT STV_SetExportShapefileDirectory(USING PARAMETERS path = '/home/geo/temp');
  STV_SetExportShapefileDirectory
```

```
SUCCESS. Set shapefile export directory: [/home/geo/temp]
```
2. Export your spatial data to a shapefile.

```sql
=> SELECT STV_Export2Shapefile(*
    USING PARAMETERS shapefile = 'visualizations/city-data.shp',
    shape = 'Polygon') OVER() FROM spatial_data;
```

```
<table>
<thead>
<tr>
<th>Rows Exported</th>
<th>File Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>185873</td>
<td>v_geo-db_node0001: /home/geo/temp/visualizations/city-data.shp</td>
</tr>
</tbody>
</table>
```

- The value asterisk (*) is the equivalent to listing all columns in the FROM clause.
- You can specify sub-directories when exporting your shapefile.
- Your shapefile must end with the file extension .shp.

3. Verify that three files now appear in the shapefile export directory.

```
$ ls
city-data.dbf  city-data.shp  city-data.shx
```

### Identifying Null Spatial Objects

You can identify null GEOMETRY and GEOGRAPHY objects using the Vertica IS NULL and IS NOT NULL constructs.

This example uses the following table, where the row with id=2 has a null value in the `geog` field.

```sql
=> SELECT id, ST_AsText(geom), ST_AsText(geog) FROM locations
   ORDER BY 1 ASC;
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>ST_AsText</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (2 3)</td>
<td>POINT (-85 15)</td>
</tr>
<tr>
<td>2</td>
<td>POINT (4 5)</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>POLYGON ((-1 2, 0 3, 1 2, -1 2))</td>
<td>POLYGON ((-24 12, -15 23, -20 27, -24 12))</td>
</tr>
<tr>
<td>4</td>
<td>LINESTRING (-1 2, 1 5)</td>
<td>LINESTRING (-42.74 23.98, -62.19 23.78)</td>
</tr>
</tbody>
</table>
```

Identify all the rows that have a null `geog` value:

```sql
=> SELECT id, ST_AsText(geom), (ST_AsText(geog) IS NULL) FROM locations
   ORDER BY 1 ASC;
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>ST_AsText</th>
<th>?column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (2 3)</td>
<td>t</td>
</tr>
<tr>
<td>2</td>
<td>POINT (4 5)</td>
<td>t</td>
</tr>
<tr>
<td>3</td>
<td>POLYGON ((-1 2, 0 3, 1 2, -1 2))</td>
<td>f</td>
</tr>
<tr>
<td>4</td>
<td>LINESTRING (-1 2, 1 5)</td>
<td>f</td>
</tr>
</tbody>
</table>
```
Identify the rows where the geog value is not null:

```sql
=> SELECT id, ST_AsText(geom), (ST_AsText(geog) IS NOT NULL) FROM locations ORDER BY 1 ASC;
```

<table>
<thead>
<tr>
<th>id</th>
<th>st_astext</th>
<th>?column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (2 3)</td>
<td>t</td>
</tr>
<tr>
<td>2</td>
<td>POINT (4 5)</td>
<td>f</td>
</tr>
<tr>
<td>3</td>
<td>LINESTRING (-1 2, 1 5)</td>
<td>t</td>
</tr>
<tr>
<td>4</td>
<td>POLYGON ((-1 2, 0 3, 1 2, -1 2))</td>
<td>t</td>
</tr>
</tbody>
</table>

(4 rows)

---

### Loading Spatial Data from Shapefiles

Vertica provides the capability to load and parse spatial data that is stored in shapefiles. Shapefiles describe points, lines, and polygons. A shapefile is made up of three required files; all three files must be present and in the same directory to define the geometries:

- .shp—Contains the geometry data.
- .shx—Contains the positional index of the geometry.
- .dbf—Contains the attributes for each geometry.

To load spatial data from a shapefile:

1. Use STV_ShpCreateTable to generate a CREATE TABLE statement.

```sql
=> SELECT STV_ShpCreateTable ( USING PARAMETERS file = '/home/geo/temp/shp-files/spatial_data.shp') OVER() AS spatial_data;
```

```
CREATE TABLE spatial_data(
    gid IDENTITY(64) PRIMARY KEY,
    uniq_id INT8,
    geom GEOMETRY(85)
);
```

(5 rows)

2. Create the table.

```sql
=> CREATE TABLE spatial_data(
    gid IDENTITY(64) PRIMARY KEY,
    uniq_id INT8,
    geom GEOMETRY(85));
```
3. Load the shapefile.

```sql
COPY spatial_data WITH SOURCE STV_ShpSource(file='/home/geo/temp/shp-files/spatial_data.shp')
  PARSER STV_ShpParser();
Rows Loaded ------------------ 10
(1 row)
```

**Supported Shapefile Shape Types**

The following table lists the shapefile shape types that Vertica supports.

<table>
<thead>
<tr>
<th>Shapefile Shape Type</th>
<th>Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null shape</td>
<td>Yes</td>
</tr>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Polyline</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>MultiPoint</td>
<td>Yes</td>
</tr>
<tr>
<td>PointZ</td>
<td>No</td>
</tr>
<tr>
<td>PolylineZ</td>
<td>No</td>
</tr>
<tr>
<td>PolygonZ</td>
<td>No</td>
</tr>
<tr>
<td>MultiPointZ</td>
<td>No</td>
</tr>
<tr>
<td>PointM</td>
<td>No</td>
</tr>
<tr>
<td>PolylineM</td>
<td>No</td>
</tr>
<tr>
<td>PolygonM</td>
<td>No</td>
</tr>
<tr>
<td>MultiPointM</td>
<td>No</td>
</tr>
<tr>
<td>MultiPatch</td>
<td>No</td>
</tr>
</tbody>
</table>
Loading Spatial Data into Tables Using COPY

You can load spatial data into a table in Vertica using a COPY statement.

To load data into Vertica using a COPY statement:

1. Create a table.

```sql
=> CREATE TABLE spatial_data (id INTEGER, geom GEOMETRY(200));
```

2. Create a text file named `spatial.dat` with the following data.

```plaintext
1|POINT(2 3)
2|LINESTRING(-1 2, 1 5)
3|POLYGON((-1 2, 0 3, 1 2, -1 2))
```

3. Use COPY to load the data into the table.

```sql
=> COPY spatial_data (id, gx FILLER LONG VARCHAR(605), geom AS ST_GeomFromText(gx)) FROM LOCAL 'spatial.dat';
Rows Loaded
------------------
3
(1 row)
```

The statement specifies a LONG VARCHAR(32000000) filler, which is the maximum size of WKT. You must specify a filler value large enough to hold the largest WKT you want to insert into the table.

Retrieving Spatial Data from a Table as Well-Known Text (WKT)

GEOMETRY and GEOGRAPHY data is stored in Vertica tables as LONG VARBINARY, which isn't human readable. You can use `ST_AsText` to return the spatial data as Well-Known Text (WKT).

To return spatial data as WKT:

```sql
=> SELECT id, ST_AsText(geom) AS WKT FROM spatial_data;
 id | WKT
-----+--------------------------------------------------
 1 | POINT (2 3)
 2 | LINESTRING (-1 2, 1 5)
```
Working with GeoHash Data

Vertica supports GeoHashes. A GeoHash is a geocoding system for hierarchically encoding increasingly granular spatial references. Each additional character in a GeoHash drills down to a smaller section of a map.

You can use Vertica to generate spatial data from GeoHashes and GeoHashes from spatial data. Vertica supports the following functions for use with GeoHashes:

- **ST_GeoHash** - Returns a GeoHash in the shape of the specified geometry.
- **ST_GeomFromGeoHash** - Returns a polygon in the shape of the specified GeoHash.
- **ST_PointFromGeoHash** - Returns the center point of the specified GeoHash.

For example, to generate a full precision and partial precision GeoHash from a single point.

```sql
=> SELECT ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)')), LENGTH(ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'))),
       partial_hash;

<table>
<thead>
<tr>
<th>partial_hash</th>
<th>LENGTH</th>
<th>partial_hash</th>
</tr>
</thead>
<tbody>
<tr>
<td>kpf0rkn3zmcswks75010</td>
<td>20</td>
<td>kpf0r</td>
</tr>
</tbody>
</table>
```

This example shows how to generate a GeoHash from a multipoint point object. The returned polygon is a geometry object of the smallest tile that encloses that GeoHash.

```sql
=> SELECT ST_AsText(ST_GeomFromGeoHash(ST_GeographyFromText('MULTIPOINT(0 0, 0.0001 0.00001)')))) AS region_1,
       ST_AsText(ST_GeomFromGeoHash(ST_GeographyFromText('MULTIPOINT(0.0001 0.00001, 0.0003 0.00002)')))) AS region_2;

region_1 | POLYGON ((0 0, 0.00137329101562 0, 0.00137329101562 0.00137329101562, 0 0.00137329101562, 0 0))
region_2 | POLYGON ((0 0, 0.010986328125 0, 0.010986328125 0.0054931640625, 0 0.0054931640625, 0 0))
```
Spatial Joins with ST_Intersects and STV_Intersect

Spatial joins allow you to identify spatial relationships between two sets of spatial data. For example, you can use spatial joins to:

- Calculate the density of mobile calls in various regions to determine the location of a new cell phone tower.
- Identify homes that fall within the impact zone of a hurricane.
- Calculate the number of users who live within a certain ZIP code.
- Calculate the number of customers in a retail store at any given time.

**Best Practices for Spatial Joins**

Use these best practices to improve overall performance and optimize your spatial queries.

Best practices for using spatial joins in Vertica include:

- Table segmentation to speed up index creation
- Adequately sizing a geometry column to store point data
- Loading Well-Known Text (WKT) directly into a Geometry column, using STV_GeometryPoint in a COPY statement
- Using OVER (PARTITION BEST) with STV_Intersect transform queries

**Best Practices Example**

**Note:**

The following example was originally published in a Vertica blog post about using spatial data in museums. To read the entire blog, see Using Location Data with Vertica Place

Before performing the steps in the following example, download place_output.csv.zip from the Vertica Place GitHub repository (https://github.com/vertica/Vertica-Geospatial). You need to use the data set from this repository.

1. Create the table for the polygons. Use a GEOMETRY column width that fits your data without being excessively large. A good column-width fit improves performance. In addition, segmenting the table by HASH provides the advantages of parallel computation.
2. Use a copy statement with ST_Buffer to create and load the polygons on which to run the intersect. By using ST_Buffer in your copy statement, you can use that function to create the polygons.

```sql
=> COPY artworks(gid, gx FILLER LONG VARCHAR, g AS ST_Buffer(ST_GeomFromText(gx),8)) FROM STDIN DELIMITER ',';
> 1, POINT(10 45)
> 2, POINT(25 45)
> 3, POINT(35 45)
> 4, POINT(35 15)
> 5, POINT(30 5)
> 6, POINT(15 5)
> .
```

3. Create a table for the location data, represented by points. You can store point data in a GEOMETRY column of 100 bytes. Avoid over-fitting your GEOMETRY column. Doing so can significantly degrade spatial intersection performance. Also, segment this table by HASH, to take advantage of parallel computation.

```sql
=> CREATE TABLE usr_data (gid identity, usr_id int, date_time timestamp, g GEOMETRY(100)) SEGMENTED BY HASH(gid) ALL NODES;
```

4. During the copy statement, transform the raw location data to GEOMETRY data. You must perform this transformation because your location data needs to use the GEOMETRY data type. Use the function STV_GeometryPoint to transform the x and y columns of the source table.

```sql
=> COPY usr_data (usr_id, date_time, x FILLER LONG VARCHAR, y FILLER LONG VARCHAR, g AS STV_GeometryPoint(x, y)) FROM LOCAL 'place_output.csv' DELIMITER ',' ENCLOSED BY '';
```

5. Create the spatial index for the polygons. This index helps you speed up intersection calculations.

```sql
=> SELECT STV_Create_Index(gid, g USING PARAMETERS index='art_index', overwrite=true) OVER () FROM artworks;
```

6. Write an analytic query that returns the number of intersections per polygon. Specify that Vertica ignore any usr_id that intersects less than 20 times with a given polygon.

```sql
=> SELECT pol_gid,
        COUNT(DISTINCT(usr_id)) AS count_user_visit
   FROM (SELECT pol_gid,
           usr_id,
           COUNT(usr_id) AS user_points_in
      FROM artworks,
      GROUP BY pol_gid, usr_id, COUNT(usr_id)) AS t
   GROUP BY pol_gid,
   ORDER BY count_user_visit;
```
(SELECT STV_Intersect(usr_id, g USING PARAMETERS INDEX='art_index') OVER(PARTITION
BEST) AS (usr_id,
FROM usr_data
WHERE date_time BETWEEN '2014-07-02 09:30:20' AND '2014-07-02 17:05:00') AS c
GROUP BY pol_gid,
    usr_id HAVING COUNT(usr_id) > 20) AS real_visits
GROUP BY pol_gid
ORDER BY count_user_visit DESC;

Optimizations in the Example Query

This query has the following optimizations:

- The time predicated appears in the subquery.
- Using the location data table avoids the need for an expensive join.
- The query uses OVER (PARTITION BEST), to improve performance by partitioning the data.
- The user_points_in provides an estimate of the combined time spent intersecting with the artwork by all visitors.

Ensuring Polygon Validity Before Creating or Refreshing an Index

When Vertica creates or updates a spatial index it does not check polygon validity. To prevent getting invalid results when you query your spatial index, you should check the validity of your polygons prior to creating or updating your spatial index.

The following example shows you how to check the validity of polygons.

1. Create a table and load spatial data.

   => CREATE TABLE polygon_validity_test (gid INT, geom GEOMETRY);
   CREATE TABLE
   => COPY polygon_validity_test (gid, gx FILLER LONG VARCHAR, geom AS St_GeomFromText(gx))
      FROM STDIN;
   Enter data to be copied followed by a newline. 
   End with a backslash and a period on a line by itself.
   >> 2|POLYGON((31 74,8 70,8 50,-36 53,-31 74))
   >> 3|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
   >> 4|POLYGON((-12 42,-12 42,27 48,14 26,-12 42))
   >> 5|POLYGON((0 0,1 0 0,2 1,1 0 0))
   >> 6|POLYGON((3 3,2 2,1 2,3,3 3))
   >> \. 
2. Use `ST_IsValid` and `STV_IsValidReason` to find any invalid polygons.

```sql
=> SELECT gid, ST_IsValid(geom), STV_IsValidReason(geom) FROM polygon_validity_test;
```

```
<table>
<thead>
<tr>
<th>gid</th>
<th>ST_IsValid</th>
<th>STV_IsValidReason</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>f</td>
<td>Self-intersection at or near POINT (2 1)</td>
</tr>
<tr>
<td>2</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>f</td>
<td>Self-intersection at or near POINT (0 0)</td>
</tr>
</tbody>
</table>
```

Now that we have identified the invalid polygons in our table, there are a couple different ways you can handle the invalid polygons when creating or refreshing a spatial index.

**Filtering Invalid Polygons Using a WHERE Clause**

This method is slower than filtering before creating an index because it checks the validity of each polygon at execution time.

The following example shows you how to exclude invalid polygons using a WHERE clause.

```sql
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index = 'valid_polygons') OVER() FROM polygon_validity_test WHERE ST_IsValid(geom) = 't';
```

**Filtering Invalid Polygons Before Creating or Refreshing an Index**

This method is faster than filtering using a WHERE clause because you incur the performance cost prior to building the index.

The following example shows you how to exclude invalid polygons by creating a new table excluding invalid polygons.

```sql
=> CREATE TABLE polygon_validity_clean AS SELECT * FROM polygon_validity_test WHERE ST_IsValid(geom) = 't';
CREATE TABLE
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index = 'valid_polygons') OVER() FROM polygon_validity_clean;
```
**STV_Intersect: Scalar Function vs. Transform Function**

The STV_Intersect functions are similar in purpose, but you use them differently.

<table>
<thead>
<tr>
<th>STV_Intersect Function Type</th>
<th>Description</th>
<th>Performance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scalar</td>
<td>Matches a point to a polygon. If several polygons contain the point, this function returns a gid value. The result is a polygon gid or, if no polygon contains the point, the result is NULL.</td>
<td>Eliminates points that do not intersect with any indexed polygons, avoiding unnecessary comparisons.</td>
</tr>
<tr>
<td>Transform</td>
<td>Matches a point to all the polygons that contain it. When a point does not intersect with any polygon in the index, the function returns no rows.</td>
<td>Processes all input points regardless of whether or not they intersect with the indexed polygons.</td>
</tr>
</tbody>
</table>

In the following example, the STV_Intersect scalar function compares the points in the points table to the polygons in a spatial index named my_polygons. STV_Intersect returns all points and polygons that match exactly:

```sql
=> SELECT gid AS pt_gid,
       STV_Intersect(geom USING PARAMETERS index='my_polygons') AS pol_gid
FROM points
ORDER BY pt_gid;
```

<table>
<thead>
<tr>
<th>pt_gid</th>
<th>pol_gid</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2</td>
</tr>
<tr>
<td>101</td>
<td></td>
</tr>
<tr>
<td>102</td>
<td>2</td>
</tr>
<tr>
<td>103</td>
<td></td>
</tr>
<tr>
<td>104</td>
<td></td>
</tr>
<tr>
<td>105</td>
<td>3</td>
</tr>
<tr>
<td>106</td>
<td></td>
</tr>
<tr>
<td>107</td>
<td></td>
</tr>
</tbody>
</table>

(8 rows)

The following example shows how to use the STV_Intersect transform function to return information about the three point-polygon pairs that match and each of the polygons they match:

```sql
=> SELECT STV_Intersect(gid, geom
       USING PARAMETERS index='my_polygons')
OVER (PARTITION BEST) AS (pt_gid, pol_id)
```
Performing Spatial Joins with STV_Intersect Functions

Suppose you want to process a medium-to-large spatial data set and determine which points intersect with which polygons. In that case, first create a spatial index using STV_Create_Index. A spatial index provides efficient access to the set of polygons.

Then, use the STV_Intersect scalar or transform function to identify which point-polygon pairs match.

Spatial Indexes and STV_Intersect

Before performing a spatial join using one of the STV_Intersect functions, you must first run STV_Create_Index to create a database object that contains information about polygons. This object is called a spatial index of the set of polygons. The spatial index improves the time it takes for the STV_Intersect functions to access the polygon data.

Vertica creates spatial indexes in a global space. Thus, any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Vertica provides functions that work with spatial indexes:

- **STV_Create_Index**—Stores information about polygons in an index to improve performance.
- **STV_Describe_Index**—Retrieves information about an index.
- **STV_Drop_Index**—Deletes a spatial index.

- STV_Intersect Scalar Function
- STV_Intersect Transform Function
When to Use ST_Intersects vs. STV_Intersect

Vertica provides two capabilities to identify whether a set of points intersect with a set of polygons. Depending on the size of your data set, choose the approach that gives the best performance:

- When comparing a set of geometries to a single geometry to see if they intersect, use the `ST_intersects` function.
- To determine if a set of points intersects with a set of polygons in a medium-to-large data set, first create a spatial index using `STV_Create_Index`. Then, use one of the `STV_Intersect` functions to return the set of pairs that intersect.

**Note:**
You can only perform spatial joins on GEOMETRY data.

Performing Spatial Joins with ST_Intersects

The `ST_intersects` function determines if two GEOMETRY objects intersect or touch at a single point.

Use `ST_intersects` when you want to identify if a small set of geometries in a column intersect with a given geometry.

Example

The following example uses `ST_intersects` to compare a column of point geometries to a single polygon. The table that contains the points has 1 million rows.

`ST_intersects` returns only the points that intersect with the polygon. Those points represent about 0.01% of the points in the table:

```sql
=> CREATE TABLE points_1m(gid IDENTITY, g GEOMETRY(100)) ORDER BY g;
=> COPY points_1m(wkt FILLER LONG VARCHAR(100), g AS ST_GeomFromText(wkt))
   FROM LOCAL '/data/points.dat' DIRECT;
Rows Loaded
----------
1000000
(1 row)
```
SELECT ST_AsText(g) FROM points_1m WHERE ST_Intersects (g, ST_GeomFromText('POLYGON((-71 42, -70.9 42, -70.9 42.1, -71 42.1, -71 42))'));

-----------------------------
POINT (-70.97532 42.03538)
POINT (-70.97421 42.0376)
POINT (-70.99004 42.07538)
POINT (-70.99477 42.08454)
POINT (-70.99088 42.08177)
POINT (-70.98643 42.07593)
POINT (-70.98832 42.07982)
POINT (-70.95921 42.00982)
POINT (-70.95115 42.02177)
...
(116 rows)

OpenText recommends that you test the intersections of two columns of geometries by creating a spatial index. Use one of the STV_Intersect functions as described in STV_Intersect: Scalar Function vs. Transform Function.

**Working with Spatial Objects from Client Applications**

The Vertica client driver libraries provide interfaces for connecting your client applications to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- **Open Database Connectivity (ODBC)**—The most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- **Java Database Connectivity (JDBC)**—Used by clients written in the Java programming language.
- **ActiveX Data Objects for .NET (ADO.NET)**—Used by clients developed using Microsoft’s .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Vertica Place supports the following new data types:

- LONG VARCHAR
- LONG VARBINARY
The client driver libraries support these data types; the following sections describe that support and provide examples.

### Using LONG VARCHAR and LONG VARBINARY Data Types with ODBC

The ODBC drivers support the LONG VARCHAR and LONG VARBINARY data types similarly to VARCHAR and VARBINARY data types. When binding input or output parameters to a LONG VARCHAR or LONG VARBINARY column in a query, use the SQL_LONGVARCHAR and SQL_LONGVARBINARY constants to set the column's data type. For example, to bind an input parameter to a LONG VARCHAR column, you would use a statement that looks like this:

```c
rc = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR, 80000, 0, (SQLPOINTER)myLongString, sizeof(myLongString), NULL);
```

**Note:**
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

### Using LONG VARCHAR and LONG VARBINARY Data Types with JDBC

Using LONG VARCHAR and LONG VARBINARY data types in a JDBC client application is similar to using VARCHAR and VARBINARY data types. The JDBC driver transparently handles the conversion (for example, between a Java String object and a LONG VARCHAR). The following example code demonstrates inserting and retrieving a LONG VARCHAR string. It uses the JDBC Types class to determine the data type of the string returned by Vertica, although it does not actually need to know whether the database column is a LONG VARCHAR or just a VARCHAR in order to retrieve the value.
import java.sql.*;
import java.util.Properties;

public class LongVarcharExample {
    public static void main(String[] args) {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();

            // How long we want the example string to be. This is
            // larger than can fit into a traditional VARCHAR (which is limited
            // to 65000.
            int length = 100000;

            // Create a table with a LONG VARCHAR column that can store
            // the string we want to insert.
            stmt.execute("DROP TABLE IF EXISTS longtable CASCADE");
            stmt.execute("CREATE TABLE longtable (text LONG VARCHAR(" + length + "))");

            // Build a long string by appending an integer to a string builder
            // until we hit the size limit. Will result in a string
            // containing 01234567890123....
            StringBuilder sb = new StringBuilder(length);
            for (int i = 0; i < length; i++)
                sb.append(i % 10);
            String value = sb.toString();

            System.out.println("String value is " + value.length() + " characters long.");

            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement("INSERT INTO longtable (text) + " VALUES(?)");

            try {
                // Insert LONG VARCHAR value
                System.out.println("Inserting LONG VARCHAR value");
                pstmt.setString(1, value);
                pstmt.addBatch();
                pstmt.executeBatch();

                // Query the table we created to get the value back.
                ResultSet rs = null;
                rs = stmt.executeQuery("SELECT * FROM longtable");
            } catch (Exception e) {
                e.printStackTrace();
            }
        } finally {
            if (conn != null) {
                conn.close();
            }
        }
    }
}
// Get metadata about the result set.
ResultSetMetaData rsmd = rs.getMetaData();
// Print the type of the first column. Should be
// LONG VARCHAR. Also check it against the Types class, to
// recognize it programmatically.
System.out.println("Column #1 data type is: " +
    rsmd.getColumnTypeName(1));
if (rsmd.getColumnType(1) == Types.LONGVARCHAR) {
    System.out.println("It is a LONG VARCHAR");
} else {
    System.out.println("It is NOT a LONG VARCHAR");
}

// Print out the string length of the returned value.
while (rs.next()) {
    // Use the same getString method to get the value that you
    // use to get the value of a VARCHAR.
    System.out.println("Returned string length: " +
        rs.getString(1).length());
} catch (SQLException e) {
    System.out.println("Error message: " + e.getMessage());
    return; // Exit if there was an error
}
// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}

Note:
Do not use inefficient encoding formats for LONG VARBINARY and
LONG VARCHAR values. Vertica cannot load encoded values larger
than 32MB, even if the decoded value is less than 32 MB in size.
For example, Vertica returns an error if you attempt to load a
32MB LONG VARBINARY value encoded in octal format, since the
octal encoding quadruples the size of the value (each byte is
converted into a backslash followed by three digits).

Using GEOMETRY and GEOGRAPHY Data Types in ODBC

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native
types and ODBC client applications treat them as binary data. However, these data types
have a format that is unique to Vertica. To manipulate this data in your C++ application, you
must use the functions in Vertica that convert them to a recognized format.
To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- **ST_GeographyFromText**—Converts a WKT to a GEOGRAPHY type.
- **ST_GeographyFromWKB**—Converts a WKB to a GEOGRAPHY type.
- **ST_GeomFromText**—Converts a WKT to a GEOMETRY type.
- **ST_GeomFromWKB**—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- **ST_AsText**—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- **ST_AsBinary**—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONGVARBINARY.

The following code example converts WKT data into GEOMETRY data using **ST_GeomFromText** and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using **ST_AsText** and **ST_AsBinary**.

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <assert.h>
#include <sstream>

// Only needed for Windows clients
#include <windows.h>

// Standard ODBC headers
#include <sql.h>
#include <sqlext.h>

// Helper function to print SQL error messages.
template<typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT i, MsgLen;
    SQLRETURN ret2;
    SQLCHAR SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER NativeError;
    i = 1;
    printf("\n");
    while (((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
        Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
        printf("error record %d\n", i);
        printf("sqlstate: %s\n", SqlState);
        printf("detailed msg: %s\n", Msg);
        printf("native error code: %d\n", NativeError);
        i++;
    }
}
```
exit(EXIT_FAILURE); // bad form... but Ok for this demo

int main()
{
        // Set up the ODBC environment
        SQLRETURN ret;
        SQLHENV hd1Env;
        ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
        assert(SQL_SUCCEEDED(ret));
        // Tell ODBC that the application uses ODBC 3.
        ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                             (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
        assert(SQL_SUCCEEDED(ret));
        // Allocate a database handle.
        SQLHDBC hd1Dbc;
        ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
        assert(SQL_SUCCEEDED(ret));
        // Connect to the database
        printf("Connecting to database.\n");
        const char *dsnName = "ExampleDB";
        const char* userID = "dbadmin";
        const char* passwd = "password123";
        ret = SQLConnect(hd1Dbc, (SQLCHAR*)dsnName,
                         SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
                         (SQLCHAR*)passwd, SQL_NTS);
        if(!SQL_SUCCEEDED(ret)) {
                printf("Could not connect to database.\n");
                reportError<SQLHDBC>(SQL_HANDLE_DBC, hd1Dbc);
        } else {
                printf("Connected to database.\n");
        }
        // Disable AUTOCOMMIT
        ret = SQLSetConnectAttr(hd1Dbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF,
                                SQL_NTS);
        // Set up a statement handle
        SQLHSTMT hd1Stmt;
        SQLAllocHandle(SQL_HANDLE_STMT, hd1Dbc, &hd1Stmt);
        // Drop any previously defined table.
        ret = SQLExecDirect(hd1Stmt, (SQLCHAR*)"DROP TABLE IF EXISTS polygons",
                             SQL_NTS);
        if(!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hd1Stmt);}
        // Run query to create a table to hold a geometry.
        ret = SQLExecDirect(hd1Stmt,

// Print each byte of polygonval buffer in hex format.
for (int z = 0; z < polygonlen; z++)
printf("%02x ",polygonval[z]);
printf("\n");
// Geometry data formatted as a string.
ret = SQLGetData(hdlStmt, 3, SQL_C_TCHAR, polygonstr, 33554432, &polygonstrlen);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
printf("Polygon in WKT format: %s\n", polygonstr);
}
} while(SQL_SUCCEEDED(ret));

free(polygonval);
free(polygonstr);
// Clean up
printf("Free handles.\n");
ret = SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
ret = SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
ret = SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
exit(EXIT_SUCCESS);
}

The output of running the above example is:
Connecting to database.
Connected to database.
Creating prepared statement
Executed batch.
Committing transaction
Committed transaction
Getting data from table.
id: 0
Polygon in WKB format: 01 03 00 00 00 01 00 00 00 05 00 00 00 00 00 00 00 00 00 f0 3f 00 00 00 00 00
00 f0 3f 00 00 00 00 00 00 f0 3f 00 00 00 00 00 00 00 40 00 00 00 00 00 00 00 40 00 00 00 00 00 00 00
40 00 00 00 00 00 00 00 40 00 00 00 00 00 00 f0 3f 00 00 00 00 00 00 f0 3f 00 00 00 00 00 00 f0 3f
Polygon in WKT format: POLYGON ((1 1, 1 2, 2 2, 2 1, 1 1))
Free handles.

Note:
Do not use inefficient encoding formats for LONG VARBINARY and LONG
VARCHAR values. Vertica cannot load encoded values larger than 32 MB,
even if the decoded value is less than 32 MB in size. For example, Vertica
returns an error if you attempt to load a 32 MB LONG VARBINARY value
encoded in octal format, since the octal encoding quadruples the size of the
value (each byte is converted into a backslash followed by three digits).

Vertica Analytic Database (9.3.x)

Using GEOMETRY and GEOGRAPHY Data Types in JDBC

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and JDBC client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your Java application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- `ST_GeographyFromText`—Converts a WKT to a GEOGRAPHY type.
- `ST_GeographyFromWKB`—Converts a WKB to a GEOGRAPHY type.
- `ST_GeomFromText`—Converts a WKT to a GEOMETRY type.
- `ST_GeomFromWKB`—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- `ST_AsText`—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- `ST_AsBinary`—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONGVARBINARY.

The following code example converts WKT and WKB data into GEOMETRY data using `ST_GeomFromText` and `ST_GeomFromWKB` and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using `ST_AsText` and `ST_AsBinary`.

```java
import java.io.InputStream;
import java.io.Reader;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.Statement;
public class GeospatialDemo {
    public static void main(String[] args) throws Exception {
        Class.forName("com.vertica.jdbc.Driver");
        Connection conn = DriverManager.getConnection("jdbc:vertica://localhost:5433/db", "user", "password");
        conn.setAutoCommit(false);
        Statement stmt = conn.createStatement();
        stmt.execute("CREATE TABLE polygons(id INTEGER PRIMARY KEY, poly GEOMETRY)"");
        // ...}
```
int id = 0;
int numBatches = 5;
int rowsPerBatch = 10;

// batch inserting WKT data
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO polygons
(id, poly) VALUES(?, ST_GeomFromText(?))");
for(int i = 0; i < numBatches; i++)
{
    for(int j = 0; j < rowsPerBatch; j++)
    {
        // Insert your own WKT data here
        pstmt.setInt(1, id);
pstmt.setString(2, "polygon((1 1, 1 2, 2 2, 2 1, 1 1))");
pstmt.addBatch();
pstmt.executeBatch();
    }
}
conn.commit();
pstmt.close();

// batch insert WKB data
pstmt = conn.prepareStatement("INSERT INTO polygons(id, poly)
VALUES(?, ST_GeomFromWKB(?))");
for(int i = 0; i < numBatches; i++)
{
    for(int j = 0; j < rowsPerBatch; j++)
    {
        // Insert your own WKB data here
        byte[] wkb = getWKB();
pstmt.setInt(1, id);
pstmt.setBytes(2, wkb);
pstmt.addBatch();
pstmt.executeBatch();
    }
}
conn.commit();
pstmt.close();

// selecting data as WKT
ResultSet rs = stmt.executeQuery("select ST_AsText(poly) from polygons");
while(rs.next())
{
    String wkt = rs.getString(1);
    Reader wktReader = rs.getCharacterStream(1);
    // process the wkt as necessary
}
rs.close();

// selecting data as WKB
rs = stmt.executeQuery("select ST_AsBinary(poly) from polygons");
while(rs.next())
{
    byte[] wkb = rs.getBytes(1);
    InputStream wkbStream = rs.getBinaryStream(1);
    // process the wkb as necessary
}
rs.close();
Using GEOMETRY and GEOGRAPHY Data Types in ADO.NET

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and ADO.NET client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your C# application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- `ST_GeographyFromText` — Converts a WKT to a GEOGRAPHY type.
- `ST_GeographyFromWKB` — Converts a WKB to a GEOGRAPHY type.
- `ST_GeomFromText` — Converts a WKT to a GEOMETRY type.
- `ST_GeomFromWKB` — Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- `ST_AsText` — Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- `ST_AsBinary` — Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONGVARBINARY.

The following C# code example converts WKT data into GEOMETRY data using `ST_GeomFromText` and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using `ST_AsText` and `ST_AsBinary`. 

```java
//binding parameters in predicates
pstmt = conn.prepareStatement("SELECT id FROM polygons WHERE ST_Contains(ST_GeomFromText(?), poly)\n";
pstmt.setString(1, "polygon((1 1, 1 2, 2 2, 2 1, 1 1))\n";
rs = pstmt.executeQuery();
while(rs.next())
{
    int pk = rs.getInt(1);
    //process the results as necessary
}
rs.close();
conn.close();

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
                new VerticaConnectionStringBuilder();
            builder.Host = "VerticaHost";
            builder.Database = "VMart";
            builder.User = "ExampleUser";
            builder.Password = "password123";
            VerticaConnection _conn = new
                VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "DROP TABLE IF EXISTS polygons";
            command.ExecuteNonQuery();
            command.CommandText = "CREATE TABLE polygons (id INTEGER PRIMARY KEY, poly GEOMETRY)";
            command.ExecuteNonQuery();
            // Prepare to insert a polygon using a prepared statement. Use the
            // ST_GeomFromText SQL function to convert from WKT to GEOMETRY.
            VerticaTransaction txn = _conn.BeginTransaction();
            command.CommandText = "INSERT into polygons VALUES(@id, ST_GeomFromText(@polygon))";
            command.Parameters.Add(new
                VerticaParameter("id", VerticaType.BigInt));
            command.Parameters.Add(new
                VerticaParameter("polygon", VerticaType.VarChar));
            command.Prepare();
            // Set the values for the parameters
            command.Parameters["id"].Value = 0;
            //
            command.Parameters["polygon"].Value =
                "polygon((1 1 1, 1 2, 2 2, 2 1, 1 1))";
            // Execute the query to insert the value
            command.ExecuteNonQuery();

            // Now query the table
            VerticaCommand query = _conn.CreateCommand();
            query.CommandText =
                "SELECT id, ST_AsText(poly), ST_AsBinary(poly) FROM polygons;";
            VerticaDataReader dr = query.ExecuteReader();
            while (dr.Read())
            {
                Console.WriteLine("ID: " + dr[0]);
            Console.WriteLine("Polygon WKT format data type: " + dr.GetDataTypeName(1) +
                " Value: " + dr[1]);
                // Get the WKB format of the polygon and print it out as hex.
                Console.Write("Polygon WKB format data type: "
                    + dr.GetDataTypeName(2));
            }
        }
    }
}
```csharp
Console.WriteLine("Value: " + BitConverter.ToString((byte[])dr[2]));
})
_conn.Close();
}
```

The example code prints the following on the system console:

<table>
<thead>
<tr>

**OGC Spatial Definitions**

Using Vertica requires an understanding of the Open Geospatial Consortium (OGC) concepts and capabilities. For more information, see the [OGC Simple Feature Access Part 1 - Common Architecture](https://www.opengeospatial.org/standards/sfa) specification.
Spatial Classes

Vertica supports several classes of objects, as defined in the OGC standards.

Point

A location in two-dimensional space that is identified by one of the following:

- X and Y coordinates
- Longitude and latitude values

A point has dimension 0 and no boundary.

Examples

The following example uses a GEOMETRY point:

```sql
=> CREATE TABLE point_geo (gid int, geom GEOMETRY(100));
CREATE TABLE
=> COPY point_geo(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

1, POINT(3 5)
.

=> SELECT gid, ST_AsText(geom) FROM point_geo;
gid | ST_AsText
-----+------------------
 1  | POINT (3 5)
(1 row)
```

The following example uses a GEOGRAPHY point:

```sql
=> CREATE TABLE point_geog (gid int, geog geography(100));
CREATE TABLE
=> COPY point_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

1, POINT(42 71)
.

=> SELECT gid, ST_AsText(geog) FROM point_geog;
gid | ST_AsText
-----+------------------
 1  | POINT (42 71)
(1 row)
```
**Multipoint**

A set of one or more points. A multipoint object has dimension 0 and no boundary.

**Examples**

The following example uses a GEOMETRY multipoint:

```sql
=> CREATE TABLE mpoint_geo (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY mpoint_geo(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter ' '|;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTIPOINT(4 7, 8 10)
>>\.
=> SELECT gid, ST_AsText(geom) FROM mpoint_geo;
gid |     st_astext
-------+-----------------------
 1 | MULTIPoint (7 8, 6 9)
(1 row)
```

The following example uses a GEOGRAPHY multipoint:

```sql
=> CREATE TABLE mpoint_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY mpoint_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter ' '|;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTIPOINT(42 71, 41.4 70)
>>\.
=> SELECT gid, ST_AsText(geom) FROM mpoint_geog;
gid |     st_astext
-------+-----------------------
 1 | MULTIPoint (42 71, 41.4 70)
(1 row)
```

**Linestring**

One or more connected lines, identified by pairs of consecutive points. A linestring has dimension 1. The boundary of a linestring is a multipoint object containing its start and end points.

The following are examples of linestrings:
**Examples**

The following example uses the GEOMETRY type to create a table, use copy to load a linestring to the table, and then queries the table to view the linestring:

```sql
=> CREATE TABLE linestring_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY linestring_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>LINESTRING(0 0, 1 1, 2 2, 3 4, 2 4, 1 5)
>>.
=> SELECT gid, ST_AsText(geom) FROM linestring_geom;
gid | ST_AsText
---+----------------------------------------
 1 | LINESTRING (0 0, 1 1, 2 2, 3 4, 2 4, 1 5)
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a linestring to the table, and then queries the table to view the linestring:

```sql
=> CREATE TABLE linestring_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY linestring_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin
delimiter ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>LINESTRING(42.1 71, 41.4 70, 41.3 72.9, 42.99 71.46, 44.47 73.21)
>>.
=> SELECT gid, ST_AsText(geog) FROM linestring_geog;
```
<table>
<thead>
<tr>
<th>gid</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>LINESTRING (42.1 71, 41.4 70, 41.3 72.9, 42.99 71.46, 44.47 73.21)</td>
</tr>
</tbody>
</table>

**Multilinestring**

A collection of zero or more linestrings. A multilinestring has no dimension. The boundary of a multilinestring is a multipoint object containing the start and end points of all the linestrings.

The following are examples of multilinestrings:

**Examples**

The following example uses the GEOMETRY type to create a table, use copy to load a multilinestring to the table, and then queries the table to view the multilinestring:

```sql
=> CREATE TABLE multilinestring_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multilinestring_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTILINESTRING((1 5, 2 4, 5 3, 6 6),(3 5, 3 7))
>>\.
```
-> SELECT gid, ST_AsText(geom) FROM multilinestring_geom;
gid | ST_AsText
---+----------------------------------
 1 | MULTILINESTRING ((1 5, 2 4, 5 3, 6 6), (3 5, 3 7))
(1 row)

The following example uses the GEOGRAPHY type to create a table, use copy to load a multilinestring to the table, and then queries the table to view the multilinestring:

-> CREATE TABLE multilinestring_geog (gid int, geom GEOGRAPHY(1000));
CREATE TABLE
-> COPY multilinestring_geog(gid, gx filler LONG VARCHAR, geom AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTILINESTRING((42.1 71, 41.4 70, 41.3 72.9), (42.99 71.46, 44.47 73.21))
>>\.
-> SELECT gid, ST_AsText(geom) FROM multilinestring_geog;
gid | ST_AsText
---+----------------------------------
 1 | MULTILINESTRING((42.1 71, 41.4 70, 41.3 72.9), (42.99 71.46, 44.47 73.21))
(1 row)

**Polygon**

An object identified by a set of closed linestrings. A polygon can have one or more holes, as defined by interior boundaries, but all points must be connected. Two examples of polygons are:

![Polygon Examples](image)

**Inclusive and Exclusive Polygons**

Polygons that include their points in clockwise order include all space inside the perimeter of the polygon and exclude all space outside that perimeter. Polygons that include their points in counterclockwise order exclude all space inside the perimeter and include all space outside that perimeter.
Examples

The following example uses the GEOMETRY type to create a table, use copy to load a polygon into the table, and then queries the table to view the polygon:

```sql
=> CREATE TABLE polygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY polygon_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON(( 2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
>>\.
=> SELECT gid, ST_AsText(geom) FROM polygon_geom;
   gid | ST_AsText
  ------
    1  | POLYGON((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
  (1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a polygon into the table, and then queries the table to view the polygon:

```sql
=> CREATE TABLE polygon_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY polygon_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
>>\.
=> SELECT gid, ST_AsText(geog) FROM polygon_geog;
   gid | ST_AsText
  ------
    1  | POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
  (1 row)
```

**Multipolygon**

A collection of zero or more polygons that do not overlap.
Examples

The following example uses the GEOMETRY type to create a table, use copy to load a multipolygon into the table, and then queries the table to view the polygon:

```sql
=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter ' |';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))

=> SELECT gid, ST_AsText(geom) FROM polygon_geom;
gid | ST_AsText
-------|-----------------
 9 | MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a multipolygon into the table, and then queries the table to view the polygon:

```sql
=> CREATE TABLE multipolygon_geog (gid int, geom GEOGRAPHY(1000));
CREATE TABLE
=> COPY multipolygon_geog(gid, gx filler LONG VARCHAR, geom AS ST_GeographyFromText(gx)) FROM stdin
delimiter ' |';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))

=> SELECT gid, ST_AsText(geom) FROM polygon_geog;
gid | ST_AsText
-------|-----------------
 1 | POLYGON(((42.1 71, 41.4 70, 41.3 72.9, 42.1 71)),((44.47 73.21, 42.99 71.46, 42.1 71, 44.47 73.21)))
(1 row)
```
Spatial Object Representations

The OGC defines two ways to represent spatial objects:

- **Well-Known Text (WKT)**
- **Well-Known Binary (WKB)**

**Well-Known Text (WKT)**

Well-Known Text (WKT) is an ASCII representation of a spatial object.

WK Ts are not case sensitive; Vertica recognizes any combination of lowercase and uppercase letters.

Some examples of valid WKTs are:

<table>
<thead>
<tr>

</table>

Invalid WKTs are:

- POINT(1 NAN), POINT(1 INF)—Coordinates must be numbers.
- POLYGON((1 2, 1 4, 3 4, 3 2))—A polygon must be closed.
- POLYGON((1 4, 2 4))—A linestring is not a valid polygon.

**Well-Known Binary (WKB)**

Well-Known Binary (WKB) is a binary representation of a spatial object. This format is primarily used to port spatial data between applications.

**Spatial Definitions**

The OGC defines properties that describe

- Characteristics of spatial objects
- Spatial relationships that can exist among objects
Vertica provides functions that test for and analyze the following properties and relationships.

**Boundary**

The set of points that define the limit of a spatial object:

- Points, multipoints, and geometrycollections do not have boundaries.
- The boundary of a linestring is a multipoint object. This object contains its start and end points.
- The boundary of a multilinestring is a multipoint object. This object contains the start and end points of all the linestrings that make up the multilinestring.
- The boundary of a polygon is a linestring that begins and ends at the same point. If the polygon has one or more holes, the boundary is a multilinestring that contains the boundaries of the exterior polygon and any interior polygons.
- The boundary of a multipolygon is a multilinestring that contains the boundaries of all the polygons that make up the multipolygon.

**Buffer**

The set of all points that are within or equal to a specified distance from the boundary of a spatial object. The distance can be positive or negative.

**Positive buffer:**

**Negative buffer:**
**Contains**

One spatial object contains another spatial object if its interior includes all points of the other object. If an object such as a point or linestring only exists along a polygon's boundary, the polygon does not contain it. If a point is on a linestring, the linestring contains it; the interior of a linestring is all the points on the linestring except the start and end points.

Contains(a, b) is spatially equivalent to within(b, a).

**Convex Hull**

The smallest convex polygon that contains one or more spatial objects.

In the following figure, the dotted lines represent the convex hull for a linestring and a triangle.
**Crosses**

Two spatial objects cross if both of the following are true:

- The two objects have some but not all interior points in common.
- The dimension of the result of their intersection is less than the maximum dimension of the two objects.

![Crossed objects diagram](image)

**Disjoint**

Two spatial objects have no points in common; they do not intersect or touch.

**Envelope**

The minimum bounding rectangle that contains a spatial object.

The envelope for the following polygon is represented by the dotted lines in the following figure.
**Equals**

Two spatial objects are equal when their coordinates match exactly. Synonymous with *spatially equivalent*.

The order of the points do not matter in determining spatial equivalence:

- LINESTRING(1 2, 4 3) equals LINESTRING(4 3, 1 2).
- POLYGON (0 0, 1 1, 1 2, 2 2, 2 1, 3 0, 1.5 —1.5, 0 0) equals POLYGON((1 1, 1 2, 2 2, 2 1, 3 0, 1.5 —1.5, 0 0, 1 1)).
- MULTILINESTRING((1 2, 4 3),(0 0, —1 —4)) equals MULTILINESTRING((0 0, —1 —4),(1 2, 4 3)).

**Exterior**

The set of points not contained within a spatial object nor on its boundary.

**GeometryCollection**

A set of zero or more objects from any of the supported classes of spatial objects.

**Interior**

The set of points contained in a spatial object, excluding its boundary.
**Intersection**

The set of points that two or more spatial objects have in common.

![Intersection Diagram]

**Overlaps**

If a spatial object shares space with another object, but is not contained within that object, the objects overlap. The objects must overlap at their interiors; if two objects touch at a single point or intersect only along a boundary, they do not overlap.

![Overlaps Diagram]
Relates

When a spatial object is spatially related to another object as defined by a DE-9IM pattern matrix string.

A DE-9IM pattern matrix string identifies how two spatial objects are spatially related to each other. For more information about the DE-9IM standard, see Understanding Spatial Relations.

Simple

For points, multipoints, linestrings, or multilinestrings, a spatial object is simple if it does not intersect itself or has no self-tangency points.

Polygons, multipolygons, and geometrycollections are always simple.

Symmetric Difference

The set of all points of a pair of spatial objects where the objects do not intersect. This difference is spatially equivalent to the union of the two objects less their intersection. The symmetric difference contains the boundaries of the intersections.

In the following figure, the shaded areas represent the symmetric difference of the two rectangles.

The following figure shows the symmetric difference of two overlapping linestrings.
**Union**

For two or more spatial objects, the set of all points in all the objects.

**Validity**

For a polygon or multipolygon, when all of the following are true:

- It is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
No two linestrings in the boundary cross. The linestrings in the boundary may touch at a point but they cannot cross.

Any polygons in the interior must be completely contained; they cannot touch the boundary of the exterior polygon except at a vertex.

**Valid polygons:**

![Valid polygon diagram]

**Invalid polygon:**

![Invalid polygon diagram]

**Within**

A spatial object is considered within another spatial object when all its points are inside the other object's interior. Thus, if a point or linestring only exists along a polygon's boundary, it is not considered within the polygon. The polygon boundary is not part of its interior.

If a point is on a linestring, it is considered within the linestring. The interior of a linestring is all the points along the linestring, except the start and end points.

Within(a, b) is spatially equivalent to contains(b, a).
Spatial Data Type Support Limitations

Vertica does not support all types of GEOMETRY and GEOGRAPHY objects. See the respective function page for a list of objects that function supports. Spherical geometry is generally more complex than Euclidean geometry. Thus, there are fewer spatial functions that support the GEOGRAPHY data type.

Limitations of spatial data type support:

- A non-WGS84 GEOGRAPHY object is a spatial object defined on the surface of a perfect sphere of radius 6371 kilometers. This sphere approximates the shape of the earth. Other spatial programs may use an ellipsoid to model the earth, resulting in slightly different data.
- You cannot modify the size or data type of a GEOMETRY or GEOGRAPHY column after creation.
- You cannot import data to or export data from tables that contain spatial data from another Vertica database.
- You can only use the STV_Intersect functions with points and polygons.
- GEOGRAPHY objects of type GEOMETRYCOLLECTION are not supported.
- Values for longitude must be between -180 and +180 degrees. Values for latitude must be between -90 and +90 degrees. The Vertica geospatial functions do not validate these values.
- GEOMETRYCOLLECTION objects cannot contain empty objects. For example, you cannot specify GEOMETRYCOLLECTION (LINESTRING(1 2, 3 4), POINT(5 6), POINT EMPTY).
- If you pass a spatial function a NULL geometry, the function returns NULL, unless otherwise specified. A result of NULL has no value.
- Polymorphic functions, such as NVL and GREATEST, do not accept GEOMETRY and GEOGRAPHY arguments.
Time Series Analytics

Time series analytics evaluate the values of a given set of variables over time and group those values into a window (based on a time interval) for analysis and aggregation. Common scenarios for using time series analytics include: stock market trades and portfolio performance changes over time, and charting trend lines over data.

Since both time and the state of data within a time series are continuous, it can be challenging to evaluate SQL queries over time. Input records often occur at non-uniform intervals, which can create gaps. To solve this problem Vertica provides:

- Gap-filling functionality, which fills in missing data points
- Interpolation scheme, which constructs new data points within the range of a discrete set of known data points.

Vertica interpolates the non-time series columns in the data (such as analytic function results computed over time slices) and adds the missing data points to the output. This section describes gap filling and interpolation in detail.

You can use **event-based windows** to break time series data into windows that border on significant events within the data. This is especially relevant in financial data, where analysis might focus on specific events as triggers to other activity.

**Sessionization** is a special case of event-based windows that is frequently used to analyze click streams, such as identifying web browsing sessions from recorded web clicks.

Vertica provides additional support for time series analytics with the following SQL extensions:

- **TIMESERIES clause** in a SELECT statement supports gap-filling and interpolation (GFI) computation.
- **TS_FIRST_VALUE** and **TS_LAST_VALUE** are time series aggregate functions that return the value at the start or end of a time slice, respectively, which is determined by the interpolation scheme.
- **TIME_SLICE** is a (SQL extension) date/time function that aggregates data by different fixed-time intervals and returns a rounded-up input TIMESTAMP value to a value that corresponds with the start or end of the time slice interval.

Gap Filling and Interpolation (GFI)

The examples and graphics that explain the concepts in this topic use the following simple schema:

```sql
CREATE TABLE TickStore (ts TIMESTAMP, symbol VARCHAR(8), bid FLOAT);
INSERT INTO TickStore VALUES ('2009-01-01 03:00:00', 'XYZ', 10.0);
INSERT INTO TickStore VALUES ('2009-01-01 03:00:05', 'XYZ', 10.5);
COMMIT;
```

In Vertica, time series data is represented by a sequence of rows that conforms to a particular table schema, where one of the columns stores the time information.

Both time and the state of data within a time series are continuous. Thus, evaluating SQL queries over time can be challenging because input records usually occur at non-uniform intervals and can contain gaps.

For example, the following table contains two input rows five seconds apart: 3:00:00 and 3:00:05.

<table>
<thead>
<tr>
<th>ts</th>
<th>symbol</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01</td>
<td>XYZ</td>
<td>10.0</td>
</tr>
<tr>
<td>2009-01-01</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
</tbody>
</table>
(2 rows)

Given those two inputs, how can you determine a bid price that falls between the two points, such as at 3:00:03 PM?

The `TIME_SLICE` function normalizes timestamps into corresponding time slices; however, `TIME_SLICE` does not solve the problem of missing inputs (time slices) in the data. Instead, Vertica provides gap-filling and interpolation (GFI) functionality, which fills in missing data points and adds new (missing) data points within a range of known data points to the output. It accomplishes these tasks with `time series aggregate functions` and the SQL `TIMESERIES Clause`.

But first, we'll illustrate the components that make up gap filling and interpolation in Vertica, starting with `Constant Interpolation`.

The images in the following topics use the following legend:

- The x-axis represents the timestamp (ts) column
- The y-axis represents the bid column.
• The vertical blue lines delimit the time slices.
• The red dots represent the input records in the table, $10.0 and $10.5.
• The blue stars represent the output values, including interpolated values.

Constant Interpolation

Given known input timestamps at 03:00:00 and 03:00:05 in the sample TickStore schema, how might you determine the bid price at 03:00:03?

A common interpolation scheme used on financial data is to set the bid price to the last seen value so far. This scheme is referred to as constant interpolation, in which Vertica computes a new value based on the previous input records.

Note:
Constant is Vertica’s default interpolation scheme. Another interpolation scheme, linear, is discussed in an upcoming topic.

Returning to the problem query, here is the table output, which shows a 5-second lag between bids at 03:00:00 and 03:00:05:

```sql
=> SELECT * FROM TickStore;

<table>
<thead>
<tr>
<th>ts</th>
<th>symbol</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:05</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
</tbody>
</table>
```

(2 rows)

Using constant interpolation, the interpolated bid price of XYZ remains at $10.0 at 3:00:03, which falls between the two known data inputs (3:00:00 PM and 3:00:05). At 3:00:05, the value changes to $10.5. The known data points are represented by a red dot, and the interpolated value at 3:00:03 is represented by the blue star.
In order to write a query that makes the input rows more uniform, you first need to understand the **TIMESERIES clause and time series aggregate functions**.

**TIMESERIES Clause and Aggregates**

The SELECT..TIMESERIES clause and time series aggregates help solve the problem of gaps in input records by normalizing the data into 3-second time slices and interpolating the bid price when it finds gaps.

**TIMESERIES Clause**

The TIMESERIES Clause is an important component of time series analytics computation. It performs gap filling and interpolation (GFI) to generate time slices missing from the input records. The clause applies to the timestamp columns/expressions in the data, and takes the following form:

```
TIMESERIES slice_time AS 'length_and_time_unit_expression'
OVER ( ... [ window-partition-clause[ , ... ] ]
... ORDER BY time_expression )
... [ ORDER BY table_column [ , ... ] ]
```

**Note:**
The TIMESERIES clause requires an ORDER BY operation on the timestamp column.

**Time Series Aggregate Functions**

Timeseries Aggregate (TSA) functions evaluate the values of a given set of variables over time and group those values into a window for analysis and aggregation.

TSA functions process the data that belongs to each time slice. One output row is produced per time slice or per partition per time slice if a partition expression is present.

The following table shows 3-second time slices where:

- The first two rows fall within the first time slice, which runs from 3:00:00 to 3:00:02. These are the input rows for the TSA function's output for the time slice starting at 3:00:00.
• The second two rows fall within the second time slice, which runs from 3:00:03 to 3:00:05. These are the input rows for the TSA function's output for the time slice starting at 3:00:03.

The result is the start of each time slice.

Examples

The following examples compare the values returned with and without the TS_FIRST_VALUE TSA function.

This example shows the TIMESERIES clause without the TS_FIRST_VALUE TSA function.

```sql
=> SELECT slice_time, bid FROM TickStore TIMESERIES slice_time AS '3 seconds' OVER(PARTITION by TickStore.bid ORDER BY ts);
```

This example shows both the TIMESERIES clause and the TS_FIRST_VALUE TSA function. The query returns the values of the bid column, as determined by the specified constant interpolation scheme.

```sql
=> SELECT slice_time, TS_FIRST_VALUE(bid, 'CONST') bid FROM TickStore TIMESERIES slice_time AS '3 seconds' OVER(PARTITION by symbol ORDER BY ts);
```

Vertica interpolates the last known value and fills in the missing datapoint, returning 10 at 3:00:03:

<table>
<thead>
<tr>
<th>First query</th>
<th>Interpolated value</th>
</tr>
</thead>
<tbody>
<tr>
<td>slice_time</td>
<td>bid</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------------</td>
</tr>
<tr>
<td>2009-01-01 03:00:00</td>
<td>10</td>
</tr>

<td>2009-01-01 03:00:00</td>
</tr>
<tr>
<td></td>
<td>2009-01-01 03:00:03</td>
</tr>
<tr>
<td>(2 rows)</td>
<td></td>
</tr>
</tbody>
</table>
Time Series Rounding

Vertica calculates all time series as equal intervals relative to the timestamp 2000-01-01 00:00:00. Vertica rounds time series timestamps as needed, to conform with this baseline. Start times are also rounded down to the nearest whole unit for the specified interval.

Given this logic, the TIMESERIES clause generates series of timestamps as described in the following sections.

Minutes

Time series of minutes are rounded down to full minutes. For example, the following statement specifies a time span of 00:00:03 - 00:05:50:

```sql
=> SELECT ts FROM (
    SELECT '2015-01-04 00:00:03'::TIMESTAMP AS tm
    UNION
    SELECT '2015-01-04 00:05:50'::TIMESTAMP AS tm
) t
TIMESERIES ts AS '1 minute' OVER (ORDER BY tm);
```

Vertica rounds down the time series start and end times to full minutes, 00:00:00 and 00:05:00, respectively:

```
t
------------------
2015-01-04 00:00:00
2015-01-04 00:01:00
2015-01-04 00:02:00
2015-01-04 00:03:00
2015-01-04 00:04:00
2015-01-04 00:05:00
(6 rows)
```

Weeks

Because the baseline timestamp 2000-01-01 00:00:00 is a Saturday, all time series of weeks start on Saturday. Vertica rounds down the series start and end timestamps accordingly. For example, the following statement specifies a time span of 12/10/99 - 01/10/00:
The specified time span starts on Friday (12/10/99), so Vertica starts the time series on the preceding Saturday, 12/04/99. The time series ends on the last Saturday within the time span, 01/08/00:

<table>
<thead>
<tr>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999-12-04 00:00:00</td>
</tr>
<tr>
<td>1999-12-11 00:00:00</td>
</tr>
<tr>
<td>1999-12-18 00:00:00</td>
</tr>
<tr>
<td>1999-12-25 00:00:00</td>
</tr>
<tr>
<td>2000-01-01 00:00:00</td>
</tr>
<tr>
<td>2000-01-08 00:00:00</td>
</tr>
</tbody>
</table>

(6 rows)

**Months**

Time series of months are divided into equal 30-day intervals, relative to the baseline timestamp 2000-01-01 00:00:00. For example, the following statement specifies a time span of 09/01/99 - 12/31/00:

```sql
=> SELECT ts FROM (  
    SELECT '1999-09-01 00:00:00'::TIMESTAMP AS tm  
    UNION  
    SELECT '2000-12-31 23:59:59'::TIMESTAMP AS tm  
 ) t  
TIMESERIES ts AS '1 month' OVER (ORDER BY tm);
```

Vertica generates a series of 30-day intervals, where each timestamp is rounded up or down, relative to the baseline timestamp:

<table>
<thead>
<tr>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999-08-04 00:00:00</td>
</tr>
<tr>
<td>1999-09-03 00:00:00</td>
</tr>
<tr>
<td>1999-10-03 00:00:00</td>
</tr>
<tr>
<td>1999-11-02 00:00:00</td>
</tr>
<tr>
<td>1999-12-02 00:00:00</td>
</tr>
<tr>
<td>2000-01-01 00:00:00</td>
</tr>
<tr>
<td>2000-03-01 00:00:00</td>
</tr>
<tr>
<td>2000-03-31 00:00:00</td>
</tr>
<tr>
<td>2000-04-30 00:00:00</td>
</tr>
</tbody>
</table>
Years

Time series of years are divided into equal 365-day intervals. If a time span overlaps leap years since or before the baseline timestamp `2000-01-01 00:00:00`, Vertica rounds the series timestamps accordingly.

For example, the following statement specifies a time span of 01/01/95 - 05/08/09, which overlaps four leap years, including the baseline timestamp:

```sql
=> SELECT ts FROM (
    SELECT '1995-01-01 00:00:00'::TIMESTAMP AS tm
    UNION
    SELECT '2009-05-08'::TIMESTAMP AS tm
) t timeseries ts AS '1 year' over (ORDER BY tm);
```

Vertica generates a series of timestamps that are rounded up or down, relative to the baseline timestamp:

```
  ts
  ------------------------
  1994-01-02 00:00:00
  1995-01-02 00:00:00
  1996-01-02 00:00:00
  1997-01-01 00:00:00
  1998-01-01 00:00:00
  1999-01-01 00:00:00
  2000-01-01 00:00:00
  2000-12-31 00:00:00
  2001-12-31 00:00:00
  2002-12-31 00:00:00
  2003-12-31 00:00:00
  2004-12-30 00:00:00
  2005-12-30 00:00:00
  2006-12-30 00:00:00
  2007-12-30 00:00:00
  2008-12-29 00:00:00
(16 rows)
```
Linear Interpolation

Instead of interpolating data points based on the last seen value (Constant Interpolation), linear interpolation is where Vertica interpolates values in a linear slope based on the specified time slice.

The query that follows uses linear interpolation to place the input records in 2-second time slices and return the first bid value for each symbol/time slice combination (the value at the start of the time slice):

```sql
=> SELECT slice_time, TS_FIRST_VALUE(bid, 'LINEAR') bid FROM Tickstore
   TIMESERIES slice_time AS '2 seconds' OVER(PARTITION BY symbol ORDER BY ts);
```

The following figure illustrates the previous query results, showing the 2-second time gaps (3:00:02 and 3:00:04) in which no input record occurs. Note that the interpolated bid price of XYZ changes to 10.2 at 3:00:02 and 10.3 at 3:00:03 and 10.4 at 3:00:04, all of which fall between the two known data inputs (3:00:00 and 3:00:05). At 3:00:05, the value would change to 10.5.

Note: The known data points above are represented by a red dot, and the interpolated values are represented by blue stars.

The following is a side-by-side comparison of constant and linear interpolation schemes.
### Constant Interpolation

The first query uses `TS_FIRST_VALUE()` and the TIMESERIES Clause to place the input records in 3-second time slices and return the first bid value for each symbol/time slice combination (the value at the start of the time slice).

**Note:**
The TIMESERIES clause requires an ORDER BY operation on the TIMESTAMP column.

```sql
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid) AS first_bid FROM TickStore
    TIMESERIES slice_time AS '3 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```
Because the bid price of stock XYZ is 10.0 at 3:00:03, the first_bid value of the second time slice, which starts at 3:00:03 is till 10.0 (instead of 10.5) because the input value of 10.5 does not occur until 3:00:05. In this case, the interpolated value is inferred from the last value seen on stock XYZ for time 3:00:03:

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>first_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:03</td>
<td>XYZ</td>
<td>10</td>
</tr>
</tbody>
</table>

The next example places the input records in 2-second time slices to return the first bid value for each symbol/time slice combination:

```
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid) AS first_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

The result now contains three records in 2-second increments, all of which occur between the first input row at 03:00:00 and the second input row at 3:00:05. Note that the second and third output record correspond to a time slice where there is no input record:

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>first_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td>10</td>
</tr>
</tbody>
</table>

Using the same table schema, the next query uses `TS_LAST_VALUE()`, with the TIMESERIES clause to return the last values of each time slice (the values at the end of the time slices).

```
Note:

Time series aggregate functions process the data that belongs to each time slice. One output row is produced per time slice or per partition per time slice if a partition expression is present.

=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Notice that the last value output row is 10.5 because the value 10.5 at time 3:00:05 was the last point inside the 2-second time slice that started at 3:00:04:

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>last_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
</tbody>
</table>

(3 rows)
Remember that because constant interpolation is the default, the same results are returned if you write the query using the CONST parameter as follows:

```sql
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid, 'CONST') AS last_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

### Linear Interpolation

Based on the same input records described in the constant interpolation examples, which specify 2-second time slices, the result of `TS_LAST_VALUE` with linear interpolation is as follows:

```sql
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid, 'linear') AS last_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

In the results, no last_bid value is returned for the last row because the query specified `TS_LAST_VALUE`, and there is no data point after the 3:00:04 time slice to interpolate.

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>last_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10.2</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td>10.4</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>(3 rows)</td>
</tr>
</tbody>
</table>

### Using Multiple Time Series Aggregate Functions

Multiple time series aggregate functions can exists in the same query. They share the same gap-filling policy as defined in the TIMESERIES clause; however, each time series aggregate function can specify its own interpolation policy. In the following example, there are two constant and one linear interpolation schemes, but all three functions use a three-second time slice:

```sql
=> SELECT slice_time, symbol,
    TS_FIRST_VALUE(bid, 'const') fv_c,
    TS_FIRST_VALUE(bid, 'linear') fv_l,
    TS_LAST_VALUE(bid, 'const') lv_c
FROM TickStore
    TIMESERIES slice_time AS '3 seconds' OVER(PARTITION BY symbol ORDER BY ts);
```

In the following output, the original output is compared to output returned by multiple time series aggregate functions.
Using the Analytic LAST_VALUE Function

Here's an example using LAST_VALUE(), so you can see the difference between it and the GFI syntax.

```sql
=> SELECT *, LAST_VALUE(bid) OVER(PARTITION by symbol ORDER BY ts) AS "last bid" FROM TickStore;
```

There is no gap filling and interpolation to the output values.

Using slice_time

In a TIMESERIES query, you cannot use the column slice_time in the WHERE clause because the WHERE clause is evaluated before the TIMESERIES clause, and the slice_time column is not generated until the TIMESERIES clause is evaluated. For example, Vertica does not support the following query:

```sql
=> SELECT symbol, slice_time, TS_FIRST_VALUE(bid IGNORE NULLS) AS fv
   FROM TickStore
   WHERE slice_time = '2009-01-01 03:00:00'
   TIMESERIES slice_time as '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
ERROR: Time Series timestamp alias/Time Series Aggregate Functions not allowed in WHERE clause
```

Instead, you could write a subquery and put the predicate on slice_time in the outer query:

```sql
=> SELECT * FROM (SELECT symbol, slice_time,
    TS_FIRST_VALUE(bid IGNORE NULLS) AS fv
    FROM TickStore
    TIMESERIES slice_time AS '2 seconds'
    OVER (PARTITION BY symbol ORDER BY ts) ) sq
```
Creating a Dense Time Series

The TIMESERIES clause provides a convenient way to create a dense time series for use in an outer join with fact data. The results represent every time point, rather than just the time points for which data exists.

The examples that follow use the same TickStore schema described in Gap Filling and Interpolation (GFI), along with the addition of a new inner table for the purpose of creating a join:

```sql
=> CREATE TABLE inner_table (ts TIMESTAMP, bid FLOAT);
=> CREATE PROJECTION inner_p (ts, bid) as SELECT * FROM inner_table ORDER BY ts, bid UNSEGMENTED ALL NODES;
=> INSERT INTO inner_table VALUES ('2009-01-01 03:00:02', 1);
=> INSERT INTO inner_table VALUES ('2009-01-01 03:00:04', 2);
=> COMMIT;
```

You can create a simple union between the start and end range of the timeframe of interest in order to return every time point. This example uses a 1-second time slice:

```sql
=> SELECT ts FROM (SELECT '2009-01-01 03:00:00'::TIMESTAMP AS time FROM TickStore UNION SELECT '2009-01-01 03:00:05'::TIMESTAMP FROM TickStore) t TIMESERIES ts AS '1 seconds' OVER(ORDER BY time);
```

The next query creates a union between the start and end range of the timeframe using 500-millisecond time slices:

```sql
=> SELECT ts FROM (SELECT '2009-01-01 03:00:00'::TIMESTAMP AS time
The following query creates a union between the start- and end-range of the timeframe of interest using 1-second time slices:

```sql
=> SELECT * FROM (  
    SELECT ts FROM (  
      SELECT '2009-01-01 03:00:00'::timestamp AS time FROM TickStore  
      UNION  
      SELECT '2009-01-01 03:00:05'::timestamp FROM TickStore) t  
      TIMESERIES ts AS '1 seconds' OVER(ORDER BY time)  
    ) AS outer_table  
    LEFT OUTER JOIN inner_table ON outer_table.ts = inner_table.ts;
```

The union returns a complete set of records from the left-joined table with the matched records in the right-joined table. Where the query found no match, it extends the right side column with null values:

<table>
<thead>
<tr>
<th>ts</th>
<th>ts</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2009-01-01 03:00:01</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>2009-01-01 03:00:02</td>
<td>1</td>
</tr>
<tr>
<td>2009-01-01 03:00:03</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>2009-01-01 03:00:04</td>
<td>2</td>
</tr>
<tr>
<td>2009-01-01 03:00:05</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(6 rows)

**Null Values in Time Series Data**

Null values are uncommon inputs for gap-filling and interpolation (GFI) computation. When null values exist, you can use time series aggregate (TSA) functions `TS_FIRST_VALUE` and `TS_LAST_VALUE` with `IGNORE NULLS` to affect output of the interpolated values. TSA
functions are treated like their analytic counterparts `FIRST_VALUE` and `LAST_VALUE`: if the timestamp itself is null, Vertica filters out those rows before gap filling and interpolation occurs.

**Constant Interpolation with Null Values**

Figure 1 illustrates a default (constant) interpolation result on four input rows where none of the inputs contains a NULL value:

![Graph showing interpolated bid values with no NULLs](image)

**Figure 1. Interpolated bid values when the input has no NULLs**

Figure 2 shows the same input rows with the addition of another input record whose bid value is NULL, and whose timestamp (ts) value is 3:00:03:
For constant interpolation, the bid value starting at 3:00:03 is null until the next non-null bid value appears in time. In Figure 2, the presence of the null row makes the interpolated bid value null in the time interval denoted by the shaded region. If TS_FIRST_VALUE(bid) is evaluated with constant interpolation on the time slice that begins at 3:00:02, its output is non-null. However, TS_FIRST_VALUE(bid) on the next time slice produces null. If the last value of the 3:00:02 time slice is null, the first value for the next time slice (3:00:04) is null. However, if you use a TSA function with IGNORE NULLS, then the value at 3:00:04 is the same value as it was at 3:00:02.

To illustrate, insert a new row into the TickStore table at 03:00:03 with a null bid value, Vertica outputs a row for the 03:00:02 record with a null value but no row for the 03:00:03 input:

```sql
=> INSERT INTO tickstore VALUES('2009-01-01 03:00:03', 'XYZ', NULL);
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
=> TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>last_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
</tbody>
</table>

(3 rows)

If you specify IGNORE NULLS, Vertica fills in the missing data point using a constant interpolation scheme. Here, the bid price at 03:00:02 is interpolated to the last known input record for bid, which was $10 at 03:00:00:
Now, if you insert a row where the timestamp column contains a null value, Vertica filters out that row before gap filling and interpolation occurred.

```sql
=> INSERT INTO tickstore VALUES(NULL, 'XYZ', 11.2);
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Notice there is no output for the 11.2 bid row:

```
slice_time | symbol | last_bid
-----------|--------|--------
2009-01-01 03:00:00 | XYZ | 10
2009-01-01 03:00:02 | XYZ | 10
2009-01-01 03:00:04 | XYZ | 10.5
(3 rows)
```

**Linear Interpolation with Null Values**

For linear interpolation, the interpolated bid value becomes null in the time interval, represented by the shaded region in Figure 3:
Figure 3. LINEAR-interpolated bid values when the input has NULL values

In the presence of an input null value at 3:00:03, Vertica cannot linearly interpolate the bid value around that time point.

Vertica takes the closest non null value on either side of the time slice and uses that value. For example, if you use a linear interpolation scheme and do not specify IGNORE NULLS, and your data has one real value and one null, the result is null. If the value on either side is null, the result is null. Therefore, to evaluate $\text{TS\_FIRST\_VALUE}(\text{bid})$ with linear interpolation on the time slice that begins at 3:00:02, its output is null. $\text{TS\_FIRST\_VALUE}(\text{bid})$ on the next time slice remains null.

```
->[ SELECT slice_time, symbol, $\text{TS\_FIRST\_VALUE}(\text{bid}, 'linear')$ AS $\text{fv}_1$ FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>fv_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td></td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td></td>
</tr>
</tbody>
</table>

(3 rows)

Data Aggregation

You can use functions such as SUM and COUNT to aggregate the results of GROUP BY queries at one or more levels.
Single-Level Aggregation

The simplest GROUP BY queries aggregate data at a single level. For example, a table might contain the following information about family expenses:

- Category
- Amount spent on that category during the year
- Year

Table data might look like this:

```sql
=> SELECT * FROM expenses ORDER BY Category;
Year | Category  | Amount
---|-----------|-----
2005 | Books     | 39.98
2007 | Books     | 29.99
2008 | Books     | 29.99
2006 | Electrical| 109.99
2005 | Electrical| 109.99
2007 | Electrical| 229.98
```

You can use aggregate functions to get the total expenses per category or per year:

```sql
=> SELECT SUM(Amount), Category FROM expenses GROUP BY Category;
SUM   | Category
-----|-------
99.96 | Books
449.96| Electrical

=> SELECT SUM(Amount), Year FROM expenses GROUP BY Year;
SUM   | Year
-----|-----
149.97| 2005
109.99| 2006
29.99 | 2008
259.97| 2007
```

Multi-Level Aggregation

Over time, tables that are updated frequently can contain large amounts of data. Using the simple table shown earlier, suppose you want a multilevel query, like the number of expenses per category per year.
The following query uses the ROLLUP aggregation with the SUM function to calculate the total expenses by category and the overall expenses total. The NULL fields indicate subtotal values in the aggregation.

- When only the Year column is NULL, the subtotal is for all the Category values.
- When both the Year and Category columns are NULL, the subtotal is for all Amount values for both columns.

Using the ORDER BY clause orders the results by expense category, the year the expenses took place, and the GROUP BY level that the GROUPING_ID function creates:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electrical</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td>Electrical</td>
<td></td>
<td>449.96</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
</tr>
</tbody>
</table>

Similarly, the following query calculates the total sales by year and the overall sales total and then uses the ORDER BY clause to sort the results:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
GROUP BY ROLLUP(Year, Category) ORDER BY 2, 1, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Electrical</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td></td>
<td>2005</td>
<td>149.97</td>
</tr>
<tr>
<td>Electrical</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td></td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td></td>
<td>2007</td>
<td>259.97</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td></td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
</tr>
</tbody>
</table>

(11 rows)

You can use the CUBE aggregate to perform all possible groupings of the category and year expenses. The following query returns all possible groupings, ordered by grouping:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
GROUP BY CUBE(Category, Year) ORDER BY 1, 2, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.3.x)
The results include subtotals for each category and each year and a total ($549.92) for all transactions, regardless of year or category.

ROLLUP, CUBE, and GROUPING SETS generate NULL values in grouping columns to identify subtotals. If table data includes NULL values, differentiating these from NULL values in subtotals can sometimes be challenging.

In the preceding output, the NULL values in the Year column indicate that the row was grouped on the Category column, rather than on both columns. In this case, ROLLUP added the NULL value to indicate the subtotal row.

### Aggregates and Functions for Multilevel Grouping

Vertica provides several aggregates and functions that group the results of a GROUP BY query at multiple levels.

### Aggregates for Multilevel Grouping

Use the following aggregates for multilevel grouping:

- **ROLLUP** automatically performs subtotal aggregations. ROLLUP performs one or more aggregations across multiple dimensions, at different levels.
- **CUBE** performs the aggregation for all permutations of the CUBE expression that you specify.
- **GROUPING SETS** let you specify which groupings of aggregations you need.

You can use CUBE or ROLLUP expressions inside GROUPING SETS expressions. Otherwise, you cannot nest multilevel aggregate expressions.
Grouping Functions

You use one of the following three grouping functions with ROLLUP, CUBE, and GROUPING SETS:

- **GROUP_ID** returns one or more numbers, starting with zero (0), to uniquely identify duplicate sets.
- **GROUPING_ID** produces a unique ID for each grouping combination.
- **GROUPING** identifies for each grouping combination whether a column is a part of this grouping. This function also differentiates NULL values in the data from NULL grouping subtotals.

These functions are typically used with multilevel aggregates.

Aggregate Expressions for GROUP BY

You can include CUBE and ROLLUP aggregates within a GROUPING SETS aggregate. Be aware that the CUBE and ROLLUP aggregates can result in a large amount of output. However, you can avoid large outputs by using GROUPING SETS to return only specified results.

```sql
...GROUP BY a,b,c,d,ROLLUP(a,b)...
...GROUP BY a,b,c,d,CUBE((a,b),c,d)...
```

You cannot include any aggregates in a CUBE or ROLLUP aggregate expression.

You can append multiple GROUPING SETS, CUBE, or ROLLUP aggregates in the same query.

```sql
...GROUP BY a,b,c,d,CUBE(a,b),ROLLUP (c,d)...
...GROUP BY a,b,c,d,GROUPING SETS ((a,d),(b,c),CUBE(a,b));...
...GROUP BY a,b,c,d,GROUPING SETS ((a,d),(b,c),(a,b),(a),(b),())... 
```

Pre-Aggregating Data in Projections

Queries that use aggregate functions such as **SUM** and **COUNT** can perform more efficiently when they use projections that already contain the aggregated data. This improved
efficiency is especially true for queries on large quantities of data.

For example, a power grid company reads 30 million smart meters that provide data at five-minute intervals. The company records each reading in a database table. Over a given year, three trillion records are added to this table.

The power grid company can analyze these records with queries that include aggregate functions to perform the following tasks:

- Establish usage patterns.
- Detect fraud.
- Measure correlation to external events such as weather patterns or pricing changes.

To optimize query response time, you can create an aggregate projection, which stores the data is stored after it is aggregated.

**Aggregate Projections**

Vertica provides three types of projections for storing data that is returned from aggregate functions or expressions:

- **Projection that contains expressions**: Projection with columns whose values are calculated from anchor table columns.
- **Live aggregate projection**: Projection that contains columns with values that are aggregated from columns in its anchor table. You can also define live aggregate projections that include user-defined transform functions.
- **Top-K projection**: Type of live aggregate projection that returns the top $k$ rows from a partition of selected rows. Create a Top-K projection that satisfies the criteria for a Top-K query.

**Recommended Use**

- Aggregate projections are most useful for queries against large sets of data.
- For optimal query performance, the size of LAP projections should be a small subset of the anchor table—ideally, between 1 and 10 percent of the anchor table, or smaller, if possible.

**Restrictions**

- DML operations on anchor tables are faster if the tables' load methods are set to DIRECT.
• MERGE operations must be *optimized* if they are performed on target tables that have live aggregate projections.
• You cannot update or delete data in temporary tables with live aggregate projections.

**Requirements**

In the event of manual recovery from an unclean database shutdown, live aggregate projections might require some time to refresh.

**Live Aggregate Projections**

A live aggregate projection contains columns with values that are aggregated from columns in its anchor table. When you load data into the table, Vertica aggregates the data before loading it into the live aggregate projection. On subsequent loads—for example, through `INSERT` or `COPY`—Vertica recalculates aggregations with the new data and updates the projection.

DML operations on anchor tables are faster if the tables' *load methods* are set to DIRECT.

**Functions Supported for Live Aggregate Projections**

Vertica can aggregate results in live aggregate projections from the following aggregate functions:

- `SUM`
- `MAX`
- `MIN`
- `COUNT`

**Aggregate Functions with DISTINCT**

Live aggregate projections can support queries that include aggregate functions qualified with the keyword DISTINCT. The following requirements apply:

- The aggregated expression must evaluate to a non-constant.
- The projection's `GROUP BY` clause must specify the aggregated expression.
For example, the following query uses SUM(DISTINCT) to calculate the total of all unique salaries in a given region:

```
SELECT customer_region, SUM(DISTINCT annual_income)::INT
FROM customer_dimension GROUP BY customer_region;
```

This query can use the following live aggregate projection, which specifies the aggregated column (annual_income) in its GROUP BY clause:

```
CREATE PROJECTION public.TotalRegionalIncome
(
    customer_region,
    annual_income,
    Count
) AS
SELECT customer_dimension.customer_region,
    customer_dimension.annual_income,
    count(*) AS Count
FROM public.customer_dimension
GROUP BY customer_dimension.customer_region,
    customer_dimension.annual_income
;
```

**Note:**
This projection includes the aggregate function COUNT, which here serves no logical objective; it is included only because live aggregate projections require at least one aggregate function.

### Creating Live Aggregate Projections

You define a live aggregate projection with the following syntax:

```
=> CREATE PROJECTION proj-name AS
    SELECT select-expression FROM table
    GROUP BY group-expression;
```

For full syntax options, see CREATE PROJECTION (Live Aggregate Projections).

For example:

```
=> CREATE PROJECTION clicks_agg AS
    SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
    GROUP BY page_id, click_time::DATE KSAFE 1;
```

For an extended discussion, see Live Aggregate Projection Example.
Requirements

The following requirements apply to live aggregate projections:

- The projection cannot be unsegmented.
- SELECT and GROUP BY columns must be in the same order. GROUP BY expressions must be at the beginning of the SELECT list.

Restrictions

The following restrictions apply to live aggregate projections:

- DML operations on anchor tables are faster if the tables' load methods are set to DIRECT.
- MERGE operations must be optimized if they are performed on target tables that have live aggregate projections.
- Live aggregate projections can reference only one table.
- Vertica does not regard live aggregate projections as superprojections, even those that include all table columns.
- You cannot modify the anchor table metadata of columns that are included in projections. You also cannot drop these columns. To make these changes, first drop all live aggregate and Top-K projections that are associated with the table.

Live Aggregate Projection Example

This example shows how you can track user clicks on a given web page using the following clicks table:

```sql
=> CREATE TABLE clicks(
    user_id INTEGER,
    page_id INTEGER,
    click_time TIMESTAMP NOT NULL);
```

You can aggregate user-specific activity with the following query:

```sql
=> SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
   WHERE click_time::DATE = '2015-04-30'
   GROUP BY page_id, click_time::DATE ORDER BY num_clicks DESC;
```

To facilitate performance of this query, create a live aggregate projection that counts the number of clicks per user:
CREATE PROJECTION clicks_agg AS
    SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
    GROUP BY page_id, click_time::DATE KSAME 1;

When you query the clicks table on user clicks, Vertica typically directs the query to the live aggregate projection clicks_agg. As additional data is loaded into clicks, Vertica pre-aggregates the new data and updates clicks_agg, so queries always return with the latest data.

For example:

```sql
=> SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
    WHERE click_time::DATE = '2015-04-30' GROUP BY page_id, click_time::DATE
    ORDER BY num_clicks DESC;
```

<table>
<thead>
<tr>
<th>page_id</th>
<th>click_date</th>
<th>num_clicks</th>
</tr>
</thead>
<tbody>
<tr>
<td>2002</td>
<td>2015-04-30</td>
<td>10</td>
</tr>
<tr>
<td>3003</td>
<td>2015-04-30</td>
<td>3</td>
</tr>
<tr>
<td>2003</td>
<td>2015-04-30</td>
<td>1</td>
</tr>
<tr>
<td>2035</td>
<td>2015-04-30</td>
<td>1</td>
</tr>
<tr>
<td>12034</td>
<td>2015-04-30</td>
<td>1</td>
</tr>
</tbody>
</table>

(5 rows)

Top-K Projections

A Top-K query returns the top k rows from partitions of selected rows. Top-K projections can significantly improve performance of Top-K queries. For example, you can define a table that stores gas meter readings with three columns: gas meter ID, time of meter reading, and the read value:

```sql
=> CREATE TABLE readings (
    meter_id INT,
    reading_date TIMESTAMP,
    reading_value FLOAT);
```

Given this table, the following Top-K query returns the five most recent meter readings for a given meter:

```sql
SELECT meter_id, reading_date, reading_value FROM readings
    LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

To improve the performance of this query, you can create a Top-K projection, which is a special type of live aggregate projection:

```sql
=> CREATE PROJECTION readings_topk (meter_id, recent_date, recent_value)
    AS SELECT meter_id, reading_date, reading_value FROM readings
```
After you create this Top-K projection and load its data (through START_REFRESH or REFRESH), Vertica typically redirects the query to the projection and returns with the pre-aggregated data.

### Creating Top-K Projections

You define a Top-K projection with the following syntax:

```
CREATE PROJECTION proj-name [(proj-column-spec)]
    AS SELECT select-expression FROM table
    LIMIT num-rows OVER (PARTITION BY expression ORDER BY column-expr);
```

For full syntax options, see CREATE PROJECTION (Live Aggregate Projections).

For example:

```
=> CREATE PROJECTION readings_topk (meter_id, recent_date, recent_value)
    AS SELECT meter_id, reading_date, reading_value FROM readings
    LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

For an extended discussion, see Top-K Projection Examples.

### Requirements

The following requirements apply to Top-K projections:

- The projection cannot be unsegmented.
- The window partition clause must use PARTITION BY.
- Columns in PARTITION BY and ORDER BY clauses must be the first columns specified in the SELECT list.
- You must use the LIMIT option to create a Top-K projection, instead of subqueries.

For example, the following SELECT statements are equivalent:

```
=> SELECT symbol, trade_time last_trade, price last_price FROM (  
    SELECT symbol, trade_time, price, ROW_NUMBER()  
    OVER(PARTITION BY symbol ORDER BY trade_time DESC) rn FROM trades) trds WHERE rn <=1;
```

```
=> SELECT symbol, trade_time last_trade, price last_price FROM trades
    LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

Both return the same results:
A Top-K projection that pre-aggregates data for use by both queries must include the LIMIT option:

```sql
=> CREATE PROJECTION trades_topk AS
    SELECT symbol, trade_time last_trade, price last_price FROM trades
    LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

### Restrictions

The following restrictions apply to Top-K projections:

- Top-K projections can reference only one table.
- Vertica does not regard Top-K projections as superprojections, even those that include all table columns.
- You cannot modify the anchor table metadata of columns that are included in projections. You also cannot drop these columns. To make these changes, you must first drop all live aggregate and Top-K projections that are associated with the table.

### Top-K Projection Examples

The following examples show how to query a table with two Top-K projections for the most-recent trade and last trade of the day for each stock symbol.

1. Create a table that contains information about individual stock trades:
   - Stock symbol
   - Timestamp
   - Price per share
   - Number of shares

```sql
=> CREATE TABLE trades(
    symbol CHAR(16) NOT NULL,
    trade_time TIMESTAMP NOT NULL,
    price NUMERIC(12,4),
    volume INT )
PARTITION BY (EXTRACT(year from trade_time) * 100 +
    EXTRACT(month from trade_time));
```
2. Load data into the table:

```
INSERT INTO trades VALUES('AAPL','2010-10-10 10:10:10'::TIMESTAMP,100.00,100);
INSERT INTO trades VALUES('AAPL','2010-10-10 10:10:10.3'::TIMESTAMP,101.00,100);
INSERT INTO trades VALUES ('AAPL','2011-10-10 10:10:10.5'::TIMESTAMP,106.1,1000);
INSERT INTO trades VALUES ('AAPL','2011-10-10 10:10:10.2'::TIMESTAMP,105.2,500);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.2'::TIMESTAMP,42.01,400);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.3'::TIMESTAMP,42.02,1000);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.4'::TIMESTAMP,42.05,100);
COMMIT;
```

3. Create two Top-K projections that obtain the following information from the trades table:
   - Return the most recent trades for each stock symbol.
   - Return the last trade on each trading day.

For each stock symbol, return the most recent trade.

```
=> CREATE PROJECTION trades_topk_a AS SELECT symbol, trade_time last_trade, price last_price
   FROM trades LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

```
symbol | last_trade | last_price
-------|-----------|----------
HPQ    | 2012-10-10 10:10:10.4 | 42.0500
AAPL   | 2011-10-10 10:10:10.5 | 106.1000
(2 rows)
```

For each stock symbol, return the last trade on each trading day.

```
=> CREATE PROJECTION trades_topk_b
   AS SELECT symbol, trade_time::DATE trade_date, trade_time, price close_price, volume
   FROM trades LIMIT 1 OVER(PARTITION BY symbol, trade_time::DATE ORDER BY trade_time DESC);
```

```
symbol | trade_date | trade_time | close_price | volume
--------|-----------|-----------|-------------|--------
HPQ     | 2012-10-10 | 2012-10-10 10:10:10.4 | 42.0500 | 100
AAPL    | 2011-10-10 | 2011-10-10 10:10:10.5 | 106.1000 | 1000
AAPL    | 2010-10-10 | 2010-10-10 10:10:10.3 | 101.0000 | 100
(3 rows)
```

In each scenario, Vertica redirects queries on the trades table to the appropriate Top-K projection and returns the aggregated data from them. As additional data is loaded into this table, Vertica pre-aggregates the new data and updates the Top-K projections, so queries always return with the latest data.
Pre-Aggregating UDTF Results

CREATE PROJECTION can define live aggregate projections that invoke user-defined transform functions (UDTFs). To minimize overhead when you query those projections, Vertica processes these functions in the background and stores their results on disk.

**Important:**
Currently, live aggregate projections can only reference UDTFs that are developed in C++.

Defining Projections with UDTFs

The projection definition characterizes UDTFs in one of two ways:

- Identifies the UDTF as a **pre-pass UDTF**, which transforms newly loaded data before it is stored in the projection ROS containers.
- Identifies the UDTF as a **batch UDTF**, which aggregates and stores projection data.

The projection definition identifies a UDTF as a pre-pass UDTF or batch UDTF in its **window partition clause**, through the keywords PREPASS or BATCH. A projection can specify one pre-pass or batch UDTF or include both (see UDTF Specification Options).

In all cases, the projection is implicitly segmented and ordered on the PARTITION BY columns.

UDTF Specification Options

Projections can invoke batch and pre-pass UDTFs singly or in combination.

**Single Pre-Pass UDTF**

Vertica invokes the pre-pass UDTF when you load data into the projection's anchor table—for example through COPY or INSERT statements. A pre-pass UDTF transforms the new data and then stores the transformed data in the projection's ROS containers.

Use the following syntax:
CREATE PROJECTION projection-name
({ projection-column | grouped-clause
    [ ENCODING encoding-type ]
    [ ACCESSRANK integer ]})
AS SELECT ..., udtf(args)
OVER(PARTITION PREPASS BY partition-columns) AS (prepass-output-columns) FROM table-ref;

Single Batch UDTF

When invoked singly, a batch UDTF transforms and aggregates projection data on mergeout, data load, and query operations. The UDTF stores aggregated results in the projection's ROS containers. Aggregation is cumulative across mergeout and load operations, and is completed (if necessary) on query execution.

Use the following syntax:

CREATE PROJECTION projection-name
({ projection-column | grouped-clause
    [ ENCODING encoding-type ]
    [ ACCESSRANK integer ]})
AS SELECT ..., udtf(args)
OVER(PARTITION BATCH BY partition-columns) AS (batch-output-columns) FROM table-ref;

Combined Pre-Pass and Batch UDTFs

You can define a projection with a subquery that invokes a pre-pass UDTF. The pre-pass UDTF returns transformed data to the outer batch query. The batch UDTF then iteratively aggregates results across mergeout operations. It completes aggregation (if necessary) on query execution.

Use the following syntax:

CREATE PROJECTION projection-name
({ projection-column | grouped-clause
    [ ENCODING encoding-type ]
    [ ACCESSRANK integer ]})
AS SELECT ..., batch-udtf(batch-args)
OVER (PARTITION BATCH BY partition-columns) AS (batch-output-columns)
FROM (SELECT ..., prepass-udtf(prepass-args)
    OVER (PARTITION PREPASS BY partition-columns) AS (prepass-output-columns)
    FROM table-ref ) sq-ref;

Important:
The outer batch UDTF arguments batch-args must exactly match the
output columns returned by the pre-pass UDTF, in name and order.

## Examples

### Single pre-pass UDTF

The following example shows how to use the UDTF `text_index`, which extracts from a text document strings that occur more than once.

The following projection specifies to invoke `text_index` as a pre-pass UDTF:

```sql
=> CREATE TABLE documents ( doc_id INT PRIMARY KEY, text VARCHAR(140));
=> CREATE PROJECTION index_proj (doc_id, text) AS SELECT doc_id, text_index(doc_id, text) OVER (PARTITION PREPASS BY doc_id) FROM documents;
```

The UDTF is invoked whenever data is loaded into the anchor table `documents`. `text_index` transforms the newly loaded data, and Vertica stores the transformed data in the live aggregate projection ROS containers.

So, if you load the following data into `documents`:

```sql
=> INSERT INTO documents VALUES (100, 'A SQL Query walks into a bar. In one corner of the bar are two tables. The Query walks up to the tables and asks - Mind if I join you?');
```

`text_index` transforms the newly loaded data and stores it in the projection ROS containers. When you query the projection, it returns with the following results:

<table>
<thead>
<tr>
<th>doc_id</th>
<th>frequency</th>
<th>term</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2</td>
<td>bar</td>
</tr>
<tr>
<td>100</td>
<td>2</td>
<td>Query</td>
</tr>
<tr>
<td>100</td>
<td>2</td>
<td>tables</td>
</tr>
<tr>
<td>100</td>
<td>2</td>
<td>the</td>
</tr>
<tr>
<td>100</td>
<td>2</td>
<td>walks</td>
</tr>
</tbody>
</table>

### Combined Pre-Pass and Batch UDTFs

The following projection specifies pre-pass and batch UDTFs `stv_intersect` and `aggregate_classified_points`, respectively:

```sql
CREATE TABLE points( point_id INTEGER, point_type VARCHAR(10), coordinates GEOMETRY(100));
CREATE PROJECTION aggregated_proj
```
AS SELECT point_type, aggregate_classified_points( sq.point_id, sq.polygon_id) OVER (PARTITION BATCH BY point_type) FROM (SELECT point_type, stv_intersect(    point_id, coordinates USING PARAMETERS index='polygons' ) OVER (PARTITION PREPASS BY point_type) AS (point_id, polygon_id) FROM points) sq;

The pre-pass query UDTF stv_intersect returns its results (a set of point and matching polygon IDs) to the outer batch query. The outer batch query then invokes the UDTF aggregate_classified_points whenever a mergeout operation consolidates projection data. Final aggregation (if necessary) occurs when the projection is queried.

The batch UDTF arguments must exactly match the output columns returned by the pre-pass UDTF stv_intersect, in name and order. In this example, the pre-pass subquery explicitly names the pre-pass UDTF output columns point_id and polygon_id. Accordingly, the batch UDTF arguments match them in name and order: sq.point_id and sq.polygon_id.

### Aggregating Data Through Expressions

You can create projections where one or more columns are defined by expressions. An expression can reference one or more anchor table columns. For example, the following table contains two integer columns, a and b:

```sql
=> CREATE TABLE values (a INT, b INT);
```

You can create a projection with an expression that calculates the value of column c as the product of a and b:

```sql
=> CREATE PROJECTION values_product (a, b, c)    AS SELECT a, b, a*b FROM values SEGMENTED BY HASH(a) ALL NODES KSAFE;
```

When you load data into this projection, Vertica resolves the expression a*b in column c. You can then query the projection instead of the anchor table. Vertica returns the pre-calculated data and avoids the overhead otherwise incurred by resource-intensive computations.

Using expressions in projections also lets you sort or segment data on the calculated results of an expression instead of sorting on single column values.

**Note:**

If a projection with expressions also includes aggregate functions such as
SUM or COUNT, Vertica treats it like a live aggregate projection.

Support for User-Defined Scalar Functions

Important:
Currently, support for pre-aggregating UDSF results is limited to C++.

Vertica treats user-defined scalar functions (UDSFs) like other expressions. On each load operation, the UDSF is invoked and returns its results. Vertica stores these results on disk, and returns them when you query the projection directly.

In the following example, the projection points_p1 specifies the UDSF zorder, which is invoked whenever data is loaded in the anchor table points. When data is loaded into the projection, Vertica invokes this function and stores its results for fast access by future queries.

```sql
=> CREATE TABLE points(point_id INTEGER, lat NUMERIC(12,9), long NUMERIC(12,9));
=> CREATE PROJECTION points_p1
    AS SELECT point_id, lat, long, zorder(lat, long) zorder FROM points
    ORDER BY zorder(lat, long) SEGMENTED BY hash(point_id) ALL NODES;
```

Requirements

- Any ORDER BY expression must be in the SELECT list.
- All projection columns must be named.

Restrictions

- DML operations on anchor tables are faster if the tables' load methods are set to DIRECT.
- MERGE operations must be optimized if they are performed on target tables that have live aggregate projections.
- Unlike live aggregate projections, Vertica does not redirect queries with expressions to an equivalent existing projection.
- Projection expressions must be immutable—that is, they must always return the same result. For example, a projection cannot include expressions that use TO CHAR (depends on locale) or RANDOM (returns different value at each invocation).
• Projection expressions cannot include Vertica meta-functions such as ADVANCE_EPOCH, ANALYZE_STATISTICS, EXPORT_TABLES, or START_REFRESH.

**Querying Data Through Expressions Example**

The following example uses a table that contains two integer columns, a and b:

```sql
=> CREATE TABLE values (a INT, b INT);
```

You can create a projection with an expression that calculates the value of column c as the product of a and b:

```sql
=> CREATE PROJECTION values_product (a, b, c) AS SELECT a, b, a*b FROM values SEGMENTED BY HASH(a) ALL NODES KSAFE;
=> COPY values FROM STDIN DELIMITER ',' DIRECT;
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
>> 3,11
>> 3,55
>> 8,9
>> 8,23
>> 16,41
>> 22,111
>> .
=>
```

To query this projection, use the name that Vertica assigns to it or to its buddy projections. For example, the following queries target different instances of the projection defined earlier, and return the same results:

```sql
=> SELECT * FROM values_product_b0;
=> SELECT * FROM values_product_b1;
```

The following example queries the anchor table:

```sql
=> SELECT * FROM values;
a | b
----+----
 3 | 11
 3 | 55
 8 |  9
 8 | 23
16 | 41
22 |111
```

Given the projection created earlier, querying that projection returns the following values:
Aggregation Information in System Tables

You can query the following system table fields for information about live aggregate projections, Top-K projections, and projections with expressions:

<table>
<thead>
<tr>
<th>Table</th>
<th>Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLES</td>
<td>TABLE_HAS_AGGREGATE_PROJECTION</td>

</tbody>
</table>
Using Flex Tables

This guide describes how to use flexible (flex) tables, which are a different kind of database table designed for loading and querying unstructured data, also called *semi-structured* data in your Vertica Analytics Platform. Flex tables can contain only unstructured, raw data, or both unstructured and columnar data. You can create a flex table with or without a schema or real columns. Hybrid tables consist of both unstructured and real columns. Both flex and hybrid tables are fully supported Vertica Analytics Platform tables, stored as projections and with the same K-safety as your database.

**Audience**

This guide is intended for use by any user or database designer or application developer interested in working with flexible tables in the database.

**Prerequisites**

This guide assumes that Vertica Analytics Platform Version 9.3.x is installed and running in your environment.

It also assumes that you are familiar with using the Vertica Analytics Platform, especially the following features and commands:

- Loading data with the `COPY` statement and its basic parameters
- Using statements to create tables `CREATE TABLE` or CTAS (create table as...)
Vertica Documentation
Using Flex Tables

l
l
l
l

Altering table definitions with the ALTER TABLE statement
Creating and using Views (CREATE VIEW)
Querying data using the SELECT statement
Using functions for your database

If you are not familiar with these tasks and features, see Getting Started.

Getting Started
Getting Started describes the basics of creating, exploring, and using flex tables. The rest of
this guide presents beyond the basics details using simple examples.

Create a Simple JSON File
Use this JSON data for the exercises in the rest of this section:
{"name":
{"name":
{"name":
{"name":
{"name":

"Everest", "type":"mountain", "height":29029, "hike_safety": 34.1}
"Mt St Helens", "type":"volcano", "height":29029, "hike_safety": 15.4}
"Denali", "type":"mountain", "height":17000, "hike_safety": 12.2}
"Kilimanjaro", "type":"mountain", "height":14000 }
"Mt Washington", "type":"mountain", "hike_safety": 50.6}

1. Copy and paste the JSON data into your favorite editor.
2. Save the file in any convenient location for loading into your Vertica database.

Create a Flex Table and Load Data
1. Create a flex table called mountains:
=> CREATE flex table mountains();

2. Load the JSON file you saved, using the flex table parser fjsonparser:
=> COPY mountains from '/home/dbadmin/data/flex/mountains.json'
parser fjsonparser();
Rows Loaded
------------5
(1 row)

Vertica Analytic Database (9.3.x)

Page 1790 of 6246


3. Query values from the sample file:

```sql
=> SELECT name, type, height FROM mountains;
name    | type    | height  
--------|---------|--------
Everest  | mountain| 29029  
Mt St Helens | volcano | 29029
Denali  | mountain| 17000  
Kilimanjaro | mountain| 14000  
Mt Washington | mountain| 
(5 rows)
```

You have now created a flex table and loaded data. Next, learn more about using flex table data in your database.

## Query More of Your Flex Table

1. Query your flex table to see the data you loaded as it is stored in the _raw_ column. The example illustrates the table contents, with Return characters added for illustration:

```sql
=> \x
Expanded display is on.
=> SELECT * FROM mountains;
[ RECORD 1 ]+-----------------------------------------------+
| __identity__ | 1
| __raw__ |
| \081\000\000\000,\000\000\000\004\000\000\000\024\000\000\000\031\000\000\000\
035\000\000\000\000\0002902934.1Everestmountain\004\000\000\000\024\000\000\000\032\0
00\
000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000
| __identity__ | 2
| __raw__ |
| \081\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000
| __identity__ | 3
| __raw__ |
| \081\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000
| __identity__ | 4
| __raw__ |
| \001\000\000\000
```

Vertica Analytic Database (9.3.x)
2. Use the mapToString() function (with the __raw__ column of mountains) to inspect its contents in readable JSON text format:

```sql
=> SELECT maptoString(__raw__) from mountains;

MAPTOSTRING

<p>|</p>
<table>
<thead>
<tr>
<th>field_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>{</td>
</tr>
<tr>
<td>&quot;height&quot;: &quot;29029&quot; ,</td>
</tr>
<tr>
<td>&quot;hike_safety&quot;: &quot;34.1&quot; ,</td>
</tr>
<tr>
<td>&quot;name&quot;: &quot;Everest&quot; ,</td>
</tr>
<tr>
<td>&quot;type&quot;: &quot;mountain&quot; }</td>
</tr>
<tr>
<td>{</td>
</tr>
<tr>
<td>&quot;height&quot;: &quot;29029&quot; ,</td>
</tr>
<tr>
<td>&quot;hike_safety&quot;: &quot;15.4&quot; ,</td>
</tr>
<tr>
<td>&quot;name&quot;: &quot;Mt St Helens&quot; ,</td>
</tr>
<tr>
<td>&quot;type&quot;: &quot;volcano&quot; }</td>
</tr>
<tr>
<td>{</td>
</tr>
<tr>
<td>&quot;height&quot;: &quot;17000&quot; ,</td>
</tr>
<tr>
<td>&quot;hike_safety&quot;: &quot;12.2&quot; ,</td>
</tr>
<tr>
<td>&quot;name&quot;: &quot;Denali&quot; ,</td>
</tr>
<tr>
<td>&quot;type&quot;: &quot;mountain&quot; }</td>
</tr>
<tr>
<td>{</td>
</tr>
<tr>
<td>&quot;height&quot;: &quot;14000&quot; ,</td>
</tr>
<tr>
<td>&quot;name&quot;: &quot;Kilimanjaro&quot; ,</td>
</tr>
<tr>
<td>&quot;type&quot;: &quot;mountain&quot; }</td>
</tr>
<tr>
<td>{</td>
</tr>
<tr>
<td>&quot;hike_safety&quot;: &quot;50.6&quot; ,</td>
</tr>
<tr>
<td>&quot;name&quot;: &quot;Mt Washington&quot;,</td>
</tr>
<tr>
<td>&quot;type&quot;: &quot;mountain&quot; }</td>
</tr>
</tbody>
</table>
```

3. Now, use the compute_flextable_keys() function to populate the mountain_keys table. Vertica generates this table automatically when you create your flex table.
4. Query the keys table (mountains_keys), and examine the results:

```sql
=> SELECT * from public.mountains_keys;
key_name     | frequency | data_type_guess
-------------|-----------|------------------
hike_safety  | 4         | varchar(20)
name         | 5         | varchar(26)
height       | 4         | varchar(20)
type         | 5         | varchar(20)
(4 rows)
```

#### Build a Flex Table View

1. Use the build_flextable_view() function to populate a view generated from the mountains_keys table.

```sql
=> SELECT build_flextable_view('mountains');
build_flextable_view
-------------------------------------------
The view public.mountains_view is ready for querying
(1 row)
```

2. Query the view mountains_view:

```sql
=> SELECT * from public.mountains_view;
hike_safety  | name       | type  | height
--------------|------------|-------|-------
50.6          | Mt Washington | mountain | 17000
34.1          | Everest    | mountain | 29029
22.8          | Kilimanjaro | mountain | 14000
15.4          | Mt St Helens | volcano | 29029
12.2          | Denali     | mountain | 17000
(5 rows)
```

3. Use the view_columns system table to query the column_name and data_type columns for mountains_view:

```sql
=> SELECT column_name, data_type from view_columns where table_name = 'mountains_view';
column_name | data_type
-------------|-----------
```
4. Review the query results:

- Notice the data_type column, its values and sizes. These are calculated when you compute keys for your flex table with compute_flextable_keys().
- Did you also notice the data_type_guess column when you queried the mountains_keys table after invoking that function?

5. With the data_type information from mountains_view, override the data_type_guess for hike_safety. Then, COMMIT the change, and rebuild the view with build_flextable_view():

   ```sql
   => UPDATE mountains_keys SET data_type_guess = 'float' where key_name = 'hike_safety';
   OUTPUT
   -------
   1
   (1 row)
   => commit;
   => SELECT build_flextable_view('mountains');
   build_flextable_view
   ------------------------------------------
   The view public.mountains_view is ready for querying
   (1 row)
   ```

6. Next, use the view_columns system table. Notice that hike_safety is now a float data type:

   ```sql
   => SELECT column_name, data_type from view_columns where table_name = 'mountains_view';
   column_name | data_type
   -------------------
   hike_safety | float
   name        | varchar(26)
   type        | varchar(20)
   height      | varchar(20)
   (4 rows)
   ```

### Create a Hybrid Flex Table

If you already know that some of the data you load and query regularly needs full Vertica performance and support, you can create a hybrid flex table. A hybrid flex table has one or more real columns that you define, and a __raw__ column to store any unstructured data.
you load. Querying real columns is faster than querying flexible data in the __raw__ column. You can define default values for the columns.

1. Create a hybrid flex table, and load the same sample JSON file:

```sql
=> CREATE flex table mountains_hybrid(name varchar(41) default name::varchar(41), hike_safety float default hike_safety::float);
=> COPY mountains_hybrid from '/home/dbadmin/Downloads/mountains.json' parser fjsonparser ();
Rows Loaded
----------
5
(1 row)
```

2. Use the `compute_flextable_keys_and_build_view()` function to populate the keys table and build the view for `mountains_hybrid`:

```sql
=> SELECT compute_flextable_keys_and_build_view('mountains_hybrid');
compute_flextable_keys_and_build_view

Please see public.mountains_hybrid_keys for updated keys
The view public.mountains_hybrid_view is ready for querying
(1 row)
```

3. Query the `mountains_hybrid_keys` table. Review the `data_type_guesses` column values again. The types list the column definitions you declared when you created the hybrid table:

```sql
=> SELECT * from mountains_hybrid_keys;
key_name | frequency | data_type_guess
----------+-----------+---------------------
height   | 4         | varchar(20)
name     | 5         | varchar(41)
type     | 5         | varchar(20)
hike_safety | 4        | float
(4 rows)
```

If you create a basic flex table, and later find you want to promote one or more virtual columns to real columns, see Materializing Flex Tables to add columns.
Materialize Virtual Columns in a Hybrid Flex Table

After you explore your flex table data, you can promote one ore more virtual columns in your flex table to real columns. You do not need to create a separate columnar table.

1. Invoke the `materialize_flexibletable_columns()` function on the hybrid table, specifying the number of virtual columns to materialize:

```sql
=> SELECT materialize_flexibletable_columns('mountains_hybrid', 3);
  materialize_flexibletable_columns

----------------------------------------------------------
```

The following columns were added to the table public.mountains_hybrid:

<table>
<thead>
<tr>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT * FROM v_catalog.materialize_flexibletable_columns_results WHERE table_schema = 'public' and table_name = 'mountains_hybrid';</td>
</tr>
</tbody>
</table>

(1 row)

2. You specified three (3) columns to materialize, but the table was created with two real columns (name and hike_safety). To fulfill your three-column specification, the function promotes only one other column, type. The next example has expanded display to list the columns vertically. Notice the ADDED status for the column that was just materialized, rather than EXISTS for the two columns you defined when creating the table:

```sql
=> \x
Expanded display is on.
=> SELECT * FROM materialize_flexibletable_columns_results where table_name = 'mountains_hybrid';
-[
  RECORD 1 ]-+---------------------------------------------------------------
| table_id | 45035996273766044 |
| table_schema | public |
| table_name | mountains_hybrid |
| creation_time | 2013-11-30 20:09:37.765257-05 |
| key_name | type |
| status | ADDED |
| message | Added successfully |
-[
  RECORD 2 ]-+---------------------------------------------------------------
| table_id | 45035996273766044 |
| table_schema | public |
| table_name | mountains_hybrid |
| creation_time | 2013-11-30 20:09:37.765284-05 |
```
3. Now, display the hybrid table definition, listing the __raw__ column and the three materialized columns. Flex table data types are derived from the associated keys tables, so you can update them as necessary. Notice that the __raw__ column has a default NOT NULL constraint:

```sql
=> \d mountains_hybrid
List of Fields by Tables
-[
  RECORD 1 ]----------------------------------------------------------
| Schema | public |
| Table   | mountains_hybrid |
| Column  | __raw__ |
| Type    | long_varbinary(130000) |
| Size    | 130000 |
| Default | t |
| Not Null| f |
| Primary Key| f |
| Foreign Key| |
-[
  RECORD 2 ]----------------------------------------------------------
| Schema | public |
| Table   | mountains_hybrid |
| Column  | name |
| Type    | varchar(41) |
| Size    | 41 |
| Default | (MapLookup(mountains_hybrid.__raw__, 'name'))::varchar(41) |
| Not Null| f |
| Primary Key| f |
| Foreign Key| |
-[
  RECORD 3 ]----------------------------------------------------------
| Schema | public |
| Table   | mountains_hybrid |
| Column  | hike_safety |
| Type    | float |
| Size    | 8 |
| Default | (MapLookup(mountains_hybrid.__raw__, 'hike_safety'))::float |
| Not Null| f |
| Primary Key| f |
| Foreign Key| |
-[
  RECORD 4 ]----------------------------------------------------------
| Schema | public |
| Table   | mountains_hybrid |
| Column  | type |
| Type    | varchar(20) |
| Size    | 20 |
| Default | (MapLookup(mountains_hybrid.__raw__, 'type'))::varchar(20) |
```
You have now completed getting started with flex table basics, hybrid flex tables, and using flex functions.

**Understanding Flex Tables**

You can create flex tables and then manage them with their associated helper, data, and map functions. Flex tables:

- Do not require schema definitions
- Do not need column definitions
- Have full Unicode support
- Support SQL queries

You can use flex tables to promote data directly from exploration to analytic operations.

Flex table features include:

- Ability to load different formats into one flex table, which lets you handle changing structure over time
- Full support of delimited and JSON data
- Extensive SQL queries and built-in analytics for the data you load
- Usability functions, which let you explore your unstructured data and then use built-in functions to materialize the data

**Exploration to Promotion**

After you create a flex table, you can quickly load data, including social media content in JSON, log files, delimited files, and other information. Previously, working with such data required significant schema design and preparation. Now, you can load and query flex tables in a few steps.

Creating flex tables is similar to creating other tables, except column definitions are optional. When you create flex tables, with or without column definitions, Vertica implicitly adds a real column to your table, called `__raw__`. This column stores loaded data. The `__raw__` column is a LONG VARBINARY column with a NOT NULL constraint. It contains the documented limits for its data type (see Long Data Types in the SQL Reference Manual. The `__raw__` column's default maximum width is 130,000 bytes (with an absolute maximum of
32,000,000 bytes). You can change the default width with the FlexTablesRawSize configuration parameter.

If you create a flex table without other column definitions, the table includes a second default column, __identity__, declared as an auto-incrementing IDENTITY (1,1) column. When no other columns are defined, flex tables use the __identity__ column for segmentation and sort order.

Loading data into a flex table encodes the record into a VMap type and populates the __raw__ column. The VMap is a standard dictionary type, pairing keys with string values as virtual columns.

### Flex Table Terms

This guide uses the following terms when describing how you work with flex tables to explore and analyze flexible data:

- **VMap**: An internal map data format.
- **Virtual Columns**: Key-value pairs contained in a flex table __raw__ column.
- **Real Columns**: Fully featured columns in flex or columnar tables.
- **Promoted Columns**: Virtual columns that have been materialized to real columns.
- **Map Keys**: Map keys are the virtual column names within VMap data.

### Is There Structure in a Flex Table?

The term *unstructured data* (sometimes called *semi-structured* or *Dark Data*) does not indicate that the data you load into flex tables is entirely without structure. However, you may not know the data’s composition or the inconsistencies of its design. In some cases, the data may not be relational.

Your data may have some structure (like JSON and delimited data). Data may be semi-structured or stringently structured, but in ways that you either do not know about or do not expect. In this guide, the term *flexible data* encompasses these and other kinds of data. You can load your flexible data directly into a flex table, and query its contents with your favorite SQL SELECT or other statements.

To summarize, you can load data first, without knowing its structure, and then query its content after a few simple transformations. In some cases, you already know the data.
structure, such as some tweet map keys, like user.lang, user.screen_name, and user.url. If so, you can query these values explicitly as soon as you load the data.

Storing Flex Table Data

While you can store unstructured data in a flex table __raw__ column, that column is implemented as a real column.

Vertica compresses __raw__ column data by about one half (1/2). While this factor is less than the compression rate for real columns, the reduction is significant for large amounts (more than 1TB) of unstructured data. After compression is complete, Vertica writes the data to disk (ROS). This approach maintains K-safety in your cluster and supports standard recovery processes should node failures occur. Flex tables are included in full backups (or, if you choose, in object-level backups).

What Happens When You Create Flex Tables?

Whenever you execute a CREATE FLEX TABLE statement, Vertica creates three objects, as follows:

- The flexible table (flex_table)
- An associated keys table (flex_table_keys)
- A default view for the main table (flex_table_view)

The _keys and _view objects are dependents of the parent, flex_table. Dropping the flex table also removes its dependents, although you can drop the _keys or _view objects independently.

You can create a flex table without specifying any column definitions (such as darkdata, in the next example). When you do so, Vertica automatically creates two tables, the named flex table (such as darkdata) and its associated keys table, darkdata_keys:

```sql
=> CREATE flex table darkdata();
CREATE TABLE => \dt dark*

<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Kind</th>
<th>Owner</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>darkdata</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata_keys</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
</tbody>
</table>
(2 rows)
```
Each flex table has two default columns, __raw__ and __identity__. The __raw__ column exists in every flex table to hold the data you load. The __identity__ column is auto-incrementing. Vertica uses the __identity__ column for segmentation and sort order when no other column definitions exist. The flex keys table (darkdata_keys) has three columns, as shown:

```sql
=> SELECT * FROM darkdata;
  __identity__ | __raw__
  --------------
  (0 rows)

=> SELECT * FROM darkdata_keys;
  key_name | frequency | data_type_guess
  --------
  (0 rows)
```

Creating a flex table with column definitions (such as darkdata1, in the next example) automatically generates a table with the __raw__ column. However, the table has no __identity__ column because columns are specified for segmentation and sort order. Two tables are created automatically, as shown in the following example:

```sql
=> CREATE FLEX TABLE darkdata1 (name VARCHAR);
CREATE TABLE

=> SELECT * FROM darkdata1;
  __raw__ | name
  --------
  (0 rows)

=> \d darkdata1*
```

Creating a flex table with at least one column definition (darkdata1 in the next example) also generates a table with the __raw__ column, but not an __identity__ column. Instead, the specified columns are used for segmentation and sort order. Two tables are also created automatically, as shown in the following example:
=> CREATE FLEX TABLE darkdata1 (name VARCHAR);
CREATE TABLE
=> \d darkdata1 *

<table>
<thead>
<tr>
<th>Schema</th>
<th>Table</th>
<th>Column</th>
<th>Type</th>
<th>Size</th>
<th>Default</th>
<th>Not Null</th>
<th>Primary Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>darkdata1</td>
<td><strong>raw</strong></td>
<td>long varbinary(130000)</td>
<td>130000</td>
<td>t</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata1</td>
<td>name</td>
<td>varchar(80)</td>
<td>80</td>
<td>f</td>
<td>f</td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)

=> \dt darkdata1 *

<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Kind</th>
<th>Owner</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>darkdata1</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata1_keys</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)

For more examples, see Creating Flex Tables.

Creating Superprojections Automatically

In addition to creating two tables for each flex table, Vertica creates superprojections for both the main flex table and its associated keys table. Using the \dj command, you can display the projections created automatically for the darkdata and darkdata1 tables in this set of examples:

=> \dj darkdata *

<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Owner</th>
<th>Node</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>darkdata1_b0</td>
<td>dbadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata1_b1</td>
<td>dbadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata1_keys_super</td>
<td>dbadmin</td>
<td>v_vmart_node0001</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata1_keys_super</td>
<td>dbadmin</td>
<td>v_vmart_node0003</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata1_keys_super</td>
<td>dbadmin</td>
<td>v_vmart_node0004</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata_b0</td>
<td>dbadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata_b1</td>
<td>dbadmin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata_keys_super</td>
<td>dbadmin</td>
<td>v_vmart_node0001</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata_keys_super</td>
<td>dbadmin</td>
<td>v_vmart_node0003</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>darkdata_keys_super</td>
<td>dbadmin</td>
<td>v_vmart_node0004</td>
<td></td>
</tr>
</tbody>
</table>

(10 rows)
Default Flex Table View

When you create a flex table, you also create a default view. This default view uses the table name with a _view suffix, as listed in the next example, which shows the list of views for darkdata and darkdata1. If you query the default view, you are prompted to use the COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW function. This view enables you to update the view after you load data so that it includes all keys and values.

```sql
=> \dv darkdata*
```

<table>
<thead>
<tr>
<th>List of View Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema</td>
</tr>
<tr>
<td>--------</td>
</tr>
<tr>
<td>public</td>
</tr>
<tr>
<td>public</td>
</tr>
</tbody>
</table>

(2 rows)

For more information, see Updating Flex Table Views.

Flex Functions

There are three sets of functions to support flex tables and extracting data into VMaps. See the following sections for more information:

- Data (helper) functions (Flex Data Functions Reference)
- Extractor functions (Flex Extractor Functions Reference)
- Map functions (Flex Map Functions Reference)

Using Clients with Flex Tables

You can use the Vertica supported client drivers with flex tables as follows:

- To load data into a flex table, you can use the INSERT statement or COPY LOCAL with the appropriate flex table parser.
- The driver metadata APIs return only real columns. For example, using a SELECT * FROM myflex; statement, when myflex has a single materialized column (name), returns the __raw__ and name columns. However, it does not return virtual columns
from within __raw__. To access virtual columns and their values, query the associated flextable_keys table, just as you would in vsql.

Creating Flex Tables

You can create a flex table or an external flex table without column definitions or other parameters. You can use any CREATE TABLE statement parameters you prefer, as usual.

Creating Basic Flex Tables

Here's how to create the table:

```sql
=> CREATE FLEX TABLE darkdata();
CREATE TABLE
```

Selecting from the table before loading any data into it reveals its two real columns, __identity__ and __raw__:

```sql
=> SELECT * FROM darkdata;
__identity__ | __raw__
-------------------+-------
(0 rows)
```

Below is an example of creating a flex table with a column definition:

```sql
=> CREATE FLEX TABLE darkdata1(name VARCHAR);
CREATE TABLE
```

When flex tables exist, you can add new columns (including those with default derived expressions), as described in Materializing Flex Tables.

Materializing Flex Table Virtual Columns

After you create your flex table and load data, you compute keys from virtual columns. After completing those tasks, you can materialize some keys by promoting virtual columns to real table columns. By promoting virtual columns, you query real columns rather than the raw data.
You can promote one or more virtual columns — materializing those keys from within the _raw data to real columns. Vertica recommends this approach to get the best query performance for all important keys. You don't need to create new columnar tables from your flex table.

Materializing flex table columns results in a hybrid table. Hybrid tables:

- Maintain the convenience of a flex table for loading unstructured data
- Improve query performance for any real columns

If you have only a few columns to materialize, try altering your flex table progressively, adding columns whenever necessary. You can use the ALTER TABLE...ADD COLUMN statement to do so, just as you would with a columnar table. See Materializing Flex Tables for ideas about adding columns.

If you want to materialize columns automatically, use the helper function MATERIALIZE_FLEXTABLE_COLUMNS

## Creating Columnar Tables from Flex Tables

You can create a regular Vertica table from a flex table, but you cannot use one flex table to create another.

Typically, you create a columnar table from a flex table after loading data. Then, you specify the virtual column data you want in a regular table, casting virtual columns to regular data types.

To create a columnar table from a flex table, darkdata, select two virtual columns, (user.lang and user.name), for the new table. Use a command such as the following, which casts both columns to varchars for the new table:

```sql
=> CREATE TABLE darkdata_full AS SELECT "user.lang"::VARCHAR, "user.name"::VARCHAR FROM darkdata;
CREATE TABLE
=> SELECT * FROM darkdata_full;
user.lang | user.name
---------- | ------------
en        | Frederick Danjou
en        | The End
en        | Uptown gentleman.
en        | ~G A B R I E L A â€
es        | Flu Beach
es        | I'm Toasterà¥
it        | laughing at clouds.
tr        | seydo shi
```
Creating Temporary Flex Tables

Before you create temporary global and local flex tables, be aware of the following considerations:

- **GLOBAL TEMP** flex tables are supported. Creating a temporary global flex table results in the `flextable_keys` table and the `flextable_view` having temporary table restrictions for their content.
- **LOCAL TEMP** flex tables must include at least one column definition. The reason for this requirement is that local temp tables do not support automatically-incrementing data (such as the flex table default `__identity__` column). Creating a temporary local flex table results in the `flextable_keys` table and the `flextable_view` existing in the local temporary object scope.
- **LOCAL TEMP** views are supported for flex and columnar temporary tables.

For global or local temp flex tables to function correctly, you must also specify the **ON COMMIT PRESERVE ROWS** clause. You must use the **ON COMMIT** clause for the flex table helper functions, which rely on commits. Create a local temp table as follows:

```
=> CREATE FLEX LOCAL TEMP TABLE good(x int) ON COMMIT PRESERVE ROWS;
CREATE TABLE
```

After creating a local temporary flex table using this approach, you can then load data into the table, create table keys, and a flex table view:

```
=> COPY good FROM '/home/release/KData/bake.json' PARSER fjsonparser();
Rows Loaded
----------
1
(1 row)
```

```
=> select compute_flextable_keys_and_build_view('good');
compute_flextable_keys_and_build_view

```

Please see `v_temp_schema.good_keys` for updated keys
The view `good_view` is ready for querying
(1 row)

Similarly, you can create global temp tables as follows:

```
=> CREATE FLEX GLOBAL TEMP TABLE good_global(x int) ON COMMIT PRESERVE ROWS;
```
After creating a global temporary flex table using this approach, you can then load data into the table, create table keys, and a flex table view:

```sql
=> COPY good_global FROM '/home/dbadmin/data/flex/bake_single.json' PARSER fjsonparser;
Rows Loaded
5
(1 row)
```

```sql
=> SELECT compute_flextable_keys_and_build_view('good_global');
compute_flextable_keys_and_build_view

Please see v_temp_schema.good_keys for updated keys
The view good_view is ready for querying
(1 row)
```

## Creating External Flex Tables

To create an external flex table:

```sql
=> CREATE flex external table mountains() AS COPY FROM 'home/release/KData/kmm_ontains.json' PARSER fjsonparser;
CREATE TABLE
```

As with other flex tables, creating an external flex table produces two regular tables: the named table and its associated _keys table. The keys table is not an external table:

```sql
=> \dt mountains
List of tables
<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Kind</th>
<th>Owner</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>mountains</td>
<td>table</td>
<td>release</td>
<td></td>
</tr>
</tbody>
</table>
(1 row)
```

You can use the helper function, `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`, to compute keys and create a view for the external table:

```sql
=> SELECT compute_flextable_keys_and_build_view ('appLog');
compute_flextable_keys_and_build_view

Please see public.appLog_keys for updated keys
The view public.appLog_view is ready for querying
(1 row)
```
1. Check the keys from the `_keys` table for the results of running the helper application:

```sql
=> SELECT * FROM appLog_keys;
---+-------------+-------------------+
key_name | frequency | data_type_guess
-----------+----------+------------------
contributors | 8 | varchar(20)
coordinates | 8 | varchar(20)
created_at | 8 | varchar(60)
entities.hashtags | 8 | long varbinary(186)
retweeted_status.user.time_zone | 1 | varchar(20)
retweeted_status.user.url | 1 | varchar(68)
retweeted_status.user.utc_offset | 1 | varchar(20)
retweeted_status.user.verified | 1 | varchar(20)
(125 rows)
```

2. Query from the external flex table view:

```sql
=> SELECT "user.lang" FROM appLog_view;

<table>
<thead>
<tr>
<th>user.lang</th>
</tr>
</thead>
<tbody>
<tr>
<td>it</td>
</tr>
<tr>
<td>en</td>
</tr>
<tr>
<td>es</td>
</tr>
<tr>
<td>en</td>
</tr>
<tr>
<td>es</td>
</tr>
<tr>
<td>tr</td>
</tr>
<tr>
<td>en</td>
</tr>
</tbody>
</table>
(12 rows)
```

**Note:**
External tables are fully supported for both flex and columnar tables. However, using external flex (or columnar) tables is less efficient than using flex tables whose data is stored in the Vertica database. Data that is maintained externally requires reloading each time you query.

## Creating a Flex Table from Query Results

You can use the CREATE FLEX TABLE AS statement to create a flex table from the results of a query.

You can use this statement to create three types of flex tables:

- Flex table with no materialized columns
- Flex table with some materialized columns
• Flex table with all materialized columns

When a flex __raw__ column is present in the CTAS query, the entire source VMap is carried to the flex table. If the query has matching column names, the key values are overridden.

**Note:**
ORDER BY and segmentation clauses are only passed to the new flex table if the relevant columns are materialized.

**Examples**

Creating a flex table with no materialized columns from a regular table causes the results of the query to be stored in the __raw__ column as a VMap.

1. Create a regular table named pets with two columns:

```sql
=> CREATE TABLE pets(age INT, name VARCHAR);
```

2. Create a flex table named family_pets by using the CTAS statement to copy the columns age and name from the pets:

```sql
=> CREATE FLEX TABLE family_pets() AS SELECT age, name FROM pets;
```

3. View the new flex table to confirm the operation has been successful and that the columns age and name have not been materialized.

```sql
=> \\
<table>
<thead>
<tr>
<th>d family_pets;</th>
</tr>
</thead>
<tbody>
<tr>
<td>List of Fields by Tables</td>
</tr>
<tr>
<td>-------------------------</td>
</tr>
<tr>
<td>Schema</td>
</tr>
<tr>
<td>---------</td>
</tr>
<tr>
<td>public</td>
</tr>
<tr>
<td>f</td>
</tr>
<tr>
<td>public</td>
</tr>
<tr>
<td>f</td>
</tr>
<tr>
<td>(2 rows)</td>
</tr>
</tbody>
</table>
```

You can create a flex table with no materialized columns from the results of a query of another flex table. This inserts all the VMaps from the source flex table into the target. This creates a flex table segmented and ordered by the ___identity__ column.
4. Create a flex table named `city_pets` by using the CTAS statement to copy the age and `__raw__` columns from `family_pets`:

```sql
=> CREATE FLEX TABLE city_pets() AS SELECT age, __raw__ FROM family_pets;
```

5. View the new flex table to confirm that the operation has been successful and the columns `age` and `__raw__` have not been materialized.

```sql
=> SELECT * FROM city_pets;
```

<table>
<thead>
<tr>
<th>Schema</th>
<th>Table</th>
<th>Column</th>
<th>Type</th>
<th>Size</th>
<th>Default</th>
<th>Not Null</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>city_pets</td>
<td><strong>identity</strong></td>
<td>int</td>
<td>8</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td></td>
<td>f</td>
<td><strong>raw</strong></td>
<td>long varbinary(130000)</td>
<td>130000</td>
<td>t</td>
<td></td>
</tr>
</tbody>
</table>

You can create a flex table with some materialized columns. This uses a syntax similar to the syntax for creating columnar tables with some materialized columns. Unlike columnar tables, however, you need to match the number of columns with the columns that are returned by the query. In the following example, our query returns three columns (amount, type, and available), but Vertica only materializes the first two.

6. Create a table named `animals` with three columns, amount, type, and available:

```sql
=> CREATE TABLE animals(amount INT, type VARCHAR, available DATE);
```

7. Create a flex table named `inventory` with columns `animal_amount` and `animal_type` using the CTAS statement to copy columns `amount, type, and available` from `animals`.

```sql
=> CREATE FLEX TABLE inventory(animal_amount, animal_type) AS SELECT amount, type, available FROM animals;
```

8. View the table data to confirm that columns `amount` and `type` have been materialized under the column names `animal_amount` and `animal_type`. Column `available` from `animals` has also been copied over but was not materialized:

```sql
=> \d inventory
```

<table>
<thead>
<tr>
<th>Schema</th>
<th>Table</th>
<th>Column</th>
<th>Type</th>
<th>Size</th>
<th>Default</th>
<th>Not Null</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Notice that including empty parentheses in the statement results in a flex table with no materialized columns:

9. Create a flex table named animals_for_sale using the CTAS statement with empty parentheses to copy columns amount, type, and available from animals into a pure flex table:

```
=> CREATE FLEX TABLE animals__for_sale() AS SELECT amount, type, available FROM animals;
```

10. View the table data to confirm that no columns were materialized:

```
=> \d animals_for_sale;
```

Omitting any parentheses in the statement causes all columns to be materialized:

11. Create a flex table named animals_sold using the CTAS statement without parentheses. This copies columns amount, type, and available from animals and materialize all columns:

```
=> CREATE FLEX TABLE animals_sold AS SELECT amount, type, available FROM animals;
```

12. View the table data to confirm that all columns were materialized:

```
=> \d animals_sold;
```
Bulk Loading Data into Flex Tables

You bulk load data into a flex table with a COPY statement, specifying one of the flex parsers:

- FAVROPARSER
- FCEFPARSER
- FCSVPARSER
- FDELIMITEDPAIRPARSER
- FDELIMITEDPARSER
- FJSONPARSER
- FREGEXPARSER

All flex parsers store the data as a single-value VMap. They reside in the VARBINARY __raw__ column, which is a real column with a NOT NULL constraint. The VMap is encoded into a single binary value for storage in the __raw__ column. The encoding places the value strings in a contiguous block, followed by the key strings. Vertica supports null values within the VMap for keys with NULL-specified columns. The key and value strings represent the virtual columns and their values in your flex table.

If a flex table data row is too large to fit in the VARBINARY __raw__ column, it is rejected. By default, the rejected data and exceptions files are stored in the standard CopyErrorLogs location, a subdirectory of the catalog directory:

```
v_mart_node003_catalog/CopyErrorLogs/trans-STDIN-copy-from-exceptions.1
v_mart_node003_catalog/CopyErrorLogs/trans-STDIN-copy-rejections.1
```

Flex tables do not copy any rejected data, due to disk space considerations. The rejected data file exists, but it contains only a new line character for every rejected record. The corresponding exceptions file lists the reason why each record was rejected.

You can specify a different path and file for the rejected data and exceptions files. To do so, use the COPY parameters REJECTED DATA and EXCEPTIONS, respectively. You can also save load rejections and exceptions in a table. For more information, see Bulk-Loading Data.
Basic Flex Table Load and Query

Loading data into your flex table is similar to loading data into a regular columnar table. The difference is that you must use the parser argument with one of the flex parsers:

```
=> COPY darkdata FROM '/home/dbadmin/data/tweets_12.json' PARSER fjsonparser();
Rows Loaded
----------------
  12
(1 row)
```

Note:
You can use many additional COPY parameters as required but not all are supported.

Loading Data into Flex Table Real Columns

If you create a hybrid flex table with one or more real column definitions, COPY evaluates each virtual column key name during data load. For each real column with a name that is identical to a virtual column key name, COPY does the following:

- Loads the keys and values as part of the VMap data in the __raw__ column
- Automatically populates real columns with the values from their virtual column counterparts

Subsequent data loads continue loading same-name key-value pairs into both the __raw__ column and the real column.

Note:
Over time, storing values in both column types can impact your licensed data limits. For more information about Vertica licenses, see Managing Licenses in the Administrator's Guide.

For example, continuing with the JSON data:

1. Create a flex table, darkdata1, with a column definition of one of the keys in the data you will load:
CREATE FLEX TABLE darkdata1 ("user.lang" VARCHAR);

2. Load data into darkdata1:

COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
----------
12
(1 row)

3. Query the user.lang column of darkdata1. Loading the JSON data file populated the column you defined:

SELECT "user.lang" FROM darkdata1;
user.lang
---------
es
es
tr
it
en
en
en
(12 rows)

Empty column rows indicate NULL values. For more information about how NULLs are handled in flex tables, see NULL Value.

4. You can query for other virtual columns (such as "user.name" in darkdata1), with similar results as for "user.lang":

SELECT "user.name" FROM darkdata1;
user.name
---------------------
I'm Toasterâ¥
Flu Beach
seydo shi
The End
Uptown gentleman.
~G A B R I E L A â¿
Frederick Danjou
laughing at clouds.
(12 rows)

**Note:**
While the results for these two queries are similar, the difference in accessing the keys and their values is significant. Data for "user.lang" has been materialized into a real table column, while "user.name" remains a virtual column. For production-level data
Usage (rather than test data sets), materializing flex table data improves query performance significantly.

Handling Default Values During Loading

You can create your flex table with a real column, named for a virtual column that exists in your incoming data. For example, if the data you load has a `user.lang` virtual column, define the flex table with that column. You can also specify a default column value when creating the flex table with real columns. The next example shows how to define a real column (`user.lang`), which has a default value from a virtual column (`user.name`):

```sql
=> CREATE FLEX TABLE darkdata1 ("user.lang" LONG VARCHAR default "user.name");
```

When you load data into your flex table, COPY uses values from the flex table data, ignoring the default column definition. Loading data into a flex table requires MAPLOOKUP to find keys that match any real column names. A match exists when the incoming data has a virtual column with the same name as a real column. When COPY detects a match, it populates the column with values. COPY returns either a value or NULL for each row, so real columns always have values.

For example, after creating the darkdata1 flex table, described in the previous example, load data with COPY:

```sql
=> COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
----------
  12
(1 row)
```

If you query the darkdata1 table after loading, the data shows that the values for the `user.lang` column were extracted:

- From the data being loaded — values for the `user.lang` virtual column
- With NULL — rows without values

In this case, the table column default value for `user.lang` was ignored:

```sql
=> SELECT "user.lang" FROM darkdata1;
user.lang
---------
it
en
es
```
Using COPY to Specify Default Column Values

You can add an expression to a COPY statement to specify default column values when loading data. For flex tables, specifying any column information requires that you list the __raw__ column explicitly. The following example shows how to use an expression for the default column value. In this case, loading populates the defined user.lang column with data from the input data user.name values:

```
=> COPY darkdata1(__raw__, "user.lang" as "user.name"::VARCHAR)
    FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser;
Rows Loaded
---------------------
   12
(1 row)
=> SELECT "user.lang" FROM darkdata1;
   user.lang
---------------------
 laughing at clouds.
 Avita Desai
 I'm Toasterâ€™
 Uptown gentleman.
 ~G A B R I E L A å¿
 Flu Beach
 seydo shi
 The End
(12 rows)
```

You can specify default values when adding columns, as described in Altering Flex Tables. When you do so, a different behavior results. For more information about using COPY, its expressions and parameters, see Bulk-Loading Data in the Administrator's Guide and COPY in the SQL Reference Manual.

Inserting Data into Flex Tables

You can load data into a Vertica flex table using a standard INSERT statement, specifying data for one or more columns. When you use INSERT, Vertica populates any materialized columns and stores the VMap data in the __raw__ column.

Vertica provides two ways to use INSERT with flex tables:
- INSERT ... VALUES
- INSERT ... SELECT

Inserting Values into Flex Tables

To insert data values into a flex table, use an INSERT ... VALUES statement. If you do not specify any columns in your INSERT ... VALUES statement, Vertica positionally assigns values to the real columns of the flex table.

This example shows two ways to insert values into a simple flex table. For both statements, Vertica assigns the values 1 and 'x' to columns a and b, respectively. This example inserts values into the two real columns defined in the flex table:

```plaintext
=> CREATE FLEX TABLE flex0 (a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO flex0 VALUES (1, 'x');
OUTPUT
--------
    1
(1 row)
```

This example inserts values into a flex table without any real columns:

```plaintext
=> CREATE FLEX TABLE flex1();
CREATE TABLE
=> INSERT INTO flex1(a,b) VALUES (1, 'x');
OUTPUT
--------
    1
(1 row)
```

For the preceding example, the __raw__ column contains the inserted data:

```plaintext
=> SELECT MapToString(__raw__) FROM flex1;
MapToString
------------------------------------------
{  "a" : "1",
   "b" : "x"
}
(1 row)
```
Using INSERT ... SELECT with Flex Tables

Using an INSERT ... SELECT statement with a flex table is similar to using INSERT ... SELECT with a regular table. The SELECT statement returns the data to insert into the target table.

However, Vertica does not require that you balance the number of columns and values. If you do not specify a value for a column, Vertica inserts NULL.

In the next example, Vertica copies the a and b values from the flex1 table, and creates columns c, d, e, and f. Because the statement does not specify a value for f, Vertica assigns it a NULL.

```sql
=> CREATE FLEX TABLE flex2();
CREATE TABLE
=> INSERT INTO flex2(a,b) SELECT a,b, '2016-08-10 11:10' c, 'Hello' d, 3.1415 e, f from flex1;
OUTPUT
--------
 1
(1 row)
=> SELECT MapToString(_raw_) FROM flex2;

MapToString
--------
{
  "a" : "1",
  "b" : "x",
  "c" : "2016-08-10 11:10",
  "d" : "Hello",
  "e" : "3.1415",
  "f" : null
}
(1 row)
```

Inserting __raw__ Columns into a Flex Table

Inserting a __raw__ column into a flex table inserts the entire source VMap into the target table. Vertica does not assign the __raw__ column to any target column. Its position in the SELECT statement does not matter.

The following two INSERT statements are equivalent.
Error Handling

Type coercion errors occur only with real columns. The insert operation fails as follows:

```
=> INSERT INTO flex4(a,b) SELECT a, __raw__, b FROM flex3;
=> INSERT INTO flex4(a,b) SELECT a, b, __raw__ FROM flex3;
```

If you try to insert values into the __raw__ column, the insert fails as follows:

```
=> CREATE FLEX TABLE my_table(a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO my_table(a, b) VALUES ('xyz', '5');
ERROR: Invalid input syntax for integer: "xyz"
```

Using Flex Tables for IDOL Data

You can create flex tables to use with the IDOL Connector Framework Server (CFS) and an ODBC client. The CFS VerticalIndexer module uses the connector to retrieve data. CFS then indexes the data into your Vertica database.

CFS supports many connectors for interfacing to different unstructured file types stored in repositories. Examples of repositories include Microsoft Exchange (email), file systems (including Word documents, images, and videos), Microsoft SharePoint, and Twitter (containing Tweets).

Connectors retrieve and aggregate data from repositories. CFS indexes the data, sending it to IDOL, IDOL OnDemand, or Vertica. The following figure illustrates a basic setup with a repository and a connector.
After you configure CFS and connect it to your Vertica database, the connector monitors the repository for changes and deletions to loaded documents, and for new files not previously added to the server. CFS then updates its server destinations automatically.

To achieve the best query results with ongoing CFS updates and deletes, Vertica recommends using live aggregate projections and top-K projections. For more information about how these projections work, and for examples of using them, see Working with Projections in the Administrator's Guide.

**ODBC Connection String for CFS**

There are several steps to setting up the CFS VerticalIndexer to load IDOL metadata into your database.

One of the first steps is to add information to the CFS configuration file. To do so, add an Indexing section to the configuration file that specifies the ODBC ConnectionString details.

Successfully loading data requires a valid database user with write permissions to the destination table. Two ODBC connection parameters (UID and PWD) specify the Vertica user and password. The following example shows a sample CFS Indexing section. The section includes a ConnectionString with the basic parameters, including a sample user (UID=fjones) and password (PWD=fjones_password):

```
[Indexing]
IndexerSections=vertica
IndexTimeInterval=30

[vertica]
IndexerType = Library
ConnectionString=Driver=Vertica;Server=123.456.478.900;Database=myDB;UID=fjones;PWD=fjones_password
```
TableName = marcomm.myFlexTable
LibraryDirectory = ./shared_library_indexers
LibraryName = verticaIndexer

For more information about ODBC connection parameters, see [ODBC Configuration Parameters](#).

## CFS COPY LOCAL Statement

CFS first indexes and processes metadata from a document repository to add to your database. Then, CFS uses the Indexing information you added to the configuration file to create an ODBC connection. After establishing a connection, CFS generates a standard COPY LOCAL statement, specifying the `fjsonparser`. CFS loads data directly into your pre-existing flex table with a statement such as the following:

```sql
=> COPY myFlexTable FROM LOCAL path_to_compressed_temporary_json_file PARSER fjsonparser();
```

```sql
=> SELECT * FROM myavro;
__identity__ | __raw__
---------------------------
(0 rows)
```

When your IDOL metadata appears in a flex table, you can optionally add new table columns, or materialize other data, as described in [Altering Flex Tables](#).

## Using Flex Table Parsers

You can load flex tables with one of several parsers, using the options that these parsers support.

## Loading Columnar Tables with Flex Parsers

You can use any of the flex parsers to load data into columnar tables. Using the flex table parsers to load columnar tables gives you the capability to mix data loads in one table. For example, you can load JSON data in one session and delimited data in another.
**Note:**
For Avro data, you can load only data into a columnar table, not the schema. For flex tables, Avro schema information is required to be embedded in the data.

The following basic examples illustrate how you can use flex parsers with columnar tables.

1. Create a columnar table, super, with two columns, age and name:

   ```sql
   CREATE TABLE super(age INT, name VARCHAR);
   CREATE TABLE
   ```

2. Enter JSON values from STDIN, using the fjsonparser():

   ```sql
   COPY super FROM stdin PARSER fjsonparser();
   Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
   >> {"age": 5, "name": "Tim"}
   >> {"age": 3}
   >> {"name": "Fred"}
   >> {"name": "Bob", "age": 10}
   >> \.
   ```

3. Query the table to see the values you entered:

   ```sql
   SELECT * FROM super;
   age | name
   ------|-------
   | Fred
   10 | Bob
   5 | Tim
   3 |
   (4 rows)
   ```

4. Enter some delimited values from STDIN, using the fdelimitedparser():

   ```sql
   COPY super FROM stdin PARSER fdelimitedparser();
   Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
   >> name | age
   >> Tim | 50
   >> 30
   >> Fred
   >> Bob | 100
   >> \.
   ```

5. Query the flex table. Both JSON and delimited data are saved in the same columnar table, super.

   ```sql
   SELECT * FROM super;
   age | name
   ------|-------
   50 | Tim
   ```
Use the `reject_on_materialized_type_error` parameter to avoid loading data with type mismatch. If `reject_on_materialized_type_error` is set to false, the flex parser will accept the data with type mismatch. Consider the following example:

Assume that the CSV file to be loaded has the following sample contents:

```
$ cat json.dat
{"created_by":"system","site_source":"flipkart_india_kol","updated_by":"system1","invoice_id":"INVDPKOL100","vendor_id":"VEN15731","total_quantity":12,"created_at":"2012-01-09 23:15:52.0"}
{"created_by":"system","site_source":"flipkart_india_kol","updated_by":"system2","invoice_id":"INVDPKOL101","vendor_id":"VEN15732","total_quantity":14,"created_at":"hello"}
```

1. Create a columnar table.

```sql
=> CREATE TABLE hdfs_test (site_source VARCHAR(200),
total_quantity int,
vendor_id varchar(200),
invoice_id varchar(200),
updated_by varchar(200),
created_by varchar(200),
created_at timestamp);
```

2. Load JSON data.

```sql
=>COPY hdfs_test FROM '/home/dbadmin/json.dat' PARSER fjsonparser() ABORT ON ERROR;
Rows Loaded
----------
2
(1 row)
```

3. View the contents.

```sql
=> SELECT * FROM hdfs_test;
site_source | total_quantity | vendor_id | invoice_id | updated_by | created_by | created_at
------------------------------------------------------------------------------------------------------------
flipkart_india_kol | 12 | VEN15731 | INVDPKOL100 | system1 | system | 2012-01-09 23:15:52
flipkart_india_kol | 14 | VEN15732 | INVDPKOL101 | system2 | system | (2 rows)
```
4. If `reject_on_materialized_type_error` parameter is set to true, you will receive errors when loading the sample JSON data.

```sql
=> COPY hdfs_test FROM '/home/dbadmin/data/flex/json.dat' PARSER fjsonparser(reject_on_materialized_type_error=true) ABORT ON ERROR;
ERROR 2035: COPY: Input record 2 has been rejected (Rejected by user-defined parser)
```

## Loading Avro Data

You can load Avro data files into flex tables and columnar tables using the parser, `favroparser`. Before loading, verify that Avro files are encoded in the Avro binary serialization encoding format, described in the [Apache Avro standard](https://avro.apache.org/). The parser also supports Snappy and deflate compression. You cannot load Avro data directly from STDIN.

### Note:

The parser `favroparser` does not support Avro files with separate schema files. The Avro file must have its related schema in the file you are loading.

You can use the following data types and optional parameters for `favroparser`.

The `favroparser` supports two data types:

- **Primitive Data Types for favroparser**
- **Complex Data Types for favroparser**

## Rejecting Data on Materialized Column Type Errors

The `favroparser` has a Boolean parameter, `reject_on_materialized_type_error`. If you set this parameter to true, Vertica rejects rows when the input data presents both of the following conditions:

- Includes keys matching an existing materialized column
- Has a value that cannot be coerced into the materialized column's data type

Suppose the flex table has a materialized column, `Temperature`, declared as a FLOAT. If you try to load a row with a `Temperature` key that has a `VARCHAR` value, `favroparser` rejects the data row.
See Also

- Manually Copying Data From Kafka

Primitive Data Types for favroparser

The `favroparser` supports the following primitive data types:

<table>
<thead>
<tr>
<th>AVRO Data Type</th>
<th>Vertica Data Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>NULL Value</td>
<td>No value</td>
</tr>
<tr>
<td>boolean</td>
<td>Boolean Data Type</td>
<td>A binary value</td>
</tr>
<tr>
<td>int</td>
<td>INTEGER</td>
<td>32-bit signed integer</td>
</tr>
<tr>
<td>long</td>
<td>INTEGER</td>
<td>64-bit signed integer</td>
</tr>
<tr>
<td>float</td>
<td>DOUBLE PRECISION (FLOAT) &lt;br&gt;Synonymous with 64-bit IEEE FLOAT</td>
<td>Single precision (32-bit) IEEE 754 floating-point number</td>
</tr>
<tr>
<td>double</td>
<td>DOUBLE PRECISION (FLOAT)</td>
<td>Double precision (64-bit) IEEE 754 floating-point number</td>
</tr>
<tr>
<td>bytes</td>
<td>BYTES</td>
<td>Sequence</td>
</tr>
</tbody>
</table>
Vertica does not have an explicit 4-byte (32-bit integer) or smaller types. Instead, Vertica encoding and compression automatically eliminate the storage overhead of values that require less than 64 bits.

Vertica copies each primitive type into the `__raw__` column of the flex table. In this copy operation, the name of the primitive type becomes a virtual column key with its corresponding value as the value of the virtual column.

If the flex table has materialized columns, `favroparser` loads the primitive data type into the corresponding Vertica type for the column. If the parsing is successful, Vertica copies the data into the materialized column; otherwise, it rejects the row.

### Complex Data Types for `favroparser`

You specify the data type of a record in the Avro file using the `type` parameter for `favroparser`. The `favroparser` supports these complex data types:

- **Records**
- **Enums**
- **Arrays**
- **Maps**
- **Unions**
- **Fixed**

This section describes attributes associated with the complex data types.

#### Records

Records have the following attributes:
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>A JSON string for the name of the record</td>
</tr>
<tr>
<td>fields</td>
<td>A JSON array used to list fields. Each field is a JSON object:</td>
</tr>
<tr>
<td></td>
<td>- name: A JSON string for the name of the field</td>
</tr>
<tr>
<td></td>
<td>- type: A JSON object used to define a schema or a JSON string used for naming a record definition</td>
</tr>
</tbody>
</table>

The name of each field is used as a virtual column name. If `flatten_records = true` and several nesting levels are present, Vertica concatenates the record names to create the key_name, as follows:

```json
{
  "type": "record",
  "name": "Profile",
  "fields": [
    {"name": "UserName", "type": "string"},
    {"name": "Address", "type": "string"}
  ]
}

{
  "type": "record",
  "name": "Profile",
  "fields": [
    {VerticaUser},
    {VerticaUser Address}
  ]
}
```

Vertica creates virtual columns for the records as follows:

<table>
<thead>
<tr>
<th>Names</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserName</td>
<td>VerticaUser</td>
</tr>
<tr>
<td>Address</td>
<td>VerticaUser Address</td>
</tr>
</tbody>
</table>
** Enums **

 Enums (enumerated values) use the type name `enum` and support the following attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>A JSON string for the name of the enum</td>
</tr>
<tr>
<td>symbols</td>
<td>A JSON array used to list symbols as JSON strings. All symbols in an enum must be unique and duplicates are prohibited</td>
</tr>
</tbody>
</table>

Example:

```json
{
    "type": "enum",
    "name": "suit",
    "symbols": ["SPADES", "HEARTS", "DIAMONDS", "CLUBS"]
}
```

Consider the preceding Avro schema with a record that contains a field with the value `HEARTS`. In this case, the key value pair copied into the `__raw__` column has `suit` as the key and `HEARTS` as the value.

** Arrays **

 Arrays use the type name `array` and support one attribute:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>The schema of the array's items</td>
</tr>
</tbody>
</table>

For example, declare an array of strings:

```json
{"type": "array", "items": "string"}
```

Similar to the capabilities for Records, you can nest and flatten Arrays using `flatten_arrays=true`:
Here is the result of flattening the array:

```json
{
    "order_details.0._name_": "OrderDetail",
    "order_details.0.product_detail.0.product_category": "electronics",
    "order_details.0.product_detail.1.product_category": "printers",
    "order_details.0.product_detail.2.product_category": "computers",
    "order_details.0.product_detail._name_": "Product",
    "order_details.0.product_detail.price": "46.21",
    "order_details.0.product_detail.product_name": "mycompany printer 123abc",
    "order_details.0.product_detail.product_status": "ONLY_FEW_LEFT",
    "__name__": "Order",
    "customer_id": "111222",
    "order_id": "2389646",
    "total": "132.43"
}
```

**Maps**

Maps use the type name `map` and support one attribute:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>values</td>
<td>The schema of the map's items</td>
</tr>
</tbody>
</table>

The `favroparser` treats map keys as strings. For example, you can declare the `map` type as a long as follows:
Similar to Records types, Maps can also be nested and flattened using `flatten_maps=true`.

The `favroparser` inserts key-value pairs from the Avro map as key-value pairs in the `__raw__` column. For an Avro record that has KeyX with value 10, and KeyY with value 20, `favroparser` loads the key-value pairs as virtual columns KeyX and KeyY, with values 10 and 20, respectively.

**Unions**

Vertica uses JSON arrays to represent Avro Unions. Consider this example:

```
{ "name":"TransactionID","type": [ "string","null"]}
```

The field `TransactionID` can be a string or null.

**Fixed**

Fixed (fixed) Avro types support two attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>A string for the name of this data type</td>
</tr>
<tr>
<td>size</td>
<td>An integer, specifying the number of bytes per value</td>
</tr>
</tbody>
</table>

For example, you can declare a 16-byte quantity:

```
{"type": "fixed", "size": 16, "name": "md5"}
```

With the preceding declaration is the Avro file schema, consider a record that contains a field with the following byte values for the key md5:

```
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, 1, 2, 3, 4, 5]
```

The `favroparser` loads the key value pair as an md5 key with the preceding byte values.
Loading Common Event Format (CEF) Data

Use the flex parser `fcefparser` to load OpenText ArcSight or other Common Event Format (CEF) log file data into columnar and flexible tables. For more information, see the [ArcSight Common Event Format (CEF) Guide](#).

When you use the parser to load arbitrary CEF-format files, it interprets key names in the data as virtual columns in your flex table. After loading, you can query your CEF data directly, regardless of which set of keys exist in each row. You can also use the associated flex table data and map functions to manage CEF data access.

### Create a Flex Table and Load CEF Data

This section uses a sample set of CEF data. All IP addresses have been purposely changed to be inaccurate, and Return characters added for illustration.

To use this sample data, copy the following text and remove all Return characters. Save the file as `CEF_sample.cef`, which is the name used throughout these examples.

```
CEF:0|ArcSight|ArcSight|6.0.3.6664.0|agent:030|Agent [test] type [testalertng] started|Low|
eventId=1 mrt=1396328230973 categorySignificance=/Normal categoryBehavior=/Execute/Start
categoryDeviceGroup=/Application categoryOutcome=/Success
categoryObject=/Host/Application/Service art=1396328241038 cat=/Agent/Started
deviceSeverity=Warning rt=1396328238937 fileType=Agent
cs2=<Resource ID="/">=Resource
c6a4=fe80:0:0:0:495d:cc3c:db1a:de71
cs2Label=Configuration Resource c6a4Label=Agent IPv6 Address ahost=SKEELES10 agt=888.99.100.1 agentZoneURI=/All Zones/ArcSight System/Private Address Space Zones/RFC1918: 888.99.0.0-888.200.255.255 av=6.0.3.6664.0 atz=Australia/Sydney aid=3DxK1G0UBACAA0cXXAZIWa\</> c6a4=fe80:0:0:0:495d:cc3c:db1a:de71
dtz=Australia/Sydney _cefVer=0.1
```

1. Create a flex table `logs`:

   ```
   => CREATE FLEX TABLE logs();
   CREATE TABLE
   ```

2. Load the sample CEF file, using the flex parser `fcefparser`:

   ```
   => COPY logs FROM '/home/dbadmin/data/CEF_sample.cef' PARSER fcefparser();
   Rows Loaded
   ```
3. Use the maptostring() function to see the contents of the logs flex table:

```sql
=> SELECT maptostring(__raw__) FROM logs;

<table>
<thead>
<tr>
<th>maptostring</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td>{</td>
</tr>
</tbody>
</table>

(1 row)
Create a Columnar Table and Load CEF Data

This example lets you compare the flex table for CEF data with a columnar table. You do so by creating a new table and load the same CEF_sample.cef file used in the preceding flex table example.

1. Create a columnar table, `col_logs`, defining the prefix names that are hard coded in `fcefparser`:

```sql
=> CREATE TABLE col_logs (version INT,
  devicevendor VARCHAR,
  deviceproduct VARCHAR,
  deviceversion VARCHAR,
  signatureid VARCHAR,
  name VARCHAR,
  severity VARCHAR);
CREATE TABLE
```

2. Load the sample file into `col_logs`, as you did for the flex table:

```sql
=> COPY col_logs FROM '/home/dbadmin/data/CEF_sample.cef' PARSER fcefparser();
Rows Loaded
-------------
1
(1 row)
```

3. Query the table. You can find the identical information in the flex table output.

```sql
=> \x
Expanded display is on.
VMart=> SELECT * FROM col_logs;
- [ RECORD 1 ]-+---------------------------------------+
  version | 0
  devicevendor | ArcSight
  deviceproduct | ArcSight
  deviceversion | 6.0.3.6664.0
  signatureid | agent:030
  name | Agent [test] type [testalertng] started
  severity | Low
```

Compute Keys and Build a Flex Table View

In this example, you use a flex helper function to compute keys and build a view for the `logs` flex table.
1. Use the `compute_flextable_keys_and_build_view` function to compute keys and populate a view generated from the logs flex table:

```sql
=> SELECT compute_flextable_keys_and_build_view('logs');
compute_flextable_keys_and_build_view
----------------------------------------------------------------------------------
Please see public.logs_keys for updated keys
The view public.logs_view is ready for querying
(1 row)
```

2. Query the `logs_keys` table to see what the function computed from the sample CEF data:

```sql
=> SELECT * FROM logs_keys;
key_name          | frequency | data_type_guess
------------------|-----------|-------------------
c6a4              | 1         | varchar(60)
c6a4label         | 1         | varchar(36)
categoryobject    | 1         | varchar(50)
categoryoutcome   | 1         | varchar(20)
categorysignificance | 1     | varchar(20)
cs2               | 1         | varchar(84)
cs2label          | 1         | varchar(44)
deviceproduct     | 1         | varchar(20)
deviceversion     | 1         | varchar(24)
devicezoneuri     | 1         | varchar(180)
dvhost             | 1         | varchar(28)
version            | 1         | varchar(20)
ghost              | 1         | varchar(20)
art                | 1         | varchar(26)
at                | 1         | varchar(22)
cat                | 1         | varchar(28)
catdt              | 1         | varchar(36)
devicevendor      | 1         | varchar(20)
dtz                | 1         | varchar(32)
dvc                | 1         | varchar(24)
filetype           | 1         | varchar(20)
mrt                | 1         | varchar(26)
_cefver            | 1         | varchar(20)
agentzoneuri       | 1         | varchar(180)
tag               | 1         | varchar(24)
aid                | 1         | varchar(50)
atz               | 1         | varchar(32)
av                 | 1         | varchar(24)
categorybehavior  | 1         | varchar(28)
categorydevicegroup | 1       | varchar(24)
deviceseverity     | 1         | varchar(28)
eventid           | 1         | varchar(28)
name               | 1         | varchar(78)
rt                 | 1         | varchar(26)
severity           | 1         | varchar(28)
signatureid        | 1         | varchar(20)
```

3. Query several columns from the `logs_view`:
Use the fcefparser Delimiter Parameter

In this example, you use the fcefparser delimiter parameter to query events located in California, New Mexico, and Arizona.

1. Create a new columnar table, CEFData3:

   ```
   => CREATE TABLE CEFData3(eventId INT, location VARCHAR(20));
   CREATE TABLE
   ```

2. Using the delimiter=',' parameter, load some CEF data into the table:

   ```
   => COPY CEFData3 FROM stdin PARSER fcefparser(delimiter=',"');
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   >> eventId=1,location=California
   >> eventId=2,location=NewMexico
   >> eventId=3,location=Arizona
   >> 
   ```

3. Query the table:

   ```
   => SELECT eventId, location FROM CEFData3;
   eventId | location
   1 | California
   2 | New Mexico
   3 | Arizona
   (3 rows)
   ```
Loading CSV Data

Use the `fcsvpars`er to load data in CSV format (comma-separated values). Since no formal CSV standard exists, Vertica supports the RFC 4180 standard as the default behavior for `fcsvpars`er. Other parser parameters simplify various combinations of CSV options into columnar or flex tables. Using `fcsvpars`er parses the following CSV data formats:

- **RFC 4180**: The RFC4180 CSV format parser for Vertica flex tables. The parameters for this format are fixed and cannot be changed.
- **Traditional**: The traditional CSV parser lets you specify the parameter values such as delimiter or record terminator. For a detailed list of parameters, please refer to the `FCSVPARSER` page.

Using Default Parser Settings

These fixed parameter settings apply to the RCF4180 format.

**Note:**
While you can change the default parser parameter values for Traditional format files, each value must be unique. For example, you can specify an ampersand (&) as a delimiter. If you do, you cannot also use an ampersand for the escape or other parameter value.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data Type</th>
<th>Fixed Value (RCF4180)</th>
<th>Default Value (Traditional)</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>CHAR</td>
<td>,</td>
<td>,</td>
</tr>
<tr>
<td>enclosed_by</td>
<td>CHAR</td>
<td>&quot;</td>
<td>&quot;</td>
</tr>
<tr>
<td>escape</td>
<td>CHAR</td>
<td>&quot;</td>
<td>\</td>
</tr>
<tr>
<td>record_terminator</td>
<td>CHAR</td>
<td>\n or \r\n</td>
<td>\n or \r\n</td>
</tr>
</tbody>
</table>

Use the `type` parameter to indicate either an RFC 4180-compliant file or a traditional-compliant file. You can specify `type` as RCF4180. However, you must first verify that the
data is compatible with the preceding fixed values for parameters of the RFC4180 format. The default value of the type parameter is RFC4180.

## Loading CSV Data (RFC4180)

Follow these steps to use `fcsvparserr` to load data in the RFC4180 CSV data format.

To perform this task, assume that the CSV file to be loaded has the following sample contents:

```
$ more /home/dbadmin/flex/flexData1.csv
sno,name,age,gender
1,John,14,male
2,Mary,23,female
3,Mark,35,male
```

1. Create a flex table:

   ```
   => CREATE FLEX TABLE csv_basic();
   CREATE TABLE
   ```

2. Load the data from the CSV file using `fcsvparserr`:

   ```
   => COPY csv_basic FROM '/home/dbadmin/flex/flexData1.csv' PARSER fcsvparserr();
   Rows Loaded
   -----------
   3
   (1 row)
   ```

3. View the data loaded in the flex table:

   ```
   => SELECT maptostring(__raw__) FROM csv_basic;
   maptostring
   -------------------------------
   {
   "age" : "14",
   "gender" : "male",
   "name" : "John",
   "sno" : "1"
   }
   {
   "age" : "23",
   "gender" : "female",
   "name" : "Mary",
   "sno" : "2"
   }
   {
   "age" : "35",
   "gender" : "male",
   "name" : "Mark",
   "sno" : "3"
   }
   (3 rows)
   ```
Loading CSV Data (Traditional)

Follow these steps to use `fcsvparser` to load data in traditional CSV data format using `fcsvparser`.

In this example, the CSV file uses $ as a delimiter and # as a record_terminator. The sample CSV file to load has the following contents:

```
$ more /home/dbadmin/flex/flexData1.csv
sno$gender$age$name#
1$male$14$John#
2$female$23$Mary#
3$male$35$Mark#
```

1. Create a flex table:

```
=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
```

2. Load the data in flex table using `fcsvparser` with parameters `type='traditional', delimiter='$' and record_terminator='#'`:

```
=> COPY csv_basic FROM '/home/dbadmin/flex/flexData2.csv' PARSER fcsvparser
(type='traditional',
delimiter='$', record_terminator='#');
Rows Loaded
----------
3
(1 row)
```

3. View the data loaded in the flex table:

```
=> SELECT maptostring(__raw__) FROM csv_basic;
maptostring
---------------------------------------------------------------
{
  "age": "14",
  "gender": "male",
  "name": "John",
  "sno": "1"
}
{
  "age": "23",
  "gender": "female",
  "name": "Mary",
  "sno": "2"
}
{
  "age": "35",
  "gender": "male",
  "name": "Mark",
  "sno": "3"
```

Rejecting Duplicate Values

You can reject duplicate values using the `reject_on_duplicate=true` option with the `fcsvparser`. The load continues after it rejects a duplicate value. The next example shows how to use this parameter and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```sql
=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_duplicate=true)
exceptions '/home/dbadmin/load_errors/except.out' rejected data '/home/dbadmin/load_errors/reject.out';
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
>> A|A
>> 1|2
>> .
=> \! cat /home/dbadmin/load_errors/reject.out
A|A
=> \! cat /home/dbadmin/load_errors/except.out
COPY: Input record 1 has been rejected (Processed a header row with duplicate keys with reject_on_duplicate specified; rejecting.). Please see /home/dbadmin/load_errors/reject.out, record 1 for the rejected record.
COPY: Loaded 0 rows, rejected 1 rows.
```

Rejecting Data on Materialized Column Type Errors

The `fcsvparser` parser has a Boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if both the following conditions exist in the input data:

- Includes keys matching an existing materialized column
- Has a key value that cannot be coerced into the materialized column's data type

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

   ```sql
   => CREATE FLEX TABLE reject_true_false(one int, two int);
   CREATE TABLE
   ```
2. Load CSV data into the table (from STDIN), using the fcsvparser with reject_on_materialized_type_error=false. While false is the default value, you can specify it explicitly, as shown. Additionally, set the parameter header=true to specify the columns for input values:

```
=> COPY reject_true_false FROM stdin PARSER fcsvparser(reject_on_materialized_type_error=false, header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> one,two
>> 1,2
>> "3","four"
>> "five",6
>> 7,8
>> .
```

3. Invoke maptostring to display the table values after loading data:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
maptostring | one | two
-----------------------------------------------
{ "one" : "1",
  "two" : "2"
} | 1 | 2
{ "one" : "3",
  "two" : "four"
} | 3 |
{ "one" : "five",
  "two" : "6"
} | 6 |
{ "one" : "7",
  "two" : "8"
} | 7 | 8
(4 rows)
```

4. Truncate the table to empty the data stored in the table:

```
=> TRUNCATE TABLE reject_true_false;
TRUNCATE TABLE
```

5. Reload the same data again, but this time, set reject_on_materialized_type_error=true:

```
=> COPY reject_true_false FROM stdin PARSER fcsvparser(reject_on_materialized_type_error=true, header=true);
Enter data to be copied followed by a newline.
```
End with a backslash and a period on a line by itself.

```plaintext
>> one,two
>> 1,2
>> "3","four"
>> "five",6
>> 7,8
>> \
```

6. Call `maptostring` to display the table contents. Only two rows are currently loaded, whereas the previous results had four rows. The rows having input values with incorrect data type have been rejected:

```sql
=> SELECT maptostring__raw__, one, two FROM reject_true_false;
maptostring | one | two
-----------------------------------------+-----+-----
{ "one" : "1",
  "two" : "2"
} | 1 | 2
{ "one" : "7",
  "two" : "8"
} | 7 | 8
(2 rows)
```

**Note:**
The parser `fcsvparser` uses null values if there is a type mismatch and you set the `reject_on_materialized_type_error` parameter to `false`.

---

**Rejecting or Omitting Empty Rows**

Valid CSV files can include empty key and value pairs. Such rows are invalid for SQL. You can control the behavior for empty rows by either rejecting or omitting them, using two boolean `FCSVPARSER` parameters:

- `reject_on_empty_key`
- `omit_empty_keys`

The following example illustrates how to set these parameters:
1. Create a flex table:

```sql
=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
```

2. Load CSV data into the table (from STDIN), using the `fcsvparser` with `reject_on_empty_key=false`. While `false` is the default value, you can specify it explicitly, as shown. Additionally, set the parameter `header=true` to specify the columns for input values:

```sql
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_empty_key=false,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> ,num
>> 1,2
>> \.
```

3. Invoke `maptostring` to display the table values after loading data:

```sql
=> SELECT maptostring(_raw_) FROM csv_basic;
maptostring
---------------------

{} '' : "1",
"num" : "2"

(1 row)
```

4. Truncate the table to empty the data stored in the table:

```sql
=> TRUNCATE TABLE csv_basic;
TRUNCATE TABLE
```

5. Reload the same data again, but this time, set `reject_on_empty_key=true`:

```sql
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_empty_key=true,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> ,num
>> 1,2
>> \.
```

6. Call `maptostring` to display the table contents. No rows are loaded because one of the keys is empty:

```sql
=> SELECT maptostring(_raw_) FROM csv_basic;
maptostring
-----------

(0 rows)
```
7. Truncate the table to empty the data stored in the table:

```
=> TRUNCATE TABLE csv_basic;
    TRUNCATE TABLE
```

8. Reload the same data again, but this time, set `omit_empty_keys=true`:

```
=> COPY csv_basic FROM stdin PARSER fcsvparser(omit_empty_keys=true,header=true);
    Enter data to be copied followed by a newline.
    End with a backslash and a period on a line by itself.
    >> ,num
    >> 1,2
    >> \
```

9. Call `maptostring` to display the table contents. One row is now loaded, and the rows with empty keys are omitted:

```
=> SELECT maptostring(_raw_) FROM csv_basic;
    maptostring
    ----------------------
    {  "num" : "2"
    }
    (1 row)
```

**Note:**

If no header names exist, `fcsvparser` uses a default header of `ucoln`, where `n` is the column offset number. If a table header name and key name match, the parser loads the column with values associated with the matching key name.

### Using the NULL Parameter

Use the COPY NULL metadata parameter with `fcsvparser` to load NULL values into a flex table.

The next example uses this parameter:

1. Create a flex table.

```
=> CREATE FLEX TABLE fcsv(c1 int);
    CREATE TABLE
```

2. Load CSV data in flex table using STDIN and NULL parameter.

```
=> COPY fcsv FROM STDIN PARSER fcsvparser() NULL 'NULL';
    Enter data to be copied followed by a newline.
```
3. Use `compute_flextable_keys_and_build_view` function to compute keys and build flex view.

```sql
=> SELECT compute_flextable_keys_and_build_view('fcsv');
```

Please see `public.fcsv_keys` for updated keys
The view `public.fcsv_view` is ready for querying
(1 row)

4. View the flex view and replace the NULL values.

```sql
=> SELECT * FROM public.fcsv_view;
a | b | c1
---+---+---
20 | 30 | 50
10 | 20 |
20 | 30 | 40
(3 rows)
```

```sql
=> SELECT a, b, ISNULL(c1, -1) from public.fcsv_view;
a | b | ISNULL
---+---+-----
20 | 30 | 50
10 | 20 | -1
20 | 30 | 40
(3 rows)
```

## Handling Column Headings

The `fcsvparser` lets you specify your own column headings with the `HEADER_NAMES=` parameter. This parameter entirely replaces column names in the CSV source header row.

For example, to use these six column headings for a CSV file you are loading, use the `fcsvparser` parameter as follows:

```
HEADER_NAMES='FIRST, LAST, SOCIAL_SECURITY, TOWN, STATE, COUNTRY'
```

Supplying fewer header names than existing data columns causes `fcsvparser` to use default names after those you supply. Default header names consist of `ucoln`, where
\( n \) is the column offset number, starting at 0 for the first column. For example, if you supply four header names for a 6-column table, fcsvparser supplies the default names ucol4 and ucol5, following the fourth header name you provide.

If you supply more headings than the existing table columns, any additional headings remain unused.

### Loading Delimited Data

You can load flex tables with one of two delimited parsers, fdelimitedparser or fdelimitedpairparser.

- Use `fdelimitedpairparser` when the data specifies column names with the data in each row.
- Use `fdelimitedparser` when the data does not specify column names or has a header row for column names.

This section describes using some options that `fdelimitedpairparser` and `fdelimitedparser` support.

### Rejecting Duplicate Values

You can reject duplicate values using the `reject_on_duplicate=true` option with the `fdelimitedparser`. The load continues after it rejects a duplicate value. The next example shows how to use this parameter and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```sql
=> CREATE FLEX TABLE delim_dupes();
CREATE TABLE
=> COPY delim_dupes FROM stdin PARSER fdelimitedparser(reject_on_duplicate=true) exceptions '/home/dbadmin/load_errors/except.out' rejected data '/home/dbadmin/load_errors/reject.out';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> A|A
>> 1|2
>> .
=> \! cat /home/dbadmin/load_errors/reject.out
A|A
=> \! cat /home/dbadmin/load_errors/except.out
```

Vertica Documentation
Using Flex Tables

Vertica Analytic Database (9.3.x)
Input record 1 has been rejected (Processed a header row with duplicate keys with reject_on_duplicate specified; rejecting.). Please see /home/dbadmin/load_errors/reject.out, record 1 for the rejected record.

Rejected Materialized Column Type Errors

Both the fjsonparser and fdelimitedparser parsers have a boolean parameter, reject_on_materialized_type_error. Setting this parameter to true causes rows to be rejected if both the following conditions exist in the input data:

- Includes keys matching an existing materialized column
- Has a value that cannot be coerced into the materialized column’s data type

Suppose the flex table has a materialized column, OwnerPercent, declared as a FLOAT. Trying to load a row with an OwnerPercent key that has a VARCHAR value causes fdelimitedparser to reject the data row.

The following examples illustrate setting this parameter.

1. Create a table, reject_true_false, with two real columns:

```sql
=> CREATE FLEX TABLE reject_true_false(one VARCHAR, two INT);
CREATE TABLE
```

2. Load JSON data into the table (from STDIN), using the fjsonparser with reject_on_materialized_type_error=false. While false is the default value, the following example specifies it explicitly for illustration:

```sql
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_error=false);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one": 1, "two": 2}
>> {"one": "one", "two": "two"}
>> {"one": "one", "two": 2}
>> .
```

3. Invoke maptostring to display the table values after loading data:

```sql
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
maptostring | one | two
-------------+-----+-----+
{            |     |
  "one" : "one",
  "two" : "2"
}            |     |
| one | 2
```
4. Truncate the table:

```sql
=> TRUNCATE TABLE reject_true_false;
```

5. Reload the same data again, but this time, set `reject_on_materialized_type_error=true`:

```sql
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_error=true);
```

Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

```json
>> {"one": 1, "two": 2}
>> {"one": "one", "two": "two"}
>> {"one": "one", "two": 2}
>> .
```

6. Call `maptoString` to display the table contents. Only two rows were loaded, whereas the previous results had three rows:

```sql
=> SELECT maptoString(__raw__), one, two FROM reject_true_false;
```

```
maptoString | one | two
-------------+-----+-----
{            |     |     
  "one" : "1",
  "two" : "2"
} | 1   | 2   
{            |     |     
  "one" : "one",
  "two" : "two"
} | one | 2   
(2 rows)```

---

**Loading JSON Data**

You can load JSON data into flex or columnar tables. This section describes some examples of using the `fjsonparser` with several of the parser options.
Checking JSON Integrity

Before loading any JSON data, be sure that the data is valid. You can verify JSON data integrity using a web tool such as JSONLint. Copy your JSON data into the tool. If any data is invalid, the tool returns a message similar to the one in this example:

```json
Parse error on line 170:....257914002502451200}{
  "id_str": "257

          ^
Expecting 'EOF', '}', ',', ']
```

Using flatten_maps and flatten_arrays Parameters

When loading JSON data, the fjsonparser uses the parameters flatten_maps and flatten_arrays to control how the parser handles the data it is loading. Here are the default settings for these two parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Change Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>flatten_maps</td>
<td>TRUE: Flatten all maps.</td>
<td>flatten_maps=FALSE</td>
</tr>
<tr>
<td>flatten_arrays</td>
<td>FALSE: Do not flatten arrays.</td>
<td>flatten_arrays=TRUE</td>
</tr>
</tbody>
</table>

You control the default the behavior by using one or both flatten_ parameters.

For JSON maps, the parser flattens all submaps, separating the levels with a period (.). Consider the following input data with a subnet:

```json
{ grade: { level: 4 } }
```

The default parser behavior results in the following map:

```json
{ "grade.level" -> "4" }
```

**Note:**
To use the bracket operators ([[ ]]) to access deeply nested JSON in VMap data, you must load the data with `flatten_maps=FALSE`, as described in Querying Nested Data.
For JSON arrays, the parser maintains the array. Consider the following input data containing a 2-element array, with values 1 and 2:

```json
{ grade: [ 1 2 ] }
```

The default parser behavior results in the following array:

```json
{ "grade": { "0" -> "1", "1" -> "2" } }
```

**Note:**
Using the parameters `flatten_maps` and `flatten_arrays` is recursive, and affects all data.

### Loading from a Specific Start Point

You can use the `fjsonparser start_point` parameter to load JSON data beginning at a specific key, rather than at the beginning of a file. Data is parsed from after the `start_point` key until the end of the file, or to the end of the first `start_point`'s value. The `fjsonparser` ignores any subsequent instance of the `start_point`, even if that key appears multiple times in the input file. If the input data contains only one copy of the `start_point` key, and that value is a list of JSON elements, the parser loads each element in the list as a row.

This section uses the following sample JSON data, saved to a file (alphanums.json):

```json
{ "A": { "B": { "C": { "d": 1, "e": 2, "f": 3 }, { "g": 4, "h": 5, "i": 6 }, { "j": 7, "k": 8, "l": 9 } } } }
```

1. Create a flex table, `start_json`:

   ```sql
   => CREATE FLEX TABLE start_json();
   CREATE TABLE
   ```

2. Load `alphanums.json` into `start_json` using the `fjsonparser` without any parameters:

   ```sql
   => COPY start_json FROM '/home/dbadmin/data/flex/alphanums.json' PARSER fjsonparser();
   Rows Loaded
   ------------
   1
   (1 row)
   ```

3. Use `map_to_string` to see the results of loading all of `alphanums.json`:
4. **Truncate `start_json` and load `alphanums.json` with the `start_point` parameter:**

```sql
=> SELECT maptostring(_raw_ _) FROM start_json;

maptostring

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;A.B.C&quot; : {</td>
<td></td>
</tr>
<tr>
<td>&quot;0.d&quot; : &quot;1&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;0.e&quot; : &quot;2&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;0.f&quot; : &quot;3&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;1.g&quot; : &quot;4&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;1.h&quot; : &quot;5&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;1.i&quot; : &quot;6&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;2.j&quot; : &quot;7&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;2.k&quot; : &quot;8&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;2.l&quot; : &quot;9&quot;</td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>

(1 row)
```

5. **Next, call `maptostring` again to compare the results of loading `alphanums.json` from `start_point='B'`:**

```sql
=> TRUNCATE TABLE start_json;
TRUNCATE TABLE
=> COPY start_json FROM '/home/dbadmin/data/flex/alphanums.json' PARSE

-> fjsonparser(start_point='B');
Rows Loaded
-----------
1
(1 row)
```

```sql
=> SELECT maptostring(_raw_ _) FROM start_json;

maptostring

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;C&quot; : {</td>
<td></td>
</tr>
<tr>
<td>&quot;0.d&quot; : &quot;1&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;0.e&quot; : &quot;2&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;0.f&quot; : &quot;3&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;1.g&quot; : &quot;4&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;1.h&quot; : &quot;5&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;1.i&quot; : &quot;6&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;2.j&quot; : &quot;7&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;2.k&quot; : &quot;8&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;2.l&quot; : &quot;9&quot;</td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>

(1 row)
```
Parsing From a Start Point Occurrence

If a start_point value occurs in multiple locations in your JSON data, you can use the start_point_occurrence integer parameter to specify the occurrence at which to start parsing. By defining start_point_occurrence, fjsonparsr begins at the nth occurrence of start_point.

Controlling Column Name Separators

By default, fjsonparsr produces column names by concatenating JSON field names with a period (.)). You can change the default separator by specifying a different character with the key_separator parameter.

Handling Special Characters

Some input JSON data can have special characters in field names. You can replace these characters by setting the suppress_nonalphanumeric_key_chars to TRUE. With this parameter setting, all special characters are converted to an underscore (_) character.

Dealing with Invalid JSON Records

If your JSON data is not perfectly formatted, your load may fail due to invalid records. You can use the RECORD_TERMINATOR parameter to skip these invalid records if your JSON records are consistently delimited by a character like a line break. Setting a record terminator will allow the FJSONPARSER to skip over invalid records and continue parsing the rest of the data.

If your records are not consistently marked by a character, you can use the COPY parameter ERROR TOLERANCE. ERROR TOLERANCE skips entire source files with invalid JSON records, while RECORD_TERMINATOR skips individual malformed JSON records. Using both ERROR TOLERANCE and RECORD_TERMINATOR within the statement will work, but if your records are consistently marked, RECORD_TERMINATOR should sufficiently deal with imperfect records.
1. Create a flex table named "fruits".

```sql
=> CREATE FLEX TABLE fruits();
CREATE TABLE
```

2. Use the FJSONPARSER and call the RECORD_TERMINATOR parameter with a termination key of E'\n' (which denotes a new line). Insert records, including an invalid record.

```sql
=> COPY fruits FROM STDIN PARSER FJSONPARSER(RECORD_TERMINATOR=E'\n');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself
>> {"name": "orange", "type": "fruit", "color": "orange", "rating": 5 }
>> {"name": "apple", "type": "fruit", "color": "green" }
>> {"name": "blueberry", "type": "fruit", "color": "blue", "rating": 10 }
>> "type": "fruit", "rating": 7 }
>> {"name": "banana", "type": "fruit", "color": "yellow", "rating": 3 }
>> .
```

3. View the flex table using MAPTOSTRING to confirm that the invalid record was skipped while the rest of the records were successfully loaded.

```sql
=> SELECT MAPTOSTRING(_raw_) FROM fruits;
maptostring
----------------------------------------------------------
{
  "color" : "orange",
  "name" : "orange",
  "rating" : "5",
  "type" : "fruit"
}
{
  "color" : "green",
  "name" : "apple",
  "type" : "fruit"
}
{
  "color" : "blue",
  "name" : "blueberry",
  "rating" : "10",
  "type" : "fruit"
}
{
  "color" : "yellow",
  "name" : "banana",
  "rating" : "3",
  "type" : "fruit"
}
(4 rows)
```
Rejecting Duplicate Values

You can reject duplicate values by using the `reject_on_duplicate=true` option with the `fjsonparser`. The next example uses this option while loading data and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```sql
=> CREATE FLEX TABLE json_dupes();
CREATE TABLE
=> COPY json_dupes FROM stdin PARSER fjsonparser(reject_on_duplicate=true)
exceptions '/home/dbadmin/load_errors/json_e.out'
rejected data '/home/dbadmin/load_errors/json_r.out';
```

Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

```
>> {"a":"1","a":"2","b":"3"}
>> \
=> \!cat /home/dbadmin/load_errors/json_e.out
COPY: Input record 1 has been rejected (Rejected by user-defined parser).
Please see /home/dbadmin/load_errors/json_r.out, record 1 for the rejected record.
COPY: Loaded 0 rows, rejected 1 rows.
```

Rejecting Data on Materialized Column Type Errors

Both the `fjsonparser` and `fdelimitedparser` parsers have a Boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if the input data:

- Includes keys matching an existing materialized column
- Has a key value that cannot be coerced into the materialized column's data type.

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

```sql
=> CREATE FLEX TABLE reject_true_false(one VARCHAR, two INT);
CREATE TABLE
```

2. Load JSON data into the table (from STDIN), using the `fjsonparser` with `reject_on_materialized_type_error=false`. While `false` is the default value, the following example specifies it explicitly for illustration:
3. Invoke maptostring to display the table values after loading data:

```sql
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
maptostring | one | two
-------------+-----+-----
{           |
  "one": "one",
  "two": "2"
}           |
| one | 2
{           |
  "one": "1",
  "two": "2"
}           |
| 1    | 2
{           |
  "one": "one",
  "two": "two"
}           |
| one | 
(3 rows)
```

4. Truncate the table:

```sql
=> TRUNCATE TABLE reject_true_false;
```

5. Reload the same data again, but this time, set reject_on_materialized_type_error=true:

```sql
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_error=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one": 1, "two": 2}
>> {"one": "one", "two": "two"}
>> {"one": "one", "two": 2}
>> 
```

6. Call maptostring to display the table contents. Only two rows were loaded, whereas the previous results had three rows:

```sql
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
maptostring | one | two
-------------+-----+-----
{           |
  "one": "1",
```
Rejecting or Omitting Empty Rows

Valid JSON files OpenText can include empty key and value pairs, such as this one:

```json
{
  "one": "one",
  "two": "2"
}
```

Such rows are invalid for SQL. To prevent this situation, you can control the behavior for empty rows, either rejecting or omitting them. You do so using two boolean parameters for the parsers `FDELIMITEDPARSER` or `FJSONPARSER`:

- `reject_on_empty_key`
- `omit_empty_keys`

Loading Matches from Regular Expressions

You can load flex or columnar tables with the matched results of a regular expression, using the `fregexparser`. This section describes some examples of using the options that the flex parsers support.

Sample Regular Expression

These examples use the following regular expression, which searches information that includes the `timestamp`, `date`, `thread_name`, and `thread_id` strings.
Caution:
For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, \(<\text{thread_id}>(?:0x)?\[0-9a-f]+\).

`'^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d \d\d+)(?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?\[0-9a-f]+)-?(?<transaction_id>[0-9a-f])?:\[((?<component>\w+)\[((?<elevel>\w+)//)(?<enode>\w+)?(?<text>.*)\)?(?<text>\.+)'`  

Using Regular Expression Matches for a Flex Table

You can load the results from a regular expression into a flex table, using the fregexparser. For a complete example of doing so, see FREGEXPARSER.

Using fregexparser for Columnar Tables

This section illustrates how to load the results of a regular expression used with a sample log file for a Vertica database. By using an external table definition, the section presents an example of using fregexparser to load data into a columnar table. Using a flex table parser for a columnar tables gives you the capability to mix data loads in one table. For example, you can load the results of a regular expression in one session, and JSON data in another.

The following basic examples illustrate this usage.

1. Create a columnar table, vlog, with the following columns:

```sql
=> CREATE TABLE vlog (  
  "text"       varchar(2322),  
  thread_id    varchar(28),  
  thread_name  varchar(44),  
  "time"       varchar(46),  
  component    varchar(30),  
  level        varchar(20),  
  transaction_id varchar(32),  
  elevel       varchar(20),  
  enode        varchar(34)  
);```
2. Use COPY to load parts of a log file using the sample regular expression presented above, with the fregexparser. Be sure to remove any line characters from this expression example before trying it yourself:

```sql
=> COPY v_log FROM '/home/dbadmin/data/flex/vertica.log' PARSER FRegexParser(pattern='^\d\d\d\d-\d\d-\d\d \d\d: \d\d: \d\d.\d+ (\d+): (?<thread_name>[A-Za-z]+): (?<thread_id>[0-9a-f]+): (?<transaction_id>[0-9a-f]+): (?<component>[0-9a-f]+): (?<level>[0-9a-f]+): (?<enode>[0-9a-f]+)@(?<elevel>[0-9a-f]+): (?<text>.*)') rejected data as table fregex_reject;
```

3. Query the time column:

```sql
=> SELECT time FROM flogs limit 10;
```

<table>
<thead>
<tr>
<th>time</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>2014-04-02 04:02:02.614</td>
</tr>
<tr>
<td>2014-04-02 04:02:51.008</td>
</tr>
<tr>
<td>2014-04-02 04:02:51.010</td>
</tr>
<tr>
<td>2014-04-02 04:02:51.012</td>
</tr>
<tr>
<td>2014-04-02 04:02:51.012</td>
</tr>
<tr>
<td>2014-04-02 04:02:51.013</td>
</tr>
<tr>
<td>2014-04-02 04:02:51.014</td>
</tr>
<tr>
<td>2014-04-02 04:02:51.017</td>
</tr>
</tbody>
</table>

(10 rows)

Using External Tables with fregexparser

By creating an external columnar table for your Vertica log file, querying the table will return updated log information. The following basic example illustrate this usage.

1. Create a columnar table, vertica_log, using the AS COPY clause and fregexparser to load matched results from the regular expression. For illustrative purposes, this regular expression has new line characters to split long text lines. Remove any line returns before testing with this expression:

```sql
=> CREATE EXTERNAL TABLE public.vertica_log
  (  
    "text" varchar(2322),
    thread_id varchar(28),
    thread_name varchar(44),
    "time" varchar(46),
    component varchar(30),
    level varchar(20),
    transaction_id varchar(32),
    elevel varchar(20),
    enode varchar(34)
  )
```
AS COPY
FROM '/home/dbadmin/data/vertica.log'
PARSER FRegexParser(pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)(?<thread_name>[A-Za-z ]+:(?<thread_id>\?0x)?[0-9a-f]+)-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]\<(?<level>\w+)\> @(?<enode>\w+)?: )?(?<text>.*');

2. Query from the external table to get updated results:

```
=> SELECT component, thread_id, time FROM vertica_log limit 10;

<table>
<thead>
<tr>
<th>component</th>
<th>thread_id</th>
<th>time</th>
</tr>
</thead>
<tbody>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
<tr>
<td>Init</td>
<td>0x16321430</td>
<td>2014-04-02 04:02:02.613</td>
</tr>
</tbody>
</table>

(10 rows)
```

### Computing Flex Table Keys

After loading data into a flex table, you can determine the set of keys that exist in the `raw` column (the map data). Two helper functions compute keys from flex table map data:

- **COMPUTE_FLEXTABLE_KEYS** determines which keys exist as virtual columns in the flex map.
- **COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW** performs the same functionality as **COMPUTE_FLEXTABLE_KEYS**, additionally building a new view. See also [Updating Flex Table Views](#).

**Note:**

If the length of a key exceeds 65,000, Vertica truncates the key.

### Using COMPUTE_FLEXTABLE_KEYS

During execution, this function calculates the following information for the flex keys table columns:
### Determining Key Data Types

By default, using `COMPUTE_FLEXTABLE_KEYS` determines non-string key values from the `__raw__` column LONG VARBINARY type. The non-string keys include these data types (and others listed in SQL Data Types):

- BOOLEAN
- INTEGER
- FLOAT
- TIMESTAMP
- DATE

### Assigning Flex Key Data Types

Use the sample CSV data in this section to compare the results of using or not using the `EnableBetterFlexTypeGuessing` configuration parameter. When the parameter is ON, the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

| Year, Quarter, Region, Species, Grade, Pond, Value, Number of Quotes, Available |
|---|---|---|---|---|---|---|---|
| 2015, 1, 2 - Northwest Oregon & Willamette, Douglas-fir, P, $615.12, 12, No |
| 2015, 1, 2 - Northwest Oregon & Willamette, Douglas-fir, SM, $610.78, 12, Yes |
| 2015, 1, 2 - Northwest Oregon & Willamette, Douglas-fir, 2S, $596.00, 20, Yes |
| 2015, 1, 2 - Northwest Oregon & Willamette, Hemlock, P, $520.00, 6, Yes |
| 2015, 1, 2 - Northwest Oregon & Willamette, Hemlock, SM, $510.00, 6, No |
To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as trees.csv).
2. Create a flex table (trees) and load trees.csv using the fcsvparser:

```
=> CREATE FLEX TABLE trees();
=> COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
```

3. Use COMPUTE_FLEXTABLE_KEYS with the trees flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('trees');
```

Please see public.trees_keys for updated keys (1 row)

4. Query the trees_keys table output:

```
=> SELECT * FROM trees_keys;
key_name       | frequency | data_type_guess
---------------|-----------|-----------------|
Year           | 6         | Integer         |
Quarter        | 6         | Integer         |
Region         | 6         | Varchar(66)     |
Available      | 6         | Boolean         |
Number of Quotes| 6         | Integer         |
Grade          | 6         | Varchar(20)     |
Species        | 6         | Varchar(22)     |
Pond Value     | 6         | Numeric(8,3)    |
(8 rows)
```

5. Set the EnableBetterFlexTypeGuessing parameter to 0 (OFF).
6. Call COMPUTE_FLEXTABLE_KEYS with the trees flex table again.
7. Query the trees_keys table to compare the data_type_guess values with the previous results. Without the configuration parameter set, all of the non-string data types are VARCHARS of various lengths:

```
=> SELECT * FROM trees_keys;
key_name       | frequency | data_type_guess
---------------|-----------|-----------------|
Year           | 6         | varchar(20)     |
Quarter        | 6         | varchar(20)     |
Region         | 6         | varchar(66)     |
Available      | 6         | varchar(20)     |
Grade          | 6         | varchar(20)     |
Number of Quotes| 6         | varchar(20)     |
Pond Value     | 6         | varchar(20)     |
Species        | 6         | varchar(22)     |
(8 rows)
```
8. To maintain accurate results for non-string data types, set the EnableBetterFlexTypeGuessing parameter back to 1 (ON).

For more information about setting the EnableBetterFlexTypeGuessing configuration parameter, see Setting Flex Table Configuration Parameters.

Calculating Key Value Column Widths

The COMPUTE_FLEXTABLE_KEYS function determines the column width for keys by determining the length of the largest value for each key, multiplied by the FlexTableDataTypeGuessMultiplier factor. For more about this configuration parameter, see Setting Flex Table Configuration Parameters.

The next example shows the results of populating the _keys table after creating a flex table (darkdata1) and loading data. The column widths are shown in parentheses, where applicable, after the value of the data_type_guess column:

```sql
=> SELECT compute_flextable_keys('darkdata1');
          compute_flextable_keys
-----------------------------------------------
Please see public.darkdata1_keys for updated keys
(1 row)

=> SELECT * from darkdata1_keys;
key_name         | frequency | data_type_guess
-----------------|-----------|------------------
created_at       | 8         | TimestampTz      
delete.status.id_str | 4         | Integer          
delete.status.user_id  | 4         | Integer          
entities.hashtags | 8         | long varbinary(186)
favorited        | 8         | Boolean          
id_str           | 8         | Integer          
in_reply_to_screen_name | 8         | Varchar(24)     
retweeted_status.contributors | 1         | Varchar(28)     
retweeted_status.coordinates | 1         | Varchar(28)     
retweeted_status.created_at | 1         | TimestampTz     
.                 |           |                  
.                 |           |                  
(125 rows)
```

Materializing Flex Tables

Once flex tables exist, you can change the table structure to promote virtual columns to materialized (real) columns. If your table is already a hybrid table, you can change existing real columns and promote other important virtual columns. This section describes some key
aspects of promoting columns, adding columns, specifying constraints, and declaring default values. It also presents some differences when loading flex or hybrid tables, compared with columnar tables.

**Note:**
Materializing virtual columns by promoting them to real columns can significantly improve query performance. Vertica recommends that you materialize important virtual columns before running large and complex queries. Promoted columns cause a small decrease in load performance.

## Adding Columns to Flex Tables

Add columns to your flex tables to promote virtual columns:

1. Add a real column with the same name as a virtual column (user.name):

   ```
   => ALTER TABLE darkdata1 ADD COLUMN "user.name" VARCHAR;
   ALTER TABLE
   ```

2. Load some data into the table.

   ```
   => COPY darkdata1 FROM '/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
   Rows Loaded
   ----------------
   12
   (1 row)
   ```

3. Query the materialized column. Notice that loading data populates the column automatically. Blank rows indicate no values or NULLs:

   ```
   => SELECT "user.name" FROM darkdata1;
   user.name
   ----------------
   I’m Toasterâ¥
   Flu Beach
   seydo shi
   The End
   Uptown gentleman.
   ~G A B R I E L A â¿
   Avita Desai
   laughing at clouds.
   (12 rows)
   ```
Adding Columns with Default Values

The section Bulk Loading Data into Flex Tables describes the use of default values, and how Vertica evaluates them during loading. As with all tables, using COPY to load data ignores any column default values.

**Note:** Adding a table column default expression to a flex table requires casting the column to an explicit data type.

1. Create a darkdata1 table with a column definition. The following example uses a column name (talker) that does not correspond to a virtual column name. Assign a default value with a virtual column name. In this example, the default value for the column talker is ("user.lang"). Since user.lang is a virtual column in the LONG VARBINARY __raw__ column, you must cast its value to VARCHAR to match the talker column definition:

   => CREATE FLEX TABLE darkdata1(talker VARCHAR default "user.lang"::VARCHAR);

2. Load some JSON data, specifying the __raw__ column:

   => COPY darkdata1 (__raw__) FROM '/test/vertica/flextable/DATA/tweets_12.json'
      PARSER fjsonparser();
   Rows Loaded
     ------------
       12
   (1 row)

3. Query the talker column. Notice that Vertica used the default column value ("user.lang"), because you specified __raw__. Blank rows indicate no values or NULLs:

   => SELECT "talker" FROM darkdata1;
   talker
    ------
      it
      en
      es
      en
      es
      tr
      en
4. Alter the table to add a column with a known virtual column name (user.name), assigning the key name as the default value (recommended), and casting it to a VARCHAR:

```sql
=> ALTER TABLE darkdata1 ADD COLUMN "user.name" VARCHAR default "user.name"::VARCHAR;
```

5. Load data again, this time without __raw__:

```sql
=> COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
```

6. Query the two real columns. Notice that talker has no values, because you did not specify the __raw__ column. The user.lang column contains values from the user.name virtual column:

```sql
=> SELECT "talker", "user.name" FROM darkdata1;
```

```
<table>
<thead>
<tr>
<th>talker</th>
<th>user.name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>laughing at clouds.</td>
</tr>
<tr>
<td></td>
<td>Avita Desai</td>
</tr>
<tr>
<td></td>
<td>I'm Toasterâ¥</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Uptown gentleman.</td>
</tr>
<tr>
<td></td>
<td>~G A B R I E L A â¿</td>
</tr>
<tr>
<td></td>
<td>Flu Beach</td>
</tr>
<tr>
<td></td>
<td>seydo shi</td>
</tr>
<tr>
<td></td>
<td>The End</td>
</tr>
</tbody>
</table>
```

7. Load data once more, this time specifying a COPY statement with a default value expression for user.name:

```sql
=> COPY darkdata1 (__raw__, "user.name" as 'QueenElizabeth'::varchar) FROM
'/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
```

```
Rows Loaded
---------
12
```

8. Query once more. Notice that the real column talker has its default values (you used __raw__). As specified in COPY, the "user.name" as 'QueenElizabeth' expression overrode the user.name default column value:
To summarize, you can set a default column value as part of the ALTER TABLE...ADD COLUMN operation. For materializing columns, the default value should reference the key name of the virtual column (as in "user.lang"). Subsequently loading data with a COPY value expression overrides the default value of the column definition.

### Changing the __raw__ Column Size

You can change the default size of the __raw__ column for flex tables you plan to create, the current size of an existing flex table, or both.

To change the default size for the flex table __raw__ column, use the following database configuration parameter (described in Setting Flex Table Configuration Parameters):

```sql
=> ALTER DATABASE DEFAULT SET FlexTableRawSize = 120000;
```

Changing the configuration parameter affects all flex tables you create after making this change.

To change the size of the __raw__ column in an existing flex table, use the ALTER TABLE statement to change the definition of the __raw__ column:

```sql
=> ALTER TABLE tester ALTER COLUMN __raw__ SET DATA TYPE LONG VARBINARY(120000);
```

**Note:**
An error occurs if you try to reduce the __raw__ column size to a value smaller than any data the column contains.
Changing Flex Table Real Columns

You can make the following changes to the flex table real columns (__raw__ and __identity__), but not to any virtual columns:

<table>
<thead>
<tr>
<th>Actions</th>
<th><strong>raw</strong></th>
<th><strong>identity</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Change NOT NULL constraints (default)</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Add primary key and foreign key (PK/FK) constraints</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Create projections</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Segment</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Partition</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Specify a user-defined scalar function (UDSF) as a default column expression in ALTER TABLE x ADD COLUMN y statement</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Note:**
While segmenting and partitioning the __raw__ column is permitted, it is not recommended due to its long data type. By default, if you do not define any real columns, flex tables are segmented on the __identity__ column.

Dropping Flex Table Columns

There are two considerations about dropping columns:

- You cannot drop the last column in your flex table's sort order.
- If you have not created a flex table with any real columns, or materialized any columns, you cannot drop the __identity__ column.
Updating Flex Table Views

Creating a flex table also creates a default view to accompany the table. The view has the name of the flex table with an underscore (_view) suffix. When you perform a select query from the default view, Vertica prompts you to run the helper function, compute_flextable_keys_and_build_view:

```
=> \dv dark*
```

<table>
<thead>
<tr>
<th>List of View Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema</td>
</tr>
<tr>
<td>---------</td>
</tr>
<tr>
<td>public</td>
</tr>
<tr>
<td>public</td>
</tr>
</tbody>
</table>

(2 rows)

```
=> SELECT * FROM darkdata_view;
```

<table>
<thead>
<tr>
<th>status</th>
</tr>
</thead>
</table>

Please run compute_flextable_keys_and_build_view() to update this view to reflect real and virtual columns in the flex table

(1 row)

There are two helper functions that create views:

- **COMPUTE_FLEXTABLE_KEYS**— See also **COMPUTE_FLEXTABLE_KEYS**
- **COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW**— Performs the same functionality as BUILD_FLEXTABLE_KEYS but also computes keys. See also **Using COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW**.

Using BUILD_FLEXTABLE_VIEW

After computing keys for a flex table (Computing Flex Table Keys), call this function with one or more arguments. The records under the key_name column of the `{flextable}_keys` table are used as view columns, along with any values for the key. If no values exist, the column value is NULL.

Regardless of the number of arguments, calling this function replaces the contents of the existing view as follows:

<table>
<thead>
<tr>
<th>Function Invocation</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>build_flextable_view ('flexible_table')</td>
<td>Changes the existing view associated with flexible_</td>
</tr>
<tr>
<td>Function Invocation</td>
<td>Results</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------</td>
</tr>
<tr>
<td><code>build_flextable_view ('flexible_table', 'view_name')</code></td>
<td>Changes the view you specify with <code>view_name</code> by using the current contents of the <code>flexible_table_keys</code> table.</td>
</tr>
<tr>
<td><code>build_flextable_view ('flexible_table', 'view_name', 'table_keys')</code></td>
<td>Changes the view you specify with <code>view_name</code> to the current contents of the <code>flexible_table_keys</code> table. Use this function to change a view of your choice with the contents of the keys of interest.</td>
</tr>
</tbody>
</table>

If you do not specify a `view_name` argument, the default name is the flex table name with a `_view` suffix. For example, if you specify the table `darkdata` as the sole argument to this function, the default view is called `darkdata_view`.

You cannot specify a custom view name with the same name as the default view `flex_table_view`, unless you first drop the default-named view and then create your own view of the same name.

Creating a view stores a definition of the column structure at the time of creation. Thus, if you create a flex table view and then promote virtual columns to real columns, you must rebuild the view. Querying a rebuilt flex table view that has newly promoted real columns produces two results. These results reflect values from both virtual columns in the map data and real columns.

**Handling JSON Duplicate Key Names in Views**

SQL is a case-insensitive language, so the names TEST, test, and TeSt are identical. JSON data is case sensitive, so that it can validly contain key names of different cases with separate values.

When you build a flex table view, the function generates a warning if it detects same-name keys with different cases in the `flextable_keys` table. For example, calling `BUILD_`
FLEXTABLE_VIEW or COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW() on a flex table with duplicate key names results in these warnings:

```sql
=> SELECT compute_flextable_keys_and_build_view('dupe');
WARNING 5821: Detected keys sharing the same case-insensitive key name
WARNING 5009: Found and ignored keys with names longer than the maximum column-name length limit
```

Please see public.dupe_keys for updated keys
The view public.dupe_view is ready for querying (1 row)

While a `flextable`_keys table can include duplicate key names with different cases, a view cannot. Creating a flex table view with either of the helper functions consolidates any duplicate key names to one column name, consisting of all lowercase characters. All duplicate key values for that column are saved. For example, if these key names exist in a flex table:

- test
- Test
- tEST

The view will include a virtual column test with values from the test, Test, and tEST keys.

**Note:**
The examples in this section include added Return characters to reduce line lengths. The product output may differ.

For example, consider the following query, showing the duplicate test key names:

```sql
=> \x
Expanded display is on.
dbt=> select * from dupe_keys;
-[ RECORD 1 ]----------------------------------------
   key_name | TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
   frequency | 2
   data_type_guess | varchar(20)
-[ RECORD 2 ]----------------------------------------
   key_name | TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
   frequency | 2
   data_type_guess | varchar(20)
-[ RECORD 3 ]----------------------------------------
```
The following query displays the dupe flex table (dupe_view). It shows the consolidated test and testtesttesttest... virtual columns. All the test, Test, and tEST virtual column values are in the test column:

```
=> SELECT * FROM dupe_view;
test |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>testtesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttest</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>upper2</td>
<td>test</td>
<td></td>
</tr>
<tr>
<td>half4</td>
<td>half4</td>
<td></td>
</tr>
<tr>
<td>upper1</td>
<td>lower1</td>
<td></td>
</tr>
<tr>
<td>half1</td>
<td>half1</td>
<td></td>
</tr>
<tr>
<td>lower2</td>
<td>lower2</td>
<td></td>
</tr>
<tr>
<td>lower3</td>
<td>lower3</td>
<td></td>
</tr>
<tr>
<td>upper1</td>
<td>upper1</td>
<td></td>
</tr>
<tr>
<td>lower2</td>
<td>lower2</td>
<td></td>
</tr>
<tr>
<td>lower3</td>
<td>lower3</td>
<td></td>
</tr>
<tr>
<td>(16 rows)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

---

**Creating a Flex Table View**

The following example shows how to create a view, dd_view, from the flex table darkdata, which contains JSON data.

```
=> CREATE VIEW dd_view AS SELECT "user.lang"::VARCHAR, "user.name"::VARCHAR FROM darkdata;
```

Query the key names you specified, and their values:
This example shows how to call build_flextable_view with the original table and the view you previously created, dd_view:

```sql
=> SELECT * FROM dd_view;
user.lang | user.name
----------------------
en   | Uptown gentleman.
en   | The End
it   | laughing at clouds.
es   | I'm Toasterâ€”
en   | ~G A B R I E L A â¿
en   | Avita Desai
tr   | seydo shi
es   | Flu Beach
(12 rows)
```

Query the view again. You can see that the function populated the view with the contents of the darkdata_keys table. Next, review a snippet from the results, with the key_name columns and their values:

```sql
=> \x
Expanded display is on.

=> SELECT * FROM dd_view;
.
.
.
user.following | 791
user.friends_count | F
user.geo_enabled | 164464905
user.id | 164464905
user.id_str
user.is_translator | F
user.lang | en
user.listed_count | 4
user.location | Uptown..
user.name | Uptown gentleman.
.
.
.
```

When building views, be aware that creating a view stores a definition of the column structure at the time the view is created. If you promote virtual columns to real columns
after building a view, the existing view definition is not changed. Querying this view with a select statement such as the following, returns values from only the __raw__ column:

```sql
=> SELECT * FROM myflextable_view;
```

Also understand that rebuilding the view after promoting virtual columns changes the resulting value. Future queries return values from both virtual columns in the map data and from real columns.

**Using COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW**

Call this function with a flex table to compute Flex table keys (see Computing Flex Table Keys), and create a view in one step.

**Querying Flex Tables**

After you create your flex table (with or without additional columns) and load data, you can perform these types of queries:

- SELECT
- COPY
- TRUNCATE
- DELETE

You can use SELECT queries for virtual columns that exist in the __raw__ column and other real columns in your flex tables. Column names are case insensitive.

**Unsupported DDL and DML Statements**

You cannot use the following DDL and DML statements with flex tables:

- CREATE TABLE flex_table AS...
- CREATE TABLE flex_table LIKE...
- SELECT INTO
- UPDATE
Determining Flex Table Data Contents

If you do not know what your flex table contains, two helper functions explore the VMap data to determine its contents. Use these functions to compute the keys in the flex table `raw` column and, optionally, build a view based on those keys:

- **COMPUTE_FLEXTABLE_KEYS**
- **COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW**

For more information about these and other helper functions, see Flex Data Functions Reference

To determine what key value pairs exist as virtual columns:

1. **Call the function as follows:**

```sql
=> SELECT compute_flextable_keys('darkdata');
compute_flextable_keys
------------------------------------------
Please see public.darkdata_keys for updated keys(1 row)
```

2. **View the key names by querying the darkdata_keys table:**

```sql
=> SELECT * FROM darkdata_keys;
```

<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>contributors</td>
<td>8</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>coordinates</td>
<td>8</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>created_at</td>
<td>8</td>
<td>varchar(60)</td>
</tr>
<tr>
<td>entities.hashtags</td>
<td>8</td>
<td>long varbinary(186)</td>
</tr>
<tr>
<td>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>retweeted_status.user.time_zone</td>
<td>1</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>retweeted_status.user.url</td>
<td>1</td>
<td>varchar(68)</td>
</tr>
<tr>
<td>retweeted_status.user.utc_offset</td>
<td>1</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>retweeted_status.user.verified</td>
<td>1</td>
<td>varchar(20)</td>
</tr>
<tr>
<td></td>
<td>(125 rows)</td>
<td></td>
</tr>
</tbody>
</table>
Querying Virtual Columns

Continuing with the JSON data example, use a SELECT statement query to explore content from the virtual columns. Then, analyze what is most important to you in case you want to materialize any virtual columns. This example shows how to query some common virtual columns in the VMap data:

```
=> SELECT "user.name", "user.lang", "user.geo_enabled" FROM darkdata1;
```

```
<table>
<thead>
<tr>
<th>user.name</th>
<th>user.lang</th>
<th>user.geo_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>laughing at clouds.</td>
<td>it</td>
<td>T</td>
</tr>
<tr>
<td>Avita Desai</td>
<td>en</td>
<td>F</td>
</tr>
<tr>
<td>I'm Toaster</td>
<td>es</td>
<td>T</td>
</tr>
<tr>
<td>Uptown gentleman.</td>
<td>en</td>
<td>F</td>
</tr>
<tr>
<td>~G A B R I E L A å¿</td>
<td>en</td>
<td>F</td>
</tr>
<tr>
<td>Flu Beach</td>
<td>es</td>
<td>F</td>
</tr>
<tr>
<td>seydo shi</td>
<td>tr</td>
<td>T</td>
</tr>
<tr>
<td>The End</td>
<td>en</td>
<td>F</td>
</tr>
</tbody>
</table>
```

(12 rows)

Querying Flex Table Keys

If you reference an undefined column ('which_column') in a flex table query, Vertica converts the query to a call to the maplookup() function as follows:

```
MAPLOOKUP(__raw__, 'which_column')
```

The maplookup() function searches the VMap data for the requested key and returns the following information:

- String values associated with the key for a row.
- NULL if the key is not found.

For more information about handling NULL values, see MAPCONTAINSKEY().
Using Functions and Casting in Flex Table Queries

You can cast the virtual columns as required and use functions in your SELECT statement queries. The next example uses a SELECT statement to query the created_at and retweet_count virtual columns, and to cast their values in the process:

```sql
=> SELECT "created_at"::TIMESTAMP, "retweet_count"::INT FROM darkdata1 ORDER BY 1 DESC;
```

<table>
<thead>
<tr>
<th>created_at</th>
<th>retweet_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-10-15 14:41:05</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15 14:41:05</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15 14:41:05</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15 14:41:05</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15 14:41:05</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15 14:41:05</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15 14:41:05</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15 14:41:04</td>
<td>1</td>
</tr>
</tbody>
</table>

(12 rows)

The following query uses the COUNT and AVG functions to determine the average length of text in different languages:

```sql
=> SELECT "user.lang", count (*), avg(length("text"))::int FROM darkdata1 GROUP BY 1 ORDER BY 2 DESC;
```

<table>
<thead>
<tr>
<th>user.lang</th>
<th>count</th>
<th>avg</th>
</tr>
</thead>
<tbody>
<tr>
<td>en</td>
<td>4</td>
<td>42</td>
</tr>
<tr>
<td>es</td>
<td>4</td>
<td>96</td>
</tr>
<tr>
<td>it</td>
<td>1</td>
<td>50</td>
</tr>
<tr>
<td>tr</td>
<td>1</td>
<td>16</td>
</tr>
</tbody>
</table>

(5 rows)

Casting Data Types in a Query

The following query requests the values of the created_at virtual column, without casting to a specific data type:
The next example queries the same virtual column, casting `created_at` to a `TIMESTAMP`. Casting results in different output and the regional time:

```sql
=> SELECT "created_at"::TIMESTAMP FROM darkdata1 ORDER BY 1 DESC;
```

```plaintext
created_at
--------------
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:04
```

### Accessing an Epoch Key

The term *EPOCH* (all uppercase letters) is reserved in Vertica for internal use.

If your JSON data includes a virtual column called `epoch`, you can query it within your flex table. However, use the `maplookup()` function to do so.

### Querying Nested Data

If you load JSON or Avro data with `flatten_arrays=FALSE` (the default), VMap data in the `__raw__` column can contain multiple nested structures. In fact, any VMap JSON or Avro data can contain nested structures. This section describes how best to query such data.
Query VMap Nested Values

To query a nested structure, you can use multiple maplookup() functions, one for each level. However, the most efficient method is to use bracket ([ ]) operators.

When parsing or extracting VMap data, the default behavior is to flatten data. Flattened VMap data concatenates key names into one long name, delimiting elements with either the default delimiter (.), or a user-defined delimiter character.

To use bracket operators for nested structures in your VMap data, the data must not be flattened. Further, you cannot use bracket operators on any existing, flattened VMap data.

To load or extract VMap data correctly, specify flatten_maps=FALSE for fjsonparser, favroparser, and the mapjsonextractor() function.

Note: While bracket operator values look similar to array element specifications, they are strings, not integers. You must enter each nested structure as a string, even if the value is an integer. For example, if the value is 2, specify it as ['2'], not [2].

Bracket Operators For Nested JSON

This example uses the following JSON data as an example of nested data. Save this data as restaurant.json:

```json
{
    "restaurant": {
        "_name_": "Bob's pizzeria",
        "cuisine": "Italian",
        "location": {
            "city": "Cambridge",
            "zip": "02140"
        },
        "menu": [
            {
                "item": "cheese pizza",
                "price": "$8.25"
            },
            {
                "item": "chicken pizza",
                "price": "$11.99"
            },
            {
                "item": "spinach pizza",
                "price": "$10.50"
            }
        ]
    }
}
```

Create a flex table, rests, and load it with the restaurant.json file:

```sql
=> COPY rests FROM '/home/dbadmin/tempdat/restaurant.json' PARSER fjsonparser (flatten_maps=false);
Rows Loaded
```
After loading your data into a flex table, there are two ways to access nested data using brackets:

- Beginning with the __raw__ column, followed by the character values in brackets
- Starting with the name of the top-most element, followed by the character values in brackets

Both methods are equally efficient. Here are examples of both:

=> SELECT __raw__['restaurant']['location']['city'] FROM rests;

<table>
<thead>
<tr>
<th><strong>raw</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Cambridge</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>

=> SELECT restaurant['location']['city'] from rests;

<table>
<thead>
<tr>
<th>restaurant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cambridge</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>

**Bracket Operators for Twitter Data**

This example shows how to extract some basic information from Twitter data.

After creating a flex table, tweets, and loading in some data, the flex table has a block of tweets.

In the following SELECT statement, notice how to specificy the __raw__ column of table tweets, followed by the bracket operators to define the virtual columns of interest (['delete'] ['status'] ['user_id']). This query uses the COUNT() function to calculate the number of deleted tweets and outputs 10 results:

=> SELECT __raw__['delete']['status']['user_id'] as UserId, COUNT(*) as TweetsDelete from tweets
 => WHERE mapcontainskey(__raw__, 'delete')
 => GROUP BY __raw__['delete']['status']['user_id']
 => ORDER BY TweetsDelete DESC, UserId ASC LIMIT 10;

<table>
<thead>
<tr>
<th>UserId</th>
<th>TweetsDelete</th>
</tr>
</thead>
<tbody>
<tr>
<td>106979547</td>
<td>4</td>
</tr>
<tr>
<td>403474369</td>
<td>4</td>
</tr>
<tr>
<td>181188657</td>
<td>3</td>
</tr>
<tr>
<td>223136123</td>
<td>3</td>
</tr>
<tr>
<td>770139481</td>
<td>3</td>
</tr>
</tbody>
</table>
Querying Flex Views

Flex tables offer the ability of dynamic schema through the application of query rewriting. Use flex views to support restricted access to flex tables. As with flex tables, each time you use a select query on a flex table view, internally, Vertica invokes the maplookup() function, to return information on all virtual columns. This query behavior occurs for any flex or columnar table that includes a __raw__ column.

This example illustrates querying a flex view:

1. Create a flex table.

   ```sql
   => CREATE FLEX TABLE twitter();
   ```

2. Load JSON data into flex table using fjsonparser.

   ```sql
   => COPY twitter FROM '/home/dbadmin/data/flex/tweets_10000.json' PARSER fjsonparser();
   Rows Loaded
   10000
   (1 row)
   ```

3. Create a flex view on top of flex table twitter with constraint retweet_count>0.

   ```sql
   => CREATE VIEW flex_view AS SELECT __raw__ FROM twitter WHERE retweet_count::int > 0;
   CREATE VIEW
   ```

4. Query the view. First 5 rows are displayed.

   ```sql
   => SELECTretweeted,retweet_count,source FROM (select __raw__ from flex_view) t1 limit 5;
<table>
<thead>

### Listing Flex Tables

You can determine which tables in your database are flex tables by querying the `is_flextable` column of the `v_catalog.tables` system table. For example, use a query such as the following to see all tables with a true (t) value in the `is_flextable` column:

```sql
=> SELECT table_name, table_schema, is_flextable FROM v_catalog.tables;
```

<table>
<thead>
<tr>
<th>table_name</th>
<th>table_schema</th>
<th>is_flextable</th>
</tr>
</thead>
<tbody>
<tr>
<td>bake1</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>bake1_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>del</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>del_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>delicious</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>delicious_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>bake</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>bake_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>appLog</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>appLog_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>darkdata</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>darkdata_keys</td>
<td>public</td>
<td>f</td>
</tr>
</tbody>
</table>

(12 rows)

### Setting Flex Table Configuration Parameters

These configuration parameters affect flex table usage:

- `EnableBetterFlexTypeGuessing`
- `FlexTableRawSize`
- `FlexTableDataTypeGuessMultiplier`

This section presents information about each of the parameters.

To change configuration parameters, and to understand parameter scope, see Setting Configuration Parameter Values and General Parameters in the Administrator's Guide.

### Using EnableBetterFlexTypeGuessing

The `EnableBetterFlexTypeGuessing` configuration parameter is 1 (ON) by default. This setting results in the `COMPUTE_FLEXTABLE_KEYS` or `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW` functions determining data types for string and non-string keys. If you change
the configuration parameter to 0 (OFF), the functions determine all flex keys as string types (\([\text{LONG}]\text{VARCHAR}\)) or (\([\text{LONG}]\text{VARBINARY}\)).

You can set this configuration parameter at the database and session level.

For examples of using both settings, see Computing Flex Table Keys.

**Specifying the FlexTableRawSize Parameter**

The FlexTableRawSize parameter defines the default width of each flex table \(\_\text{raw}\_\) column. This column is a \text{LONG VARBINARY} data type, and contains the map data you load into the table.

Setting this configuration parameter does not affect any existing flex tables, only the default width for new flex tables you create after changing FlexTableRawSize.

Effective Vertica 9.2.1, you can set this configuration parameter at the database and session level.

To change the \(\_\text{raw}\_\) column width of an existing flex table, use the ALTER TABLE statement, described in Materializing Flex Tables.

**Redefining the FlexTableDataTypeGuessMultiplier**

After loading data into a flex table, each key in the \(\_\text{raw}\_\) column is a \text{LONG VARBINARY} data type.

When you compute flex table keys with either of the functions, COMPUTE_FLEXTABLE KEYS or COMPUTE_FLEXTABLE KEYS_AND_BUILD_VIEW, the functions cast each key to the applicable Vertica data type. The key value length is determined by the key's largest value, multiplied by the FlexTableDataTypeGuessMultiplier factor. Padding the column width with the multiplier supports future data load key values at least twice the largest key value previously loaded.

The flex keys table that both flex functions populate is used to create the associated flex table view.
Note:
The FlexTableDataTypeGuessMultiplier value is not used to calculate the width of any real columns in a flex table.

**Flex Data Functions Reference**

The flex table data helper functions supply information you need to query the data you load. For example, suppose you don't know what keys are available in the map data. If not, you can use the `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW` function to populate a keys table and build a view. The functions aid in querying flex table and other VMap data.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>COMPUTE_FLEXTABLE_KEYS</strong></td>
<td>Computes map keys from the map data in a flextable_data table, and populates the flextable_data_keys table with the computed keys. Use this function before building a view.</td>
</tr>
<tr>
<td><strong>BUILD_FLEXTABLE_VIEW</strong></td>
<td>Uses the keys in the flextable_data_keys table to create a view definition (flextable_data_view) for the flextable_data table. Use this function after computing flex table keys.</td>
</tr>
<tr>
<td><strong>COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW</strong></td>
<td>Performs both of the preceding functions in one call.</td>
</tr>
<tr>
<td><strong>MATERIALIZE_FLEXTABLE_COLUMNS</strong></td>
<td>Materializes a default number of columns (50) or more or less, if specified.</td>
</tr>
<tr>
<td><strong>RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW</strong></td>
<td>Replaces the flextable_data_keys table and the flextable_data_view, linking both the keys table and the view to the parent flex table.</td>
</tr>
</tbody>
</table>

While the functions are available to all users, they are applicable only to:

- Flex tables
- Associated `flex_table_keys` tables
- Associated `flex_table_view` views

By computing keys and creating views from flex table data, the functions allow you to perform SELECT queries. One function restores the original keys table and view that you specified when you first created the flex table.
Flex Table Dependencies

Each flex table (*flextable*) has two dependent objects:

- *flextable_keys*
- *flextable_view*

While both objects are dependent on their parent table, (*flextable*), you can drop either object independently. Dropping the parent table removes both dependents, without a CASCADE option.

Associating Flex Tables and Views

The helper functions automatically use the dependent table and view if they are internally linked with the parent table. You create both when you create the flex table. You can you drop either the _keys table or the _view, and re-create objects of the same name. However, if you do so, the new objects are not internally linked with the parent flex table.

In this case, you can restore the internal links of these objects to the parent table. To do so, drop the _keys table and the _view before calling the `RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW` function. Calling this function re-creates either, or both, the _keys table and the _view.

The remaining helper functions perform the tasks described in this section.

BUILD_FLEXTABLE_VIEW

Creates, or re-creates, a view for a default or user-defined _keys table, ignoring any empty keys.

**Note:**
If the length of a key exceeds 65,000, Vertica truncates the key.

**Syntax**

```
```
Arguments

[database.]schema  Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:

myschema.thisDbObject

If you specify a database, it must be the current database.

flex-table  The flex table name. By default, this function builds or rebuilds a view for the input table with the current contents of the associated flex_table_keys table.

view-name  A custom view name. Use this option to build a new view for flex-table with the name you specify.

user-keys-table  Specifies a keys table from which to create the view. Use this option if you created a custom user_keys table from the flex table map data, rather than from the default flex_table_keys table. The function builds a view from the keys in user_keys table, rather than from the flex_table_keys table.

Examples

The following examples show how to call build_flextable_view with 1, 2, or 3 arguments.

Creating a Default View

To create, or re-create, a default view:

1. Call the function with an input flex table, darkdata:

```sql
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata');
build_flextable_view

The view public.darkdata_view is ready for querying
(1 row)
```

The function creates a view with the default name (darkdata_view) from the darkdata_keys table.
2. Query a key name (user.id) from the new or updated view:

```sql
=> SELECT "user.id" FROM darkdata_view;
user.id
---------
340857907
727774963
390498773
288187825
164464905
125434448
601328899
352494946
(12 rows)
```

**Creating a Custom Name View**

To create, or re-create, a view with a custom name:

1. Call the function with two arguments, an input flex table, darkdata, and the name of the view to create, dd_view:

```sql
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view');
build_flextable_view
-------------------------------------
The view public.dd_view is ready for querying
(1 row)
```

2. Query a key name (user.lang) from the new or updated view (dd_view):

```sql
=> SELECT "user.lang" FROM dd_view;
user.lang
---------
tr
en
es
en
it
es
en
(12 rows)
```

**Creating a View from a Custom Keys Table**

To create a view from a custom_keys table with build_flextable_view, the custom table must have the same schema and table definition as the default table (darkdata_keys). Create a custom keys table, using any of these three approaches:

1. Create a columnar table with all keys from the default keys table for a flex table (darkdata_keys):
CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys;

2. Create a columnar table without content (LIMIT 0) from the default keys table for a flex table (darkdata_keys):

CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys LIMIT 0;

CREATE TABLE kdb=>
SELECT * FROM new_darkdata_keys;

key_name | frequency | data_type_guess
----------|-----------|------------------
         |           |                 
(0 rows)

3. Create a columnar table without content (LIMIT 0) from the default keys table, and insert two values ('user.lang', 'user.name') into the key_name column:

CREATE TABLE dd_keys AS SELECT * FROM darkdata_keys limit 0;
CREATE TABLE =>
INSERT INTO dd_keys (key_name) values ('user.lang');
OUTPUT
-------
1
(1 row)
=> INSERT INTO dd_keys (key_name) values ('user.name');
OUTPUT
-------
1
(1 row)
=> SELECT * FROM dd_keys;
key_name | frequency | data_type_guess
----------|-----------|------------------
user.lang |           |                 |
user.name |           |                 |
(2 rows)

4. After creating a custom keys table, call build_flextable_view with all arguments (an input flex table, the new view name, the custom keys table):

SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view', 'dd_keys');
build_flextable_view
-----------------------------------------------
The view public.dd_view is ready for querying
(1 row)

5. Query the new view:

=> SELECT * FROM dd_view;

=> CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys;
See Also

- COMPUTE_FLEXTABLE_KEYS
- COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW
- MATERIALIZE_FLEXTABLE_COLUMNS
- RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW

**COMPUTE_FLEXTABLE_KEYS**

Computes the virtual columns (keys and values) from the flex table VMap data. Use this function to compute keys without creating an associated table view. To also build a view, use **COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW**.

**Note:**
If the length of a key exceeds 65,000, Vertica truncates the key.

The function stores its results in the associated flex_keys table, which has the following columns:

- key_name
- frequency
- data_type_guess

For more information, see **Computing Flex Table Keys**.

**Syntax**

`COMPUTE_FLEXTABLE_KEYS('[[database.]schema.]flex-table')`

**Arguments**

<table>
<thead>
<tr>
<th>*database.]*schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>myschema.thisDbObject</td>
<td></td>
</tr>
</tbody>
</table>
If you specify a database, it must be the current database.

| flex-table | Name of a flex table. |

Using Data Type Guessing

The results of the flex_keys table data_type_guess column depend on the EnableBetterFlexTypeGuessing configuration parameter. By default, the parameter is 1 (ON). This setting results in the function returning all non-string keys in the data_type_guess column as one of the following types (and others listed in SQL Data Types):

- BOOLEAN
- INTEGER
- FLOAT
- TIMESTAMP
- DATE

Setting the configuration parameter to 0 (OFF), results in the function returning only string types ([LONG]VARCHAR) or ([LONG] VARBINARY) for all values in the data_type_guess column of the flex_keys table.

Assigning Flex Key Data Types

Use the sample CSV data in this section to compare the results of using or not using the EnableBetterFlexTypeGuessing configuration parameter. When the parameter is ON, the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

<table>
<thead>
<tr>
<th>Year, Quarter, Region, Species, Grade, Pond Value, Number of Quotes, Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015, 1, 2 - Northwest Oregon &amp; Willamette, Douglas-fir, P, $615.12, 12, No</td>
</tr>
<tr>
<td>2015, 1, 2 - Northwest Oregon &amp; Willamette, Douglas-fir, SM, $610.78, 12, Yes</td>
</tr>
<tr>
<td>2015, 1, 2 - Northwest Oregon &amp; Willamette, Douglas-fir, 2S, $596.00, 20, Yes</td>
</tr>
<tr>
<td>2015, 1, 2 - Northwest Oregon &amp; Willamette, Hemlock, P, $520.00, 6, Yes</td>
</tr>
<tr>
<td>2015, 1, 2 - Northwest Oregon &amp; Willamette, Hemlock, SM, $510.00, 6, No</td>
</tr>
<tr>
<td>2015, 1, 2 - Northwest Oregon &amp; Willamette, Hemlock, 2S, $490.00, 14, No</td>
</tr>
</tbody>
</table>

To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as trees.csv).
2. Create a flex table (trees) and load trees.csv using the fcsvparsers.
CREATE FLEX TABLE trees;
COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser;

3. Use COMPUTE_FLEXTABLE_KEYS with the trees flex table.

=> SELECT COMPUTE_FLEXTABLE_KEYS('trees');

        COMPUTE_FLEXTABLE_KEYS
---------------------------------------------------------------------
Please see public.trees_keys for updated keys
(1 row)

4. Query the trees_keys table output:

=> SELECT * FROM trees_keys;

<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year</td>
<td>6</td>
<td>Integer</td>
</tr>
<tr>
<td>Quarter</td>
<td>6</td>
<td>Integer</td>
</tr>
<tr>
<td>Region</td>
<td>6</td>
<td>Varchar(66)</td>
</tr>
<tr>
<td>Available</td>
<td>6</td>
<td>Boolean</td>
</tr>
<tr>
<td>Number of Quotes</td>
<td>6</td>
<td>Integer</td>
</tr>
<tr>
<td>Grade</td>
<td>6</td>
<td>Varchar(20)</td>
</tr>
<tr>
<td>Species</td>
<td>6</td>
<td>Varchar(22)</td>
</tr>
<tr>
<td>Pond Value</td>
<td>6</td>
<td>Numeric(8,3)</td>
</tr>
</tbody>
</table>

(8 rows)

5. Set the EnableBetterFlexTypeGuessing parameter to 0 (OFF).
6. Call COMPUTE_FLEXTABLE_KEYS with the trees flex table again.
7. Query the trees_keys table to compare the data_type_guess values with the previous results. Without the configuration parameter set, all of the non-string data types are VARCHARS of various lengths:

=> SELECT * FROM trees_keys;

<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Quarter</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Region</td>
<td>6</td>
<td>varchar(66)</td>
</tr>
<tr>
<td>Available</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Grade</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Number of Quotes</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Pond Value</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Species</td>
<td>6</td>
<td>varchar(22)</td>
</tr>
</tbody>
</table>

(8 rows)

8. To maintain accurate results for non-string data types, set the EnableBetterFlexTypeGuessing parameter back to 1 (ON).

For more information about setting the EnableBetterFlexTypeGuessing configuration parameter, see Setting Flex Table Configuration Parameters.
See Also

- MATERIALIZE_FLEXTABLE_COLUMNS
- RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW

COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW

Combines the functionality of BUILD_FLEXTABLE_VIEW and COMPUTE_FLEXTABLE_KEYS to compute virtual columns (keys) from the VMap data of a flex table and construct a view. Creating a view with this function ignores empty keys. If you do not need to perform both operations together, use one of the single-operation functions instead.

Note:
If the length of a key exceeds 65,000, Vertica truncates the key.

Syntax

COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('flex-table')

Arguments

| flex-table | Name of a flex table |

Examples

This example shows how to call the function for the darkdata flex table.

```sql
=> SELECT COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('darkdata');

compute_flextable_keys_and_build_view

Please see public.darkdata_keys for updated keys
The view public.darkdata_view is ready for querying
```
See Also

- BUILD_FLEXTABLE_VIEW
- COMPUTE_FLEXTABLE_KEYS
- MATERIALIZE_FLEXTABLE_COLUMNS
- RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW

MATERIALIZE_FLEXTABLE_COLUMNS

Materializes virtual columns listed as key_names in the flextable_keys table you compute using either COMPUTE_FLEXTABLE_KEYS or COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW.

Note:
Each column that you materialize with this function counts against the data storage limit of your license. To check your Vertica license compliance, call the AUDIT() or AUDIT_FLEX() functions.

Syntax

MATERIALIZE_FLEXTABLE_COLUMNS('[[database.]schema.]flex-table' [, n-columns [, keys-table-name] ])

Arguments

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>flex-table</td>
<td>The name of the flex table with columns to materialize. Specifying only the flex table name attempts to materialize up</td>
</tr>
</tbody>
</table>
to 50 columns of key names in the default flex_table_keys table. When you use this argument, the function:

- Skips any columns already materialized
- Ignores any empty keys

To materialize a specific number of columns, use the optional parameter \( n\text{-}columns \), described next.

<table>
<thead>
<tr>
<th>( n\text{-}columns )</th>
<th>The number of columns to materialize. The function attempts to materialize the number of columns from the flex_table_keys table, skipping any columns already materialized. Vertica tables support a total of 1600 columns, which is the largest value you can specify for ( n\text{-}columns ). The function orders the materialized results by frequency, descending, key_name when materializing the first ( n ) columns.</th>
</tr>
</thead>
</table>
| \( keys\text{-}table\text{-}name \) | The name of a flex_keys_table from which to materialize columns. The function:

- Materializes the number of columns (value of \( n\text{-}columns \)) from \( keys\text{-}table\text{-}name \)
- Skips any columns already materialized
- Orders the materialized results by frequency, descending, key_name when materializing the first \( n \) columns. |

### Examples

The following example shows how to call \texttt{MATERIALIZE\_FLEXTABLE\_COLUMNS} to materialize columns. First, load a sample file of tweets (\texttt{tweets\_10000.json}) into the flex table \texttt{twitter\_r}.

After loading data and computing keys for the sample flex table, call \texttt{materialize_flextable_columns} to materialize the first four columns:

```sql
=> COPY twitter_r FROM '/home/release/KData/tweets_10000.json' parser fjsonparser();
Rows Loaded
---------------
10000
(1 row)
=> SELECT compute_flextable_keys ('twitter_r');
compute_flextable_keys

-----------------------------------------------
```
Please see public.twitter_r_keys for updated keys
(1 row)

=> select materialize_flextable_columns('twitter_r', 4);
materialize_flextable_columns

The following columns were added to the table public.twitter_r:
  contributors
  entities.hashtags
  entities.urls

For more details, run the following query:
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and table_name = 'twitter_r';

(1 row)

The last message in the example recommends querying system table MATERIALIZE_FLEXTABLE_COLUMNS_RESULTS for the results of materializing the columns, as shown:

=> SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and table_name = 'twitter_r';
table_id | table_schema | table_name | creation_time  | key_name | status | message
----------+--------------+------------+----------------+---------+--------+-----------------------------
        45035996273733172 | public       | twitter_r  | 2013-11-20 17:00:27.945484-05 | contributors | ADDED | Added successfully
45035996273733172 | public       | twitter_r  | 2013-11-20 17:00:27.94551-05  | entities.hashtags | ADDED | Added successfully
45035996273733172 | public       | twitter_r  | 2013-11-20 17:00:27.945519-05 | entities.urls | ADDED | Added successfully
45035996273733172 | public       | twitter_r  | 2013-11-20 17:00:27.945532-05 | created_at | EXISTS | Column of same name already
(4 rows)

See Also

- BUILD_FLEXTABLE_VIEW
- COMPUTE_FLEXTABLE KEYS
- COMPUTE_FLEXTABLE KEYS_AND_BUILD_VIEW
- RESTORE_FLEXTABLE_DEFAULT KEYS_TABLE_AND_VIEW
RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW

Restores the _keys table and the _view. The function also links the _keys table with its associated flex table, in cases where either table is dropped. The function also indicates whether it restored one or both objects.

Syntax

RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('flex-table')

Arguments

| flex-table | Name of a flex table |

Examples

This example shows how to invoke this function with an existing flex table, restoring both the _keys table and _view:

```sql
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
\n```

The keys table public.darkdata_keys was restored successfully.
The view public.darkdata_view was restored successfully.
(1 row)

This example illustrates that the function restored darkdata_view, but that darkdata_keys did not need restoring:

```sql
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
\n```

The keys table public.darkdata_keys already exists and is linked to darkdata.
The view public.darkdata_view was restored successfully.
(1 row)

After restoring the _keys table, there is no content. To populate the flex keys, call the COMPUTE_FLEXTABLE_KEYS meta function.

Flex Extractor Functions Reference

The extractor scalar functions process polystructured data:

Each function accepts input data that is:

- Existing database content
- A table
- Returned from an expression
- Entered directly

These functions do not parse data from an external file source. All functions return a single VMap value. The extractor functions can return data with NULL-specified columns.

This section describes each extractor function.

**MAPDELMITTEDEXTRACTOR**

Extracts data with a delimiter character, and other optional arguments, returning a single VMap value. The USING PARAMETERS phrase specifies optional parameters for the function.

**Syntax**

```sql
MAPDELMITTEDEXTRACTOR (record_value USING PARAMETERS delimiter=character [,header_names= value,] [trim= value,] [treat_empty_val_as_null = value,])
```
Arguments

| record_value | VARCHAR | String containing a JSON or delimited format record on which the expression will be applied. |

Parameters

<table>
<thead>
<tr>
<th>delimiter</th>
<th>VARCHAR</th>
<th>Single delimiter character.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default value:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>header_names</th>
<th>VARCHAR</th>
<th>[Optional] Specifies header names for columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default value: ucoln</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Where $n$ is the column offset number, starting with 0 for the first column. The function uses default values if you do not specify values for the header_names parameter.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>trim</th>
<th>BOOLEAN</th>
<th>[Optional] Trims white space from header names and field values.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default value: true</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>treat_empty_val_as_null</th>
<th>BOOLEAN</th>
<th>[Optional] Specifies that empty fields become NULLs, rather than empty strings ('').</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default value: true</td>
</tr>
</tbody>
</table>

Examples

These examples use a short set of delimited data:

<table>
<thead>
<tr>
<th>Name</th>
<th>CITY</th>
<th>New city</th>
<th>State</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tom</td>
<td>BOSTON</td>
<td>boston</td>
<td>MA</td>
<td>01</td>
</tr>
<tr>
<td>Eric</td>
<td>Burlington</td>
<td>BURLINGTON</td>
<td>MA</td>
<td>02</td>
</tr>
<tr>
<td>Jamie</td>
<td>cambridge</td>
<td>CAMBRIDGE</td>
<td>MA</td>
<td>08</td>
</tr>
</tbody>
</table>
To begin, save this data as `delim.dat`.

1. Create a flex table, `dflex`:

```sql
=> CREATE FLEX TABLE dflex();
CREATE TABLE
```

2. Use COPY to load the `delim.dat` file. Use the flex tables `fdelimitedparser` with the `header='false'` option:

```sql
=> COPY dflex FROM '/home/release/kmm/flextables/delim.dat' parser fdelimitedparser (header='false');
Rows Loaded
-----------
   4
(1 row)
```

3. Create a columnar table, `dtab`, with an identity `id` column, a `delim` column, and a column to hold a VMap, named `vmap`:

```sql
=> CREATE TABLE dtab (id IDENTITY(1,1), delim varchar(128), vmap long varbinary(512));
CREATE TABLE
```

4. Use COPY to load the `delim.dat` file into the `dtab` table. For the `mapdelimitedextractor` function, add a header row with `USING PARAMETERS header_names=` option to specify the header row for the sample data, along with `delimiter '!'`:

```sql
=> COPY dtab(delim, vmap AS MAPDELIMITEDEXTRACTOR (delim
    USING PARAMETERS header_names='Name|CITY|New City|State|Zip') FROM
  '/home/dbadmin/data/delim.dat' DELIMITER '!');
Rows Loaded
-----------
   4
(1 row)
```

5. Use `maptostring` for the flex table `dflex` to view the `__raw__` column contents. Notice the default header names in use (`ucol0` – `ucol4`), since you specified `header='false'` when you loaded the flex table:

```sql
=> SELECT MAPTOSTRING(__raw__) FROM dflex limit 10;
maptostring

{  
  "ucol0" : "Jamie",
  "ucol1" : "cambridge",
  "ucol2" : "CAMBRIDGE",
  "ucol3" : "MA",
  "ucol4" : "08"
}
6. Use `maptostring` again, this time with the `dtab` table's `vmap` column. Compare the results of this output to those for the `flex` table. Note that `maptostring` returns the `header_name` parameter values you specified when you loaded the data:

```sql
=> SELECT MAPTOSTRING(vmap) FROM dtab;

maptostring

| { "CITY" : "CITY", "Name" : "Name", "New City" : "New city", "State" : "State", "Zip" : "zip" }
| { "CITY" : "BOSTON", "Name" : "Tom", "New City" : "boston", "State" : "MA", "Zip" : "02121" }
| { "CITY" : "Burlington", "Name" : "Eric", "New City" : "BURLINGTON", "State" : "MA", "Zip" : "02482" }
```
7. Query the `delim` column to view the contents differently:

```sql
=> SELECT delim FROM dtab;
   delim
-----------------------
 Name|CITY|New city|State|zip
 Tom|BOSTON|boston|MA|02121
 Eric|Burlington|BURLINGTON|MA|02482
 Jamie|cambridge|CAMBRIDGE|MA|02811
(4 rows)
```

---

### MAPJSONEXTRACTOR

Extracts content of repeated JSON data objects, including nested maps, or data with an outer list of JSON elements. The USING PARAMETERS phrase specifies optional parameters for the function. Empty input does not generate a Warning or Error.

**Note:** The function fails if the output size of the function is greater than 65000.

**Syntax**

```sql
MAPJSONEXTRACTOR (record_value [USING PARAMETERS [flatten_maps=value]
                     [flatten_arrays=value]
                     [reject_on_duplicate=value]
                     [reject_on_empty_key=value]
                     [omit_empty_keys=value]
                     [start_point=value]])
```
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record_value</td>
<td>VARCHAR</td>
<td>String containing a JSON or delimited format record on which the expression will be applied.</td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flatten_maps</td>
<td>BOOLEAN</td>
<td>[Optional] Flattens sub-maps within the JSON data, separating map levels with a period (.)&lt;br&gt;<strong>Default value:</strong> true</td>
</tr>
<tr>
<td>flatten_arrays</td>
<td>BOOLEAN</td>
<td>[Optional] Converts lists to sub-maps with integer keys. Lists are not flattened by default.&lt;br&gt;<strong>Default value:</strong> false</td>
</tr>
<tr>
<td>reject_on_duplicate</td>
<td>BOOLEAN</td>
<td>[Optional] Specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues.&lt;br&gt;<strong>Default value:</strong> false</td>
</tr>
<tr>
<td>reject_on_empty_key</td>
<td>BOOLEAN</td>
<td>[Optional] ReJECTS any row containing a key without a value (reject_on_empty_key=true).&lt;br&gt;<strong>Default value:</strong> false</td>
</tr>
<tr>
<td>omit_empty_keys</td>
<td>BOOLEAN</td>
<td>[Optional] Omits any key from the load data that does not have a value (omit_empty_keys=true).&lt;br&gt;<strong>Default value:</strong> false</td>
</tr>
<tr>
<td>start_point</td>
<td>CHAR</td>
<td>[Optional] Specifies the name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the start_point value. The parser processes data after the first instance, and up to the second, ignoring any remaining data.&lt;br&gt;<strong>Default value:</strong> none</td>
</tr>
</tbody>
</table>
Examples

These examples use the following sample JSON data:

```json
{  "id": "5001",  "type": "None" }
{  "id": "5002",  "type": "Glazed" }
{  "id": "5005",  "type": "Sugar" }
{  "id": "5007",  "type": "Powdered Sugar" }
{  "id": "5004",  "type": "Maple" }
```

Save this example data as bake_single.json, and load that file.

1. Create a flex table, `flexjson`:

```sql
=> CREATE FLEX TABLE flexjson();
CREATE TABLE
```

2. Use COPY to load the `bake_single.json` file with the `fjsonparser` parser:

```sql
=> COPY flexjson FROM '/home/dbadmin/data/bake_single.json' parser fjsonparser();  
Rows Loaded                        5  
(1 row)
```

3. Create a columnar table, `coljson`, with an identity column `id`, a `json` column, and a column to hold a VMap, called `vmap`:

```sql
=> CREATE TABLE coljson(id IDENTITY(1,1), json varchar(128), vmap long varbinary(10000));
CREATE TABLE
```

4. Use COPY to load the `bake_single.json` file into the `coljson` table, using the `mapjsonextractor` function:

```sql
=> COPY coljson (json, vmap AS MapJSONExtractor(json)) FROM '/home/dbadmin/data/bake_ 
  single.json';
Rows Loaded                        5  
(1 row)
```

5. Use the `maptostring` function for the flex table `flexjson` to output the `__raw__` column contents as strings:

```sql
=> SELECT MAPTOSTRING(__raw__) FROM flexjson limit 5;
maptostring
----------------------------------------
{
```
6. Use the maptostring function again, this time with the coljson table's vmap column and compare the results. The element order differs:

```sql
=> SELECT MAPTOSTRING(vmap) FROM coljson limit 5;
maptostring
-----------------------------------------------
{ "id" : "5001",
 "type" : "None"
 }
{ "id" : "5002",
 "type" : "Glazed"
 }
{ "id" : "5004",
 "type" : "Maple"
 }
{ "id" : "5005",
 "type" : "Sugar"
 }
{ "id" : "5007",
 "type" : "Powdered Sugar"
 }
(5 rows)
```
See Also

- MAPDELIMITEDEXTRACTOR
- MAPREGEXEXTRACTOR

MAPREGEXEXTRACTOR

Extracts data from a regular expression and returns the results as a VMap. Use the USING PARAMETERS pattern= phrase, followed by the regular expression.

Syntax

MAPREGEXEXTRACTOR (record_value USING PARAMETERS pattern = phrase 
[,use jit = value,] 
[record terminator = value,] 
[logline column = value]])

Arguments

| record_value       | VARCHAR | String containing a JSON or delimited format record on which the expression will be applied. |

Parameters

| pattern=           | VARCHAR | The regular expression as a string.  
|                   |         | **Default value:** An empty string (""). |
| use jit            | BOOLEAN | [Optional] Uses just-in-time compiling when parsing the regular expression.  
|                   |         | **Default value:** false. |
| record terminator  | VARCHAR | [Optional] The character used to separate input records. |
**Examples**

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread_name, and thread_id strings.

**Caution:**
For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, \(<\text{thread_id}(?:0x)?[0-9a-f]+\).

```
'^\(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+\)
 \(?<thread_name>[A-Za-z] \)?\(?<thread_id>(?:0x)?[0-9a-f]+\)
\(?<\text>\w+\)' \(?<\text>\w+\) @\(?<\text>\w+\): \)
\(?<\text>\w+\)
```

The following examples may include newline characters for display purposes.

1. Create a flex table, `flogs`:

   ```sql
   => CREATE FLEX TABLE flogs();
   CREATE TABLE
   ```

2. Use COPY to load a sample log file (`vertica.log`), using the flex table `fregexparser`. Note that this example includes added line characters for displaying long text lines.

   ```sql
   => COPY flogs FROM '/home/dbadmin/tempdat/vertica.log' PARSER FREGEXPARSER(pattern='^\(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+\) \(?<thread_name>[A-Za-z] \)?\(?<thread_id>(?:0x)?[0-9a-f]+\)\(?<\text>\w+\)\)
\(?<\text>\w+\) @\(?<\text>\w+\): \)
\(?<\text>\w+\)' \(?<\text>\w+\) @\(?<\text>\w+\): \)
\(?<\text>\w+\)
   Rows Loaded
   81399
   (1 row)
   ```
3. Use MapToString to return the results from calling MapRegexExtractor with a regular expression. The output returns the results of the function in string format.

```sql
=> SELECT MAPTOSTRING(MapregexExtractor(E'2014-04-02 04:02:51.011
TM Moveout:0x2aab9000f860-a000000002067 [Txn] <INFO>
Begin Txn: a000000002067 \"Moveout: Tuple Mover\" using PARAMETERS
pattern="(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+)"
  (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f]+)?(?<component>\w+)
\(?<level>\w+\) (?<text>.*)") FROM flogs where __identity__=13;
maptostring

---
{
  "component": "Txn",
  "level": "INFO",
  "text": "Begin Txn: a000000002067 'Moveout: Tuple Mover'",
  "thread_id": "0x2aab9000f860",
  "thread_name": "TM Moveout",
  "time": "2014-04-02 04:02:51.011",
  "transaction_id": "a0000000002067"
}
(1 row)
```

Flex Map Functions Reference

The flex map functions let you extract and manipulate nested map data.

The first argument of all flex map functions (except emptymap() and mapaggregate()) takes a VMap. The VMap can originate from the __raw__ column in a flex table or be returned from a map or extraction function.

All map functions (except for emptymap() and mapaggregate()), accept either a LONG VARBINARY or a LONG VARCHAR map argument.

In the following example, the outer maplookup() function operates on the VMap data returned from the inner maplookup() function:

```sql
=> maplookup(maplookup(ret_map, 'batch'), 'scripts')
```

You can use flex map functions with:
• Flex tables
• Their associated `{flextable}_keys` table
• Automatically generated `{flextable}_view` views.

However, use of these functions does not apply to standard Vertica tables.

**EMPTYMAP**

Constructs a new VMap with one row but without keys or data. Use this transform function to populate a map without using a flex parser. Instead, you use either from SQL queries or from map data present elsewhere in the database.

**Syntax**

```sql
EMPTYMAP()
```

**Arguments**

None

**Examples**

Create an Empty Map

```sql
=> SELECT EMPTYMAP();
emptymap
-----------------------------
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000
(1 row)
```

Create an Empty Map from an Existing Flex Table

If you create an empty map from an existing flex table, the new map has the same number of rows as the table from which it was created.

This example shows the result if you create an empty map from the `darkdata` table, which has 12 rows of JSON data:
=> SELECT EMPTYMAP() FROM darkdata;

```
emptymap
```
(12 rows)

### See Also

- `MAPCONTAINSKEY`
- `MAPCONTAINSVALUE`
- `MAPITEMS`
- `MAPKEYS`
- `MAPKEYSINFO`
- `MAPLOOKUP`
- `MAPSIZE`
- `MAPTOSTRING`
- `MAPVALUES`
- `MAPVERSION`

### MAPAGGREGATE

Returns a LONG VARBINARY VMap with keys and value pairs supplied from two VARCHAR input columns of an existing columnar table. Using this function requires specifying an `over()` clause for the source table.

### Syntax

```
MAPAGGREGATE(source_column1, source_column2)
```
**Arguments**

<table>
<thead>
<tr>
<th>source_column1</th>
<th>Table column with values to use as the keys of the key/value pair of the returned VMap data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_column2</td>
<td>Table column with values to use as the values in the key/value pair of the returned VMap data.</td>
</tr>
</tbody>
</table>

**Examples**

This example creates a columnar table `btest`, with two VARCHAR columns, named `keys` and `values`, and adds three sets of values:

```sql
=> CREATE TABLE btest(keys varchar(10), values varchar(10));
CREATE TABLE
=> COPY btest FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> one|1
>> two|2
>> three|3
>> .
```

After populating the `btest` table, call `mapaggregate()`, using the `OVER(PARTITION BEST)` clause. This call returns the `raw_map` data:

```sql
=> SELECT MAPAGGREGATE(keys, values) OVER(PARTITION BEST) FROM btest;
raw_map
-----------------------------------------------
{"one": "1","three": "3","two": "2"}
(1 row)
```

The next example illustrates using `MAPTOSTRING()` with the returned `raw_map` from `mapaggregate()` to see the values:

```sql
=> SELECT MAPTOSTRING(raw_map) FROM (SELECT MAPAGGREGATE(keys, values) OVER(PARTITION BEST) FROM btest) bit;
maptoString
-----------------------------------------------
{"one": "1","three": "3","two": "2"}
(1 row)
```

- MAPCONTAINSKEY
- MAPCONTAINVALUE
- MAPITEMS
- MAPKEYS
- MAPKEYSINFO
- MAPLOOKUP
- MAPSIZE
- MAPTOSTRING
- MAPVALUES
- MAPVERSION

MAPCONTAINSKEY

Determines whether a VMap contains a virtual column (key). This scalar function returns true (t), if the virtual column exists, or false (f) if it does not. Determining that a key exists before calling maplookup() lets you distinguish between NULL returns. The maplookup() function uses for both a non-existent key and an existing key with a NULL value.

Syntax

MAPCONTAINSKEY(VMap_data, 'virtual_column_name')

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMap_data</td>
<td>Any VMap data. The VMap can exist as:</td>
</tr>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>- Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>- Other database content</td>
</tr>
<tr>
<td>virtual_column_name</td>
<td>The name of the key to check.</td>
</tr>
</tbody>
</table>
Examples

This example shows how to use the mapcontainskey() functions with maplookup(). View the results returned from both functions. Check whether the empty fields that maplookup() returns indicate a NULL value for the row (t) or no value (f):

You can use mapcontainskey() to determine that a key exists before calling maplookup(). The maplookup() function uses both NULL returns and existing keys with NULL values to indicate a non-existent key.

```sql
=> SELECT MAPLOOKUP(_raw_, 'user.location'), MAPCONTAINSKEY(_raw_, 'user.location')
FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
------------|------------------
| t | t | t | t | t |
Chile | t
Narnia | t
Uptown.. | t
chicago | t | f | f | f
(12 rows)
```

See Also

- MAPAGGREGATE
- MAPCONTAINSVALUE
- MAPITEMS
- MAPKEYS
- MAPKEYSINFO
- MAPLOOKUP
- MAPSIZE
- MAPSTRING
- MAPVALUES
- MAPVERSION
**MAPCONTAINSVALUE**

Determines whether a VMap contains a specific value. Use this scalar function to return true (t), if the value exists, or false (f), if it does not.

**Syntax**

```plaintext
MAPCONTAINSVALUE(VMap_data, 'virtual_column_value')
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMap_data</td>
<td>Any VMap data. The VMap can exist as:</td>
</tr>
<tr>
<td></td>
<td>• The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>• Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>• Other database content</td>
</tr>
<tr>
<td>virtual_column_value</td>
<td>The value whose existence you want to confirm.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows how to use mapcontainsvalue() to determine whether or not a virtual column contains a particular value. Create a flex table (ftest), and populate it with some virtual columns and values. Name both virtual columns one:

```plaintext
=> CREATE FLEX TABLE ftest();
CREATE TABLE
=> copy ftest from stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one":1, "two":2}
>> {"one":"one","2":"2"}
=> .
```

Call mapcontainsvalue() on the ftest map data. The query returns false (f) for the first virtual column, and true (t) for the second, which contains the value one:

```plaintext
=> SELECT MAPCONTAINSVALUE(__raw__, 'one') FROM ftest;
mapcontainsvalue
```
See Also

- EMPTYMAP
- MAPAGGREGATE
- MAPCONTAINSKEY
- MAPITEMS
- MAPKEYS
- MAPKEYSINFO
- MAPLOOKUP
- MAPSIZE
- MAPTOSTRING
- MAPVALUES
- MAPVERSION

MAPITEMS

Returns information about items in a VMap. Use this transform function with one or more optional arguments to access polystructured values within the VMap data. This function requires an OVER() clause.

Syntax

MAPITEMS(VMap_data [, passthrough_arg [, ...]] )

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The <strong>raw</strong> column of a flex table</td>
</tr>
</tbody>
</table>
Data returned from a map function such as maplookup() and other database content.

<table>
<thead>
<tr>
<th><strong>max_key_length</strong></th>
<th>In a raw column, determines the maximum length of keys that the function can return. Keys that are longer than max_key_length cause the query to fail. Defaults to the smaller of VMap column length and 65K.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>max_value_length</strong></td>
<td>In a raw column, determines the maximum length of values the function can return. Values that are larger than max_value_length cause the query to fail. Defaults to the smaller of VMap column length and 65K.</td>
</tr>
<tr>
<td><strong>passthrough_arg</strong></td>
<td>[Optional] One or more arguments indicating keys within the map data in VMap_data.</td>
</tr>
</tbody>
</table>

**Examples**

The following examples illustrate using MAPITEMS() with the over(PARTITION BEST) clause.
This example determines the number of virtual columns in the map data using a flex table, labeled darkmountain. Query using the count() function to return the number of virtual columns in the map data:

```sql
=> SELECT COUNT(keys) FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
count
-------
 19
(1 row)
```

The next example determines what items exist in the map data:

```sql
=> SELECT * FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
keys  | values
------|-------
hike_safety | 50.6
name | Mt Washington
type | mountain
height | 17000
hike_safety | 12.2
name | Denali
type | mountain
height | 29029
hike_safety | 34.1
name | Everest
type | mountain
height | 14000
hike_safety | 22.8
name | Kilimanjaro
type | mountain
height | 29029
hike_safety | 15.4
name | Mt St Helens
type | volcano
(19 rows)
```

The following example shows how to restrict the length of returned values to 100000:

```sql
=> SELECT LENGTH(keys), LENGTH(values) FROM (SELECT MAPITEMS(__raw__ USING PARAMETERS max_value_length=100000) OVER() FROM t1) x;
   LENGTH | LENGTH
----------|-------
       9   | 98899
(1 row)
```

Directly Query a Key Value in a VMap

Review the following JSON input file, simple.json. In particular, notice the array called three_Array, and its four values:

```json
{
   "one": "one",
   "two": 2,
```
1. Create a flex table, mapper:

=> CREATE FLEX TABLE mapper();
CREATE TABLE

1. Load simple.json into the flex table mapper:

=> COPY mapper FROM '/home/dbadmin/data/simple.json' parser fjsonparser (flatten_arrays=false, flatten_maps=false);
Rows Loaded
--------------
1
(1 row)

2. Call MAPKEYS on the flex table's __raw__ column to see the flex table's keys, but not the key submaps. The return values indicate three_Array as one of the virtual columns:

=> SELECT MAPKEYS(__raw__) OVER() FROM mapper;
 keys
--------------
 five_Map
 four
 one
 six
 three_Array
 two
 (6 rows)

3. Call mapitems on flex table mapper with three_Array as a pass-through argument to the function. The call returns these array values:

=> SELECT __identity__, MAPITEMS(three_Array) OVER(PARTITION BY __identity__) FROM mapper;
 __identity__ | keys | values
--------------|------|------

- MAPCONTAINSKEY
- MAPCONTAINSVALUE
- MAPKEYS
- MAPKEYSINFO
- MAPLOOKUP
- MAPSIZE
- MAPTOSTRING
- MAPVALUES
- MAPVERSION

MAPKEYS

Returns the virtual columns (and values) present in any VMap data. This transform function requires an over(PARTITION BEST) clause.

Syntax

MAPKEYS(VMap_data)

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>Other database content</td>
</tr>
</tbody>
</table>

| max_key_ | In a __raw__ column, specifies the maximum length of keys that the function |

(4 rows)
**Examples**

**Determine Number of Virtual Columns in Map Data**

This example shows how to create a query, using an `over(PARTITION BEST)` clause with a flex table, `darkdata` to find the number of virtual column in the map data. The table is populated with JSON tweet data.

```sql
=> SELECT COUNT(keys) FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
    count
    -------
     550
(1 row)
```

**Query Ordered List of All Virtual Columns in the Map**

This example shows a snippet of the return data when you query an ordered list of all virtual columns in the map data:

```sql
=> SELECT * FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
    keys
    -------------------------------
    contributors
    coordinates
    created_at
    delete.status.id
    delete.status.id_str
    delete.status.user_id
    delete.status.user_id_str
    entities.hashtags
    entities.media
    entities.urls
    entities.user_mentions
    favorited
    geo
    id
    
    user.statuses_count
    user.time_zone
    user.url
    user.utc_offset
    user.verified
(125 rows)
```

**Specify the Maximum Length of Keys that MAPKEYS Can Return**

<table>
<thead>
<tr>
<th><strong>Length</strong></th>
<th>can return. Keys that are longer than <code>max_key_length</code> cause the query to fail. Defaults to the smaller of VMap column length and 65K.</th>
</tr>
</thead>
</table>
See Also

- EMPTYMAP
- MAPAGGREGATE
- MAPCONTAINSKEY
- MAPCONTAINSVALUE
- MAPITEMS
- MAPKEYSINFO
- MAPLOOKUP
- MAPSIZE
- MAPTOSTRING
- MAPVALUES
- MAPVERSION

MAPKEYSINFO

Returns virtual column information from a given map. This transform function requires an over(PARTITION BEST) clause.

Syntax

MAPKEYSINFO(VMap_data)

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
</tbody>
</table>
Data returned from a map function such as maplookup() or other database content.

\[ max\_key\_Length \]

In a \[\_\_raw\_\_] column, determines the maximum length of keys that the function can return. Keys that are longer than \[max\_key\_Length\] cause the query to fail. Defaults to the smaller of VMap column length and 65K.

## Returns

This function is a superset of the MAPKEYS() function. It returns the following information about each virtual column:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keys</td>
<td>The virtual column names in the raw data.</td>
</tr>
<tr>
<td>length</td>
<td>The data length of the key name, which can differ from the actual string</td>
</tr>
<tr>
<td></td>
<td>length.</td>
</tr>
<tr>
<td>type_oid</td>
<td>The OID type into which the value should be converted. Currently, the type</td>
</tr>
<tr>
<td></td>
<td>is always 116 for a LONG VARCHAR, or 199 for a nested map that is stored as</td>
</tr>
<tr>
<td></td>
<td>a LONG VARBINARY.</td>
</tr>
<tr>
<td>row_num</td>
<td>The number of rows in which the key was found.</td>
</tr>
<tr>
<td>field_num</td>
<td>The field number in which the key exists.</td>
</tr>
</tbody>
</table>

## Examples

This example shows a snippet of the return data you receive if you query an ordered list of all virtual columns in the map data:

```sql
=> SELECT * FROM (SELECT MAPKEYSINFO(darkdata._raw_) OVER(PARTITION BEST) FROM darkdata) AS a;
```
Specify the Maximum Length of Keys that MAPKEYSINFO Can Return

```sql
=> SELECT MAPKEYSINFO(__raw__ USING PARAMETERS max_key_length=100000) OVER() FROM mapper;
```

<table>
<thead>
<tr>
<th>keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>five_Map</td>
</tr>
<tr>
<td>four</td>
</tr>
<tr>
<td>one</td>
</tr>
<tr>
<td>six</td>
</tr>
<tr>
<td>three_Array</td>
</tr>
<tr>
<td>two</td>
</tr>
</tbody>
</table>

(6 rows)

- MAPSIZE
- MAPTOSTRING
- MAPVALUES
- MAPVERSION

**MAPLOOKUP**

Returns single-key values from VMAP data. This scalar function returns a LONG VARCHAR, with values, or NULL if the virtual column does not have a value.
Using maplookup is case insensitive to virtual column names. To avoid loading same-name values, set the fjsonparser parser reject_on_duplicate parameter to true when data loading.

You can control the behavior for non-scalar values in a VMAP (like arrays), when loading data with the fjsonparser or favroparser parsers and its flatten-arrays argument. See Loading JSON Data and the FJSONPARSER reference.

For information about using maplookup() to access nested JSON data, see Querying Nested Data.

Syntax

MAPLOOKUP(VMap_data, 'virtual_column_name' [USING PARAMETERS [case_sensitive={false | true}] [, buffer_size=n] ] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMap_data</td>
<td>Any VMap data. The VMap can exist as:</td>
</tr>
<tr>
<td></td>
<td>• The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>• Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>• Other database content</td>
</tr>
<tr>
<td>virtual_column_name</td>
<td>The name of the virtual column whose values this function returns.</td>
</tr>
<tr>
<td>buffer_size</td>
<td>[Optional parameter] Specifies the maximum length (in bytes) of each value returned for virtual_column_name. To return all values for virtual_column_name, specify a buffer_size equal to or greater than (=&gt;) the number of bytes for any returned value. Any returned values greater in length than buffer_size are rejected. Default value: 0 (No limit on buffer_size)</td>
</tr>
<tr>
<td>case_sensitive</td>
<td>[Optional parameter] Specifies whether to return values for virtual_column_name if keys with different cases exist. Example: (... USING PARAMETERS case_sensitive=true)</td>
</tr>
</tbody>
</table>
Examples

This example returns the values of one virtual column, user.location:

```sql
=> SELECT MAPLOOKUP(__raw__, 'user.location') FROM darkdata ORDER BY 1;
maplookup
-------------
Chile
Nesnia
Uptown
  
  chicago
(12 rows)
```

Using maplookup buffer_size

Use the buffer_size= parameter to indicate the maximum length of any value that maplookup returns for the virtual column you specify. If none of the returned key values can be greater than n bytes, use this parameter to allocate n bytes as the buffer_size.

For the next example, save this JSON data to a file, simple_name.json:

```json
{
  "name": "sierra",
  "age": "63",
  "eyes": "brown",
  "weapon": "doggie"
}
{
  "name": "janis",
  "age": "10",
  "eyes": "blue",
  "weapon": "humor"
}
{
  "name": "ben",
  "age": "43",
  "eyes": "blue",
  "weapon": "sword"
}
{
  "name": "jen",
  "age": "38",
  "eyes": "green",
  "weapon": "shopping"
}
```
1. Create a flex table, logs.
2. Load the simple_name.json data into logs, using the fjsonparser. Specify the flatten_arrays option as True:

   ```sql
   => COPY logs FROM '/home/dbadmin/data/simple_name.json'
       PARSER fjsonparser(flatten_arrays=True);
   ```

3. Use maplookup with buffer_size=0 for the logs table name key. This query returns all of the values:

   ```sql
   => SELECT MAPLOOKUP(_raw_, 'name' USING PARAMETERS buffer_size=0) FROM logs;
   MapLookup
   ------------
   sierra
   ben
   janis
   jen
   (4 rows)
   ```

4. Next, call maplookup() three times, specifying the buffer_size parameter as 3, 5, and 6, respectively. Now, maplookup() returns values with a byte length less than or equal to (<=) buffer_size:

   ```sql
   => SELECT MAPLOOKUP(_raw_, 'name' USING PARAMETERS buffer_size=3) FROM logs;
   MapLookup
   -----------
   ben
   jen
   (4 rows)
   => SELECT MAPLOOKUP(_raw_, 'name' USING PARAMETERS buffer_size=5) FROM logs;
   MapLookup
   -----------
   janis
   jen
   ben
   (4 rows)
   => SELECT MAPLOOKUP(_raw_, 'name' USING PARAMETERS buffer_size=6) FROM logs;
   MapLookup
   -----------
   sierra
   janis
   jen
   ben
   (4 rows)
   ```

**Disambiguate Empty Output Rows**

This example shows how to interpret empty rows. Using maplookup without first checking whether a key exists can be ambiguous. When you review the following output, 12 empty rows, you cannot determine whether a user.location key has:
A non-NULL value
A NULL value
No value

```sql
=> SELECT MAPLOOKUP(__raw__, 'user.location') FROM darkdata;
maplookup
----------
```

(12 rows)

To disambiguate empty output rows, use the `mapcontainskey()` function in conjunction with `maplookup()`. When `maplookup` returns an empty field, the corresponding value from `mapcontainskey` indicates `t` for a NULL or other value, or `f` for no value.

The following example output using both functions lists rows with NULL or a name value as `t`, and rows with no value as `f`:

```sql
=> SELECT MAPLOOKUP(__raw__, 'user.location'), MAPCONTAINSKEY(__raw__, 'user.location')
    FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
----------+-------------------
       t |                   
       t |                   
       t |                   
       t |                   
       f | No value          
       f | No value          
       f | No value          
       f | No value          
```

(12 rows)

**Check for Case-Sensitive Virtual Columns**

You can use `maplookup()` with the `case_sensitive` parameter to return results when key names with different cases exist.

1. Save the following sample content as a JSON file. This example saves the file as `repeated_key_name.json:`
2. Create a flex table, dupe, and load the JSON file:

```sql
=> CREATE FLEX TABLE dupe();
CREATE TABLE dbt=> COPY dupe FROM '/home/release/KData/repeated_key_name.json' parser fjsonparser();
Rows Loaded
------------
 8
(1 row)
```

See Also

- EMPTYMAP
- MAPAGGREGATE
- MAPCONTAINSKEY
- MAPCONTAINSVALUE
MAPSIZE

Returns the number of virtual columns present in any VMap data. Use this scalar function to determine the size of keys.

Syntax

MAPSIZE(VMap_data)

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>Other database content</td>
</tr>
</tbody>
</table>

Examples

This example shows the returned sizes from the number of keys in the flex table darkmountain:

```sql
=> SELECT MAPSIZE(__raw__) FROM darkmountain;
mapsize
--------
 3
 4
 4
 4
 4
```

- MAPVALUES
- MAPVERSION

MAPTOSTRING

Recursively builds a string representation VMap data, including nested JSON maps. Use this transform function to display the VMap contents in a readable LONG VARCHAR format. Use maptostring to see how map data is nested before querying virtual columns with mapvalues().

Syntax

MAPTOSTRING(VMap_data [using parameters canonical_json={true | false}])

Arguments

<table>
<thead>
<tr>
<th>VMap_data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>- Data returned from a map function such as maplookup()</td>
</tr>
<tr>
<td></td>
<td>- Other database content</td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.3.x)  Page 1927 of 6246
### Parameters

<table>
<thead>
<tr>
<th>canonical_json</th>
<th>=bool</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Optional parameter]</td>
<td></td>
</tr>
</tbody>
</table>

Produces canonical JSON output by default, using the first instance of any duplicate keys in the map data.

Use this parameter as other UDF parameters, preceded by using parameters, as shown in the examples. Setting this argument to false maintains the previous behavior of maptostring() and returns same-name keys and their values.

Default value: canonical-json=true

### Examples

The following example shows how to create a sample flex table, darkdata and load JSON data from STDIN. By calling maptostring() twice with both values for the canonical_json parameter, you can see the different results on the flex table __raw__ column data.

1. Create sample table:

   ```sql
   => CREATE FLEX TABLE darkdata();
   CREATE TABLE
   ```

2. Load sample JSON data from STDIN:

   ```sql
   => COPY darkdata FROM stdin parser fjsonparser;
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   >> {"aaa": 1, "aaa": 2, "AAA": 3, "bbb": "aaa""bbb"}
   >> 
   ```

3. Call maptostring() with its default behavior using canonical JSON output, and then review the flex table contents. The function returns the first duplicate key and its value ("aaa": "1") but omits remaining duplicate keys ("aaa": "2"):

   ```sql
   => SELECT MAPTOSTRING (__raw__) FROM darkdata;
   maptostring
   ------------------------------------------
   {  "AAA" : "3",
     "aaa" : "1",
   ```
“bbb” : "aaa\"bbb"
}
(1 row)

4. Next, call `maptostring()` with using parameters `canonical_json=false`). This time, the function returns the first duplicate keys and their values:

```sql
=> SELECT MAPTOSTRING(__raw__ using parameters canonical_json=false) FROM darkdata;
------------------------------------------------------------------------
{| "aaa":  "1",
 "aaa":  "2",
 "AAA":  "3",
 "bbb":  "aaa\"bbb"
}
(1 row)
```

- `MAPVERSION`

**MAPVALUES**

Returns a string representation of the top-level values from a VMap. This transform function requires an `over()` clause.

**Syntax**

`MAPVALUES(VMap_data)`
# Arguments

| VMap_data                      | The VMap from which values should be returned. The VMap can exist as:  
|-------------------------------|-----------------------------------------------------------------------  
|                               | • The __raw__ column of a flex table  
|                               | • Data returned from a map function such as maplookup()  
|                               | • Other database content  

| max_value_length              | In a __raw__ column, specifies the maximum length of values the function can return. Values that are larger than max_value_length cause the query to fail. Defaults to the smaller of VMap column length and 65K. |

# Examples

The following example shows how to query a darkmountain flex table, using an over() clause (in this case, the over(PARTITION BEST) clause) with mapvalues().
=> SELECT * FROM (SELECT MAPVALUES(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
values
-----------------
29029 34.1
Everest mountain 29029
15.4
Mt St Helens volcano 17000
12.2
Denali mountain 14000
22.8
Kilimanjaro mountain 50.6
Mt Washington mountain
(19 rows)

Specify the Maximum Length of Values that MAPVALUES Can Return

=> SELECT MAPVALUES(__raw__ USING PARAMETERS max_value_length=100000) OVER() FROM mapper;
keys
----------
five_Map
two
(6 rows)

- MAPSIZE
- MAPTOSTRING
- MAPVERSION
**MAPVERSION**

Returns the version or invalidity of any map data. This scalar function returns the map version (such as 1) or -1, if the map data is invalid.

### Syntax

MAPVERSION(VMap_data)

### Arguments

| VMap_data | The VMap data either from a `__raw__` column in a flex table or from the data returned from a map function such as maplookup(). |

### Examples

The following example shows how to use mapversion() with the darkmountainflex table, returning mapversion 1 for the flex table map data:

```sql
=> SELECT MAPVERSION(__raw__) FROM darkmountain;
mapversion
-----------
    1
    1
    1
    1
    1
(5 rows)
```

Flex Parsers Reference

Vertica supports several parsers to load different types of data into flex tables.

Unlike with columnar tables, you must specify which parser to use when loading flex tables. You can use each flex parser to load the parser's associated type of data into columnar tables.

All parsers store the data as a single Vmap in the LONG VARBINARY __raw__ column. If a data row is too large to fit in the column, it is rejected. Vertica supports null values for loading data with NULL-specified columns.

For information about how you can use each type of flex parser, see Using Flex Table Parsers.

FAVROPARSER

Parses data from an Avro file. The input file must use binary serialization encoding. Use this parser to load data into columnar, flex, and hybrid tables.

Note:
The parser favroparser does not support Avro files with separate schema files. The Avro file must have its related schema in the file you are loading.

Syntax

FAVROPARSER ( [parameter-name='value'][,...] )
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>flatten_arrays</td>
<td>Boolean, specifies whether to flatten all Avro arrays. Key names are concatenated with nested levels.</td>
<td>false</td>
</tr>
<tr>
<td>flatten_maps</td>
<td>Boolean, specifies whether to flatten all Avro maps. Key names are concatenated with nested levels.</td>
<td>true</td>
</tr>
<tr>
<td>flatten_records</td>
<td>Boolean, specifies whether to flatten all Avro records. Key names are concatenated with nested levels.</td>
<td>true</td>
</tr>
<tr>
<td>reject_on_materialized_type_error</td>
<td>Boolean, specifies whether to reject any row value for a materialized column that the parser cannot coerce into a compatible data type. See Using Flex Table Parsers.</td>
<td>false</td>
</tr>
</tbody>
</table>

Examples

This example shows how to create and load a flex table with Avro data using favroparser. After loading the data, you can query virtual columns.

1. Create a flex table for Avro data, avro_basic:

   ```sql
   -> CREATE FLEX TABLE avro_basic();
   CREATE TABLE
   ```

2. Use the favroparser to load the data from an Avro file (weather.avro).
3. Query virtual columns from the avro flex table:

```sql
=> SELECT station, temp, time FROM avro_basic;
station | temp | time
---------|------|---------
mohali   | 0    | -619524000000
lucknow  | 22   | -619506000000
norwich  | -11  | -619484400000
ams      | 111  | -655531200000
baddi    | 78   | -655509600000
(5 rows)
```

For more information, see Loading Avro Data.

- FCSVPARSER
- FDELIMITEDPARSER
- FDELIMITEDPAIRPARSER
- FJSONPARSER
- FREGEXPARSER

**FCEFPARSER**

 Parses ArcSight Common Event Format (CEF) log files. The `fcefparser` loads values directly into any table column with a column name that matches a source data key. The parser stores the data loaded into a flex table in a single VMap.

**Syntax**

```
FAVROPARSER ( [parameter-name='value'[,...]] )
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>Single-character delimiter. Default value: ' '</td>
</tr>
<tr>
<td>record_terminator</td>
<td>Single-character record terminator. Default value: newline</td>
</tr>
<tr>
<td>trim</td>
<td>Boolean, specifies whether to trim white space from header names and key values. Default value: true</td>
</tr>
<tr>
<td>reject_on_unescaped_delimiter</td>
<td>Boolean, specifies whether to reject rows containing unescaped delimiters. The CEF standard does not permit them. Default value: false</td>
</tr>
</tbody>
</table>

Examples

The following example illustrates creating a sample flex table for CEF data, with two real columns, eventId and priority.

1. Create a flex table cefdata:

   ```
   => create flex table cefdata();
   CREATE TABLE
   ```

2. Load some basic CEF data, using the flex parser fcefparser:

   ```
   => copy cefdata from stdin parser fcefparser();
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   => CEF:0|ArcSight|ArcSight|2.4.1|machine:20|New alert|High|
   => 
   ```

3. Use the mapToString() function to view the contents of your cefdata flex table:
4. Select some virtual columns from the `cefdatab` flex table:

```sql
= select deviceproduct, severity, deviceversion from cefdata;

deviceproduct | severity | deviceversion
--------------|----------|----------------
ArcSight       | High     | 2.4.1
(1 row)
```

For more information, see [Loading Common Event Format (CEF) Data](#).

- `FREGEXPARSER`

**FCSVPARSER**

 Parses CSV format (comma-separated values) data. Use this parser to load CSV data into columnar, flex, and hybrid tables. All data must be encoded in Unicode UTF-8 format. The parser `fcsvparser` supports the [RFC 4180](https://tools.ietf.org/html/rfc4180) de facto standard for CSV data, and other options, to accommodate variations in CSV file format definitions. Invalid records will be rejected.
## Syntax

FCSVPARSER ( [parameter-name='value',..] )

## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| type | Specifies the default parameter values for the parser, one of the following strings:  
  - rfc4180  
  - traditional  
  You do not have to use the type parameter when loading data that conforms to the RFC 4180 standard (such as MS Excel files). See Loading CSV Data for the RFC4180 default parameters, and other options you can specify for traditional CSV files.  
  **Default**: RFC4180 |
| delimiter | A single-character value used to separate fields in the CSV data.  
  **Default**: , (for rfc4180 and traditional) |
| escape | A single-character value used as an escape character to interpret the next character in the data literally.  
  **Default**:  
  - rfc4180: "  
  - traditional: \\ |
| enclosed_by | Specifies a single-character value. Use and enclosed_by value to include a value that is identical to the delimiter, but should be interpreted literally. For |
example, if the data delimiter is a comma (,), and you want to use a comma within the data ("my name is jane, and his is jim").

**Default:** "

### record_terminator

A single-character value used to specify the end of a record.

**Default:**

- `rfc4180: \n`
- `traditional: \r\n`

### header

Boolean, specifies whether to use the first row of data as a header column. When `header=true` (default), and no header exists, fcsvparser uses a default column heading. The default header consists of `ucoln`, where `n` is the column offset number, starting with 0 for the first column. You can specify custom column heading names using the `header_names` parameter, described next.

If you specify `header=false`, the fcsvparser parses the first row of input as data, rather than as column headers.

**Default:** `true`

### header_names

A list of column header names, delimited by the character defined by the parser's delimiter parameter. Use this parameter to specify header names in a CSV file without a header row, or to override the column names present in the CSV source. To override one or more existing column names, specify the header names to use. This parameter overrides any header row in the data.

### trim

Boolean, specifies whether to trim white
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>omit_empty_keys</td>
<td>Boolean, specifies how the parser handles header keys without values. If true, keys with an empty value in the header row are not loaded.</td>
<td>true</td>
</tr>
<tr>
<td>reject_on_duplicate</td>
<td>Boolean, specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues.</td>
<td>false</td>
</tr>
<tr>
<td>reject_on_empty_key</td>
<td>Boolean, specifies whether to reject any row containing a key without a value.</td>
<td>false</td>
</tr>
<tr>
<td>reject_on_materialized_type_error</td>
<td>Boolean, specifies whether to reject any materialized column value that the parser cannot coerce into a compatible data type. See Loading CSV Data.</td>
<td>false</td>
</tr>
</tbody>
</table>

**Examples**

This example shows how you can use `fcsvparser` to load a flex table, build a view, and then query that view.

1. Create a flex table for CSV data:

   ```sql
   => CREATE FLEX TABLE rfc();
   CREATE TABLE
   ```

2. Use `fcsvparser` to load the data from STDIN. Specify that no header exists, and enter some data as shown:
3. Run the `compute_flextable_keys_and_build_view` function, and query the `rfc_view`. Notice that the default enclosed_by character permits an escape character ("') within a field ("20"'5"). Thus, the resulting value was parsed correctly. Since no header existed in the input data, the function added `ucoln` for each column:

```sql
=> SELECT compute_flextable_keys_and_build_view('rfc');
```

```
compute_flextable_keys_and_build_view

Please see public.rfc_keys for updated keys
The view public.rfc_view is ready for querying
(1 row)
```

```sql
=> SELECT * FROM rfc_view;
```

```
ucol0 | ucol1 | ucol2
--------+--------+--------
10 | 10 | 20
10 | 10 | 30
10 | "20"'5 | 90
(3 rows)
```

For more information and examples of using other parameters of this parser, see Loading CSV Data.

- FREGEXPARSER
FDELIMITEDPAIRPARSER

Parses delimited data files. This parser provides a subset of the functionality in the parser fdelimitedparser. Use the fdelimitedpairparser when the data you are loading specifies pairs of column names with data in each row.

Syntax

FDELIMITEDPAIRPARSER ( [parameter-name='value'][,..] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>Specifies a single-character delimiter.</td>
</tr>
<tr>
<td>Default: ' '</td>
<td></td>
</tr>
<tr>
<td>record_terminator</td>
<td>Specifies a single-character record terminator.</td>
</tr>
<tr>
<td>Default: newline</td>
<td></td>
</tr>
<tr>
<td>trim</td>
<td>Boolean specifies whether to trim white space from header names and key values.</td>
</tr>
<tr>
<td>Default: true</td>
<td></td>
</tr>
</tbody>
</table>

Examples

The following example illustrates creating a sample flex table for simple delimited data, with two real columns, eventId and priority.

1. Create a table:

```sql
=> create flex table CEFData(eventId int default(eventId::int), priority int default (priority::int));
CREATE TABLE
```
2. Load a sample delimited OpenText ArcSight log file into the CEFData table, using the `fcefparser`:

```sql
=> copy CEFData from '/home/release/kmm/flextables/sampleArcSight.txt' parser fdelimitedpairparser();
  Rows Loaded | 200
```

3. After loading the sample data file, use `maptoString()` to display the virtual columns in the `__raw__` column of CEFData:

```sql
=> select maptoString(__raw__) from CEFData limit 1;
```

```sql

```
```
```
4. Select the `eventID` and `priority` real columns, along with two virtual columns, `atz` and `destinationgeoregioncode`:

```sql
=> select eventID, priority, atz, destinationgeoregioncode from CEFData limit 10;
+----------------+---------+-----+-------------------------+
| eventID | priority | atz | destinationgeoregioncode |
|---------+----------+-----+-------------------------|
| 1218325417 | 5        |     | America/Los_Angeles     |
| 1219383333 | 8        |     | America/Los_Angeles     |
| 1219533691 | 9        |     | America/Los_Angeles     |
| 1220034458 | 5        |     | America/Los_Angeles     |
| 1220034578 | 9        |     | America/Los_Angeles     |
| 1220067119 | 5        |     | America/Los_Angeles     |
| 1220142122 | 5        |     | America/Los_Angeles     |

- FJSONPARSER
- FREGEXPARSER

FDELIMITEDPARSER

Parses data using a delimiter character to separate values. The fdelimitedparser loads delimited data, storing it in a single-value VMap. You can use this parser to load data into columnar and flex tables.

**Note:**

By default, fdelimitedparser treats empty fields as NULL, rather than as an empty string (' '). This behavior makes casting easier. Casting a NULL to an integer (NULL::int) is valid, while casting an empty string to an integer (' '::int) is not. If required, use the treat_empty_val_as_null parameter to change the default behavior of fdelimitedparser.

Syntax

FDELIMITEDPARSER ( [parameter-name='value'][, ...] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>Single character delimiter.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong></td>
</tr>
<tr>
<td>record_terminator</td>
<td>Single-character record terminator.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>trim</td>
<td>Boolean, specifies whether to trim white space from header names and key values.</td>
</tr>
<tr>
<td>header</td>
<td>Boolean, specifies that a header column exists. The parser uses col### for the column names if you use this parameter but no header exists.</td>
</tr>
<tr>
<td>omit_empty_keys</td>
<td>Boolean, specifies how the parser handles header keys without values. If omit_empty_keys=true, keys with an empty value in the header row are not loaded.</td>
</tr>
<tr>
<td>reject_on_duplicate</td>
<td>Boolean, specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues.</td>
</tr>
<tr>
<td>reject_on_empty_key</td>
<td>Boolean, specifies whether to reject any row containing a key without a value.</td>
</tr>
<tr>
<td>reject_on_materialized_type_error</td>
<td>Boolean, specifies whether to reject any row value for a materialized column that the parser cannot coerce into a compatible data type. See Using Flex Table Parsers.</td>
</tr>
<tr>
<td>treat_empty_val_as_null</td>
<td>Boolean, specifies that empty fields become NULLs, rather than empty strings ('').</td>
</tr>
</tbody>
</table>
Examples

1. Create a flex table for delimited data:

   \[
   \text{T} \rightarrow \text{CREATE FLEX TABLE delim_flex ()};
   \]

   CREATE TABLE

2. Use the \text{fdelimitedparser} to load some delimited data from STDIN, specifying a comma (,) column delimiter:

   \[
   \Rightarrow \text{COPY delim_flex FROM STDIN parser fdelimitedparser (delimiter=',');};
   \]

   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   \[
   \text{deviceproduct, severity, deviceversion}
   \text{ArcSight, High, 2.4.1}
   \text{.}
   \]

   You can now query virtual columns in the delim_flex flex table:

   \[
   \Rightarrow \text{SELECT deviceproduct, severity, deviceversion from delim_flex;}
   \]

   \[
   \begin{array}{|c|c|c|}
   \hline
   \text{deviceproduct} & \text{severity} & \text{deviceversion} \\
   \hline
   \text{ArcSight} & \text{High} & 2.4.1 \\
   \hline
   \end{array}
   \]

   (1 row)

- FCSVPARSER
- FDELIMITEDPAIRPARSER
- FJSONPARSER
- FREGEXPARSER

FJSONPARSER

Parses and loads a JSON file. This file can contain either repeated JSON data objects (including nested maps), or an outer list of JSON elements. For a flex table, the parser stores the JSON data in a single-value VMap. For a hybrid or columnar table, the parser
loads data directly in any table column with a column name that matches a key in the JSON source data.

Syntax

\[ \text{FJSONPARSER} \left( \left[ \text{parameter-name}='value'[,..] \right] \right) \]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>flatten_maps</td>
<td>Boolean, specifies whether to flatten sub-maps within the JSON data, separating map levels with a period (.).</td>
<td>true</td>
</tr>
<tr>
<td>flatten_arrays</td>
<td>Boolean, specifies whether to convert lists to sub-maps with integer keys. Lists are not flattened by default.</td>
<td>false</td>
</tr>
<tr>
<td>reject_on_duplicate</td>
<td>Boolean, specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues.</td>
<td>false</td>
</tr>
<tr>
<td>reject_on_empty_key</td>
<td>Boolean, specifies whether to reject any row containing a key without a value.</td>
<td>false</td>
</tr>
<tr>
<td>omit_empty_keys</td>
<td>Boolean, specifies whether to omit any key from the load data that does not have a value.</td>
<td>false</td>
</tr>
<tr>
<td>record_terminator</td>
<td>When set, any invalid JSON records are skipped and parsing continues with the next record. Records must be</td>
<td></td>
</tr>
</tbody>
</table>
terminated uniformly. For example, if your input file has JSON records terminated by newline characters, set this parameter to `E'\n')`. If any invalid JSON records exist, parsing continues after the next record_terminator.

When you omit this parameter, parsing ends at the first invalid JSON record.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>reject_on_materialized_type_error</code></td>
<td>Boolean, specifies whether to reject a data row that contains a materialized column value that cannot be coerced into a compatible data type.</td>
</tr>
<tr>
<td><strong>Default:</strong></td>
<td><code>false</code></td>
</tr>
<tr>
<td><code>start_point</code></td>
<td>String that specifies the name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the <code>start_point</code> value. The value is loaded for each object in the file. The parser processes data after the first instance, and up to the second, ignoring any remaining data.</td>
</tr>
<tr>
<td><code>start_point_occurrence</code></td>
<td>Integer that indicates the n&lt;sup&gt;th&lt;/sup&gt; occurrence of the value you specify with <code>start_point</code>. Use in conjunction with <code>start_point</code> when load data has multiple start values and you know the occurrence at which to begin parsing.</td>
</tr>
<tr>
<td><strong>Default:</strong></td>
<td><code>1</code></td>
</tr>
<tr>
<td><code>suppress_nonalphanumeric_key_chars</code></td>
<td>Boolean, specifies whether to suppress non-alphanumeric characters in JSON key values. The parser replaces these characters with an underscore (_) when this parameter is true.</td>
</tr>
<tr>
<td><strong>Default:</strong></td>
<td><code>false</code></td>
</tr>
</tbody>
</table>
| `key_separator`                                | Specifies a non-default character for the
Examples

Load JSON Data Without Optional Parameters

1. Create a flex table, super, with two columns, age and name:

   => create table super(age int, name varchar);

   CREATE TABLE

2. Enter values using the fjsonparser(), and query the results:

   => copy super from stdin parser fjsonparser();
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   >> {"age": 5, "name": "Tim"}
   >> {"age": 3}
   >> {"name": "Fred"}
   >> {"name": "Bob", "age": 10}
   >> \
   => select * from super;
   age | name
   --------
   5 | Tim
   3 | Bob
   10 | Fred
   (4 rows)

For other examples, see Loading JSON Data.

- FAVROPARSER
- FCEFPARSER
- FCSPARSER
- FDELIMITEDPARSER
- FDELIMITEDPAIRPARSER
- FREGEXPARSER
**FREGEXPARSER**

Parses a regular expression, matching columns to the contents of the named regular expression groups.

**Syntax**

FREGEXPARSER (pattern=[parameter-name='value'][,..])

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern</td>
<td>Specifies the regular expression of data to match.</td>
</tr>
<tr>
<td>Default: Empty string (&quot;&quot;&quot;)</td>
<td></td>
</tr>
<tr>
<td>use_jit</td>
<td>Boolean, specifies whether to use just-in-time compiling when parsing the regular expression.</td>
</tr>
<tr>
<td>Default: false</td>
<td></td>
</tr>
<tr>
<td>record_terminator</td>
<td>Specifies the character used to separate input records.</td>
</tr>
<tr>
<td>Default: \n</td>
<td></td>
</tr>
<tr>
<td>logline_column</td>
<td>A string that captures the destination column containing the full string that the regular expression matched.</td>
</tr>
<tr>
<td>Default: Empty string (&quot;&quot;&quot;)</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread_name, and thread_id strings.

**Caution:**

For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first
copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, `(thread_id)(?:0x)?[0-9a-f]+).

```
'^(?<time>\d{4}-\d{2}-\d{2} \d{2}:\d{2}:\d{2}.) (?<thread_name>[A-Za-z \+]):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f]+)((?<component>[0-9a-f]+))
\((?<level>\w+)\) ?(?<enode>\w+) @(?<elevel>\w+)?:
)?(?<text>.*);
```

1. Create a flex table (vlog) to contain the results of a Vertica log file. For this example, we made a copy of a log file in the directory /home/dbadmin/data/vertica.log:

```sql
=> create flex table vlog1();
CREATE TABLE
```

2. Use the fregexparser with the sample regular expression to load data from the log file. Be sure to remove any line characters before using this expression shown here:

```sql
=> copy vlog1 from '/home/dbadmin/tempdat/KMvertica.log'
PARSER FREGEXPARSER(pattern='^(?<time>\d{4}-\d{2}-\d{2} \d{2}:\d{2}:\d{2}.) (?<thread_name>[A-Za-z \+]):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f]+)((?<component>[0-9a-f]+))
\((?<level>\w+)\) ?(?<enode>\w+) @(?<elevel>\w+)?:
)?(?<text>.*);
```

Rows Loaded
-----------
31049
(1 row)

3. After successfully loading data, use the MAPTOSTRING() function with the table's __raw__ column. The four rows (limit 4) that the query returns are regular expression results of the KMvertica.log file, parsed with fregexparser. The output shows thread_id values with a preceding 0x or without:

```sql
=> select maptostring(__raw__) from vlog1 limit 4;
mptostring
-----------------------------------------
   { "text" : " [Init] <INFO> Log /home/dbadmin/VMart/v_vmart_node0001_catalog/vertica.log opened; #2",
    "thread_id" : "0x7f2157e287c0",
    "thread_name" : "Main",
    "time" : "2017-03-21 23:30:01.704"
  }

  { "text" : " [Init] <INFO> Processing command line: /opt/vertica/bin/vertica -D
/home/dbadmin/VMart/v_vmart_node0001_catalog -C VMart -n v_vmart_node0001 -h
10.20.100.247 -p 5433 -P 4803 -Y ipv4",
    "thread_id" : "0x7f2157e287c0",
```

Using Management Console

Management Console (MC) is the Vertica in-browser monitoring and management tool. Its graphical user interface provides a unified view of your Vertica database operations.

Through user-friendly, step-by-step screens, you can create, configure, manage, and monitor your Vertica databases and their associated clusters.

You can use MC to operate your Vertica database in Eon Mode or in Enterprise Mode. You can use MC to provision and deploy a Vertica Eon Mode database.

To get started using MC, see Getting Started with MC.

Getting Started with MC

Use Management Console to monitor the performance of your Vertica clusters. This tool provides a graphical view of your Vertica database cluster, nodes, network status, and detailed monitoring charts and graphs.

MC allows you to:

- Create, import, and connect to Vertica databases.
- Manage your Vertica database and clusters.
- Receive and view messages regarding the health and performance of your Vertica database and clusters.
- View diagnostics and support information for Management Console.
- Manage application and user settings for Management Console.
MC Installation Process

To install MC, complete these tasks:

1. Verify that you meet the requirements listed in Before You Install MC.
2. Follow the steps listed in Installing Management Console.
3. After you have installed MC, configure it according to the instructions in Configuring MC.

Connecting to MC

To connect to Management Console:

1. Open an HTML-5 compliant browser.
2. Enter the IP address or host name of the host on which you installed MC (or any cluster node if you installed Vertica first), followed by the MC port you assigned when you configured MC.

For example, enter one of:

https://00.00.00.00:5450/

or

https://hostname:5450/

3. When the MC logon dialog appears, enter your MC username and password and click Log in.

Note:
When MC users log in to the MC interface, MC checks their privileges on Vertica Data Collector (DC) tables on MC-monitored databases. Based on DC table privileges, along with the role assigned the MC user, each user’s access to the MC’s Overview, Activity and Node details pages could be limited. See About MC Privileges and Roles for more information.

If you do not have an MC username/password, contact your MC administrator.
Viewing the Home Page

After you connect to MC and sign in, the Home page displays. This page is the entry point to all Vertica database clusters and users managed by MC. Information on this page, as well as throughout the MC interface, will appear or be hidden, based on the permissions (access levels) of the user who is logged in. The following image is what an MC super administrator sees.

Tasks

Operations you can perform in Management Console are grouped into the following areas:

- **Provision.** Create new Vertica databases, or import existing ones to manage and monitor with MC. You can also import a Vertica cluster that resides in a Hadoop environment. See Managing Database Clusters.
• **Manage.** View all the clusters and databases monitored by MC, stop and remove databases, and view details about databases and clusters. See Viewing Cluster Infrastructure.

**MC Tools**

• **MC Settings.** Configure MC and user settings, as well as use the MC interface to install Vertica on a cluster of hosts. See Managing MC Settings.

• **Message Center.** View, sort, and search database messages and optionally export messages to a file. See Monitoring Database Messages in MC.

• **MC Diagnostics.** View and resolve MC-related issues, as well as browse Vertica agent and audit logs. See Troubleshooting with MC Diagnostics.

**Recent Databases**

The **Recent Databases** section displays all databases that you created on or imported into MC. It lists each database name, its number of nodes, and two actions:

• **Fast Tasks.** Key tasks you can perform on that database using MC.

• **Go to Database.** View the Overview page, which displays a dynamic dashboard of your database's health and activity. Explore the tabs below your dashboard, which provide more ways to manage the database.

You can install and manage multiple databases with MC, but you can have only one database running on a single cluster at a time. UP databases appear in green and DOWN databases are red.

An empty space under Recent Databases means that you have not yet created or imported a database into the MC interface, or do not have permission to view any databases managed by MC.

**Managing MC Users, Roles and Privileges**

If you are an administrator, you can use **MC Settings** to grant MC users privileges to one or more Vertica users. MC users are not the same as system (Linux) users. MC users are external to the database, and their information is stored on an internal database on the MC application or web server. See About MC Users for further details.
You can create MC users using either of two authentication techniques, LDAP or MC (internal). See Creating an MC User. After you create the MC users, you can manage them from MC Settings page. Refer to Managing MC Users.

To control the level of access for the MC Users, you can grant them privileges (through roles) from the MC Settings page. MC supports two groups of privileges:

- MC Configuration Privileges
- MC Database Privileges

The MC super account is the default user. The super user needs to create all other MC users. Refer to About MC Privileges and Roles for further information on MC roles.

For further details about MC Users, Privileges and Roles, see Managing Users And Privileges.

Creating a Cluster Using MC - Process Flow

After you install and configure MC, you can use it to create a Vertica cluster on hosts where Vertica software is not installed. Complete the following tasks:

1. Prepare the Hosts - Prepare each host that will become a node in the cluster.
2. Create a Private Key File - MC needs password-less SSH to connect to hosts and install Vertica software. Create a private key to enable MC access to the hosts.
3. Use the MC Cluster Installation Wizard - Use the wizard to install a Vertica cluster on hosts that do not have Vertica software already installed on them.
4. Validate Hosts and Create the Cluster - Host validation is the process where the MC runs tests against each host in a proposed cluster. You must validate hosts before the MC can install Vertica on each host.

After you successfully create a cluster using MC, see Create a Database on a Cluster.

Creating a Database

MC provides a step-by-step wizard to install a new Vertica database on an existing cluster.

For a more in-depth description of this process, see Create an Empty Database Using MC.

Note:
To provision a new cluster and a new database on AWS resources (this
Create a Database

1. Connect to Management Console, and log in.
2. On the Home page, click Existing Infrastructure. The Database and Cluster View page appears; this is a summary of your environment, clusters, and databases.
3. In the row labeled Clusters, click the existing cluster you want to create a database on. (If a database is already running on it, first stop the database.) When a dialog box identifying that cluster appears, click Create Database. The database creation wizard starts.

View your new database any time under the Available Databases section of the Management Console home page. See Managing Database Clusters for more about further managing your cluster, instances, and database using MC.

See Also

- Create an Empty Database Using MC
- Importing an Existing Database Into MC
- Creating a Cluster Using MC - Process Flow
Provisioning Databases Using MC

Management Console allows all users to create, import, and connect to Vertica databases using the **MC Provision Databases** tab.

- Import cluster or database using IP discovery
- Create a new cluster
- **Import and Monitor in a Hadoop Environment**

Fast Tasks

The Fast Tasks page offers a few important tasks to get you started managing your database through MC.

On the MC home page in the **Recent Databases** section, click **Fast Tasks** in the Actions column of any available database.

The Fast Tasks page provides the following options:

- **Manage and View Your Vertica Database.** See the monitoring dashboard for your database. Explore the tabs below your dashboard, which provide more ways to manage the database.
- **Connect to your Vertica Database Using SQL.** Use Management Console to run SQL queries on your database from within your browser.
- **Load Your Data into Vertica Database.** The Data Load Activity page allows you to monitor and perform data loading jobs. To load data from an S3 bucket into pre-existing tables in your database, select the Instance tab and click **New S3 Data Load**

If you installed Management Console with Provisioning through the AWS Marketplace, you had the option to install a database pre-loaded with example clickstream analytic data. If you did so, the Fast Tasks page lists two additional links:

- **Play with Example Data in Your Vertica Database (PDF).** This PDF guide provides instructions and example SQL queries you can use in Vertica to analyze the example data.
- **Vertica Workbook for Tableau (PDF).** This PDF guide provides instructions on how to analyze the example data pre-loaded into Vertica, using a Tableau dashboard.
Monitoring Existing Infrastructure Using MC

Use Management Console to monitor the health of your Vertica databases and clusters. Click the **Infrastructure** button on the Home page to see the Databases and Clusters page. Then click the cluster of interest to view the health of the nodes in that cluster and the key information associated with the cluster such as:

- Vertica version
- Number of hosts
- CPU type
- Last updated date
- Node list.

You can also zoom in and out for better view of this page.

On the Databases and Clusters page or the Home page, click the database which you want to monitor, to go to its **Overview** page:

You can perform the following tasks from the Overview page:

- View **Quick Stats** to get instant alerts and information about your cluster's status.
- View **Status Summary** that provides a general overview of the status of your cluster (as shown in preceding figure).
• Analyze **System Health** using a comprehensive summary of your system resource usage and node information, with configurable statistics that allow you to specify acceptable ranges of resource usage.
• Use **Query Synopsis** to monitor system query activity and resource pool usage.

For Eon mode databases, the **Status Summary** and **Query Synopsis** pages allow you to display information for the entire database. If subclusters are defined, you can also display information for a specific subcluster or node, or the nodes not assigned to a subcluster.

Additionally, you can perform the following tasks from the Overview page:

• Monitoring Cluster Nodes
• Monitoring Cluster CPU/Memory
• Monitoring Cluster Performance

### Monitoring System Resources

On the main window, you can click the database, and navigate to the **MC Activity** tab to monitor system resources such as:

• Queries
• Internal Sessions
• User Sessions
• Memory Usage
• System Bottlenecks
• User Query Phases
• Table Treemap
• Query Monitoring
• Resource Pool Monitoring

### Monitoring Node and MC User Activity

You can use the **MC Manage** page to monitor node activity. When you click the node you want to investigate, the Node Detail page opens and provides:

• Summary information for the node
• Resources consumed by the node for last three hours

You can also browse and export log-level data from AgentTools and Vertica log files. MC retains a maximum of 2000 log records. See Monitoring Node Activity for further details.

Use **MC Diagnostics** tab and navigate to **Audit Log** page to manage MC User activity. See Monitoring MC User Activity Using Audit Log.
Monitoring Messages in Databases Managed by MC

You can view critical database related messages from MC Message Center. The MC Message Center reports on several critical database-related conditions using a color code to indicate the message severity. See Monitoring Database Messages in MC for further details.

You can also search and sort database messages, mark messages read or unread and delete them. You can filter messages by message type, and export messages. Refer to Searching Database Messages Managed by MC and Exporting MC-managed Database Messages and Logs.

Monitoring and Configuring Resource Pools

Use the MC Activity page to monitor resource pools. Select the resource pool you want to monitor. MC displays the following charts for the selected pool:

- Resource Usages in Pool
- Memory Usage in Node and Subclusters
- Average Query Execution and Query Time in Pool
- Resource Rejections in Pool

If you are a database administrator, you can click the database you want on the main window. You can then use the MC Settings tab to view and edit the resource pool parameters. Only the database administrator can monitor and configure the resource pools in Management Console.

See Monitoring Resource Pools for further information.

Running Database Designer Using MC

You can use Database Designer to create a comprehensive design, which allows you to create new projections for all tables in your database.
Additionally, you can use Database Designer to create an incremental design. An incremental design creates projections for all tables referenced in the queries you supply.

To run Database Designer using MC, follow the steps listed at Running Database Designer with Management Console.

**Managing Queries Using MC**

Management Console allows you to view the query plan of an active query or a manually entered query specified by the user.

1. On the MC Home Page, click the database you want to view the Overview page.
2. Select the Activity tab to view the query activity.
3. Click the Explain tab to access the query plan.

See Working with Query Plans in MC and Accessing Query Plans in Management Console for further information.

Management Console provides two options for viewing the query plan: Path Information and Tree Path. For details on each, refer Query Plan View Options.

Additionally, you can also Viewing Projection and Column Metadata using the MC Explain tab.

**See Also**

- Expanding and Collapsing Query Paths
- Clearing Query Data

**Profiling Queries Using MC**

Management Console allows you to view profile data for a query.

- On the MC Home Page, click the database to view the Overview page.
- Click the Explain tab to perform tasks related to profiling a query.

See Viewing Profile Data in MC for further details.

On the Explain tab, you can view the following profile data using MC:
You can use any of the four different formats to view the profile data:

- Path Information view
- Query Drilldown view
- Tree Path view
- Profile Analysis view

See Viewing Different Profile Outputs for detailed explanation of each view.

Additionally, Management Console supports different color codes for viewing the progress of profiling a query. For an explanation of these color codes, see Monitoring Profiling Progress.

See Also

- Viewing Profile Data in MC

Managing Client Connections

Each client session to MC uses a connection from MaxClientSessions, a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages.

Tip:
You can increase the value for MaxClientSessions on an MC-monitored database to account for extra sessions. See Managing Sessions for details.

Managing MC Settings

The MC Settings page allows you to configure properties specific to Management Console. To access the page, go to the Management Console home page. Under MC Tools, click
**MC Settings.** On the **MC Settings** page, you can control the following settings and more:

**MC Configuration Settings**

- Change Management Console and agent default port assignments (Configuration tab).

**MC Monitoring Settings**

- Control the following monitoring settings in Management Console:
  - Enable checks and set alert thresholds for spread retransmit rate. This setting is disabled by default. The recommended alert threshold for spread retransmit rate is 10%.
  - Set alert thresholds for free Management Console disk space checks. The recommended alert threshold is 500 MB.
  - Exclude MC queries from activity charts.
  - Set refresh intervals for MC charts and pages.

**MC Security and Authentication Settings**

- To allow Management Console connections only from browsers using TLS 1.2 and higher (Configuration tab).
  - Click **Disable TLS 1.0 and 1.1 connections from browser.**
  - This setting ensures that Management Console will connect to the Vertica server using a version of TLS no lower than 2.0.
- Upload a new SSL certificate or view the current certificate (SSL Certificates tab).
- Use LDAP for user authentication (Authentication tab).
- Enable and disable username and password auto-complete at Management Console login. (After disabling, clear your browser's cache.) (Configuration tab)

**MC User Management Settings**

- Create new Management Console users and, with their user credentials, map them to an database managed by Management ConsoleC on the Vertica server. See **Creating an MC User** and **Managing MC Users.**
**MC Extended Monitoring Settings**

- Configure [Extended Monitoring](#), which allows you to monitor more long-term data in Management Console:
  - Set up an external storage database for Extended Monitoring. See [Managing the Storage Database](#).
  - Enable or disable Extended Monitoring on your databases. See [Managing Extended Monitoring on a Database](#).

**Other MC Settings**

- View your version of Vertica or upload a new Vertica binary file
- Customize the look and feel of Management Console with themes. See [Customizing Look and Feel](#).
- Configure Management Console to use an alternative data source to monitor your database. See [Monitoring External Data Sources in Management Console](#).
- Enable Management Console to send email alerts. See [Set Up Email](#).

**Modifying Database-Specific Settings**

To inspect or modify settings related to a database managed by Management Console, go to the **Existing Infrastructure** page. On this page, select a running database to see its Overview page. From the bottom of the Overview page, click the **Settings** tab to make modifications to database-specific settings.

**Backing Up MC**

Before you [upgrade MC](#), Vertica recommends that you back up your MC metadata (configuration and user settings). Use a storage location external to the server on which you installed MC.

1. On the target server (where you want to store MC metadata), log in as root or a user with sudo privileges.
2. Create a backup directory as in following example:
3. Copy the `/opt/vconsole` directory to the new backup folder:

```
# cp -r /opt/vconsole /backups/mc/mc-backup-20130425
```

## Upgrading And Uninstalling MC

To upgrade or uninstall MC refer to [Installing Vertica](#).

- To upgrade MC, follow the steps listed on [Upgrading Management Console Manually](#).
- To uninstall MC, refer [Uninstalling Management Console](#).

## Managing Users And Privileges

A Management Console administrator can grant MC users access to one or more Vertica databases through the MC interface. In this section, we discuss about MC Users and their privileges.

- [About MC Users](#)
- [About MC Privileges and Roles](#)
About MC Users

Unlike database users, which you create on the Vertica database and then grant privileges and roles through SQL statements, you create MC users on the Management Console interface. MC users are external to the database. Their information is stored on an internal database on the MC application/web server. Their access to both MC and to databases managed by MC is controlled by groups of privileges (also referred to as access levels). MC users are not system (Linux) users; they are entries in the MC internal database.

Permission Group Types

There are two types of permission groups on MC, those that apply to MC configuration and those that apply to database access:

- **MC configuration** privileges are made up of roles that control what users can configure on the Management Console, such as modify MC settings, create and import Vertica databases, restart MC, create a Vertica cluster through the MC interface, and create and manage MC users.
- **MC database** privileges are made up of roles that control what users can see or do on a Vertica database monitored by MC, such as view the database cluster state, query and session activity, monitor database messages and read log files, replace cluster nodes, and stop databases.

If you are using MC, you might want to allow one or more users in your organization to configure and manage MC, and you might want other users to have database access only. You can meet these requirements by creating MC users and granting them a role from each privileges group. See Creating an MC User for details.

MC User Types

There are five types of role-based users on MC:

- The default superuser administrator (Linux account) who gets created when you install and configure MC and oversees all of MC. See SUPER Role (mc).
- Users who can configure all aspects of MC and control all databases managed by MC. See ADMIN Role (mc).
• Users who can configure MC user settings and monitor all databases managed by MC. See MANAGER Role (MC).
• Users who can configure some aspects of MC user settings and monitor all databases managed by MC. See IT Role (mc).
• Users who cannot configure MC and have access to one or more databases managed by MC. See NONE Role (mc).

You create users and grant them privileges (through roles) on the MC Settings page in the User management tab.

Creating Users and Choosing an Authentication Method

You create users and grant them privileges (through roles) on the MC Settings page. You can also choose how to authenticate their access to MC.

• To add users who are authenticated against the MC, click User Management
• To add users who are authenticated through your organization's LDAP repository, click Authentication

MC supports only one method for authentication, so if you choose MC, all MC users will be authenticated using their MC login credentials.

Default MC Users

The MC super account is the only default user. The super or another MC administrator must create all other MC users.

• About MC Privileges and Roles
• Granting Database Access to MC Users
Creating an MC User

MC provides two authentication schemes for MC users: LDAP or MC (internal). The method you choose when you configure MC is the method MC uses to authenticate all MC users. It is not possible to authenticate some MC users against LDAP and other MC users against credentials in the database through MC.

- **MC (internal) authentication.** Internal user authorization is specific to MC itself. You create a user with a username and password combination. This method stores MC user information in an internal database on the MC application/web server, and encrypts passwords. Note that these MC users are not system (Linux) users; they are entries in the MC’s internal database.

- **LDAP authentication.** All MC users—except for the MC super administrator, which is a Linux account—are authenticated based on search criteria against your organization's LDAP repository. MC uses information from LDAP for authentication purposes only and does not modify LDAP information. Also, MC does not store LDAP passwords but passes them to the LDAP server for authentication.

Instructions for creating new MC users are in this topic.

- If you chose MC authentication, follow the instructions under Create a New User Authenticated by MC.
- If you chose LDAP authentication, follow the instructions under Create a New User from LDAP.

See Configuring MC, About MC Users and LDAP Authentication for more information.

**Prerequisites**

Before you create an MC user, ensure that:

- You have created a database directly on the server or through the MC interface, or you imported an existing database cluster into the MC interface. See Managing Database Clusters.
- You have created a database user account (source user) on the server, which has the privileges and/or roles you want to map to the new (target) MC user. See Creating a Database User.
- You know which MC privileges you want to grant to the new MC user. See About MC Privileges and Roles.
You will be mapping the MC user to a Vertica DB user who has sysmonitor privileges assigned, or to the Vertica database super user. Without sysmonitor (or super user) privileges, the mapped MC user will not be able to view information in MC monitoring tables, and will not be able to load Kafka streaming data.

If you have not yet met the first two above prerequisites, you can still create new MC users; you just won’t be able to map them to a database until after the database and target database user exist. To grant MC users database access later, see Granting Database Access to MC Users.

Create a New User Authenticated by MC

1. Sign in to MC as an administrator and navigate to MC Settings > User Management.
2. Click Add.
3. Enter the MC username.

   **Note:**
   It is not necessary to give the MC user the exact same name as the database user account you’ll map the MC user to in Step 7. What matters is that the source database user has privileges and/or roles similar to the database role you want to grant the MC user. The most likely scenario is that you map multiple MC users to a single database user account.

4. Let MC generate a password or create one by clicking Edit password. If LDAP has been configured, the MC password field will not appear.
5. Optionally enter the user's e-mail address.
6. Select an MC configuration permissions level. See MC Configuration Privileges. Your choice in this field also fills in the appropriate User API Key value.
7. Next to the DB access levels section, click Add to grant this user database permissions.

   1. Choose a database. Select a database from the list of MC-discovered (databases that were created on or imported into the MC interface).
   2. Database username. Enter an existing database user name or, if the database is running, click the ellipsis […] to browse for a list of database users, and select a name from the list.
   3. Database password. Enter the password to the database user account (not this username's password).
4. **Restricted access.** Choose a database level (ADMIN, IT, or USER) for this user.
5. Click OK to close the Add permissions dialog box.
6. If the Vertica database is configured to require TLS, select Yes in the Use TLS Connection drop-down. MC launches the Certificates wizard to let you configure TLS. See Completing the MC Certificates Wizard.
8. Leave the user's Status as enabled (the default). If you need to prevent this user from accessing MC, select disabled.
9. Click Add User to finish.

**Create a New LDAP-authenticated User**

When you add a user from LDAP on the MC interface, options on the Add a new user dialog box are slightly different from when you create users without LDAP authentication. Because passwords are store externally (LDAP server) the password field does not appear. An MC administrator can override the default LDAP search string if the user is found in another branch of the tree. The Add user field is pre-populated with the default search path entered when LDAP was configured.

1. Sign in to MC and navigate to MC Settings > User management.
2. Click Add and provide the following information:
   1. LDAP user name.
   2. LDAP search string.
   3. User attribute, and click Verify user.
   4. User's email address.
   5. MC configuration role. NONE is the default. See MC Configuration Privileges for details.
   6. Database access level. See MC Database Privileges for details.
   7. Accept or change the default user's Status (enabled).
3. Click Add user.

If you encounter issues when creating new users from LDAP, you'll need to contact your organization's IT department.

**How MC Validates New Users**

After you click OK to close the Add permissions dialog box, MC tries to validate the database username and password entered against the selected MC-managed database or
against your organization's LDAP directory. If the credentials are found to be invalid, you are asked to re-enter them.

If the database is not available at the time you create the new user, MC saves the username/password and prompts for validation when the user accesses the Database and Clusters page later.

- Granting Database Access to MC Users
- Creating a Database User

Managing MC Users

You manage MC users through the following pages on the Management Console interface:

- MC Settings > User management
- MC Settings > Resource access

Who Manages Users

The MC superuser administrator (SUPER Role (mc)) and users granted ADMIN Role (mc) manage all aspects of users, including their access to MC and to MC-managed databases.

Users granted IT Role (mc) can enable and disable user accounts.

See About MC Users and About MC Privileges and Roles for more information.

Editing an MC user's information follows almost the same steps as creating a new user, except that you select an existing user and click Edit. The user's information will be pre-populated, so that you can edit and save it.

The only user account you cannot alter or remove from the MC interface is the MC super account.
What Kind of User Information You Can Manage

You can change the following user properties:

- MC password
- Email address. This field is optional. If the user is authenticated against LDAP, the email field is pre-populated with that user's email address if one exists.
- MC Configuration Privileges role
- MC Database Privileges role

You can also change a user's status (enable/disable access to MC) and delete users.

About User Names

After you create and save a user, you cannot change that user's MC user name, but you can delete the user account and create a new user account under a new name. The only thing you lose by deleting a user account is its audit activity, but MC immediately resumes logging activity under the user's new account.
About MC Privileges and Roles

As introduced in About MC Users, you control user access to MC through groups of privileges (also referred to as access levels) that fall into two types, those that apply to MC configuration, and those that apply to MC-managed Vertica databases.

MC Permission Groups

- **MC configuration** privileges are made up of roles that control what users can configure on the Management Console, such as modify MC settings, create and import Vertica databases, restart MC, create a Vertica cluster through the MC interface, and create and manage MC users.
- **MC database** privileges are made up of roles that control what users can see or do on a Vertica database monitored by MC, such as view the database cluster state, query and session activity, monitor database messages and read log files, replace cluster nodes, and stop databases.

**Note:**
When you grant an MC user a database role, that user inherits the privileges assigned to the database user account to which the MC user is mapped. For maximum access, use the dbadmin username and password.

MC database privileges cannot alter or override the Vertica database user's privileges and roles.

**Note:**
If TLS/SSL is configured in mutual mode on the Vertica database, each MC user must be configured with an individual client certificate and private key, to log into the database from MC. See Configuring TLS for MC Users, for Mutual Mode. If the individual certificate has not been configured, you see an error message. See your Management Console administrator.

MC Configuration Privileges

When you create an MC user, you assign them an MC configuration access level (role). MC roles control a user's ability to create users and manage MC settings on the MC interface.

In addition to an MC role, users also have a database role that controls their database-specific privileges. See MC Database Privileges.

MC Roles and Privileges You Can Assign Users

You can assign a user one of the following MC access levels:

- **ADMIN Role (mc)**—Full access to all MC functionality.
- **MANAGER Role (MC)**—Access to MC user management functionality. Access to non-database MC alerts.
- **IT Role (mc)**—Limited access to MC user management functionality. Access to MC log and to non-database MC alerts.
- **NONE Role (mc)**—Database access only, to the databases an administrator assigns to this user.

You grant MC configuration privileges at the same time you create the user's account, on the User Management tab of the MC Settings page. You can change MC access levels using this page. See Creating an MC User for details.

You can also use the User Management tab to grant users access to one or more databases managed by MC. See MC Database Privileges for details.
**MC Configuration Privileges By User Role**

You grant the following configuration privileges by MC role.

---

**SUPER Role (mc)**

The default superuser administrator, called **Super** on the MC UI, is a Linux user account that gets created when you install and configure MC. During the configuration process, you can assign the Super any name you like; it need not be dbadmin.

The MC SUPER role, a superset of the **ADMIN Role (mc)**, has the following privileges:

- Oversees the entire Management Console, including all MC-managed database clusters

  **Note:**
  
  This user inherits the privileges/roles of the user name supplied when importing a Vertica database into MC. Vertica recommends that you use the database administrator's credentials.

- Creates the first MC user accounts and assigns them an MC configuration role
- Grants MC users access to one or more MC-managed Vertica databases by assigning **MC Database Privileges** to each user

The MC super administrator account is unique. Unlike other MC users you create, including other MC administrators, the MC super account cannot be altered or dropped, and you cannot grant the SUPER role to other MC users. The only property you can change for the MC super is the password. Otherwise the SUPER role has the same privileges on MC as the **ADMIN Role (mc)**.

On MC-managed Vertica databases, SUPER has the same privileges as **ADMIN Role (db)**.
The MC super account does not exist within the LDAP server. This account is also different from the special dbadmin account that gets created during a Vertica installation, whose privileges are governed by the DBADMIN. The Vertica-created dbadmin is a Linux account that owns the database catalog and storage locations and can bypass database authorization rules, such as creating or dropping schemas, roles, and users. The MC super does not have the same privileges as dbadmin.

**See Also**

- Configuring MC
- About MC Privileges and Roles
- Creating an MC User
- Granting Database Access to MC Users
- Managing MC Users

**ADMIN Role (mc)**

This user account is the user who can perform all administrative operations on Management Console, including configure and restart the MC process and add, change, and remove all user accounts. By default, MC administrators inherit the database privileges of the main database user account used to set up the database on the MC interface. Therefore, MC administrators have access to all MC-managed databases. Grant the ADMIN role to users you want to be MC administrators.

The difference between this ADMIN user and the default Linux account, the MC SUPER role, is you cannot alter or delete the MC SUPER account, and you can't grant the SUPER role to any other MC users. You can, however, change the access level for other MC administrators, and you can delete this user's accounts from the MC interface.

The following list highlights privileges granted to the ADMIN role:

- Modify MC settings, such as storage locations and ports, restart the MC process, and reset MC to its original, unconfigured state
- Audit license activity and install/upgrade a Vertica license
- Upload a new SSL certificate
- Use LDAP for user authentication
- View the MC log, alerts and messages
- Add new users and map them to one or more Vertica databases by granting an MC database-level role
- Select a database and add multiple users at once
- Manage user roles and their access to MC
- Remove users from the MC
- Monitor user activity on the MC interface
- Stop and start any MC-managed database
- Create new databases/clusters and and import existing databases/clusters into MC
- Remove databases/clusters from the MC interface
- View all databases/clusters imported into MC

**About the MC Database Administrator Role**

There is also an MC database administrator (ADMIN) role that controls a user's access to MC-managed databases. The two ADMIN roles are similar, but they are not the same, and you do not need to grant users with the ADMIN (mc) role an ADMIN (db) role because MC ADMIN users automatically inherit all database privileges of the main database user account that was created on or imported into MC.

The following table summarizes the primary difference between the two ADMIN roles, but see ADMIN Role (db) for details specific to MC-managed database administrators.

<table>
<thead>
<tr>
<th>MC configuration ADMIN role</th>
<th>MC database ADMIN role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform all administrative operations on the MC itself, including restarting the MC process. Privileges extend to monitoring all MC-created and imported databases but anything database-related beyond that scope depends on the user's privileges granted on the database through GRANT statements.</td>
<td>Perform database-specific activities, such as stop and start the database, and monitor query and user activity and resources. Other database operations depend on that user's privileges on the specific database. This ADMIN role cannot configure MC.</td>
</tr>
</tbody>
</table>

**MANAGER Role (MC)**

Users assigned the Manager role can configure user settings in MC. The Manager role allows full access to the User Management tab in MC Settings. Managers can also view a full list of databases monitored by MC on the Home page, view the MC log, and see non-database MC alerts.

The Manager role has similar configuration privileges to the IT configuration role. Unlike IT users, Managers can also create, edit, and delete users in User Settings.

Managers can:
• Add, edit, delete users
• Add, change, delete user permissions
• Map users to one or more databases
• Enable or disable user access to MC

• Reset user passwords
• View the full list of databases monitored by MC on the MC Home page
• View the MC log
• View non-database MC alerts

**IT Role (mc)**

MC IT users can monitor all MC-managed databases, view MC-level (non database) messages, logs, and alerts, disable or enable user access to MC, and reset non-LDAP user passwords. You can also assign MC IT users specific database privileges, which you do by mapping IT users to a user on a database. In this way, the MC IT user inherits the privileges assigned to the database user to which he/she is mapped.

**About the MC IT (database) Role**

There is also an IT database administrator (IT) role that controls a user's access to MC-managed databases. If you grant an MC user both IT roles, it means the user can perform some configuration on MC and also has access to one or more MC-managed databases. The database mapping is not required, but it gives the IT user wider privileges.

The two IT roles are similar, but they are not the same. The following table summarizes the primary difference between them, but see IT Role (db) for details.

<table>
<thead>
<tr>
<th>MC configuration IT role</th>
<th>MC database IT role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitor MC-managed database, view non-database messages, and manage user access</td>
<td>Monitor databases on which the user has privileges, view the database overview and activity pages, monitor the node state view messages and mark them read/unread, view database settings. Can also be mapped to one or more Vertica databases.</td>
</tr>
</tbody>
</table>
**NONE Role (mc)**

The default role for all newly-created users on MC is NONE, which prevents users granted this role from configuring the MC. When you create MC users with the NONE role, you grant them an MC database-level role. This assignment maps the MC user to a user account on a specific database and specifies that the NONE user inherits the database user’s privileges to which he or she is mapped.

Which database-level role you grant this user with NONE privileges—whether ADMIN (db) or IT (db) or USER (db)—depends on the level of access you want the user to have on the MC-managed database. Database roles have no impact on the ADMIN and IT roles at the MC configuration level.

**MC Database Privileges**

When you create MC users, you first assign them MC configuration privileges, which controls what they can do on the MC itself. In the same user-creation operation, you grant access to one or more MC-managed databases. MC database access does not give the MC user privileges directly on Vertica; it provides MC users varying levels of access to assigned database functionality through the MC interface.

Assign users an MC database level through one of the following roles:

- **ADMIN Role (db)**—Full access to all databases managed by MC. Actual privileges ADMINs inherit depend on the database user account used to create or import the Vertica database into the MC interface.
- **Associate Role (Database)**—Full access to all databases managed by MC. Cannot start, stop, or drop a database. Actual privileges that Associates receive depend on those defined for the database user account to which the Associate user is mapped.
- **IT Role (db)**—Can start and stop a database but cannot remove it from the MC interface or drop it.
- **USER Role (db)**—Can view database information through the database Overview and Activities pages but is restricted from viewing more detailed data.
**Mapping MC Users to Database to Avoid Conflicts**

When you assign an MC database level to an MC user, map the MC user account to a database user account to ensure that:

- The MC user inherits the privileges assigned to that database user
- You prevent the MC user from doing or seeing anything not allowed by the privileges for the user account on the server database

Privileges assigned to the database user supersede privileges of the MC user if there is a conflict, such as stopping a database. When the MC user logs into MC using an MC user name and password, Vertica compares privileges for database-related activities to the privileges on the database account to which you mapped the MC user. Vertica allows the user to perform operations in MC only when that user has both MC privileges and corresponding database privileges.

**Tip:**
As a best practice, you should identify, in advance, the appropriate Vertica database user account that has privileges or roles similar to one of the MC database roles.

See [Creating an MC User](#) for more information.

**MC Database Privileges By Role**

The following table summarizes MC database-level privileges by user role. The table shows the default privileges each role has. Operations marked "database user privilege" are dependent on the privileges of the Vertica database user account to which the MC user is mapped.

<table>

</table>

**ADMIN Role (db)**

ADMIN is a **superuser** with full privileges to monitor MC-managed database activity and messages. Other database privileges (such as stop or drop the database) are governed by the user account on the Vertica database that this ADMIN (db) user is mapped to. ADMIN is the most permissive role and is a superset of privileges granted to the Associate Role (Database), IT, and USER roles.

The ADMIN user has the following database privileges by default:

- View the database Overview page
- View and delete database messages
- Mark messages read or unread
- Start the database
- View the Manage page
- View node details
- Start or stop a node
- View database settings
- View the following database Activity page charts:
  - Queries
  - Internal Sessions
  - User Sessions
• System Bottlenecks

• User Query Phases

The following database operations depend on the database user's role that you mapped this ADMIN user to:

• Install or audit a license
• Rebalance, stop, or drop databases
• Add, replace, or remove nodes
• Manage database settings
• View Database Designer
• View additional information on the database Activity page:

• Detailed information in the Queries chart Detail page
• Table Treemap chart
• Query Monitoring chart
• Resource Pools Monitoring chart

**Note:**
Database access granted through Management Console never overrides roles granted on a specific Vertica database.

**About the ADMIN (MC configuration) Role**

There is also an MC configuration administrator role that defines what the user can change on the MC itself. The two ADMIN roles are not the same. Unlike the MC configuration role of ADMIN, which can manage all MC users and all databases imported into the UI, the MC database ADMIN role has privileges only on the databases you map this user to. The following table summarizes the primary difference between them. See [ADMIN Role (mc)](https://docs.vertica.com) for additional details.

<table>
<thead>
<tr>
<th>MC database ADMIN role</th>
<th>MC configuration ADMIN role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform database-specific activities, such as stop and start the database, and monitor query and user activity and resources. Other database operations depend on that user's privileges on the specific database. This ADMIN role cannot configure MC.</td>
<td>Perform all administrative operations on the MC itself, including restarting the MC process. Privileges extend to monitoring all databases created and imported by MC. Anything database-related beyond that scope depends on the user's privileges granted on the database through GRANT statements.</td>
</tr>
</tbody>
</table>
**Associate Role (Database)**

The Associate role is an MC database access role. It is similar to the Admin role. It has privileges to monitor activity and messages on databases managed by MC. Unlike Admin users, Associate users cannot start, stop, or drop the database. The Associate user role is mapped to a user account on the database. This mapped user role determines what other database privileges the Associate role has (such as modifying settings, installing licenses, and viewing the database designer).

The Associate user has the following database privileges by default:

- View the database Overview page
- View and delete database messages
- Mark messages read or unread
- View the Manage page
- View node details
- View database settings

The following database operations depend on the database user's role that you mapped this Associate user to:

- Install or audit a license
- Manage database settings
- View Database Designer
- View the database Activity page

**Note:**

Database access granted through Management Console never overrides roles granted on a specific Vertica database.

**IT Role (db)**

IT can view most details about an MC-managed database, such as messages (and mark them read/unread), the database overall health and activity/resources, cluster and node state, and MC settings. You grant and manage user role assignments through the **MC Settings > User management** page on the MC.
About the IT (MC configuration) Role

There is also an IT role at the MC configuration access level. The two IT roles are similar, but they are not the same. If you grant an MC user both IT roles, it means the user can perform some configuration on MC and also has access to one or more MC-managed databases. The following table summarizes the primary difference between them, but see IT Role (mc) for additional details.

<table>
<thead>
<tr>
<th>MC database IT</th>
<th>MC configuration IT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitor databases on which the user has privileges, view the database overview</td>
<td>Monitor MC-managed database, view non-database messages, and manage user access.</td>
</tr>
<tr>
<td>and activity pages, monitor the node state view messages and mark them read/</td>
<td></td>
</tr>
<tr>
<td>unread, view database settings.</td>
<td></td>
</tr>
</tbody>
</table>

**USER Role (db)**

USER has limited database privileges, such as viewing database cluster health, activity/resources, and messages. MC users granted the USER database role might have higher levels of permission on the MC itself, such as the IT Role (mc). Alternatively, USER users might have no (NONE) privileges to configure MC. How you combine the two levels is up to you.

Granting Database Access to MC Users

If you did not grant an MC user a database-level role when you created the user account, you can do so in the User Management tab in MC Settings.

Granting the user an MC database-level role associates the MC user with a database user's privileges and ensures that the MC user cannot do or see anything not allowed by the privileges set up for the user account on the server database. When that MC user logs in to MC, his or her MC privileges for database-related activities are compared to that user's privileges on the database itself. Only when the user has both MC privileges and corresponding database privileges will the operations be exposed in the MC interface.
**Prerequisites**

Before you grant database access to an MC user, see the prerequisites in Creating an MC User.

**Grant a Database-Level Role to an MC user**

1. Log in to Management Console as an administrator and navigate to MC Settings > User management.
2. Select an MC user and click Edit.
3. Verify the MC Configuration Privileges are what you want them to be. NONE is the default.
4. Next to the DB access levels section, click Add and provide the following database access credentials:
   1. **Choose a database.** Select a database from the list of MC-discovered (databases that were created on or imported into the MC interface).
   2. **Database username.** Enter an existing database user name or, if the database is running, click the ellipsis [...] to browse for a list of database users, and select a name from the list.
   3. **Database password.** Enter the password to the database user account (not this username's password).
   4. **Restricted access.** Choose a database level (ADMIN, IT, or USER) for this user.
5. Click OK to close the Add permissions dialog box.
6. If the Vertica database is configured to require TLS, select Yes in the Use TLS Connection drop-down. MC launches the Certificates wizard to let you configure TLS. See Completing the MC Certificates Wizard.
5. Optionally change the user's Status (enabled is the default).
6. Click Save.

**How MC Validates New Users**

After you click OK to close the Add permissions dialog box, MC tries to validate the database username and password entered against the selected MC-managed database or against your organization's LDAP directory. If the credentials are found to be invalid, you are asked to re-enter them.
If the database is not available at the time you create the new user, MC saves the username/password and prompts for validation when the user accesses the Database and Clusters page later.

**Managing Client Connections**

Each client session to MC uses a connection from MaxClientSessions, a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages.

**Tip:**
You can increase the value for MaxClientSessions on an MC-monitored database to account for extra sessions. See [Managing Sessions](#) for details.
Managing Database Clusters

Management Console allows you to monitor multiple databases on one or more clusters at the same time. MC administrators can see and manage all databases and clusters monitored by MC, while non-administrative MC users see only databases on which they have been assigned the appropriate access levels.

Depending on your access level, the database and cluster-related management operations you can perform through MC include:

- Create an empty database in an existing cluster.
- Create a cluster and database on AWS or on-premise.
- Import an existing database/cluster into the MC interface.
- Start the database, unless it is already running (green).
- Stop the database, if no users are connected.
- Remove the database from the MC interface.

**Note:**
Remove does not drop the database. A Remove operation leaves it in the cluster, hidden from the UI. To add the database back to the MC interface, import it using the IP address of any cluster node. A Remove operation also stops metrics gathering on that database, but statistics gathering automatically resumes after you re-import.

- Drop the database after you ensure no users are connected. Drop is a permanent action that drops the database from the cluster.

In databases and clusters created using MC with Provisioning, AWS instance operations are available from MC, like stop, start, reboot and terminate. These AWS operations can be performed on the whole cluster or one instance at a time. See the sections Managing a Cluster on AWS Resources and Managing AWS Instances sections in Viewing and Managing Your Cluster.

Viewing Cluster Infrastructure

For a summary of all databases and clusters currently monitored by MC, click View Your Infrastructure on the MC Home page.
The first tab on the Infrastructure page, **Database and Cluster View**, is overview of the infrastructure of all the clusters and databases currently monitored by MC.

Three rows are displayed: Infrastructure, Clusters, and Databases.

- **Infrastructure.** Specifies the type of environment on which your clusters reside:
  - Cloud: Names the cloud platform, such as AWS
  - On premise: "Data Center"
  - Apache Hadoop: "Hadoop Environment"
- **Clusters.** Click a cluster to see its full details. From the dialog that opens, you can:
  - Add the cluster's master API key
  - View or Manage the cluster page
  - Remove the cluster from MC monitoring
  - Create a new database on the cluster (if all other databases on the cluster are stopped)
- **Databases.** A numbered badge on the top right displays the number of highest-priority messages from that database that are in your inbox. If a handshake icon (ollider) displays next to "Type," that indicates the database is running in Eon Mode. If the handshake is absent, the database is running in Enterprise Mode. Click any database for more details. From the dialog that opens, you can:
  - View the database's Overview page
  - Stop or start the database
  - Drop the database (if the database is stopped)
  - Remove the database from MC monitoring

In the screen capture below, MC is monitoring two different clusters that both reside on an AWS environment. One database is running on each cluster. The DemoDB database, displayed on the left, has a handshake icon next to its Type label that indicates it is running in Eon Mode. The VMart database on the 3-node cluster, displayed on the right, is running in Enterprise Mode.
Viewing and Managing Your Cluster

The Cluster page shows a node-based visualization of your cluster. This page shows the cluster’s host addresses, the installed version of Vertica running, and a list of the databases on the cluster that Management Console is currently monitoring.
From this page, you can also create a new empty database on the cluster, or import any existing databases MC discovers on the cluster.

MC displays different options depending on whether you imported the cluster to MC, or created the cluster using MC:

- **Imported cluster**: MC displays monitoring information about the cluster.
- **Cluster created using Management Console**: MC displays both monitoring information and management options for third-party cloud platforms such as AWS. For clusters you created using the current MC, the Cluster page provides cluster and instance management options.

## Go to the Cluster Page

To view the Cluster page:

1. From the Home page, click **View Your Infrastructure** to go to the **Infrastructure page**. This page lists all the clusters and associated clusters the MC is monitoring.
2. Click any cluster listed on the Infrastructure page. Select **View** or **Manage** from the dialog that displays, to view its Cluster page. (In a Cloud environment, if MC was deployed from a cloud template the button says "Manage". Otherwise, the button says "View".)

**Note:**
You can click the pencil icon beside the cluster name to rename the cluster. Enter a name that is unique within MC.

## Monitor Imported Clusters

Whether you have imported or created a cluster using MC, you can view information about it through the Cluster page.

This page includes the following information:

- **Node visualization**: A visualization of all nodes within the cluster. Icons at the top right of each node indicate if the nodes are up. Click any node to see details about its host name, CPU information and total memory. If there are many nodes in the cluster, use the Zoom Level slider at the bottom right of the page to zoom the visualization in or out.
- **Node List**: A list of all the node IPs within the cluster. Click any node in the list to see details about it.
• **Cluster Summary:** A summary of details about the cluster, including the version of Vertica running on the cluster and the number of hosts. If the cluster is running on cloud-platform resources such as AWS, you can also see region and instance type information.

• **Databases:** Lists all databases monitored by MC and their current state.
  - At the bottom of the Databases section, click **Create New** to [create a new empty database](#) using Management Console.
  - This section also lists any Vertica databases on this cluster, if existing, that are not yet monitored by Management Console. See [Importing an Existing Database Into MC](#) for the process of importing a discovered database.

The screen capture below shows an overview of a 3-node on-premises cluster, which was created using the command line and imported into Management Console. This cluster has a running Enterprise Mode database on it.

---

**Manage a Cluster Created on AWS with the Cluster Creation Wizard**

If you installed Vertica from the AWS Marketplace [using AWS resources](#), MC offers cluster management operations that are specific to the cloud. In this way, you can manage a cluster running on AWS without going to the AWS console.
**Note:** The AWS management operations to add or terminate instances are only available for clusters on AWS resources that were created using the current MC. Add and terminate capabilities are disabled for any cluster imported to MC, even if the imported cluster is on an AWS environment.

If you upgrade the cluster's Vertica version manually through the command line, AWS management operations in MC become disabled for the cluster, even if you created that cluster using MC. Make sure to upgrade the cluster's Vertica version through MC in order to preserve AWS management capabilities for that cluster in MC.

In the screen capture below, the Cluster page shows a 4-node cluster, which was provisioned using the Cluster Creation wizard. (See Provisioning a New Vertica Cluster and Database on AWS in MC.)

You can perform the following operations on your cluster through the cluster page:

- **Start Cluster.** Start all the instances in the cluster. Available at the top of the Cluster page.
- **Stop Cluster.** Stop all the instances in the cluster. You must first stop any running database on the cluster. Available at the top of the cluster page.
- **Reboot Cluster.** Restart all instances in the cluster. Available under the Advanced menu at the top of the page.
- **Terminate Cluster.** Terminate all instances in the cluster, the databases on it, and all AWS resources from the cluster. The Terminate Cluster operation is available under the Advanced menu at the top of the page.
For Enterprise Mode databases, this operation *permanently deletes* any data you had on the cluster or its databases.

For Eon Mode databases, the data is preserved in communal storage and you can later [*revive the database in a new cluster*](#). When you choose to terminate the cluster, MC gives you the option to also stop the database before termination, which is recommended in order to safely revive later.

You can also manage individual instances in your cluster.

To do so, in the **Instance List** panel, select the IP address of any instance in your cluster that you want to perform the action on. Then click an icon from the menu at the top of the panel. Hover over an icon to read the action it performs.

- **Start Instance.** Start an individual instance in the cluster.
- **Stop Instance.** Stop an individual instance in the cluster.
- **Add Instance.** Add another instance to your cluster. When you select this action, MC opens the Add AWS Instance wizard, where you specify volume and storage information for the instance. You must supply your AWS key pair (and a Vertica Premium Edition license if you are adding more nodes to the cluster than a Community Edition license allows). You can add up to 10 instances at a time using the Add Instance action.
- **Restart Instance.** Restart an individual instance in the cluster.
- **Terminate Instance.** Permanently remove the instance from your cluster.

**Configure TLS for a Vertica Database Already Monitored in Management Console**

1. In MC, on the **Clusters > DatabaseName > Overview** page, click **Settings** in the lower tabs.
2. On the **Settings** page, click the **Security** tab.
3. On the **Security** page, under **Configure TLS Connection to Database**, in the **Use TLS Connection to Database** drop-down, select **Enabled**.

4. MC displays "Configure Management Console to use secured connection to query Vertica database or Modify existing configuration." Below it, click **Configure TLS Connection**. This launches the Certificates wizard which allows you to configure TLS for the database.

5. See **Configuring TLS for a Monitored Database in MC**

---

**Create an Empty Database Using MC**

You can create a new database on an existing Vertica cluster through the **Management Console** interface.

MC provides a step-by-step wizard to install a new Vertica database on an existing cluster.

Depending on how you installed MC, the screens you see will differ:

- If you installed MC with an RPM, follow the steps in this wizard below.
- If you installed MC on Amazon Web Services (AWS) resources using a CloudFormation Template, you will see this wizard further below.

**Note:**

To provision a new database *and* cluster on AWS resources (this might be the case if you installed Vertica using a CloudFormation Template), see **Provisioning a New Vertica Cluster and Database on AWS in MC**. To provision a new database and cluster on-premise, see **Creating a Cluster Using MC** in the Installation Guide.

---

**Create a Database (Using MC Installed Through an RPM)**

1. Connect to Management Console, and log in.
2. On the Home page, click **Existing Infrastructure**. The Database and Cluster View page appears; this is a summary of your environment, clusters, and databases.

3. If no databases exist on the cluster, continue to the next step; otherwise:
1. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop**.

2. Wait for the running database to have a status of *Stopped*.

4. In the row labeled Clusters, click the existing cluster you want to create a database on. (If a database is already running on it, first stop the database.) When a dialog box identifying that cluster appears, click **Create Database**. The database creation wizard starts.

5. Follow the steps in the wizard to successfully create a database.

You can close the web browser during the process and sign back in to MC later; the creation process continues unless an unexpected error occurs.

**Create a Database (Using MC Installed Through a CFT)**

You will see this wizard if you [installed Vertica on AWS Resources using a CloudFormation Template](https://example.com).

1. Connect to Management Console, and log in.

2. On the Home page, click **Existing Infrastructure**. The Database and Cluster View page appears; this is a summary of your environment, clusters, and databases.

3. If no databases exist on the cluster, continue to the next step; otherwise:

   1. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop**.

   2. Wait for the running database to have a status of *Stopped*.

4. In the row labeled Clusters, click the existing cluster you want to create a database on. When a dialog box identifying that cluster appears, click **Create Database**. The database creation wizard starts.
5. When a dialog box identifying that cluster appears, click **Create Database**. The database creation wizard starts.

6. Choose a mode for your database: Eon Mode or Enterprise Mode. The default is Eon Mode. Note that you cannot switch the mode on your database after creation. (For a summary of the difference between modes, see Creating a Database in the Administrator’s Guide.)

7. Follow the cluster creation wizard and enter the parameters for your new cluster and database. (Use the authentication method you selected in the CloudFormation Console when launching your AWS resources and MC.)

   If you choose Enterprise Mode, the wizard offers two paths:
   - **Quick Create** provides default values during cluster creation.
   - **Custom Create** allows you to specify EC2 instance types and other AWS resources for your Vertica cluster instances.

8. After confirming the details you have provided for your new cluster, click **Create**. The dialog shows you the progress of the creation process, which takes a few minutes. (You can leave or close the browser during this process; to return to this progress window, select Create a New Vertica Database Cluster on the home page.)

   **Note:**
   During Eon Mode database creation, use an existing Amazon S3 bucket in the same region as your instances for your communal storage location. Specify a new subfolder name, which Vertica will dynamically create within the existing S3 bucket. For example, s3://existingbucket/newstorage1. You can create a new subfolder within existing ones, but database creation will roll back if you do not specify any new subfolder name.

9. The dialog displays a success message when the creation process completes. Click **Get Started** to view the Fast Tasks page.
View your new database any time under the **Available Databases** section of the Management Console home page. See [Managing Database Clusters](#) for more about further managing your cluster, instances, and database using MC.

- Troubleshooting with MC Diagnostics
- Restarting MC

## Importing an Existing Database Into MC

If you have already created a Vertica database, you can import it into MC to monitor its health and activity.

When you install MC on the same cluster as the existing database you intend to monitor, MC automatically discovers the cluster and any databases installed on it, whether those databases are currently running or are down.

![Note](image)

*Note:*

If you haven't created a database and want to create one through the MC, see [Create an Empty Database Using MC](#).

## Import a Database Existing on a Monitored Cluster

The following procedure describes how to import an existing database that is on a cluster MC is already monitoring.

1. **Connect** to Management Console and sign in as an MC administrator.
2. On the MC [Home page](#), click **View Your Infrastructure**.
3. On the Databases and Clusters page, click the cluster and click **View** in the dialog box that opens.
4. On the left side of the page under the Databases heading, click **Import Discovered**.

![Tip](image)

*Tip:*

A running database appears as Monitored; any non-running databases appear as Discovered. MC supports only one running database on a
You must shut down a running database on a cluster in order to monitor another database on that cluster.

5. In the **Import Database** dialog box:

- Select the database you want to import.
- Optionally clear auto-discovered databases you don't want to import.
- Supply the database administrator username and password and click **Import**. (Supplying a non-administrator username prevents MC from displaying some charts after import.)
- If the Vertica database is configured for TLS security, you need to configure TLS for all Management Console connections to this database over JDBC. Click **Use TLS**. Management Console launches the Certificates wizard. See **MC Certificates Wizard**.

After Management Console connects to the database it opens the **Manage** page, which provides a view of the cluster nodes. See **Monitoring Cluster Status** for more information.

You perform the import process once per existing database. Next time you connect to Management Console, your database appears under the Recent Databases section on the Home page, as well as on the Databases and Clusters page.

**Note:**
The system clocks in your cluster must be synchronized with the system that is running Management Console to allow automatic discovery of local clusters.

---

**Import a Database Existing on a New Cluster**

If the database you intend to monitor is on a cluster MC is not currently monitoring, MC cannot automatically discover it. You can import it with the following procedure.

1. **Connect** to Management Console and sign in as an MC administrator.
2. On the MC **Home page**, click **Import a Vertica Database Cluster**.
3. Enter the IP address of one of the database's cluster nodes.
4. Enter the master API key for the cluster. Find the key here: `/opt/vertica/config/apikeys.dat`
5. In the **Import Database** dialog box:
• Select the database you want to import.
• Optionally clear auto-discovered databases you don't want to import.
• Supply the database administrator username and password and click **Import.**  
  (Supplying a non-administrator username prevents MC from displaying some charts after import.)
• To configure TLS security for all Management Console connections to this database over JDBC, click **Use TLS.** Management Console launches the Certificates wizard. For instructions on completing the wizard, see Configuring TLS While Importing a Database on MC.

### Managing Clusters on AWS in MC

Management Console provides specific resources for managing database clusters on AWS.

You can provision an Eon Mode or Enterprise Mode database cluster on AWS. For details, see Provisioning a New Vertica Cluster and Database on AWS in MC.

You can revive an Eon Mode database cluster on AWS. For more information, see Reviving an Eon Mode Database on AWS in MC. Note that you cannot revive an Enterprise Mode database.

The MC provision and revive wizards for AWS configure separate volumes for the data, depot, catalog, and temp database directories. The specific volumes it uses for each directory depend upon the mode and the specific AWS instance type you select when you provision or revive the cluster. For details on the volumes configured for clusters on AWS, see:

- Eon Mode Volume Configuration Defaults for AWS
- Enterprise Mode Volume Configuration Defaults for AWS

### Provisioning a New Vertica Cluster and Database on AWS in MC

If you deployed Management Console on Amazon Web Services (AWS) resources using a CloudFormation Template, MC provides a step-by-step wizard that allows you to create a Vertica cluster and database.
You provision new Vertica clusters in the same VPC and subnet as the Vertica MC instance. Using the wizard, you can create an initial cluster of up to 60 hosts.

**Note:** To provision a new database and cluster on-premise, see Creating a Cluster Using MC in the Installation Guide. If you installed MC using an RPM, follow the steps in the Installation Guide.

1. On the MC home page, click **Create a New Vertica Database Cluster**.
2. Choose a mode for your database: Eon Mode or Enterprise Mode. You cannot switch the database mode after creation.
3. Follow the cluster creation wizard and enter the parameters for your new cluster and database.

   - By default, Vertica creates your cluster in the same subnet as your MC instance. If you want to manage all Vertica clusters in the same VPC (virtual private cloud), you can provision your Vertica database in a different subnet than the MC instance. To do so, on the AWS Credentials page, select Show Advanced Options and enter a value in the Subnet field.

   **Important:**
   If you specify a different subnet for your database, make sure to secure the subnet.

   - When launching MC with provisioning, use the authentication method you selected in the CloudFormation Console.
4. If you choose Enterprise Mode, complete the wizard by following one of these two paths:
   - **Quick Create** provides default values during cluster creation.
   - **Custom Create** allows you to specify EC2 instance types and other AWS resources for your Vertica cluster instances.
5. If you choose Eon Mode, in the **Vertica Version** field, select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can select RedHat, CentOS, or Amazon Linux for the operating system.

   **Vertica Version**

   - Please select Target Vertica Version
  
   | Version - 9.1.1-1, OS - Amazon Linux 2.0, AMI - ami-049b09d5560f30657 |
   | Version - 9.1.1-1, OS - Red Hat 7.4, AMI - ami-0980bb674192e1ba |

6. Complete the rest of your login credentials and select Next.
7. In the **EC2 Instance Type** field, select the cloud instance type to use for your database cluster. Accept the defaults for the depot, catalog, and temp volumes. The wizard automatically configures separate volumes for the depot, catalog, and temp directories, based on the instance type you select. The last step displays a confirmation page showing the configured volumes. For details on the volume configurations that MC provides, see Eon Mode Volume Configuration Defaults for AWS and Enterprise Mode Volume Configuration Defaults for AWS.

8. Also in Eon Mode, but only in the **Custom Create** path, for each EBS volume you can select whether the volume should be encrypted. With AWS, only 4th and 5th generation instance types (c4, r4, and m4; c5, r5, and m5) support encrypting EBS volumes.

9. Optionally, you can tag the EC2 instances. In the **Tag EC2 instances** field, if another cluster is already running, MC fills those fields with the tag values for the first instance in the cluster. You can accept the defaults, or enter new tag values.

10. On the summary page, review the details you entered for your new cluster.

11. Click **Create**. The dialog shows you the progress of the creation process, which takes a few minutes. (You can leave or close the browser during this process. To return to this progress window, select **Create a New Vertica Database Cluster** on the home page.)

   **Note:**
   
   During Eon Mode database creation, use an existing S3 bucket in the same region as the instances for your communal storage location. You must also specify a new, nonexisting subfolder name that Vertica then dynamically creates within the existing S3 bucket. Use a format beginning with `s3://`. For example, `s3://existingbucket/newsubfolder1`.

12. The dialog displays a success message when the creation process completes. Click **Get Started** to view the **Fast Tasks** page.

To view your new database, go to the **Available Databases** section of the MC home page.

For more information about further managing your cluster, instances, and database using MC, see **Managing Database Clusters**.

**Reviving an Eon Mode Database on AWS in MC**

An **Eon Mode database** keeps an up-to-date version of its data and metadata in its communal storage location. After a cluster hosting an Eon Mode database is stopped, this data and metadata continue to reside in communal storage. When you revive the database
later, Vertica uses the data in this location to restore the database in the same state on a newly provisioned cluster.

If Management Console has been installed using a CloudFormation template from the AWS Marketplace, you can use the Provision and Revive wizard in Management Console.

You can only revive an Eon Mode database if it is version 9.1.0 or higher.

During a revive of your database, when you select a Vertica version that is higher than the version of the original database in the communal storage, Vertica upgrades your database to match the Vertica version you selected. This upgrade may cause the database revive to take longer. To bypass this upgrade, select the Vertica version of your original database.

**Note:**
After your Vertica database has been upgraded, you can not downgrade your database later.

See Shutting Down and Reviving An Eon Mode Database for how to revive a database using admintools.

**Note:**
If you need to revive your database on a previously existing cluster, you must revive it using admintools, not Management Console. For example, use admintools if you stopped a cluster whose hosts use instance storage where data is not persistently stored, and plan to bring back the database on the same cluster.

**Prerequisites**

- The communal storage location (an AWS S3 bucket) of the stopped Eon Mode database you plan to revive. (For how to stop or terminate a cluster using Management Console, see Viewing and Managing Your Cluster.)
- The username and password of the Eon Mode database you plan to revive.
- An AWS account with permissions to create a VPC, subnet, security group, instances, and roless
- An Amazon key pair for SSH access to an instance.
**Revive the Database**

You use a wizard in Management Console to provision a new cluster and revive a database onto it. For the new cluster, Management Console automatically provisions the same number of instances used by the database when it was last shut down.

**Caution:**
You should not use the same communal storage location for running multiple databases, as it causes data corruption. To avoid corruption, you should also never use the revive functionality to simultaneously run the same Eon Mode database on different clusters.

1. From the Management Console home page, click **Provision and Revive an Eon Mode Database**. The Provision and Revive an Eon Mode Database wizard opens.
2. Enter your cloud credentials and cluster preferences. Your cluster must be in the same region as your communal storage location's S3 bucket. To revive the cluster in a new region, you must:
   a. Create a new S3 bucket in the new region.
   b. Copy the previous S3 bucket's contents into it.
   c. Provide the new S3 bucket URL in Step 3.
3. By default, Vertica creates your cluster in the same subnet as your Management Console instance. If you want to manage all Vertica clusters in the same VPC, you can provision your Vertica database in a different subnet than the Management Console instance. To do so, on the **AWS Credentials** page, select **Show Advanced Options** and enter a value in the **Subnet** field.

**Important:**
If you specify a different subnet for your database, make sure to secure the subnet.

4. Enter the S3 URL of the database you are reviving. When you enter an S3 bucket location, Management Console discovers all known Eon Mode databases.
5. Select the correct database to revive.
6. Provide the database administrator credentials for the database you are reviving. These credentials are the same as the ones used by the database in the previous cluster.
7. In the **Database Version** field, choose the desired Vertica database version. Select from the latest hotfix of recent Vertica releases. For each Vertica version, you can select from a list of associated Linux operating systems.
If you select a Vertica version that is higher than the version of the original database in the communal storage, Vertica upgrades your database to match the Vertica version you selected. This upgrade may cause the database revive to take longer. To bypass this upgrade, select the Vertica version of your original database.

**Note:**
After your Vertica database has been upgraded, you cannot downgrade your database later.

8. Choose instance types for the cluster. Management Console provisions the same number of instances used by the database when it was last shut down. The wizard automatically configures separate volumes for the depot, catalog, and temp directories, based on the instance type you select. The last step displays a confirmation page showing the configured volumes. For details on the volume configurations that MC provides, see Eon Mode Volume Configuration Defaults for AWS and Enterprise Mode Volume Configuration Defaults for AWS.

**Caution:**
To ensure against data loss, choose instances that use EBS storage. EBS storage is durable, while instance store is temporary. For Eon mode, Management Console displays an alert to inform the user of the potential data loss when terminating instances that support instance store.

9. Choose whether to encrypt your EBS volumes. With AWS, only 4th and 5th generation instance types (c4, r4, and m4; c5, r5, and m5) support encrypting EBS volumes.

10. Optionally, you can tag the instances. In the **Tag EC2 instances** field, if another cluster is already running, Management Console fills those fields with the tag values for the first instance in the cluster. You can accept the defaults, or enter new tag values.

11. Review your choices, accept the license agreement, and click **Create** to revive the database on a new cluster. If the version of Management Console you use to revive is higher than that of the database, Management Console first notifies you that it is about to automatically upgrade the database. After starting the revive process, the wizard displays its progress. After a successful revive, the database starts automatically.

12. When the revive process is complete, click **Get Started** to navigate to the **Fast Tasks** page.
Eon Mode Volume Configuration Defaults for AWS

When you provision or revive an Eon Mode database cluster, Management Console configures separate volumes for the depot, catalog, and temp directories. The specific volumes and sizes that Management Console configures vary depending on the AWS instance type you select when provisioning or reviving the cluster.

MC follows these rules when allocating resources for these directories for an Eon Mode database cluster:

- **Depot**: Allocate instance store if available with the selected instance type. Otherwise, allocate EBS volumes. (In Eon Mode on AWS, S3 is the backup.)
- **Catalog**: Always allocate an EBS volume, to ensure the catalog is durable.
- **Temp**: Allocate instance store if available with the selected instance type. Otherwise, allocate EBS volumes.

### Note:
Table below includes all instances types that include instance store.

<table>
<thead>
<tr>

Enterprise Mode Volume Configuration Defaults for AWS

When you provision an Enterprise Mode database cluster, Management Console configures separate volumes for the data, catalog, and temp directories.

The specific volumes and sizes that MC uses vary depending on the AWS instance type you select when provisioning the cluster.

MC follows these rules when selecting resources for these directories for an Enterprise Mode database cluster:

- Data: Always use EBS volumes, to ensure the data is durable.
- Catalog: Always use an EBS volume, to ensure the catalog is durable.
- Temp: If the chosen instance type offers instance store, then use volumes from instance store.

**Note:**
Table below includes all instance types that include instance store.
<table>
<thead>
<tr>
<th>Instance Type API Name</th>
<th>Instance Storage</th>
<th>Data</th>
<th>Catalog</th>
<th>Temp</th>
</tr>
</thead>

### Import and Monitor in a Hadoop Environment

You can use Management Console to connect to and monitor a Vertica database that resides in an Apache Hadoop environment.

#### Connecting to Ambari and Importing Vertica Within a Hadoop Environment

To import your Vertica database that resides in a Hadoop environment, connect to that Hadoop environment in Management Console through an Apache Ambari server. Then, through that connection, import Vertica.

Before you connect and import, you must:

- Install Vertica on a Hadoop cluster
- Install Apache Ambari version 1.6.1 or 2.1.0
- Enable Ganglia on your Hadoop cluster, to get the most information from your Hadoop environment

To connect to an Ambari server:

1. From the Management Console home page, select **Provisioning**. Then, click **Connect using an Ambari server to import Vertica within a Hadoop environment**.
2. In the **Provision Access within Hadoop Environment** window, enter a new Ambari connection with your username and password. If you already have an existing connection, a window opens that allows you to select an existing connection from the drop-down menu.

3. In the next window, select the Hadoop cluster where the Vertica database you want to monitor resides. MC will discover Hadoop clusters that are currently monitored by the Ambari server you specify.

   A window appears confirming that your Hadoop cluster is saved. If MC currently does not monitor Vertica clusters in the specified Hadoop environment, you have the option to import Vertica clusters at this time.

4. Enter the IP address for the Vertica database you want to import and monitor. If Vertica is running on multiple hosts, enter the IP address of one of them.

5. Enter the API key for the Vertica cluster. The API key is generated during Vertica installation and you can find it in the `/opt/vertica/config/apikeys.dat` file.

6. When the next window displays the discovered databases, select one or more database you want to import, along with the database username and password.
7. Confirm that the import is successful. If it is, a success message appears. Click **Done** to go to the **Existing Infrastructure** page.

To import an additional Vertica cluster within a Hadoop environment, click **Import Cluster or database using IP address discovery** under **Provisioning**. Management Console will automatically associate the cluster with the existing Hadoop environment.

**Monitoring Vertica Within a Hadoop Environment**

To monitor the Vertica clusters in a Hadoop environment, navigate to the **Existing Infrastructure** page:
Click to select the Hadoop environment, and then click View Vertica Databases.

The resulting screen displays information about the Vertica databases that reside in a Hadoop environment:
You can monitor information like resource usage, Hadoop services, and database and connection status.

**Updating and Removing an Ambari Connection**

To update or remove an existing Ambari connection, go to the MC **Existing Infrastructure** page, and click on the relevant Hadoop environment.

To update a connection, click **Update Ambari Connection**. Step through the wizard to update the connection.

To remove a connection, select **Update Ambari Connection** and choose **Remove Connection**, or click **Discontinue Monitoring** and then confirm that you want to remove the connection. Removing the connection also removes all Vertica databases associated with this connection from MC monitoring. You can re-import the databases later if needed.

**See Also:**

**Integrating with Apache Hadoop**

**Connecting Securely from MC to a Vertica Database**

When you use MC to monitor and manage a Vertica database, MC (running in a browser) connects as the client to the Vertica database server.
MC Uses JDBC for Most Database Connections

MC uses Java Database Connectivity (JDBC) for most connections to a Vertica database, including:

- Retrieving database information to display in charts
- Running SQL queries through JDBC
- Configuring and updating database properties
- Configuring the database for extended monitoring

Exception

When MC uses Agents to perform AdminTools tasks, MC does not use JDBC to connect to the database.

Vertica Software Supports TLS

Vertica databases and Vertica MC support TLS up to version 1.2. This topic and its subtopics describe configuring TLS in MC for JDBC connections to a Vertica database.

About Certificate File Formats

MC requires that all certificate and key files for upload to MC must be in PEM (Privacy-enhanced Electronic Mail) format.

Vertica Database Security Dictates How MC Connects

The TLS/SSL security you configure for a database in MC must be consistent with the security configured on the database itself.
Whether the Vertica database has TLS/SSL configured in server mode or mutual mode, you should configure TLS/SSL for that database in MC to match.

To find out how a Vertica database is configured, see Determining the TLS/SSL Mode of a Vertica Database.

You can configure TLS/SSL in either server mode or mutual mode in MC.

The rest of this topic and related topics use the term TLS, TLS/SSL, and SSL interchangeably.

**TLS Server Mode**

When the MC client connects to a Vertica database configured in *server mode*:

- The client requests and verifies the server's credentials.
- The client does not need to present a client certificate and private key file to the server.
- The MC administrator must configure the CA certificate that can verify server's certificate on MC when MC connects to the database over JDBC.

**TLS Mutual Mode**

When the MC client connects to a Vertica database configured in *mutual mode*:

- The MC client requests and verifies the database server's credentials.
- The server also requests and verifies the MC client's credentials.
- Each MC user is a separate client, and must present a valid client certificate file and private key file pair (*keypair*), namely a certificate signed by a CA recognized by the Vertica database server as valid.
- The MC administrator must configure:
  - The CA certificate to verify the Vertica database server certificate.
  - A client certificate and private key file (*keypair*) for each MC user. The keypair can be unique for each user, or shared by multiple users, depending on how client authentication is configured on the Vertica database. See Implementing Client Authentication.
  - Each MC user must be configured to map correctly to a user who is configured on the Vertica database server.

For more information on how Vertica supports TLS/SSL security, see TLS Protocol.
MC Administrator Configures MC Security

Only MC users having Admin or Super privileges on a database are able to configure TLS certificates and keys on MC for database connections. The topics in this section use "MC administrator" to refer to both of these roles. For more information about MC user roles and privileges, see About MC Users.

As the MC administrator, when you first configure security in MC for a Vertica database that requires mutual mode, you configure these certificates for the Vertica database:

- The server certificate and public key of the database.
- Your own client certificate and private key, as the first configured MC user mapped to a Vertica database user.

Configuring TLS/SSL on MC

MC provides the Certificates wizard for configuring TLS certificates for all JDBC connections to the database, to ensure those connections are secure.

In MC, there are three scenarios in which you need to configure TLS security for a Vertica database:

- While you are importing a database to monitor in MC. See Configuring TLS While Importing a Database on MC.
- When you want to add security for a database that is already monitored by MC. See Configuring TLS for a Monitored Database in MC.
- When you need to configure client security for an individual MC user who is mapped to a user who has privileges on the Vertica database server, because the database requires mutual authentication. See Configuring TLS for MC Users, for Mutual Mode.

Adding Certificates to MC for Later Use

You may want to add multiple CA certificates or client certificates to MC all at one time, to streamline the configuration of security when you are importing databases to MC or creating MC users. For details, see Adding CA Certificates in MC and Adding Client Certificates and Key Files in MC.
# To Connect Successfully, MC and Database Security Must Match

<table>
<thead>
<tr>
<th>MC Security</th>
<th>Vertica Database Security</th>
<th>Does the connection succeed?</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>Connection succeeds, and it is open and therefore unsecured.</td>
</tr>
<tr>
<td>TLS server mode</td>
<td>TLS server mode</td>
<td>Connection succeeds provided MC can verify the server's certificate using the CA certificate configured on MC.</td>
</tr>
</tbody>
</table>
| TLS mutual mode | TLS mutual mode | Connection succeeds provided:  
  - MC can verify the server's certificate using the CA certificate configured on MC.  
  - The server can verify the client certificate and private key that MC presents as belonging to a mapped user on the Vertica database. |
<p>| None        | TLS server mode | MC attempts to establish an open connection. The connection fails if the Vertica database requires |</p>
<table>
<thead>
<tr>
<th>None</th>
<th>TLS mutual mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS server mode</td>
<td>None</td>
</tr>
<tr>
<td>TLS mutual mode</td>
<td>None</td>
</tr>
</tbody>
</table>

**TLS for client connections.** For more information, see:

- [Implementing Client Self-Authentication](#)
- [CREATE AUTHENTICATION](#)

MC attempts to establish an open connection. The connection fails if the Vertica database requires TLS for client connections. The connection fails because MC does not present what the database requires: a valid client certificate and private key that the database can verify as belonging to a mapped database user.

MC attempts to connect to the database securely, however the connection fails as the database is not configured with TLS certificates.

MC attempts to connect to the database securely, however the connection fails as the database is not configured with TLS certificates.
Determining the TLS/SSL Mode of a Vertica Database

When you configure TLS/SSL security in Management Console, you must configure the security mode to match what the Vertica database is configured to require: server mode or mutual mode. To find out how the Vertica database is configured:

1. Open a command window.
2. Log into the Vertica database.
3. Enter the following vsq1 command:

   ```sql
   SELECT * FROM configuration_parameters WHERE parameter_name ILIKE '%ssl%';
   ```

   This command queries the `configuration_parameters` table. It returns a list of the `security parameters` whose names contain the string 'ssl'. (For this exercise, ignore `DataSSLParams`.) By looking at the values of these parameters, you can determine whether TLS/SSL security is enabled on the Vertica database, and whether it is configured in server mode or mutual mode:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EnableSSL</td>
<td>Controls whether the use of TLS/SSL is enabled or disabled on connections to the Vertica database.</td>
</tr>
<tr>
<td></td>
<td>• 0 (default): Disabled</td>
</tr>
<tr>
<td></td>
<td>• 1: Enabled</td>
</tr>
<tr>
<td>SSLCA</td>
<td>Indicates Vertica’s own certificate authority (CA). If this parameter is not empty, then it contains the contents of a root.crt file (i.e. a PEM certificate) that Vertica trusts. If SSLCA is set (not NULL) on the server, that means the Vertica database server has TLS/SSL configured and the server will require that the client present a valid certificate, to gain access to the Vertica database.</td>
</tr>
<tr>
<td></td>
<td>Changes to this parameter apply only to new connections.</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSLCertificate</td>
<td>Sets the SSL certificate. If TLS/SSL is enabled, this parameter contains the Vertica database server certificate, which the Vertica database server provides when asked by clients to verify itself. Includes the contents of the <code>server.crt</code> file, but excludes the file name. Changes to this parameter apply only to new connections.</td>
</tr>
<tr>
<td>SSLPrivateKey</td>
<td>The server's private key, visible only to <code>dbadmin</code> users. This parameter is set to the contents of the <code>server.key</code> file; it excludes the file name. Changes to this parameter apply only to new connections.</td>
</tr>
</tbody>
</table>

## Configuring TLS While Importing a Database on MC

To configure TLS as you are importing an existing Vertica database on MC:

1. Follow the steps in [Importing an Existing Database Into MC](#).

2. In the **Import Vertica** window, select the database and click the **Use TLS** checkbox.

   ![Select 'Use TLS' checkbox](image)
3. Click **Configure TLS and Import DB** to launch and complete the Certificates wizard.

**MC Certificates Wizard**

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details. Screenshots below represent one version of what you may see.

1. The first wizard screen provides helpful overview information. Read it, and click **Configure TLS Certificates** to continue.

   ![Configure TLS Connection Certificates](image)

   **Configure TLS Connection Certificates**

   **Configure TLS Certificates for Database:**

   To protect privacy and verify data integrity, you can configure Vertica and database clients to use Secure Socket Layer (SSL). TLS allows secure connection and communication between the client and the server. The SSL protocol uses a trusted third party called a Certificate Authority (CA). Both the owner of a certificate and the party that relies on the certificate trust the CA.

   Vertica supports the following authentication methods under Transport Layer Security (TLS) v1.0, v1.1, and v1.2 protocol:

   - To know more about TLS Authentication please see the [Doc Here](#)

   This Wizard will guide you to Configure TLS certificates for Database's JDBC Connections from MC.

   **NOTE:** TLS Parameters should already be configured on Vertica Database

2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.
Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
  - To add another CA certificate, click **Add More CA Certificates**.
  - Continue adding additional CA certificates until you are finished.
- **Choose a certificate alias from previously uploaded certificates** Select the alias for the previously uploaded CA certificate you wish to configure for the current database.

3. When you are done adding CA certificates, click **Next**.
4. The **Configure Client Certificate** screen displays the check box **Add Client Certificate and Private Key for Mutual Mode TLS Connection**.
5. If the database is configured for **server mode**, you do not need a client certificate or key.
   - Leave the **Add Client Certificate** check box unchecked and click **Review**.
   - Skip to step 10.
6. If the database is configured for **mutual mode**:
   - Click the **Add Client Certificate** check box.
   - Select one of the options below.
     - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.)
To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain**. MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next**.

To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain file field, select the file, and click **Open**.

**Configure TLS Connection Certificates**

- **Configure Client Certificate and Private Key for TLS Connection**
  - Add Client Certificate and Private Key for Mutual Mode TLS connection
  - Upload Client Certificate and Private key files on MC
  - Manually upload Client Certificate and Private Key on MC host and provide paths
  - Choose Client Certificate and Private Key Alias of previously uploaded keypair to use for this database

**Client Certificate and Private Key Alias**
- client_certKey_bg

**Client Private Key file**
- clientkey.key

**Upload Client Certificate/Certificate chain file**
- clientcert.pem

- **Manually upload client Certificate and Private Key on MC host and provide paths** AVOIDS sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths**. MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next**.
Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database. (To use existing certificate and key files.)

7. Complete the detail fields for the client certificate and private key option you have chosen above, then click Next.
8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

**Note:**
All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click **Review**. The wizard displays a review window with the TLS options you have configured.

10. Select one of these options:
    - To modify your TLS choices, click **Back**.
    - To confirm your choices:
        - If you are importing a database, click **Configure TLS and Import DB**.
        - If you are configuring TLS for a database already imported to MC, click **Configure TLS for DB**.
        - Click **Close** to complete the wizard.
    - To close the wizard without importing the database and without setting up TLS configuration, click **Cancel**.
Configuring TLS for a Monitored Database in MC

This procedure describes how to configure TLS for all JDBC connections to a database that is already being monitored in MC. Note that the Vertica database should already be configured with the TLS certificates required for TLS connections.

1. In MC, navigate to Databases and Clusters > DB-name > Settings and click the Security tab in the left navigation bar.
2. In the Configure TLS Connection for Database section, click Enabled in the drop-down beside Use TLS Connection to database.
3. Click Configure TLS Connection to launch and complete the Certificates wizard.

MC Certificates Wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details. Screenshots below represent one version of what you may see.

1. The first wizard screen provides helpful overview information. Read it, and click Configure TLS Certificates to continue.
2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.

Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
To add another CA certificate, click **Add More CA Certificates.**

Continue adding additional CA certificates until you are finished.

**Choose a certificate alias from previously uploaded certificates** Select the alias for the previously uploaded CA certificate you wish to configure for the current database.

3. When you are done adding CA certificates, click **Next.**

4. The **Configure Client Certificate** screen displays the check box **Add Client Certificate and Private Key for Mutual Mode TLS Connection.**

5. If the database is configured for **server mode,** you do not need a client certificate or key.
   - Leave the **Add Client Certificate** check box unchecked and click **Review.**
   - Skip to step 10.

6. If the database is configured for **mutual mode:**
   - Click the **Add Client Certificate** check box.
   - Select one of the options below.
     - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.)
     - To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain.** MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next.**
     - To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain file field, select the file, and click **Open.**
• Manually upload client Certificate and Private Key on MC host and provide paths Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click Add More Certificate Paths. MC reinitializes the path field so you can add another path. After you add the last certificate path, click Next.
Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database. (To use existing certificate and key files.)

7. Complete the detail fields for the client certificate and private key option you have chosen above, then click Next.
8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

Note:
All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click Review. The wizard displays a review window with the TLS options you have configured.

10. Select one of these options:
   - To modify your TLS choices, click Back.
   - To confirm your choices:
     - If you are importing a database, click Configure TLS and Import DB.
     - If you are configuring TLS for a database already imported to MC, click Configure TLS for DB.
     - Click Close to complete the wizard.
   - To close the wizard without importing the database and without setting up TLS configuration, click Cancel.
Configuring TLS for MC Users, for Mutual Mode

You can configure TLS for existing MC users who are already mapped to Vertica database user ids. You would do so if you had just configured TLS in mutual mode on a previously unsecured Vertica database, and needed to configure a client certificate and private key for each MC user who accesses that database.

1. In MC, navigate to **MC Settings** and click the **User Management** tab.
2. Select a user from the list and click **Edit**.
3. In the **Add permissions** window:
   - Choose the database for which you want to edit this MCC user's security permissions.
   - MC displays the database username to which this MC user is currently mapped.
   - In the **Restrict Access** drop-down, choose **Admin, Associate, IT, or User** to specify the privilege level for this user.
   - In the **Use TLS Connection** drop-down, choose **Yes**.
   - Click **Configure TLS for user** to launch and complete the Certificates wizard.

MC Certificates Wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details. Screenshots below represent one version of what you may see.

1. The first wizard screen provides helpful overview information. Read it, and click **Configure TLS Certificates** to continue.
2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.

Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
To add another CA certificate, click **Add More CA Certificates.**
Continue adding additional CA certificates until you are finished.
- **Choose a certificate alias from previously uploaded certificates** Select the alias for the previously uploaded CA certificate you wish to configure for the current database.

3. When you are done adding CA certificates, click **Next.**
4. The **Configure Client Certificate** screen displays the check box **Add Client Certificate and Private Key for Mutual Mode TLS Connection.**
5. If the database is configured for **server mode**, you do not need a client certificate or key.
   - Leave the **Add Client Certificate** check box **unchecked** and click **Review.**
   - Skip to step 10.
6. If the database is configured for **mutual mode:**
   - Click the **Add Client Certificate** check box.
   - Select one of the options below.
     - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.
       - To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain.** MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next.**
       - To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain file field, select the file, and click **Open.**
• **Manually upload client Certificate and Private Key on MC host and provide paths** Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths**. MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next**.
Choose **Client Certificate and Private Key alias** of previously uploaded keypair to use for this database. (To use existing certificate and key files.)
7. Complete the detail fields for the client certificate and private key option you have chosen above, then click Next.

8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

**Note:**
All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click Review. The wizard displays a review window with the TLS options you have configured.

10. Select one of these options:
    - To modify your TLS choices, click Back.
    - To confirm your choices:
        - If you are importing a database, click **Configure TLS and Import DB**.
        - If you are configuring TLS for a database already imported to MC, click **Configure TLS for DB**.
        - Click Close to complete the wizard.
    - To close the wizard without importing the database and without setting up TLS configuration, click **Cancel**.
Updating TLS Security for MC Connections

Maintaining TLS security for MC JDBC connections to a Vertica database is an ongoing process. Initially, you as the MC administrator must configure the appropriate certificates and keys. As time passes, certificates expire or otherwise become invalid. To maintain TLS security in MC, you must configure new certificates to replace any that are about to expire.

If any of the certificates that secure an MC connection to a Vertica database changes or expires, the MC administrator must update the TLS configuration for that database on MC to ensure that unexpired certificates are available so that connections can succeed.

- To update the certificates, simply configure new certificates for the connection between MC and that Vertica database.
- To configure new certificates for a database monitored in MC, see Configuring TLS for a Monitored Database in MC.
- To configure new client certificates for an MCC user, see Configuring TLS for MC Users, for Mutual Mode.
- To replace an expiring or invalid certificate for a database or client, see Updating a TLS Certificate in MC.

MC flags the current certificate for a given connection with a "use me" bit. This bit is set only for the current certificate. When you configure a new certificate for a given connection, the new certificate is marked current, and the previous certificate (although still present in the trust store or keystore) is no longer marked as the current certificate.
MC Icons Display Database TLS Status

MC displays an icon at top left of the database in the Database and Cluster/Infrastructure view, that shows the current TLS status of the database:

<table>
<thead>
<tr>
<th>Icon Description</th>
<th>Status Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gray lock icon</td>
<td>TLS is configured on this database and also in MC.</td>
</tr>
<tr>
<td>Gray lock icon with orange alert triangle</td>
<td>Database is configured to use TLS but MC is not configured to use a TLS connection. An internal MC job checks the status of MC's connection.</td>
</tr>
<tr>
<td>Red lock with red X</td>
<td>Both the database and MC are configured for TLS, but MC is not able to connect using TLS.</td>
</tr>
<tr>
<td>No icon at top left</td>
<td>The database is not configured to use TLS, and MC is not configured to connect to the database using TLS, either. When neither side has TLS configured, all connections are open and unsecured.</td>
</tr>
</tbody>
</table>
TLS Status Icons in Breadcrumbs

The same icons appear in the breadcrumbs to the left of the database name, to show the current TLS security status of the database:

Enabling or Disabling TLS for a Database in MC

To enable TLS for all JDBC connections from MC to a Vertica database, configure the certificate and key appropriate for that connection. See:

- Configuring TLS While Importing a Database on MC
- Configuring TLS for a Monitored Database in MC
- Configuring TLS for MC Users, for Mutual Mode

Disabling a TLS Connection

Under some conditions, you as the system administrator might need to disable TLS for JDBC connections from MC to a Vertica database. Here are some examples:

- The TLS certificates are expired and you have not yet obtained new certificates.
- The TLS certificates and keys are revoked and the user does not have new certificates and keys, but you still want to allow that user to connect from MC to the database to show monitoring information and run queries.

To disable TLS for connecting to a Vertica database:

1. In MC, navigate to Home > Databases and Clusters > DatabaseName > Settings.
2. Click the Security tab in the left navigation bar.
3. In the Use TLS Connection to database drop-down, choose Disabled.

Note:
To reenable TLS for a database connection after you disable it, you must reconfigure the necessary certificates.
Disabling TLS for a database removes the configuration that tells MC to use the current certificates and keys for a given database, for all users. If it is a mutual mode TLS connection and each user had a separate client certificate and private key configured for that database, to re-enable TLS you must reconfigure the certificate and key for each user individually, for that database.

Re-enabling a Disabled TLS Connection

1. In MC, navigate to Home > Databases and Clusters > DatabaseName > Settings.
2. Click the Security tab in the left navigation bar.
3. In the Use TLS Connection to database drop-down, choose Enabled.
4. MC displays Configure MC to use secured connection to query Vertica database or modify existing configuration.
5. To finish re-enabling TLS, click Configure TLS Connection to launch the Certificates Wizard.
6. Complete the Certificates wizard.

Managing TLS Certificates in MC

MC maintains a secure list containing all the CA certificates, and the client certificates or certificate chains and their corresponding key files, that you have uploaded into MC.

To manage the certificates already uploaded to MC, navigate to Home > MC Settings > SSL/TLS Certificates. This screen controls the TLS security settings for all of MC.

The top pane displays information about the current TLS certificate used to secure the user's browser connection to the MC server. You can add a new certificate to replace it. See Managing the Certificate for the Browser Connection to the MC Server.

<table>
<thead>

</tr>
</tbody>
</table>

Current SSL certificate information for Browser connection to MC Server
The middle and lower panes allow you to add and remove CA and client certificates in MC.

**Manage TLS Certificates for Database Connection**

*NOTE: Only certificates that are not associated with a database can be removed*

You can perform the following tasks to manage your TLS certificates and keys in MC.

- Adding TLS Certificates in MC
- Removing TLS Certificates from MC
- Dissociating a TLS Certificate from a Database in MC

For the security settings for a specific database, open the database in MC and navigate to Home > Databases and Clusters > DatabaseName > Settings and click the Security tab in the left navigation bar.

**See Also**

Connecting Securely from MC to a Vertica Database

**Removing TLS Certificates from MC**

You can remove one or more TLS certificates from the MC, provided the certificates are not associated with a database. To remove a certificate:
1. From the MC home page, navigate to **MC Settings > SSL/TLS Certificates**.
2. In the **Manage TLS Certificates for Database Connection** section, locate the row or rows for one or more CA or client certificates you want to remove. This example shows only the **CA Certificates** pane:

   **Manage TLS Certificates for Database Connection**

   *NOTE: Only certificates that are not associated with a database can be removed*

   **CA Certificates**

<table>
<thead>
<tr>
<th>Select (All)</th>
<th>Certificate Alias</th>
<th>Database associated</th>
<th>MC User (Mapped DB User)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ca-cert-db</td>

<td>uidadmin (uidadmin), alice (vertica_a)</td>
</tr>
<tr>
<td>✔️</td>
<td>CA_cert_02</td>
<td></td>
<td></td>
</tr>
<tr>
<td>✔️</td>
<td>CA_cert_01</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   ![Screen shot of Manage TLS Certificates for Database Connection](image)

   3. If the **Database associated** field is empty for that certificate, you can click to select the certificate for removal, and click **Remove Selected**. In the illustration above, CA_cert_02 and CA_cert_01 are selected for removal.

   **Note:**
   You cannot remove a certificate that is still associated with a database. First, **dissociate the certificate** from the database, then execute the above procedure to remove it.

   If you remove one client certificate that is part of a certificate chain, MC removes the entire certificate chain.

### Dissociating a Certificate from a Database in MC

Before you can **remove a certificate** from MC, you must be sure the certificate is not associated with (being used by) any databases. The MC administrator can disassociate a certificate from a database in MC using either of these methods:
Configuring a New Certificate on the Database in MC

When you configure a new certificate to serve a specific purpose on a database in MC, the new certificate replaces the old certificate. The newly configured certificate is now associated with the database, and the old certificate is no longer associated and can be removed.

Navigate to Databases and Clusters > DbName > Database Settings > Configure TLS.

For details, see Configuring TLS for a Monitored Database in MC.

Removing the TLS Configuration on the Database

In some cases, it may be appropriate to disable TLS for a database in MC. Disabling TLS for the database dissociates all the certificates configured for that database. For more information, see Enabling or Disabling TLS for a Database in MC.

Adding TLS Certificates in MC

You can add one or more certificates to MC for later use, without immediately associating the certificates with a database. Adding certificates ahead of time makes it easier to configure security for a database or for one or more MC users, because you can just choose a CA or client certificate from a list rather than having to add it to MC during the configuration steps.

Adding CA Certificates in MC

You can add one or more CA certificates to MC for later use.

See Adding CA Certificates in MC.
Adding Client Certificates and Keys in MC

You can add one or more client certificate and private key pairs to MC. In each pair, you can add either a single certificate, a preexisting certificate chain, or a series of client certificates that MC uses to create a new certificate chain.

See Adding Client Certificates and Key Files in MC.

Adding a New Certificate for the Browser Connection

You can view the existing TLS certificate for the browser connection to the MC server, or add a new certificate to replace it.

See Managing the Certificate for the Browser Connection to the MC Server.

Bulk-Configure a Group of MC Users for TLS

You as the MC administrator can create multiple MC users and map them all to the same database user id on the Vertica database server side. You map the users in MC when you create them. For details, see Creating an MC User.

You can then configure all the MC users that are mapped to a single Vertica database user id, to use the same client certificate or certificate chain and private key in MC, in a single bulk configuration process:

1. Navigate to MC Home > Databases and Clusters > DbName> Settings > Security.
2. Click Configure TLS Connection to launch the MC certificates wizard.
3. Complete steps 1 through 3 in the wizard to configure a CA certificate and the client certificate or certificate chain and key that you want to use for multiple MC users. For details, see Completing the MC Certificates Wizard.
4. After you complete these steps, the wizard displays the Apply TLS configuration to MC users mapped to database page as step 4 in the left wizard pane.
5. To apply the same CA certificate, client certificate and key you just configured to one or more additional users, click the check boxes for those users.
6. To complete the configuration, click Review. MC displays a confirmation screen:

7. To complete the configuration of this CA certificate for the database and this client certificate/key pair for the selected MC users, click **Configure TLS for DB**.

8. MC confirms that the action was a success. Click **Close** to close the Certificate wizard.
**Updating a TLS Certificate in MC**

When a TLS certificate is about to expire, has already expired, or otherwise becomes unusable, it needs to be updated.

This is the method for updating a certificate:

1. In MC, add the new certificate that will replace the expiring or invalid certificate. See Adding TLS Certificates in MC.

   **Note:**
   You can add and configure the new certificate for the database or user whose existing certificate is or will soon be invalid, as a single step, or two steps. Configuring the new certificate for the database dissociates the previously configured certificate from that database. See Connecting Securely from MC to a Vertica Database.

2. After the old certificate has been dissociated from all databases and users, you can remove it from the MC. See Removing TLS Certificates from MC

**Adding CA Certificates in MC**

To add one or more CA certificates for later use in MC:

1. From the MC home page, navigate to MC Settings > SSL/TLS Certificates.
2. Under Manage TLS Certificates for Database Connection, click Add New CA Certificate.
3. In the Add new CA certificates for TLS connection window, enter an alias for the certificate, to make it easier to refer to later.
4. Click Browse to locate the certificate file you want to add. MC opens an Explorer window.
5. Select the file you want to upload, and click Open.

   **Note:**
   Make sure the certificate file is unexpired, and is not protected by a
6. To add just this one certificate, click **Add New CA**. MC adds the certificate to its list.

![Add new CA certificate for TLS connection](image)

7. To add additional CA certificates, click **Add More CA Certificates**. MC adds the certificate to a list, and clears the fields so you can enter the next CA certificate.

8. Repeat the process until you have entered the last certificate you want to add.

9. Click **Add New CA** to add all the CA certificates in the list to the MC:

![Add new CA certificate for TLS connection](image)

---

**See Also**

*Managing TLS Certificates in MC*
Adding Client Certificates and Key Files in MC

To add one or more client certificates with their private key files to MC for later use:

1. Navigate to Home > MC Settings > SSL/TLS Certificates.

   **Note:**
   When you add a client certificate to MC, you always add it with its private key file. The client certificate and its key are a **key pair**.

3. Click one of these file upload options:

   | Upload Client Certificate and Private Key for TLS Connection | With this option, you paste a certificate and key into browser fields. MC posts the certificate and key from your browser to the MC server via an https connection over the network, secured with TLS/SSL. |
   | Manually upload Client Certificate and Private Key on MC host and provide paths | Sending the certificates from your browser to the MC server across an https network connection may not be what your preference. If so, you can use this option to specify the paths on the MC server host where you have manually uploaded the client certificate and private key files, instead. The URL of your MC browser shows the IP address of the MC host. Using this option, MC does not handle the transfer of the certificate and key files to the MC server; you do. |

4. To provide a single client certificate and private key with either input option:
   - Enter a recognizable alias for the key pair.
   - Browse and select the private key file or provide the path.
   - Browse and select the client certificate file or provide the path.
   - Click Add New Client Certificate.
   - MC adds the key pair to its list.

5. To upload several certificates and private keys and create a certificate chain:
Enter an alias for the key pair.
Browse and select the private key file or provide the path.
Browse and select the client certificate file or provide the path.
Click Add Certificate to Chain (or Add More Certificate Paths).
Repeat the process until you have added the last certificate and key for this certificate chain.
Click Add New Client Certificate.

MC adds the resulting certificate chain to its list.

Managing the Certificate for the Browser Connection to the MC Server

To view or replace the current SSL/TLS certificate that MC uses for the user's browser's HTTPS connection to the MC server:
1. From the MC home page, navigate to **MC Settings > SSL/TLS Certificates**.

   The top pane displays the current certificate for the browser connection to the MC server, including the certificate's expiration date:

   ![Certificate Information](image)

   **Current SSL certificate information for Browser connection to MC Server**

<table>
<thead>
<tr>
<th>Issued To</th>
<th>Issued By</th>
<th>Validity Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>Common Name (CN)</td>
<td>Vertica</td>
<td>Issued On: 2018-02-12</td>
</tr>
<tr>
<td>Organization (O)</td>
<td>Vertica</td>
<td>Expires On: 2028-02-10</td>
</tr>
<tr>
<td>Organizational Unit (OOU)</td>
<td>Vertica</td>
<td></td>
</tr>
</tbody>
</table>

2. To replace the current certificate, click **Browse** next to the **Upload a new SSL certificate** field.

   MC opens an explorer window.

3. Select the certificate file you wish to upload and click **Open**. The certificate file must be in PEM (Privacy-enhanced Email Message) format.

   MC replaces the prior certificate with the new certificate.

*Importing a New Certificate to MC*

**Managing MC Settings**

The **MC Settings** page allows you to configure properties specific to Management Console. To access the page, go to the Management Console home page. Under **MC Tools**, click **MC Settings**. On the **MC Settings** page, you can control the following settings and more:

**MC Configuration Settings**

- Change Management Console and agent default port assignments (Configuration tab).
MC Monitoring Settings

- Control the following monitoring settings in Management Console:
  - Enable checks and set alert thresholds for spread retransmit rate. This setting is disabled by default. The recommended alert threshold for spread retransmit rate is 10%.
  - Set alert thresholds for free Management Console disk space checks. The recommended alert threshold is 500 MB.
  - Exclude MC queries from activity charts.
  - Set refresh intervals for MC charts and pages.

MC Security and Authentication Settings

- To allow Management Console connections only from browsers using TLS 1.2 and higher (Configuration tab).
  - Click Disable TLS 1.0 and 1.1 connections from browser.
  - This setting ensures that Management Console will connect to the Vertica server using a version of TLS no lower than 2.0.
- Upload a new SSL certificate or view the current certificate (SSL Certificates tab).
- Use LDAP for user authentication (Authentication tab).
- Enable and disable username and password auto-complete at Management Console login. (After disabling, clear your browser's cache.) (Configuration tab)

MC User Management Settings

- Create new Management Console users and, with their user credentials, map them to an database managed by Management ConsoleC on the Vertica server. See Creating an MC User and Managing MC Users.

MC Extended Monitoring Settings

- Configure Extended Monitoring, which allows you to monitor more long-term data in Management Console:
  - Set up an external storage database for Extended Monitoring. See Managing the Storage Database.
• Enable or disable Extended Monitoring on your databases. See Managing Extended Monitoring on a Database.

Other MC Settings

• View your version of Vertica or upload a new Vertica binary file
• Customize the look and feel of Management Console with themes. See Customizing Look and Feel.
• Configure Management Console to use an alternative data source to monitor your database. See Monitoring External Data Sources in Management Console.
• Enable Management Console to send email alerts. See Set Up Email.

Modifying Database-Specific Settings

To inspect or modify settings related to a database managed by Management Console, go to the Existing Infrastructure page. On this page, select a running database to see its Overview page. From the bottom of the Overview page, click the Settings tab to make modifications to database-specific settings.

Customizing Look and Feel

Management Console themes provide a unique look and feel to the Management Console interface. Access these themes through the Theme page in MC Settings.

Changing Themes

Only administrators, who have access to MC Settings, can alter themes. The selected theme is visible to all Management Console users.

To apply a new theme on Management Console, go to MC Settings > Theme. On the Theme page, select a theme from the drop-down menu. A preview of the selected theme appears. Click Apply in the upper right hand of the page to apply the change.
Available Themes

The OpenText Theme is the default Management Console theme. This theme includes the colors and styles used by OpenText branding.
The Vertica Classic theme features a dark background and green accents, evoking classic computer terminal interfaces.
Changing MC or Agent Ports

When you configure MC, the Configuration Wizard sets up the following default ports:

- **5450**—Used to connect a web browser session to MC and allows communication from Vertica cluster nodes to the MC application/web server
- **5444**—Provides MC-to-node and node-to-node (agent) communications for database create/import and monitoring activities

If You Need to Change the MC Default Ports

A scenario might arise where you need to change the default port assignments for MC or its agents. For example, perhaps one of the default ports is not available on your Vertica cluster, or you encounter connection problems between MC and the agents. The following topics describe how to change port assignments for MC or its agents.

See Also

- Ensure Ports Are Available

How to Change the Agent Port

Changing the agent port takes place in two steps: at the command line, where you modify the config.py file and through a browser, where you modify MC settings.

Change the Agent Port in config.py

1. Log in as root on any cluster node and change to the agent directory:
   
   ```bash
   # cd /opt/vertica/agent
   ```

2. Use any text editor to open config.py.
3. Scroll down to the `agent_port = 5444` entry and replace 5444 with a different port number.
4. Save and close the file.
5. Copy config.py to the /opt/vertica/agent directory on all nodes in the cluster.
6. Restart the agent process by running the following command:

   ```
   # /etc/init.d/vertica_agent restart
   ```

   **Note:**
   If you are using Red Hat Enterprise Linux/CentOS 7, use the following command instead:

   ```
   # /opt/vertica/sbin/vertica_agent restart
   ```

7. Repeat (as root) Step 6 on each cluster node where you copied the config.py file.

### Change the Agent Port on MC

1. Open a web browser and connect to MC as a user with **MC ADMIN** privileges.
2. Navigate to **MC Settings > Configuration**.
3. Change Default Vertica agent port from 5444 to the new value you specified in the config.py file.
4. Click **Apply** and click **Done**.
5. Restart MC so MC can connect to the agent at its new port. See **Restarting MC**.

### How to Change the MC Port

Use this procedure to change the default port for MC’s application server from 5450 to a different value.

1. Open a web browser and connect to MC as a user with **MC ADMIN** privileges.
2. On the MC Home page, navigate to **MC Settings > Configuration** and change the Application server running port value from 5450 to a new value.
3. In the change-port dialog, click **OK**.
4. ** Restart MC.**
5. Reconnect your browser session using the new port. For example, if you changed the port from 5450 to 5555, use one of the following formats:

   ```
   https://00.00.00.00:5555/
   ```
**Backing Up MC**

Before you upgrade MC, Vertica recommends that you back up your MC metadata (configuration and user settings). Use a storage location external to the server on which you installed MC.

1. On the target server (where you want to store MC metadata), log in as root or a user with sudo privileges.
2. Create a backup directory as in following example:
   
   ```bash
   # mkdir /backups/mc/mc-backup-20130425
   ```

3. Copy the `/opt/vconsole` directory to the new backup folder:
   
   ```bash
   # cp -r /opt/vconsole /backups/mc/mc-backup-20130425
   ```
Troubleshooting with MC Diagnostics

The Management Console Diagnostics page, which you access from the Home page, helps you resolve issues within the MC process, not the database.

What You Can Diagnose

- View Management Console logs, which you can sort by column headings, such as type, component, or message).
- Search within messages for key words or phrases and search for log entries within a specific time frame.
- Export database messages to a file.
- Reset console parameters to their original configuration.

Caution:
Reset removes all data (monitoring and configuration information) from storage and forces you to reconfigure MC as if it were the first time.

- Restart the Management Console process. When the process completes, you are directed back to the login page.

Viewing the MC Log

If you want to browse MC logs (not database logs), navigate to the Diagnostics > MC Log page.

This page provides a tabular view of the contents at /opt/vconsole/log/mc/mconsole.log, letting you more easily identify and troubleshoot issues related to MC.

You can sort log entries by clicking the column header and search within messages for key words, phrases, and log entries within a specific time frame. You can also export log messages to a file.
Exporting the User Audit Log

When an MC user makes changes on Management Console, whether to an MC-managed database or to the MC itself, their action generates a log entry that contains data you can export to a file.

If you perform an MC factory reset (restore MC to its pre-configured state), you automatically have the opportunity to export audit records before the reset occurs.

To Manually Export MC User Activity

1. From the MC Home page, click Diagnostics and then click Audit Log.
2. On the Audit log viewer page, click Export and save the file to a location on the server.

To see what types of user operations the audit logger records, see Monitoring MC User Activity Using Audit Log.
Restarting MC

You might need to restart the MC web/application server for a number of reasons, such as after you change port assignments, use the MC interface to import a new SSL certificate, or if the MC interface or Vertica-related tasks become unresponsive.

Restarting MC requires ADMIN Role (mc) or SUPER Role (mc) privileges.

How to Restart MC through the MC Interface (Using Your Browser)

1. Open a web browser and connect to MC as an administrator.
2. On MC's Home page, click Diagnostics.
3. Click Restart Console and then click OK to continue or Cancel to return to the Diagnostics page.

The MC process shuts down for a few seconds and automatically restarts. After the process completes, you are directed back to the sign-in page.

How to Restart MC at the Command Line

If you are unable to connect to MC through a web browser for any reason, such as if the MC interface or Vertica-related tasks become unresponsive, you can run the vertica-consoled script with start, stop, or restart arguments.

Follow these steps to start, stop, or restart MC.

1. As root, open a terminal window on the server on which MC is installed.
2. Run the vertica-consoled script:

   # /etc/init.d/vertica-consoled { stop | start | restart }

For versions CentOS 7 and above, run:

   # systemctl { stop | start | restart } vertica-consoled
Important:
The `systemctl` function requires you to both start and stop services explicitly. If you kill or stop the `vertica-consoled` process without using `systemctl stop`, you cannot start the MC process again with the original `systemctl start` command. Instead, you must run `systemctl stop vertica-consoled` before running `systemctl start vertica-consoled`.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>stop</code></td>
<td>Stops the MC application/web server.</td>
</tr>
</tbody>
</table>
| `start` | Starts the MC application/web server.  
  **Caution:** Use `start` only if you are certain MC is not already running. As a best practice, stop MC before you issue the `start` command. |
| `restart` | Restarts the MC application/web server. This process will report that the stop didn't work if MC is not already running. |

How to Restart MC on an AMI

You can use the following steps to restart an MC AMI instance.

1. SSH into the MC host as user `dbadmin`:

   ```
   $ ssh -i example.pem dbadmin@52.xx.xx.xx
   ```

2. Run the `vertica-consoled` script using `sudo`:

   ```
   # sudo /etc/init.d/vertica-consoled { stop | start | restart }
   ```

Starting over

If you need to return MC to its original state (a "factory reset"), see [Resetting MC to Pre-Configured State](#).
Resetting MC to Pre-Configured State

If you decide to reset MC to its original, preconfigured state, you can do so on the Diagnostics page by clicking Factory Reset.

**Tip:**
Consider trying one of the options described in Restarting MC first.

A factory reset removes all metadata (about a week's worth of database monitoring/configuration information and MC users) from storage and forces you to reconfigure MC again, as described in Configuring MC in Installing Vertica.

After you click Factory Reset, you have the chance to export audit records to a file by clicking Yes. If you click No (do not export audit records), the process begins. There is no undo.

Keep the following in mind concerning user accounts and the MC.

- When you first configure MC, during the configuration process you create an MC superuser (a Linux account). Issuing a Factory Reset on the MC does not create a new MC superuser, nor does it delete the existing MC superuser. When initializing after a Factory Reset, you must logon using the original MC superuser account.
- Note that, once MC is configured, you can add users that are specific to MC. Users created through the MC interface are MC specific. When you subsequently change a password through the MC, you only change the password for the specific MC user. Passwords external to MC (i.e., system Linux users and Vertica database passwords) remain unchanged.

For information on MC users, refer to the sections, Creating an MC User and MC configuration privileges.

Avoiding MC Self-Signed Certificate Expiration

When you connect to MC through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.
To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

**Running Queries in Management Console**

You can use the Query Runner to run SQL queries on your database through Management Console (MC). After executing a query, you can also get the query plan and profile information for the query on this page.

To reach the Query Runner, select your database from the Home page or the Databases and Clusters page to view your database's Overview page. Select Query Execution at the bottom of the Overview page.

To familiarize yourself with how queries work in Vertica, you can refer to the Queries section of the documentation, as well as the SQL Reference Manual.
Limitations

You cannot execute COPY LOCAL statements using the Query Runner. To do so, use the vsq1 client installed on the server. See Using vsq1. (To use MC to import data from Amazon S3 storage to your Vertica database, see Loading Data From Amazon S3 Using MC.)

Manually commit any transactions (INSERT and COPY statements) you perform by adding the COMMIT statement in the text box after the transaction statements. If you do not do so, the transaction rolls back.

In the following example, to insert values into table1, include a COMMIT statement in the text box and execute the two statements together:

```
INSERT INTO table1 VALUES (1,2);
COMMIT;
```

Format

To input a series of queries, delimit them with a semicolon (;).

To automatically format the SQL text you have input, click the Format icon (</>).

Privileges

It is important when running queries in MC that the database administrator has correctly set up MC user privileges. The administrator must map all MC user profiles to their corresponding database user.

The Query Runner only permits MC users to perform actions that their corresponding Vertica database roles allow.

To set up user mappings, go to Home > MC Settings > User Management.
For more about how mapping MC user profiles to database users works, see Granting Database Access to MC Users. For information about database-level users and privileges, see the Database Users and Privileges section of the documentation.

**Execute a Query**

The Query Runner provides several ways to input a query to run:

- **Input text.** Enter the text for a query or series of queries into the text box.
- **Import a SQL script.** Click the Upload icon (发展阶段) to the top right of the text box to upload a SQL script (plain text file, typically with an extension of `.sql`). The queries from that file appear in the text box.
- **Enter a previous query from the Query History tab.** The Query History tab, on the left side of the page, displays the last 100 queries you have executed using the Query Runner on your current device and browser. Click any previous query in this tab to enter that query into the text box.

Hover over a query in the Query History tab to view all the query text. To clear queries from your history, hover over an individual query and click x, or click Clear all at the top of the tab. Click the star to the left of any query to favorite it, so it won't be cleared when you click Clear all.

Click **Execute Query** to run the queries you have input.

You can also execute only a portion of the text entered into the text box, as long as the selected text is a valid query. To do so, select that portion of the text. The Execute selected text as query button then appears below the text box.

For example, you might execute only a part of the entered text if you have uploaded a SQL script that containing multiple queries, but you decide to run only one of those queries.

To customize your execution settings, click the Settings icon (发展阶段) at the top right of the text box:

- **Row Limit:** Set the maximum number of rows to return. By default, the limit is 10000 rows.
- **Search Path:** Specify the schema to query.
Get Query Results

The Query Runner returns results in a table format. If you ran multiple queries simultaneously, the results window displays a tab for each set of results. View the number of rows returned and the query execution time at the bottom of the results window.

If your result returns many columns, you can click **Auto-resize all columns** in the top right of the results window for a better fit, or click and drag column borders to manually resize individual columns.

Sort results by clicking on a column name, or use the search bar to narrow down results.

Query Plans and Profiles

Each query result also displays an option to retrieve the plan or profile for that query.
After retrieving a plan or profile, you can expand or collapse the results view to see different levels of detail. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata, if it is available.

Note that the Query Runner does not automatically provide query profiles for queries that run for less than 1 second. To do so, prepend the word PROFILE to the query and run it.

You can also profile your query on the **Query Plan** page. The Query Plan page provides more details about both plan and profile results, including a query plan drilldown by node, a tree path view, and a profile analysis.

**Keyboard Shortcuts**

The Query Runner provides the following keyboard shortcuts:

- **?:** Press the question mark to display or dismiss a list of the available keyboard shortcuts. (You can also click the question mark icon at the top right of the text box to view this list.)
- **alt + ↑:** Press alt + up arrow to decrease the height of the text box.
- **alt + ↓:** Press alt + down arrow to increase the height of the text box.
- **ctrl + enter:** Press ctrl + enter to run the query.
- **ctrl + shift + enter:** Press ctrl + shift + enter to run selected text.

Working with Query Plans in MC

Management Console can show you a query plan in easy-to-read format, where you can review the optimizer's strategy for executing a specific query. You can view a query plan in either of two ways:

- View the plan of an active query.
- View the plan for any query that you manually specify.

Access the Plan of an Active Query

1. At the bottom of the Management Console window, click the Activity tab.
2. From the list at the top of the page, select Queries.
3. On the activity graph, click the data point that corresponds to the query you want to view.
4. In the View Plan column, click Explain next to the command for which you want to view the query plan. Only certain queries use query plans—for example, SELECT, INSERT, DELETE, and UPDATE.
5. In the Explain Plan window, click Explain. Vertica generates the query plan.
6. (Optional) View the output in Path Information view or Tree Path view. To do so, click the respective view buttons on the left of the output box.

Access the Plan for a Specific Query

1. Locate the query for which you want to see the query plan in either of the following ways:
• **Queries Not Running** — In the Explain window, type or paste the query text into the text box.
• **Queries Currently Running** — In the Find a Query By ID input window, perform one of the following actions:
  • Enter the query statement and transaction ID.
  • Click the **Browse Running Queries** link.

**Caution:**
Entering the word **EXPLAIN** before the query results in a syntax error.

2. Click **Explain**. Vertica generates the plan.

   If the query is invalid, Management Console highlights in red the parts of your query that might have caused a syntax error.

3. (Optional) View the output in Path Information view or Tree Path view. To do so, click the respective view buttons on the left of the output box.

---

## Accessing Query Plans in Management Console

You can access query plans in Management Console in two ways:

- In the Detail page for query-related charts on the database's Activity page, click **Explain** next to a query to view a plan for that query.
- Enter a query manually on the Explain page and click **Explain Plan**.

In both cases, the following window opens:
You can also enter the transaction ID and statement ID or browse running or completed queries in the Find a Query input window:

In the output window, you can perform the following tasks related to the query you entered:

- Expand and collapse query paths.
- Clearing query data.
- View projection and column metadata.
- Use different query plan views.
Query Plan View Options

Vertica Management Console provides two views for displaying query plans:

- Path Information
- Tree Path

**Note:**
Query Plan Drilldown and Profile Analysis output views are only available when you run **PROFILE**.

You can change the query plan view using the icons on the bottom portion of the **Explain** page.

The **Path Information** view displays the query plan path. You can expand or collapse the view to see different levels of detail. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata, if it is available.
The **Tree Path** view details the query plan in the form of a tree. When you run EXPLAIN, the tree view does not contain any metrics because the query has not yet executed.

---

**Expanding and Collapsing Query Paths**

The EXPLAIN window initially displays the full query plan as generated by the EXPLAIN command. Query plans can be lengthy, so you might want to modify the display so you can focus only on areas of interest:
- Collapse All collapses all query paths, and displays only a summary of each path.
- Expand All expands all query paths.
- Click the first line of a path to display details for that path. To collapse that path, click its first line again.

For details about EXPLAIN command output, see EXPLAIN-Generated Query Plans.

**Clearing Query Data**

After you finish reviewing the current query data, click Clear All to clear the query text and data. Alternatively, to display information about another query, enter the query text and click Explain or Profile.

**Viewing Projection and Column Metadata**

In the Management Console EXPLAIN window, when query paths are expanded in the Path Information view, Projection lines contain a projection name and Materialize lines contain one or more column names.

To view metadata for a projection or a column, click the object name. A pop-up window displays the metadata. The following image on the left shows example projection metadata and the image on the right shows example column metadata.

**Note:**
Most system tables do not have metadata.
Creating a Database Design in Management Console

Database Designer creates a design that provides excellent performance for ad-hoc queries and specific queries while using disk space efficiently. Database Designer analyzes the logical schema definition, sample data, and sample queries, and creates a physical schema that you can deploy.

For more about how Database Designer works, see the Creating a Database Design section of the documentation, and About Database Designer.

To use Management Console to create an optimized design for your database, you must be a DBADMIN user or have been assigned the DBDUSER role.

Management Console provides two ways to create a design:

- **Wizard**—This option walks you through the process of configuring a new design. Click Back and Next to navigate through the Wizard steps, or Cancel to cancel creating a new design.

  To learn how to use the Wizard to create a design, see Using the Wizard to Create a Design.

- **Manual**—This option creates and saves a design with the default parameters.

  To learn how to create a design manually, see Creating a Design Manually.
Tip:
If you have many design tables that you want Database Designer to consider, it might be easier to use the Wizard to create your design. In the Wizard, you can submit all the tables in a schema at once; creating a design manually requires that you submit the design tables one at a time.

Using the Wizard to Create a Design

Take these steps to create a design using the Management Console's Wizard:

1. On your database's dashboard, click the **Design** tab at the bottom of the page to navigate to the Database Designer page.

   The left side of the Database Designer page lists the database designs you own, with the most recent design you worked on highlighted. That pane also lists the current status of the design. Details about the most recent design appear in the main pane.

   The main pane contains details about the selected design.
2. To create a new design, click **New Design**.
3. Enter a name for your design, and click **Wizard**.
   
   For more information, see **Design Name**.

4. Navigate through the Wizard using the **Back** and **Next** buttons.

5. To build the design immediately after exiting the Wizard, on the **Execution Options** window, select **Auto-build**.

   **Important:**
   Vertica does not recommend that you auto-deploy the design from the Wizard. There may be a delay in adding the queries to the design, so if the design is deployed but the queries have not yet loaded, deployment may fail. If this happens, reset the design, check the
Queries tab to make sure the queries have been loaded, and deploy the design.

6. When you have entered all the information, the Wizard displays a summary of your choices. Click **Submit Design** to build your design.

![Summary](image)

- About Database Designer
- Creating a Design Manually
Creating a Design Manually

To create a design using Management Console and specify the configuration, take these steps.

1. On your database's dashboard, click the **Design** tab at the bottom of the page to navigate to the Database Designer page.

   The left side of the Database Designer page lists the database designs you own, with the most recent design you worked on highlighted. That pane also lists the current status of the design. Details about the most recent design appear in the main pane.

   The main pane contains details about the selected design.

![Database Designer Page](image-url)
2. To create a new design, click **New Design**.

3. Enter a name for your design and select **Manual**.

   The main *Database Design* window opens, displaying the default design parameters. Vertica has created and saved a design with the name you specified, and assigned it the default parameters.

   For more information, see *Design Name*.

4. On the **General** window, modify the design type, optimization objectives, K-safety, Analyze Correlations Mode, and the setting that allows Database Designer to create unsegmented projections.

   If you choose **Incremental**, the design automatically optimizes for the desired queries, and the K-safety defaults to the value of the cluster K-safety; you cannot change these values for an incremental design.

   Analyze Correlations Mode determines if Database Designer analyzes and considers column correlations when creating the design. For more information, see *DESIGNER_SET_ANALYZE_CORRELATIONS_MODE*.

5. Click the **Tables** tab. You must submit tables to your design.

6. To add tables of sample data to your design, click **Add Tables**. A list of available tables appears; select the tables you want and click **Save**. If you want to remove tables from your design, click the tables you want to remove, and click **Remove Selected**.

   If a design table has been dropped from the database, a red circle with a white exclamation point appears next to the table name. Before you can build or deploy the design, you must remove any dropped tables from the design. To do this, select the dropped tables and and click **Remove Selected**. You cannot build or deploy a design if any of the design tables have been dropped.

7. Click the **Queries** tab. To add queries to your design, do one of the following:

   - To add queries from the **QUERY REQUESTS** system table, click **Query Repository**. In the Queries Repository dialog that appears, you can sort queries by most recent, most frequently executed, and longest running. Select the desired queries and click **Save**. All valid queries that you selected appear in the **Queries** window.
   - To add queries from a file, select **Upload**. All valid queries in the file that you select are added to the design and appear in the **Queries** window. (This option is only available for the **MC super administrator role**.)
Database Designer checks the validity of the queries when you add the queries to the design and again when you build the design. If it finds invalid queries, it ignores them.

If you have a large number of queries, it may take time to load them. Make sure that all the queries you want Database Designer to consider when creating the design are listed in the Queries window.

8. Once you have specified all the parameters for your design, you should build the design. To do this, select your design and click Build Design.
9. Select Analyze Statistics if you want Database Designer to analyze the statistics before building the design.

For more information see Statistics Analysis.

10. If you do not need to review the design before deploying it, select Deploy Immediately. Otherwise, leave that option unselected.
11. Click Start. On the left-hand pane, the status of your design displays as Building until it is complete.
12. To follow the progress of a build, click Event History. Status messages appear in this window and you can see the current phase of the build operation. The information in the Event History tab contains data from the OUTPUT_EVENT_HISTORY system table.

13. When the build completes, the left-hand pane displays Built. To view the deployment script, select your design and click Output.
14. After you deploy the design using Management Console, the deployment script is deleted. To keep a permanent copy of the deployment script, copy and paste the SQL commands from the Output window to a file.
15. Once you have reviewed your design and are ready to deploy it, select the design and click Deploy Design.
16. To follow the progress of the deployment, click Event History. Status messages appear in this window and you can see the current phase of the deployment operation.

In the Event History window, while the design is running, you can do one of the following:

- Click the blue button next to the design name to refresh the event history listing.
- Click Cancel Design Run to cancel the design in progress.
- Click Force Delete Design to cancel and delete the design in progress.
17. When the deployment completes, the left-hand pane displays Deployment Completed. To view the deployment script, select your design and click Output.

Your database is now optimized according to the parameters you set.
Getting Tuning Recommendations in MC

If queries perform sub-optimally, you can get tuning recommendations for them, as well as for hints about optimizing database objects, by using Workload Analyzer.

Workload Analyzer is a Vertica utility that analyzes system information in Vertica system tables. It then returns a set of tuning recommendations based on statistics, system and data collector events, and database/table/projection design. You can use these recommendations to tune query performance.

View Workload Analyzer Recommendations

Workload Analyzer recommendations are available through the database's Overview page.

1. On the right side of the Overview page in the Quick Stats bar, view the Workload Analyzer module. This module alerts you to the number of recommendations Workload Analyzer has generated.

2. Click the number to view Workload Analyzer recommendations on the Database Designer page. The Workload Analyzer Results dialog displays tuning recommendations and the resource cost of running each command (Low, Medium, or High).

For more information about tuning recommendations and costs, see Analyzing Workloads in the Administrator's Guide and ANALYZE_WORKLOAD in the SQL Reference Manual.

The following image shows a list of Workload Analyzer tuning recommendations for a database. In the output, Workload Analyzer advises that you run the Database Designer on several tables and provides the cost estimate of running these operations.
Note that the cost of running Database Designer is high. When you see a high cost, you might want to run the recommended tuning action after hours.

<table>
<thead>
<tr>
<th>Tuning recommendation</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>run database designer on table online_sales.call_center_dimension</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table online_sales.online_page_dimension</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table online_sales.online_sales_fact</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.casey</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.date_dimension</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.employee_dimension</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.helpful_button_stage</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.inventory_fact</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.my_table</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.num_test</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.num_test2</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.numeric_table</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.product_dimension</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.promotion_dimension</td>
<td>HIGH</td>
</tr>
<tr>
<td>run database designer on table public.sample_table</td>
<td>HIGH</td>
</tr>
</tbody>
</table>

MC displays fifteen recommendations per page and includes a message at bottom left, which lets you know where you are within the total number of recommendations; for example, "Showing n-nn of nn entries." Depending on the total number of recommendations, you can move forward and backward through them by clicking the arrows at bottom right.

**Tip:**
You can force the Workload Analyzer task to run immediately by clicking **Update Recommendations** over the Cost column.
Set and Disable Workload Analyzer Events

On MC, Workload Analyzer automatically begins monitoring data one minute after the MC process starts. Workload Analyzer then runs once per day, or immediately after you import a database to MC. It continually gathers data in the background as long as the database is running. If you haven't created a database yet, or if the database is down, Workload Analyzer does nothing until the database is back up.

By default, Workload Analyzer runs each day at 2 AM. To optimize when Workload Analyzer uses resources, you can set Workload Analyzer to run at a different time for any or all databases that MC monitors. You can also set MC to never run Workload Analyzer automatically.

1. On the Home page, click **MC Settings**.
2. Click the **Monitoring** tab.
3. Under the **Workload Analyzer Assistant** section of the Monitoring page, select your time zone.
4. Select the radio button for one of the options:
   - **All Databases**: Select a time from the list. Workload Analyzer will run at that time on all databases that MC monitors.
   - **Specific Database at Specific Time**: Select a database and a time from the list. At the time you specify, Workload Analyzer will run at that time on the database you selected.
   - **Do Not Run Workload Analyzer On Any Database**: MC will never run Workload Analyzer automatically on any database it monitors.
5. Click **Apply** at the top right of the page.

For additional information about tuning recommendations and their triggering event, see **Workload Analyzer Recommendations**.

- **Analyzing Workloads**
- **Getting Tuning Recommendations**
Monitoring Using MC

Management Console gathers and retains history of important system activities about your MC-managed database cluster, such as performance and resource utilization. You can use MC charts to locate performance bottlenecks on a particular node, to identify potential improvements to Vertica configuration, and as a reference for what actions users have taken on the MC interface.

**Note:**
MC directly queries Data Collector tables on the MC-monitored databases themselves. See Management Console Architecture in Vertica Concepts. For how to set up MC to query an alternative database for monitoring data, see Extended Monitoring.

The following list describes some of the areas you can monitor and troubleshoot through the MC interface:

- Multiple database cluster states and key performance indicators that report on the cluster's overall health
- Information on individual cluster nodes specific to resources
- Database activity in relation to CPU/memory, networking, and disk I/O usage
- Layout of subclusters, and resource utilization and query workload on subclusters. (Available in Eon mode databases only, where the database includes one default subcluster, and may include additional user-defined subclusters.)
- Query concurrency and internal/user sessions that report on important events in time
- Cluster-wide messages
- Database and agent log entries
- MC user activity (what users are doing while logged in to MC)
- Issues related to the MC process
- Error handling and feedback

**About Chart Updates**

MC retrieves statistical data from the production database to keep the charts updated. The charts also update dynamically with text, color, and messages that Management Console receives from the agents on the database cluster. This information can help you quickly resolve problems.
Each client session to MC uses a connection from MaxClientSessions, a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages.

**Tip:**
You can increase the value for MaxClientSessions on an MC-monitored database to account for extra sessions. See Managing Sessions for details.

### Monitoring Same-Name Databases on MC

If you are monitoring two databases with identical names on different clusters, you can determine which database is associated with which cluster by clicking the database icon on MC's Databases and Clusters page to view its dialog box. Information in the dialog displays the cluster on which the selected database is associated.
Viewing the Overview Page

The Overview page displays a dynamic dashboard view of your database.

The page provides three tabs: Status Summary, System Health, and Query Synopsis. Access these tabs by clicking one of the three icons at the top left of the Overview page. Each tab contains charts and filters displaying information about your cluster. The QuickStats widgets on the right of the page display alerts and statistics about the state of your cluster.

Information on this page updates every two minutes, however you can adjust that value in the MC Settings page on the Monitoring tab. You can postpone updates by deselecting Auto Refresh in the toolbar.

Chart Viewing Options

You can specify time frames for some charts, which display a calendar icon in their title bars. Click the calendar icon to specify the time frame for that module.

On the Status Summary tab, you can select Synchronize charts to simultaneously apply the specified time frame to all charts on that tab.

If you have enabled extended monitoring on your database, MC can display longer ranges of data in certain charts. See Extended Monitoring. If a chart is using extended monitoring data, the rocket ship icon appears in the title bar:
You can expand some charts to view them in larger windows. Click the expand icon in the title bar to do so:

### Changing What the Chart Displays

The charts on the Overview page can display information about the nodes in your database, or the activity in all your database subclusters, in a single subcluster, or on the nodes that are not assigned to a subcluster. Use the dropdown in the title bar to select the type of information you want to display in the chart.

**Note:**
The dropdown list in the CPU/Memory/Disk I/O chart below, and all other MC charts, appears only for Eon Mode databases, and only if subclusters are defined.

![CPU/Memory/Disk I/O Chart](chart.png)

### Zooming to Show Chart Details

There are several steps you can take to show increasing levels of detail in a chart.

You can click the expand icon in the title bar to view the chart in a larger window:
You can use the cursor to outline a small area you want to expand, shown as a gray rectangle below:

When you release the cursor, the detail area expands to full size:

Hover over any line or point on the chart to see details about those specific data points. This works before or after you expand the chart:

**What the Lines and Dots on the Chart Represent**

The legend below the CPU/Memory/Disk I/O chart explains what the lines and dots on the chart represent.
Each line represents the average of the nodes you selected in the dropdown. If you selected Database - Nodes, the line represents the average for all the nodes in the database. If you selected one subcluster, the line represents the average for the nodes in that subcluster.

Each dot represents an individual entity within your dropdown choice. If you chose Database - Nodes, each dot represents one node in the database. If you chose Database - Subclusters, each dot represents one subcluster in the database. If you chose a single subcluster or the unassigned subclusters, each dot represents an individual node within that set.

You can hover over any line or dot to see a summary about it. You can click on a dot to display the Node Details page for that dot.

**Quick Stats**

The Quick Stats sidebar on the right of the page provides instant alerts and information about your cluster's status.
- **Database Nodes Health** displays which nodes are down, critical, recovering, or up. Critical and recovering nodes are included in the total nodes considered "up" by the database. Click a node value to open the Manage page.
- **Running and Queued Queries** displays current queries in the database. Click the query values to open the Query Monitoring charts.
• **Projections** displays the number of total projections, unsegmented projections, and unsafe projections for the database schema with the most projections. Click a value to open the Table Treemap chart.

• **Disk Space Usage** alerts you to the number of nodes that are low on disk space. Click the value to go to the Manage page. On the Manage page, the Storage Used KPI View is displayed.

• **Workload Analyzer** analyzes system information retained in [SQL system tables](https://www.vertica.com/docs/9.3.x/VerticaAnalyticDatabase/usersguide/vertica-9.3.x Users Guide.html) and provides tuning recommendations, along with the cost (low, medium, or high) of running the command. See [Analyzing Workloads](https://www.vertica.com/docs/9.3.x/VerticaAnalyticDatabase/usersguide/vertica-9.3.x Users Guide.html) for more information.

• **I/O Wait Notices** displays the number of nodes that, in the last hour, have recorded Disk I/O waits and Network I/O waits exceeding the wait threshold (1 second for Disk and 0 seconds for Network).

• **License Consumption** displays the number of licenses your database uses, and the percentage of your Vertica Community Edition or Premium Edition license being used.

• **Unread Messages** display the number of unread messages and alerts for the database. This count differs from the number of total messages across all your databases. Click the value to open the Message Center.

### Status Summary

The Status Summary tab displays four modules that provide a general overview of the status of your cluster:
The **CPU/Memory/Disk I/O Usage** module shows cluster resource usage. The chart displays the number of nodes in the database cluster and plots average and per-node percentages for CPU, memory, and disk I/O usage.

- Select a resource type from the legend to remove or add it from the chart display.
- Click a data point (which represents a node) to open the Manage page. See Monitoring Cluster CPU/Memory.

The **General Pool Activity** module displays GENERAL pool activity. The chart displays average query queue times, average GENERAL pool free memory, and resource rejections. Use this chart to see how much free memory there is in GENERAL pool, or if there have been high queue times.

- Click the dropdown in the title bar to view the GENERAL pool usage for the entire database (the default), for a specific subcluster, or for the nodes not assigned to a subcluster.
- Click the expand icon in the title bar to open the chart in a bigger window.
- Click a data point to open the Resource Pools Monitoring chart. See Managing Workloads.

The **Thresholds Notifications** module displays alerts generated when a threshold has been exceeded in the database. Notifications are categorized by System Health and Performance.

- In the module, you can acknowledge an alert (which marks it as read) or click the X to stop monitoring that threshold (which stops you receiving similar alerts in the future).
- Customize thresholds and alert priorities for these notifications in the Thresholds tab of the database Settings page. See Customizing Threshold-Based Notifications.

The **Queries** module displays query statistics. The first pie chart displays running and queued queries in the last 24 hours. The second chart displays completed and failed queries for the time frame you specify. Click a query count number above the chart to open the Query Monitoring chart. See Monitoring Running Queries.
**System Health**

The System Health tab provides a summary of your system resource usage and node information, with filters that allow you to view resource usage within the ranges you specify.

**Note:** Adjusting the filters on the System Health tab does not affect any database or MC settings.

- The **Memory Usage** filter displays the number of nodes with high and low memory usage. Move the sliders to adjust the memory usage range filter. For example, if you specify a range of 25% to 75% memory usage, the filter displays how many nodes are using less than 25% of memory (Low) and how many are using more than 75% (High). Hover your cursor over the Low and High values to see lists of what nodes fall, respectively, below or above the memory usage range you specified. Click a node value to go to the Manage page, which displays the Memory Utilization KPI View.

- The **Spread Retransmission Rate** filter displays the number of nodes with high spread retransmission rates. When a node's retransmission rate is too high, it is not communicating properly with other nodes. Move the slider to adjust the retransmission rate filter. Hover your cursor over the Nodes value to see a list of what nodes exceeded the
spread retransmission rate you specified. Click the node value to view spread retransmit rate alerts in the Message Center.

- The **CPU Usage** chart displays the number of nodes with high and low CPU usage. Move the sliders to adjust the CPU usage range filter. Hover your cursor over the Low and High values to see lists of what nodes are below or above range you specified. Click a node value to go to the Manage page, which displays the CPU Utilization KPI View.

- The **Reboot Rate** filter displays the number of times nodes in the cluster have rebooted within the specified time frame. Use this filter to discover if nodes have gone down recently, or if there have been an unusual number of reboots. Move the slider to adjust the number of days. Hover over the Times value to see a list of the nodes that have rebooted and the times at which they did so.

- The **Disk Space Usage** filter displays the number of nodes with high disk space usage. Move the slider to adjust the disk usage filter. Hover your cursor over the Nodes value to see a list of what nodes exceed the acceptable range. Click the nodes value to go to the Manage page, which displays the Storage Used KPI View.

- The **Cluster Clock Skew Rate** module displays the number of nodes that exceed a clock skew threshold. Nodes in a cluster whose clocks are not in sync can interfere with time-related database functions, the accuracy of database queries, and Management Console's monitoring of cluster activity.

---

**Query Synopsis**
The Query Synopsis page provides two modules that report system query activity and resource pool usage:

- The **Query Statistics** module displays four bar charts that provide an overview of running, queued queries, failed, and completed queries in the past 24 hours.
  - Select one of the options at the top of the module to group the queries by **Resource Pools, Users, Nodes, or Subclusters**.
  - Click a bar on the chart to view details about those queries the [Query Monitoring](#) activity chart.
- The **User Query Type Distribution** chart provides an overview of user and system query activity. The chart reports the types of operations that ran. The default is to display the types of operations that ran on all nodes in the database. Use the dropdown in the title bar to display the types of operations that ran on the nodes in a specific subcluster, or on the nodes not assigned to a subcluster.
  - Hover your cursor over chart points for more details.
  - Select a type of operation from the legend to remove or add it from the chart display.
  - To zoom to a certain time frame, you can adjust the sliders at the bottom of the chart.
  - Click a bar in the graph to open the [Queries](#) chart.
Monitoring Cluster Nodes

For a visual overview of all cluster nodes, click the running database on the Databases and Clusters page and click the Manage tab at the bottom of the page to open the cluster status page.

The cluster status page displays the nodes in your cluster.

The appearance of the nodes indicate the following states:

- **Healthy**: The nodes appear green.
- **Up**: A small arrow to the right of the node points upward.
- **Critical**: The node appears yellow and displays a warning icon to the right.
- **Down**: The node appears red. To the right of the node, a red arrow points downwards.
- **Unplugged**: An orange outlet and plug icon appears to the right.

You can get information about a particular node by clicking it, an action that opens the node details page.
Filtering What You See

If you have a large cluster, where it might be difficult to view dozens to hundreds of nodes on the MC interface, you can filter what you see. The Zoom filter shows more or less detail on the cluster overall, and the Health Filter lets you view specific node activity; for example, you can slide the bar all the way to the right to show only nodes that are down. A message next to the health filter indicates how many nodes in the cluster are hidden from view.

On this page, you can perform the following actions on your database cluster:

- Add, remove and replace nodes
- Rebalance data across all nodes
- Stop or start (or restart) the database
- Refresh the view from information MC gathers from the production database
- View key performance indicators (KPI) on node state, CPU, memory, and storage utilization (see Monitoring Cluster Performance for details)

Note:
Starting, stopping, adding, and dropping nodes and rebalancing data across nodes works with the same functionality and restrictions as those same tasks performed through the Administration Tools.

If You Don't See What You Expect

If the cluster grid does not accurately reflect the current state of the database (for example if the MC interface shows a node in INITIALIZING state, but when you use the Administration Tools to View Database Cluster State, you see that all nodes are UP), click the Refresh button in the toolbar. Doing so forces MC to immediately synchronize with the agents and update MC with new data.

Don't press the F5 key, which redisplay the page using data from MC and ignores data from the agent. It can take several seconds for MC to enable all database action buttons.
Monitoring Subclusters in MC

Subclusters are available in Eon mode databases only, for managing workloads and resource utilization. MC makes it easy to view and monitor your subclusters, so that you can track how queries are performing and how well your subcluster resources are balanced. Your MC or Vertica administrator can use the information to make adjustments if necessary to improve your query throughput and system performance.

The charts on the Database Overview page allow you to view and drill down into the resource usage of all nodes, all subclusters, individual subclusters, or the unassigned nodes. For details, see Charting Subcluster Resource Usage in MC.

You can view statistics for the individual nodes in each subcluster, and the unassigned nodes, in table format on the Database Manage page, in the Subclusters tab. The Subclusters tab also provides node actions. See Viewing Subcluster Layout in MC. Note that if you create a subcluster but you do not assign any nodes to it, that subcluster will not display on the Database Manage page Subclusters tab.

See the topics that cover these MC pages, all of which display information about resource usage and database activity on Eon mode database subclusters:

- Viewing the Overview Page
- Database Overview page > Status Summary tab > CPU/Memory/Disk I/O chart
- Database Overview page > Status Summary tab > General Pool Activity chart
- Database Overview page > Query Synopsis tab > Query Statistics chart
- Database Overview page > Query Synopsis tab > User Query Type Distributions chart
- Monitoring Running Queries
- Database Activity page > Query Monitoring page
- Monitoring Resource Pools
- Database Activity page > Resource Pools Monitoring page > Memory Usage chart
- Viewing Subcluster Layout in MC
- Database Manage page > Subclusters tab

Charting Subcluster Resource Usage in MC

On the Database Overview page, in the CPU/Memory/Disk I/O chart and the Database General Pool Usage chart, you can use the dropdown in the title bar to focus the chart on:
• All nodes in the database
• All subclusters in the database
• An individual subcluster, by name
• The nodes not assigned to any subcluster

For example, the CPU/Memory/Disk I/O chart dropdown allows you to choose the database nodes, one named subcluster, all subclusters, or the nodes unassigned to a subcluster (Subcluster: unassigned):

If you choose **Database - Subclusters**, the line in a given color represents the trend of all subclusters averaged together for that statistic, and each dot of the same color represents an individual subcluster at a certain time, for that same statistic.

For more in-depth information on how expand detail areas of charts and drill into the details, see [Viewing the Overview Page](#).

**Viewing Subcluster Layout in MC**

If your Eon mode database has subclusters defined, the MC **Database Manage** page displays two tabs, the **Database** tab and the **Subclusters** tab.

The **Subclusters** tab lets you view, sort, and search for subclusters and view their layout and statistics. The page includes the following statistics in table form for the nodes in each subcluster, and for any unassigned nodes:

- Node name
- Private IP address
- Status (UP or DOWN)
• CPU Usage %
• Memory Usage %
• Disk Usage %

Searching for Nodes

To find a particular node, enter its node name or IP address in the "node name or IP" search field at the top right of the Subclusters tab. Searching for nodes is especially helpful if your cluster is very large. To find a specific node, enter its complete node name or IP address. Enter a partial node name or IP address to find all nodes whose name or IP address contains that string. For example, if you enter "240" in the search field, MC would find both of the following nodes:

Node name: MyNode24018
Node IP address: 1.160.10.240

Note that wildcards are not supported in the search field.

Stopping, Starting, or Removing Nodes

The right column provides icons for executing node actions. You can stop or start a node, or remove a node, in the subcluster. Removing a node also removes it from the database. Only the Start, Stop, and Remove actions are available on this page.

Note:
If you change the layout of your subcluster, for example by removing nodes, you must rebalance shards. See REBALANCE_SHARDS.
Sorting Nodes Within a Subcluster

You can sort the nodes within each subcluster by the values in any column, by clicking on the column heading.

Collapsing or Expanding a Subcluster, or the Entire Table

To collapse a subcluster section to one summary row, click the minus icon or the subcluster heading. To collapse the entire table to summary rows, click the minus icon or "Collapse All".

To expand a collapsed subcluster section, click the plus icon or the subcluster heading. To expand the entire table, click the plus icon or Expand All.

Note: If you create a subcluster, but you do not assign any nodes to it, the subcluster will not display on the Database Manage page Subclusters tab.

Subclusters

Monitoring Node Activity

If a node fails on an MC-managed cluster or you notice one node is using higher resources than other cluster nodes—which you might observe when monitoring the Overview page—open the Manage page and click the node you want to investigate.

The Node Details page opens and provides summary information for the node (state, name, total memory, and so on), as well as resources the selected node has been consuming for the last three hours, such as average CPU, memory, disk I/O percent usage, network consumption in kilobytes, and the percentage of disk storage the running queries have been using. You can also browse and export log-level data from AgentTools and Vertica log files. MC retains a maximum of 2000 log records.
For a more detailed view of node activity, use the mouse to drag-select around a problem area in one of the graphs, such as the large spike in network traffic in the above image. Then hover over the high data point for a summary.

- Viewing the Overview Page
- Monitoring Cluster Performance

Monitoring Cluster Performance

Key Performance Indicators (KPIs) are a type of performance measurement that let you quickly view the health of your database cluster through MC's Manage page. These metrics, which determine a node's color, make it easy for you to quickly identify problem nodes.

Metrics on the database are computed and averaged over the latest 30 seconds of activity and dynamically updated on the cluster grid.

How to Get Metrics on Your Cluster

To view metrics for a particular state, click the menu next to the KPI View label at the bottom of the Manage page, and select a state.

MC reports KPI scores for:

- **Node state**—(default view) shows node status (up, down, k-safety critical) by color; you can filter which nodes appear on the page by sliding the health filter from left to right
- **CPU Utilization**—average CPU utilization
- **Memory Utilization**—average percent RAM used
- **Storage Utilization**—average percent storage used

After you make a selection, there is a brief delay while MC transmits information back to the requesting client. You can also click Sync in the toolbar to force synchronization between MC and the client.

Node Colors and What They Mean

Nodes in the database cluster appear in color. Green is the most healthy and red is the least healthy, with varying color values in between.
Each node has an attached information dialog box that summarizes its score. It is the score's position within a range of 0 (healthiest) to 100 (least healthy) that determines the node’s color bias. Color bias means that, depending on the value of the health score, the final color could be slightly biased; for example, a node with score 0 will be more green than a node with a score of 32, which is still within the green range but influenced by the next base color, which is yellow. Similarly, a node with a score of 80 appears as a dull shade of red, because it is influenced by orange.

MC computes scores for each node's color bias as follows:

- 0-33: green and shades of green
- 34-66: yellow and shades of yellow
- 67-100: red and shades of red

If the unhealthy node were to consume additional resources, its color would change from a dull orange-red to a brighter red.

**Filtering Nodes From the View**

The health filter is the slider in the lower left area of page. You can slide it left to right to show or hide nodes; for example, you might want to hide nodes with a score smaller that a certain value so the UI displays only the unhealthy nodes that require immediate attention. Wherever you land on the health filter, an informational message appears to the right of the filter, indicating how many nodes are hidden from view.

Filtering is useful if you have many nodes and want to see only the ones that need attention, so you can quickly resolve issues on them.

**Monitoring Cluster CPU/Memory**

On the MC Overview page, the **CPU/Memory** subsection provides a graph-based overview of cluster resources during the last hour, which lets you quickly monitor resource distribution across nodes.

This chart plots average and per-node percentages for both CPU and memory with updates every minute—unless you clear Auto Refresh Charts in the toolbar. You can also filter what
the chart displays by clicking components in the legend at the bottom of the subsection to show/hide those components. Yellow data points represent individual nodes in the cluster at that point in time.

**Investigating Areas of Concern**

While viewing cluster resources, you might wonder why resources among nodes become skewed. To zoom in, use your mouse to drag around the problem area surrounding the time block of interest.

After you release the mouse, the chart refreshes to display a more detailed view of the selected area. If you hover your cursor over the node that looks like it's consuming the most resources, a dialog box summarizes that node's percent usage.

For more information, click a data point (node) on the graph to open MC's node details page. To return to the previous view, click **Reset zoom**.

**See Also**

- Monitoring Node Activity

**Monitoring Database Storage**

The Infrastructure page's **Storage View** provides a summary of the amount of data stored across your database, and the persistent location of that data. Use this view to monitor how much of your storage capacity your databases are using.

For a database running in Eon Mode, MC also displays bar charts in the Storage View that illustrate shard subscription status. Use these charts to determine if your current subscription layout is optimal for querying your Eon Mode database. For information about using subscription status charts, see **Monitoring Subscription Status in Eon Mode**.
Monitor Storage Usage

The storage summary table lists all databases currently monitored by MC and information about their storage:

- **Database Size.** Click **Load Size** to calculate the total size of the database.
- **Database Mode.** Vertica databases run in Enterprise Mode, or **Eon Mode**.
- **Storage Type.** Enterprise Mode databases list the OS of the local nodes where data is stored. Eon Mode databases list the type of communal storage location where it stores its data. Eon Mode currently supports only S3-compatible storage locations.
- **View.** The options displayed in this column depend on the database mode and type of data on the database.
  - **Vertica Tables Storage:** For Enterprise Mode databases only. Click for a dialog listing the node and local directories where Vertica table data is stored.
  - **Communal/Depot Storage:** For Eon Mode databases only. Click for a dialog displaying location paths for your depot and communal storage.
  - **Communal Storage Subscription:** For Eon Mode databases only. Click to view bar charts at the bottom of the Storage View page, illustrating shard subscription status. For more about these charts, see **Monitoring Subscription Status in Eon Mode**.
  - **External Tables:** Available when there are **Working with External Data** tables in your database. Click for a dialog displaying details about all external tables. (Also see **Monitoring Table Utilization and Projections**.)
  - **HCatalog Details:** Available when your Vertica database has access to Hive tables. (See **Using the HCatalog Connector**.) Click for a dialog displaying details about HCatalog schemas. For any HCatalog schema, click View Tables for details.
about all tables accessible through that schema. (Also see Monitoring Table Utilization and Projections.)

In front of Eon Mode database names in the list, a plus icon displays. Click the icon to expand more details about the database's depot capacity and usage. The depot is cache-like storage where Eon Mode databases keep local copies of communal storage data for faster query access.

- Click **Percentage Used** to view the Depot Activity chart for that database.
- Click **View Depot Details by Nodes** to see a dialog displaying location paths and depot usage information.

## Monitoring Subscription Status in Eon Mode

To view subscription charts for any Eon Mode database you monitor, click **View Your Infrastructure** on the MC Home page. Then click the **Storage View** tab.

Click the **Details** action for that database in the storage summary list (highlighted in red in the image below).

![Storage View](image)

When you click **Details**, two charts become available on the bottom half of the page: The Sharding Subscription chart, and the Node Subscription chart. You can switch between these two charts using the drop down menu to the right of the chart title.
Why Monitor Shard and Node Subscriptions?

Shards are segments of the data that is stored persistently in your Eon Mode database's communal storage location, for example Amazon S3 in the cloud or PureStorage if your cluster is on premises. Each node in the database subscribes to a subset of those shards. In this way, the node gets updated on when to populate its depot with new data from communal storage. (See Shards and Subscriptions.)

For K-safety in an Eon Mode database, shards should have multiple node subscribers to ensure that even if a node goes down or is being used by another query, the data on that shard is still available on other nodes. If a shard has no node subscribers, that could indicate that data loss is occurring.

Subscriptions go through several transitions, which are illustrated by colors in the subscription charts:

- **Pending (Yellow).** The node is ready to subscribe to a certain shard. It cannot yet serve queries because it is not actively subscribed to the shard yet.
- **Passive (Blue/Teal).** The node could potentially serve queries for a shard it is passively subscribed to, but its depot contents for that shard may not yet be up to date, which could negatively impact query performance. The passively subscribed node is waiting for an active node subscriber of the shard to send it the most recent data.
- **Active (Green).** The node is actively subscribed to the shard, can load new data from communal storage, and can serve queries for data in that shard. The actively subscribed node sends data from that shard to other subscribed nodes.
- **Removing (Dark Red/Maroon).** The node is unsubscribing from the shard. It may have the most recent data from that shard, but that state is temporary until data from that shard is cleaned up.
- **Inactive (Red).** The subscribed node is down. It can no longer serve queries for that shard.

Operations such as adding or removing nodes or rebalancing shards can change which nodes subscribe to which shards. Shard subscription changes can prevent object-level restore from backups, though full restore is always possible. If shard subscriptions change, consider making a backup with the new configuration.

### Monitor Sharding Subscription

The Sharding Subscription chart displays how many nodes are subscribed to each shard in your database, and what type of subscription it is.

You can hover over any bar in the chart to see which nodes are subscribed to the shard. Click on a subscription type in the legend to show or hide it in the chart display.

The example below shows the shard subscription status for a running Eon Mode database. The database has three nodes that are up, and one node (Node 4) that has been added to the cluster, but is down.
You can hover over any bar in the chart to see which nodes are subscribed to the shard. In this example, nodes 1 and 3 have active subscriptions to the first shard (green); nodes 1 and 2 to the second shard; and nodes 2 and 3 to the third shard.

The active subscriptions are evenly spread across the shards. This is a k-safe Eon Mode database.

Node 4 was subscribed to two shards; however, because it is down, its subscriptions to the shards are now inactive (red).

Monitor Node Subscriptions

Use this chart to view how many shards each node in your database is subscribed to, and the state of those subscriptions. The number of shards each node is subscribed to should be about the same to prevent overworking any given node.

Hover over any bar to see the shards it is subscribed to. The color of the bar indicates the state of each subscription. Click on a subscription type in the legend to show or hide it in the chart display.

The example below shows the same database from the Sharding Subscription example above. Nodes 1 through 3 are each actively subscribed to two shards (green). At least two nodes are subscribed to every shard in the database (which you can double check using the Sharding Subscription chart), ensuring that even if one of the nodes is down or being used in a query, another node is still actively subscribed and can access the data of that shard.

Since Node 4 is down, the chart shows that both its shard subscriptions are now inactive.

- Elasticity

Monitoring System Resources

MC’s Activity page provides immediate visual insight into potential problem areas in your database’s health by giving you graph-based views of query and user activity, hardware and memory impact, table and projection usage, system bottlenecks, and resource pool usage.

Select one of the following charts in the toolbar menu:

- Queries
- Internal Sessions
- User Sessions
- Memory Usage
- System Bottlenecks
- User Query Phases
- Monitoring Table Utilization and Projections
- Query Monitoring
How up to date is the information?

System-level activity charts automatically update every five minutes, unless you clear Auto Refresh in the toolbar. Depending on your system, it could take several moments for the charts to display when you first access the page or change the kind of resource you want to view.

Chart Viewing Options

You can specify time frames for some charts, which display a calendar icon in their title bars. Click the calendar icon to specify the time frame for that module.

If you have enabled extended monitoring on your database, MC can display longer ranges of data in certain charts. See Extended Monitoring. If a chart is using extended monitoring data, the rocket ship icon appears in the title bar:

You can expand some charts to view them in larger windows. Click the expand icon in the title bar to do so:
Monitoring Query Activity

The Queries chart displays information about query concurrency and average resource usage for CPU/memory, network activity, and disk I/O percent based on maximum rated bandwidth.

Hover over a data point for more information about percent usage for each of the resource types.
If you click a data point, MC opens a details page for that point in time, summarizing the number of user queries and system queries. This page can help you identify long-running queries, along with the query type. You can sort table columns and export the report to a file.

**Monitoring Key Events**

On the main Queries page, MC reports when a key event occurred, such as a Workload Analyzer or rebalance operation, by posting a *Workload Analyzer* (Workload Analyzer) and/or *RBL* (rebalance) label on the resource section of the chart.

**Filtering Chart Results**

The default query concurrency is over the last hour. The chart automatically refreshes every five minutes, unless you clear the Auto Refresh option in the toolbar. You can filter results for 1 hour, 1 day, or up to 1 week, along with corresponding average resource usage. You can also click different resources in the legend to show or hide those resources.

To return to the main Queries page, use the slider bar or click the 1h button.

**Viewing More Detail**

To zoom in for detail, click-drag the mouse around a section or use the sliding selector bar at the bottom of the chart. After the detailed area displays, hover your cursor over a data point to view the resources anchored to that point in time.

For more detail about user or system queries, click a data point on one of the peaks. A *Detail* page opens to provide information about the queries in tabular format, including the query type, session ID, node name, query type, date, time, and the actual query that ran.

The bottom of the page indicates the number of queries it is showing on the current page, with Previous and Next buttons to navigate through the pages. You can sort the columns and export contents of the table to a file.

To return to the main Queries page, click `<database name> Activity` in the navigation bar.
Monitoring Internal Sessions

The Internal Sessions chart provides information about Vertica system activities, such as Tuple Mover and rebalance cluster operations, along with their corresponding resources, such as CPU/memory, networking, and disk I/O percent used.

Hover your cursor over a bar for more information. A dialog box appears and provides details.

Filtering Chart Results

You can filter what the chart displays by selecting options for the following components. As you filter, the Records Requested number changes:

- **Category**—Filter which internal session types (moveout, mergeout, rebalance cluster) appear in the graph. The number in parentheses indicates how many sessions are running on that operation.
- **Session duration**—Lists time, in milliseconds, for all sessions that appear on the graph. The minimum/maximum values on which you can filter (0 ms to n ms) represent the minimum/maximum elapsed times within all sessions currently displayed on the graph. After you choose a value, the chart refreshes to show only the internal sessions that were greater than or equal to the value you select.
- **Records requested**—Represents the total combined sessions for the Category and Session Duration filters.

Monitoring User Sessions

The User Sessions charts provide information about Vertica user activities for all user connections open to MC.

Choose **User Sessions** from the menu at the top of your database's Activity page to view these charts.
**View Open Sessions**

The Open Sessions tab displays a table of currently open sessions for each user. You can close a session or cancel a query on this tab by selecting that option from the Actions column.

![Open Sessions Table](image)

Click any row to open a Session Details dialog that shows more extensive information about that session.
To configure the Open Sessions page display:

- Use the **Sort Users** button at the top right of the page to sort by user name or number of open sessions.
- Use the **Toggle Columns** button at the top right of the page to select which columns to display. Each table displays session information by column, such as the session start time or the...
View All User Sessions

The All Sessions tab displays a history of all user sessions in a swim lane chart.
**What Chart Colors Mean**

Bars outlined with a dotted line are currently running sessions.

Sessions are divided into two colors, yellow and blue.

- Yellow bars represent user (system) sessions. If you click a yellow bar, MC opens a Detail page that shows all queries that ran or are still running within that session.
- Blue bars represent user requests (transactions within the session). If you click a blue bar in the graph, MC opens a Detail page that includes information for that query request only.

When you hover your mouse over a transaction bar, a dialog box provides summary information about that request, such as which user ran the query, how long the transaction took to complete, or whether the transaction is still running.

**Filter Chart Results**

Extremely busy systems will show a lot of activity on the interface, perhaps more than you can interpret at a glance. You can filter chart results in several ways:

- **Zoom.** The context chart at the bottom of the page highlights in blue which section of the All Sessions chart you are viewing. Click and drag the blue box left or right to view earlier or later user sessions. Click and drag the edges of the blue box to zoom in or out.
- **Select fewer users.** Click the filter icon ( ) at the top of the page. A menu of a menu of all available users appears below. Deselect users to exclude from the chart.

- **Change the session duration (how long a session took to run).** Click the Filter icon ( ) at the top of the page. The Filter sessions and queries by duration field appears below. Enter the minimum session length (in seconds) to display on the chart and click Update.
• **Specify a time frame.** Click the Calendar icon (alendar) at the top of the page to display the From and To fields. Using the fields, select the time frame to display in the chart and click **Update**.

---

**Monitoring System Memory Usage**

The Memory Usage chart shows how system memory is used on individual nodes over time. Information the chart displays is stored based on Data Collector retention policies, which a superuser can configure. See **Configuring Data Retention Policies**.

The first time you access the Memory Usage chart, MC displays the first node in the cluster. MC remembers the node you last viewed and displays that node when you access the Activity page again. To choose a different node, select one from the Nodes drop-down list at the bottom of the chart. The chart automatically refreshes every five minutes unless you disable the Auto Refresh option.

---

**Tip:**

On busy systems, the Node list might cover part of the graph you want to see. You can move the list out of the way by dragging it to another area on the page.

---

**Types of System Memory**

The Memory Usage chart displays a stacking area for the following memory types:

- swap
- free
- fcache (file cache)
- buffer
- other (memory in use by all other processes running on the system besides the main Vertica process, such as the MC process or **agents**)
- Vertica
- rcache (Vertica ROS cache)
- catalog

When you hover over a data point, a dialog box displays percentage of memory used during that time period for the selected node.
Monitoring System Bottlenecks

The System Bottlenecks chart helps you quickly locate performance bottlenecks on a particular node. The first time you access the Activity page, MC displays the first node in the cluster. To choose a different node, select one from the Nodes drop-down list at the bottom of the chart.

The System Bottlenecks chart reports what MC identifies as the most problematic resource during a given time interval. You can use this chart as a starting point for investigation.

How MC Gathers System Bottleneck Data

Every 15 minutes, MC takes the maximum percent values from various system resources and plots a single line with a data point for the component that used the highest resources at that point in time. When a different component uses the highest resources, MC displays a new data point and changes the line color to make the change in resources obvious. Very busy databases can cause frequent changes in the top resources consumed, so you might notice heavy chart activity.
In the following example, at 08:24 the maximum resources used changed from Disk I/O to CPU. The System Bottlenecks charts denotes this with a change in line color from brown to green.

![System Bottlenecks Chart](image)

### The Components MC Reports on

MC reports maximum percent values for the following system components:

- Average percent CPU usage
- Average percent memory usage
- Maximum percent disk I/O usage
- Percent data sent over the network (TX)
- Percent data received over the network (RX)

### How MC Handles Conflicts in Resources

If MC encounters two metrics with the same maximum percent value, it displays one at random. If two metrics are very close in value, MC displays the higher of the two.

### Monitoring User Query Phases

The User Query Phases chart provides information about the query execution phases that a query goes through before completion. Viewing this chart helps you identify at a glance queries possibly delayed because of resource contention.

**Note:**
For a list of query phases, see [Query Phase Duration](#).
Each bar, bound by a gray box, represents an individual query. Within a query, a different color represents each query phase. The chart does not show phases for queries with durations of less than 4 seconds. Blank spaces within a query represent waiting times, as in the image below.

Hover over a phase in the query for information on the phase type and duration.

The chart shows queries run over the last 15 minutes. The chart automatically refreshes every five minutes, unless you clear the Auto Refresh option in the toolbar.

**Filtering Chart Results**

You can filter what the chart displays by selecting options for the user running the query, minimum query duration, and minimum phase duration.
Viewing More Detail

To zoom in for detail, click-drag the mouse around a section of the chart. Click Reset Zoom, located at the top right corner of the chart, to restore the chart to its original view.

For more detail, click a query bar. The Detail page opens to provide information about the queries in tabular format, including the query type, session ID, node name, query type, date, time, the actual query that ran, and an option to run Explain Plan or profile the query. Click a table column header to sort the queries by that category.

To export the contents of the table to a file, click Export, located at the upper right of the page.

To return to the main Queries page, click Activity in the navigation bar.

Monitoring Table Utilization and Projections

The Table Utilization activity page helps you monitor tables and projections in your database by schema.
Use the Table Utilization charts for a listing of all the tables in a schema, which you can filter and sort; or view them by size and usage in a treemap visualization. These charts allow you to identify outliers among your tables, such as those that are large or overused.

The Projections Summary, located on the right side of the page, provides an overview of the projections in the schema. You can use this summary to help identify if projections are evenly distributed across nodes.

**Visualize Tables**

MC shows you the public schema by default. To specify which schema to view, choose one from the Schemas menu at the top of the activity page. The summary of tables and projections in that schema appear on the page.

MC visualizes your available tables by schema in a table chart or as a treemap chart. From the Show As menu, choose Table for a tabular chart or Map for a treemap chart. By default, MC displays the Table chart.

**Show as:** [Table | Map]

Depending on the number of tables in the schema, the chart may be crowded. To narrow it down, use the Show Only filter at the top of the page to display only the largest 100 tables, smallest 100 tables, or external tables.
View the Table Chart

The Table chart is a tabular view of the schema's table data. Use the tabular view to filter or sort on any columns, and view the explicit values for row counts and utilization.

The columns display each table's:

- **Table Name**. Click this name to see the Table Details page.
- **Table Type**: Internal, Working with External Data or HCatalog. (Details such as row count and usage are not available for external and HCatalog types.)
- **Row Count**.
- **Usage in Queries**, by percentage of time the table is queried.
- **Row count and Usage**, visualized as a bar. The length of the bar indicates row count; a darker color indicates higher usage.
- **Table Definition**. The COPY statement table definition, only applicable to external tables.

Hover over any row in the chart to view the table's properties (shown for inventory_fact in the screen capture below). Click the table name to view its more in-depth Table Details page.
**View the Treemap Chart**

In the Treemap visualization, tables are represented by boxes, nested by size and colored by usage. Darker colors indicate higher table usage.

Hover over a table to view more details, or click to view its Table Details page.

![Treemap Chart]

**View Table Details**

The Table Details page displays a detailed overview of internal Vertica tables. (This is not available for external and HCatalog tables.) Click a table name on the Table Utilization Activity page to open its Table Details page in a new window.

You can view the following details:

- **Table Properties.** Table properties (such as row count and owner).
- **Projections.** The properties of the table's columns and projections.
- **Storage by Node.** The table's storage utilization per node, in MB.
- **# Deleted Rows by Node.** Vertica allocates physical storage to deleted rows until they are purged by the Tuple Mover.
- **# Delete Vectors by Node.** Vertica creates small containers called delete vectors when DELETE or UPDATE statements run on a table. A large number of delete vectors can adversely impact performance. (See Deletion Marker Mergeout.)

![Image](image.jpg)

*Note: If you have deleted table rows recently, Management Console may not display the most recent row count. MC updates the row count when mergeout occurs. See Mergeout.*

### Projections Summary

The Projections Summary is located in a side bar on the right side of the Table Utilization page. It displays the following statistics of all projections in a schema:

- **Total projections.**
- **Segmented projections**, the number of projections segmented across multiple nodes.
- **Unsegmented projections**, the number of projections that are not segmented across multiple nodes.
- **Projections Showing Distribution Skew**, the number of projections unevenly distributed across nodes. Tables with fewer than 1000 rows are not counted. Move the slider to configure filter by distribution skew percentage.
- **Projections Having >= Containers Per Node.** Move the slider to specify the minimum number of containers.
- **Unsafe Projections**, the number of projections with a K-safety less than the database's K-safety.
- Unused Projections.
- Not Up to Date Projections.

Click a projections number to view a list of the specified projections and their properties. For more about projections, see Working with Projections.

- Working with External Data
- Using the HCatalog Connector

### Monitoring Running Queries

The **Query Monitoring** activity page displays the status of recent and currently running queries, and resource information by user and node. For Eon Mode databases, you can also display the status of queries by subcluster. From this page, you can profile a query or cancel a running query.

Use this page to check the status of your queries, and to quickly cancel running or queued queries to free up system resources. This page can help you identify where resources are being used, and which queries, users, nodes, or subclusters are using the most resources.

The **Query Monitoring** page includes four tables, displayed as tabs:

- Running queries
- Queued queries
- Completed queries
- Failed queries
From the **Actions** column you can:

- **Cancel.** Cancel a running or queued query.
- **Close session.** Close a session for a running or queued query.
- **Explain.** Open the **Query Plan** page for any query.
- **Profile.** Profile any query on the **Query Plan** page.

The four bar charts at the bottom of the page display aggregate query usage by node or user. Hover over a bar with your cursor to see its value. When sorted by value, the left-most bar in each chart represents the node or user with the highest value.

The Query Monitoring page refreshes every 20 seconds by default. To change the refresh interval, click the **Page Settings** button in the upper-right corner of the page. A dialog appears. Type the new refresh interval, in milliseconds, in the text box.
**Sorting or Searching Queries by Session ID or Client Label**

The Query Monitoring Activity > Running Queries page includes columns that display the **Session ID** and **Client Label** for each query. You can sort the queries by Session ID or Client Label, or use the search field below either column to search for queries with a specific Session ID or Client Label.

**Filtering Chart Results**

Use the search field below each column title to narrow down your chart results. (For example, if you enter the text `SELECT product_description` in the **Search Queries** field and select a specific node in the **Initiator Node** column, the chart returns only queries which both contain that text and were initiated on the node you specified.)

Click a column title to sort the order of the queries by that category.

There may be a large number of results for Completed and Failed Queries. Use the **Customize** section at the top of these two tabs to further filter your chart results. For either tab, you can select a custom date and time range for your results.

In the Completed Queries tab, click **Data** to enter additional query information to filter based on any of the following fields:

- User
- Request
- Request Duration
- Node
- Request label

**Viewing More Details**

Click a query to view the entire query.
In the Failed Queries chart, click the plus (+) icon next to a failed query to see the failure details for each node involved in the query's execution.

To export the data in one of the Query Monitoring tables, click the table's tab, then click the Export ( ) button in the upper-right corner of the page. The browser downloads the data for that chart in a .dat file. The data exported includes columns that may not be visible in the MC, including the minimum and maximum values for Memory, Thread Count, and Open File Handles.

**Monitoring Catalog Memory**

The Catalog Memory activity page displays the catalog memory for each node. Use this page to check for sudden changes in catalog memory, or discrepancies in memory distribution across your nodes.

The Catalog Memory page displays:

- **A node details table.** The table lists the details of each node in the database, including their current catalog memory and total memory usage.
- **A catalog memory chart.** A line graph visualization of each node's catalog memory usage over time. Each line represents a node. The color legend at the bottom of the chart indicates the color of each node's line.

In the image below, catalog memory begins at 0GB for all three nodes. Over the next twenty minutes, catalog memory increases to 0.04GB in the second node (orange), then the first node (cyan), and finally in the third node (dark blue). Starting at 16:55, note that the three overlapping node lines appear as one line when all three nodes have the same catalog memory.
Filtering Chart Results

If you have many nodes in your database, you may want to display only certain nodes in the catalog memory chart. You can remove nodes from the chart in two ways:

- Deselect the node’s check box in the node details table.
- Deselect the node in the color legend below the chart.

Viewing More Details

Hover over any line in the chart to view the time, node name, and catalog size.

At the bottom of the chart is a summary bar that shows a quick overview of the catalog memory over time. Move the sliders on either side of the chart to zoom in on a specific time frame in the chart. When zoomed in, you can use the scrollbar to move forward or backward in time.
Monitoring Depot Activity in MC

If your database is in Eon Mode, you can use the Depot Activity page to monitor query activity, churn, and settings for your database’s depot. The depot (see Eon Mode Architecture) is a cache-like component on each node that improves query performance by preventing your queries from having to go to communal storage every time. Instead the queries access the depot, which contains local copies of your data.

To view the Depot Activity page, select the Activity tab at the bottom of your database’s Overview page, then select Depot Activity Monitoring from the chart list. The Depot Activity page has two tabs:

- **At a Glance**: The default, described below
- **Depot Content**: Described in Monitoring Depot Content in MC

The Depot Activity Monitoring page is not available when the database is in Enterprise Mode. See Using Eon Mode for more about Vertica database modes.

### At a Glance Tab

The At a Glance tab has three sections:

- Current Depot Usage and Depot Configuration (left pane)
- User Queries Depot Hits and Misses, Fetches and Evictions (upper-right pane)
- Communal Storage Access Calls (lower-right pane)
Current Depot Usage and Depot Configuration

Current Depot Usage on the left side of the page, displays the following statistics:

- **Overall**
  - **Depot Capacity:** Total depot capacity for all nodes in the database, added together.
  - **Depot in Use:** Total depot space currently in use, on all nodes in the database added together.
  - **Database Size:** Select Calculate to show the total size of the database, in GB.
  - **View More on Database Storage:** Click to see the Storage View tab, with details on the storage for this database.

- **Usage by Node**
  - Lists the number of bytes in the depot and percentage used, for each node in the database.
  - **View More:** Click to display depot usage for individual nodes.

- **Depot Configuration**
  - **Participating Nodes:** Number of nodes covered by these statistics.
  - **Max Depot Limit:** Total amount of depot space on all the participating nodes.
  - **Depot for Writes:** Whether the depot is Enabled or Disabled for write operations.
  - **Depot for Reads:** Whether the depot is Enabled or Disabled for read operations.
  - **Depot Operations for Query:** Displays the current value of the Eon Mode system parameter DepotOperationsForQuery. This parameter specifies whether the depot fetches a file required by query from communal storage because it is not in the depot. This parameter also determines whether the depot evicts other files to make space for the fetched file. Possible values are:
    - **ALL** (default): When a query reads files that are not in the depot, the depot fetches the files from communal storage, and, if necessary, evicts other files.
    - **FETCHES:** When a query reads files that are not in the depot, the depot fetches those files only if space is available without evicting other files.
    - **NONE:** When a query reads files that are not in the depot, the depot does not fetch the files.

- **View documentation on Depot configuration:** Displays documentation on Eon Mode parameters for depot configuration.
Retention limits for monitoring depot activity. Click the following DC tables link to see the retention policies. The retention policies determine how long Vertica retains the monitoring information that the depot activity charts display. Consider increasing retention limits, such as that of Depot Reads, to display a longer history of activity.

Monitor Queries Involving Depot Versus Communal Storage

The User Queries Depot Hits and Misses chart shows how your queries are interacting with the depot over time:

Query Depot Hits and Misses

- The color-coded graph lines show how many queries were accessing the depot or communal storage, or both, at any given time.
- The left y-axis indicates the number of queries.

For optimal performance, the majority of queries should access your depot, which is local. To maximize depot access, size your depot so it fits your frequently accessed data.

When the depot size is more limited, queries access communal storage more often to retrieve all the necessary data. A more limited depot size may be necessary due to storage costs, but accessing communal storage can impact query performance.

Depot Fetches and Evictions

- The colored bars on the User Queries Depot Hits and Misses chart show the moments when your queries are causing data to be fetched to or evicted from the depot, as measured in megabytes.
- The right y-axis shows how much data was fetched or evicted.

Whenever a query fetches new data from communal storage because it is not in the depot, if the depot is full, Vertica makes space for the new data by evicting older data.

Use the fetches and evictions bars to monitor churn (how many files are getting pushed out of the depot), and how up-to-date your depot's data is. Churn occurs when, with a limited depot size, the depot must begin to fetch and evict data more frequently. If you observe that queries are consistently slower due to accessing communal storage, and notice the depot keeps experiences frequent churn, you might benefit from increasing your depot's size limit.
For Details

- Hover over a point on the query line to see details about the number of queries that ran.
- Hover over a Fetches or Evictions bar graph to see details about the number of bytes fetched or evicted.
- Click the line or bar to view the Query Details page, which provides information about every query that ran in the selected timespan.

Monitor Communal Storage Access Calls

The **Communal Storage Access Calls** chart in the lower pane of the At a Glance tab shows how many of each type of API call executed in each timespan of the chart.

Monitoring Resource Pools

Management Console allows database administrators to monitor and configure resource pools through the **Activity** and **Configuration** pages. These pages help you manage workloads by providing visual representations of resource usage as well as resource pool configuration options.

Monitoring Resource Pools Charts

You can monitor your resource pools using the **Resource Pools Monitoring** charts, accessible through the Management Console **Activity** page.
Select a resource pool to view using the **Resource Pool** menu, located in the leftmost sidebar. In the sidebar, **Current Usage Activity** displays the pool's real-time statistics.

Monitor the selected resource pool using the following charts, which display the pool's historic data:

- **Resource Usages for Pool**: Shows the historically averaged acquired memory usage by each pool across all nodes. The graph uses two y-axes, one that shows memory size, and a second that shows the total number of running queries. Data is collected every hour. Hover over a data point for a summary of the memory usage at that specific point.

- **Memory Usage in Node**: Shows the historically acquired memory usages by all pools across all nodes. Data is collected every hour. Hover over a data point for a summary of the memory usage at that specific point. Use the title bar dropdown to display the memory usage for a specific node. For Eon mode databases, you can also display the memory usage for a specific **subcluster**, all subclusters, or nodes not assigned to a subcluster. An Eon mode database has one default subcluster, and may have additional user-defined subclusters.

- **Average Query Execution and Query Time in Pool**: Shows the averaged query queue time plotted against the query execution time by each pool across all nodes. Data is collected every minute. Hover over data to get the average query execution and queue time in the specified pool. Click a data point to show detailed individual query information.
• **Resource Rejections in Pool**: Shows the historical total number of resource requests that were rejected in each pool across all nodes. Data is collected every hour. Click a data point to show rejection details and reasons in a pop-up window.

**Configuring Resource Pools in MC**

Database administrators can view information about resource pool parameters and make changes to existing parameters through the Management Console **Configuration** page. You can also create and remove new resource pools, assign resource pool users, and assign cascading pools.

See [Configuring Resource Pools in Management Console](#)

**Permissions**

Only the database administrator can monitor and configure resource pools in Management Console.

**See Also**

• [Configuring Resource Pools in Management Console](#)
• [Querying Resource Pool Data](#)

**Configuring Resource Pools in Management Console**

Database administrators can view information about resource pool parameters and make changes to existing parameters in MC through the Resource Pools Configuration page. You can also create and remove new resource pools, assign resource pool users, and assign cascading pools.

You can also access the Configuration page from the Resource Pools Monitoring chart, accessible through the Management Console Activity page. Click the tools icon on the top of the leftmost sidebar.
Permissions for Monitoring and Configuring Resource Pools

Only the database administrator can monitor and configure resource pools in Management Console.

Modify Resource Pool Parameters

2. Use the parameter fields to view and modify parameters for the resource pool. Hover your cursor in the parameter field to display information about that parameter.
3. Click Apply to save your changes. A success message appears.

Modify Resource Pool Users

To add or remove resource pool users:

3. The dialog displays users assigned to the resource pool in the Current Pool Users list. The Other Users list displays all other resource pool users are displayed, along with the pool to which they are currently assigned.
   1. To add users to the resource pool: Select the desired users from Other Users list and click Add.
   2. To remove users from the resource pool: Select the users to be removed from the Current Pool Users list and click Remove.
4. Click Apply to save your changes. A success message appears.

Create and Remove Resource Pools

Database administrators can use MC to create resource pools and assign resource pool users, and remove user-generated resource pools.

To create a resource pool:

2. Enter the new resource pool's parameters in the fields.
3. Click Create Pool. A success message appears.

To remove a resource pool:

1. First, remove all users from the resource pool to be deleted. This can be done on the Resource Pool Configuration Page.
2. When all users have been removed from the resource pool, choose the resource pool from the Resource Pools field on the Resource Pool Configuration Page. Parameter fields for that resource pool appear.
4. Click OK in the Confirm dialog. A success message appears.

Monitoring Database Messages in MC

As Management Console monitors your database, it periodically checks your system's health and performance. MC then generates messages to alert you about the state of your system. You can view and manage these messages in the Message Center.

Getting New Message Notifications

The Messages icon appears in the top-right of any database-specific page on MC (such as the Overview page or Activity page). The icon displays a new messages badge. The badge displays how many highest priority messages you have received recently.

The messages badge displays the color and letter of that priority:

- Red (H): High Priority
- Orange (N): Needs Attention
- Blue (I): Informational

In addition, the Thresholds Notification widget on the Overview page displays a summary of alerts about exceeded thresholds. Only high-priority threshold alerts appear in the Thresholds Notification widget. You can set the priority of alerts for different thresholds in the Thresholds tab on your database's Settings page.

Viewing Message Center

You can look at a preview of your most recent messages without navigating away from your current page. Click the Message Center icon in the top-right corner of Management Console to view the notification menu. The menu appears as a drop-down preview of your inbox. From this menu, you can delete, archive, or mark your messages as read.
You can access the Message Center in three ways:

- Click the **Message Center** button on the MC Home Page. The Message Center displays messages about the most recent database you have viewed.

Manage Information

- Click the **Messages** icon in the top-right of any database-specific page on MC. (For example, the icon appears on the Overview and Activity pages). A menu of your recent messages appears. Click **Message Center** in the top-right of the menu to reach
the Message Center for the database you most recently viewed.

- Click the Messages widget on the right side of the Overview page.

Filtering Recent Messages

By default, Message Center displays up to 600 of a database's most recent messages from the past week.

To see more messages:
1. Click **Retrieval of Old Messages** in the top-right of the page.
2. Use the drop-down **From** and **To** calendars to select a time range from which to retrieve older messages. You can specify days, hours, and minutes.
3. Click **Search** to display the messages from the specified time frame.

Depending on your database, you may have received hundreds of recent messages in the past seven days. To help you find the messages most relevant to you, Message Center provides several ways to filter recent messages:

- **By search term:** Use the search field at the top of the page to filter messages by any search term, such as description or date.
- **By database:** View a specific database’s messages by choosing it from the **Showing:** [database] drop-down list at the top of the page. Message Center’s default view lists up to 600 of the most recent messages for each database MC monitors.
- **By time period:** Message Center groups your recent messages by **Today,** **Yesterday,** and **This Week.** Click any of these headings to collapse that section of messages.
- **By message priority:** Messages are categorized as **High Priority,** **Needs Attention,** or **Informational.** The number of messages of each priority level appears at the top-right of the page. By default, all priority levels are displayed in the inbox. To filter messages of one priority level out of your current view, click a message count value at the top of the inbox to deselect it.
- **By threshold messages:** MC generates messages indicating when certain thresholds are exceeded in your database. To view only messages related to exceeded thresholds, click the **Thresholds** Messages tab on the left-hand side of the page. To modify these alert thresholds, go to the **Thresholds** tab, which appears in your database’s **Settings** page.

By default, Message Center displays up to 600 recent entries per database. You can adjust the maximum limit of messages the Message Center displays in the `/opt/vconsole/config/console.properties` file. To adjust the limit, change the number in the following line:

```
messageCenter.maxEntries=600
```

### Managing and Archiving Messages

Message Center archives all messages you mark as read. To mark messages as read or unread, select a message or multiple messages in the Message Center and click **Mark Read** or **Mark Unread.**

You can also perform the following tasks:
• See an archived message—Click Archived Messages on the right side of the Message Center. Then, use the From and To fields at the top of the page to select a date range from which to display archived messages.
• Sort archived messages by Type, Database Name, Description, or Date—Click any filter at the top of the Message Center.
• Delete messages permanently—if you prefer to delete messages, rather than archiving them, select the messages to delete. Then, click Delete Msgs.

Viewing Message Details

Within the Message Center, click the plus (+) symbol next to a message to get more information about the issue. You can also query the V_MONITOR.EVENT_CONFIGURATIONS table to get information about events. See the SQL Reference Manual for details.

Message Priority Levels

MC sorts messages by priority level and prioritizes them with color codes:

• High Priority (Red)
• Needs Attention (Orange)
• Informational (Blue)

At the top of your inbox, the Message Center displays the number of messages that fall within each level of priority.

Click any of the values to deselect them. This filters that type of message out of your current inbox view. For example, suppose you want to view the High Priority messages in your inbox. To remove lower-priority messages, you can click the message count values for the categories labeled Needs Attention and Informational. Doing so removes them from your current view.

Messages in the inbox are additionally labeled with one of seven subcategories, according to priority:

• High Priority: Emergency (0), Alert (1)
• Need Attention: Critical (2), Error (3)
• Informational: Warning (4), Info (5), Notice (6)
See Also

- Customizing Threshold-Based Notifications
- Exporting MC-managed Database Messages and Logs

Message Types

MC generates both default notifications and customizable threshold notifications.

Threshold Notifications

MC generates threshold-based notifications when the database exceeds the specified limits on the following thresholds.

- License Status
  - License Usage
- System Health
  - Node Health
    - Node CPU
    - Node Memory
    - Node Disk Usage
    - Node Disk I/O
    - Node CPU I/O Wait
    - Node Reboot Rate
    - Node Catalog Memory
    - Node State Change
- Network Health
  - Network I/O Error
- System Performance
  - Query
    - Queued Query Number
    - Failed Query Number
    - Spilled Query Number
    - Retried Query Number
    - Query Running Time
• Resource Pool
  • Queries Reaching the Max Allowed Execution Time
  • Queries With Resource Rejections
  • Ended Query With Queue Time Exceeding Limit
  • Ended Query With Run Time Exceeding Limit

MC provides default settings for these notifications. You can customize threshold notification settings in the Thresholds tab in the database Settings page. Threshold notifications appear in the Message Center. High-priority threshold alerts also appear on the Overview Page. See Customizing Threshold-Based Notifications for how to prioritize alerts.

## Default Notifications

By default, MC also generates messages about the database that appear only in the Message Center. You might receive messages about the following database-related conditions:

• Low disk space
• Read-only file system
• Loss of K-safety
• Current fault tolerance at critical level
• Too many ROS containers
• WOS overflow
• Change in node state
• Recovery error
• Recovery failure
• Recovery lock error
• Recovery projection retrieval error
• Refresh error
• Refresh lock error
• Workload Analyzer operations
• Tuple Mover error
• Timer service task error
• Last Good Epoch (LGE) lag
• License size compliance
• License term compliance
Customizing Threshold-Based Notifications

Management Console can generate notifications when your database exceeds threshold limits that you specify. You can configure threshold notifications per database in the Thresholds tab, which appears on your database's Settings page.

You can enable and modify message thresholds for each database that MC monitors. MC then generates a message indicating when a threshold is exceeded. For example, you can set the threshold for node disk usage to a 20% minimum and 80% maximum. As MC monitors node disk usage, it notifies you when any nodes exceed those minimum or maximum thresholds.

MC categorizes customizable message thresholds by license use, system health, and system performance. See Message Types for a list of the customizable thresholds available in MC.

Configuring Settings for Thresholds

Message thresholds have the following configurable settings:

- Enabling and disabling threshold-specific messages
- Threshold values
- Check time interval
- Alert Priority
- Email Destination
- Email Interval

Configure your notification settings, and click Apply to save your changes. If a message threshold has not been set previously, MC displays the default threshold for that setting.

Setting Priorities

You can set a notification to one of three priorities. If a threshold value is exceeded, MC:

- Priority 1 — Sends you an email notification, displays a message in the Overview page, and creates an message in the Message Center.
• Priority 2 — Displays a message in the Overview page, and creates an message in the Message Center.
• Priority 3 — Creates a message in the Message Center.

Setting Email Notifications

In order for MC to send email notifications, you must first provide MC with SMTP server settings. See Set Up Email.

When you set a threshold to Priority 1, MC can send email notifications to subscribed users.

To subscribe users to a threshold email message:

1. Set the threshold's Alert Priority field to Priority 1: Overview and Email. The Email Destination and Email Interval fields appear.
2. Click the browsing icon next to the Email Destination field. The Subscriber List dialog box opens.
3. You can add emails in one of two ways:
   • Select from the list of existing MC users with associated email addresses. (See Managing MC Users for how to add email addresses to user profiles.)
   • Provide an additional email address in the Entering New Email field. Click the plus (+) icon next to the field to add the address.
4. Click OK.
5. Select an option from the Email Interval field to choose how frequently users receive email notifications about the threshold if it is exceeded.
6. Click Apply at the top-right of the page to save your email subscriber settings.

• Message Types
• Set Up Email
• Managing MC Users
Set Up Email

Management Console can generate email alerts about high-priority database thresholds. To receive email alerts, you must first configure your SMTP settings in MC.

You must be an administrator to provide SMTP settings.

To set up MC to send email:

1. Select the Email Gateway tab on the MC Settings page.
2. Provide the following information about your SMTP server:
   - SMTP Server (Hostname). Maximum length is 255 characters. You can enter either the hostname or IP address.
   - SMTP server port.
   - Session Type (SSL or TLS).
   - SMTP Username.
   - SMTP Password.
   - Originating Email Alias. MC sends alerts from the email address you provide.
3. Click Test at the top of the page. MC validates your SMTP settings and sends a test email to the inbox of the email alias you provided.
4. Verify that you successfully received the test email.
5. Click Apply at the top-right of the page to save the settings.

With email settings completed, you can configure MC to send high-priority threshold alerts through email. See Customizing Threshold-Based Notifications.

Searching Database Messages Managed by MC

The Management Console Message Center displays the 10,000 most recent database messages, starting with the most recent record.

If more than 600 recent messages exist for a database, MC returns a message letting you know that only the most recent 600 entries are shown, so you have the option to filter.
**Changing Message Search Criteria**

You can use the search field at the top right of the Message Center to filter your messages by any search term, such as database name, description, or date.

Additionally, click on any filter at the top of the Message Center to sort message by Type, Database Name, Description, or Date. To further filter messages, you can select a database from the Database Name drop down list, type a keyword in the Description filter, or enter a range of dates in the Date filter.

**Retrieving Additional Messages**

If more than 10,000 messages exist, older messages that occurred before the 10,000 messages do not appear in the Message Center by default. You can click **Retrieve Additional Alerts** to filter for these older messages.

To specify which messages to retrieve, click **Retrieve Additional Alerts**. The Search for Messages dialog appears. Choose a date range, one or more message types, or one or more message types within a specific date range. Click **OK** to view the messages in that range.

![Search for messages dialog](image)

You can adjust the maximum limit of recent messages the Message Center displays in the `/opt/vconsole/config/console.properties` file. To adjust the limit, change the number in the following line:

```properties
messageCenter.maxEntries=5000
```
Specifying Date Range Searches

For date range searches, MC starts at the beginning of the time range and either returns all messages up to the specified end time or 10,000 messages, whichever comes first. You can filter message searches on the following date ranges:

- Any date-to-date period, including hour and minute
- Any time period up to now (forward searches)
- Any time period before now (backward searches)

After you specify a date range, click **Done** to close the calendar, and then click **OK** to see the results in the Message Center.

Exporting MC-managed Database Messages and Logs

You can export the contents of database messages, log details, query details, and MC user activity to a file.

Information comes directly from the MC interface. This means that if the last five minutes of `vertica.log` information displays on the interface, you can save that five minutes of data to a file, not the entire log. When you filter messages or logs, MC exports only the filtered results.
Depending on how you set your browser preferences, when you export messages you can view the output immediately or specify a location to save the file. System-generated file names include a timestamp for uniqueness.

The following table shows, by record type, the MC pages that contain content you can export, the name of the system-generated file, and what that file's output contains:

<table>
<thead>
<tr>
<th>Message type</th>
<th>Where you can export on MC</th>
<th>System-generated filename</th>
<th>Contents of exported file</th>
</tr>
</thead>
</table>
| All db-related message types | **Message Center page** | vertica-alerts-<timestamp>.csv | Exports messages in the Message Center to a .csv file. Message contents are saved under the following headings:  
  - Create time  
  - Severity  
  - Database  
  - Summary (of message)  
  - Description (more details) |
| MC log files | **Diagnostics page** | mconsole-<timestamp>.log | Exports MC log search results from MC to a .log file under the following headings:  
  - Time  
  - Type (message severity)  
  - Component (such as TM, Txn, Recover, and so on)  
  - Message |
<p>| Vertica logs | <strong>Manage page</strong> | vertica-vertica-&lt;db&gt;-&lt;timestamp&gt;.log | Exports vertica log search results from MC to a .log file |</p>
<table>
<thead>
<tr>
<th>Message type</th>
<th>Where you can export on MC</th>
<th>System-generated filename</th>
<th>Contents of exported file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agent logs</td>
<td><strong>Manage page</strong>&lt;br&gt;Click any node to get to the details and then click the VerticaLog tab.</td>
<td><strong>vertica-agent-&lt;db&gt;-&lt;timestamp&gt;.log</strong></td>
<td>Exports agent log search results from MC to a .log file under the following headings:&lt;br&gt;- Time&lt;br&gt;- Type (message severity)&lt;br&gt;- Component (such as TM, Txn, Recover, and so on)&lt;br&gt;- Message</td>
</tr>
<tr>
<td>Query details</td>
<td><strong>Activity page</strong>&lt;br&gt;Click any query spike in the Queries graph to get to the Detail page.</td>
<td><strong>vertica-querydetails-&lt;db&gt;-&lt;timestamp&gt;.dat</strong></td>
<td>Exports query details for the database between &lt;timestamp&gt; and &lt;timestamp&gt; as a tab-delimited .dat file. Content is saved under the following headings:&lt;br&gt;- Query type&lt;br&gt;- Session ID&lt;br&gt;- Node name</td>
</tr>
</tbody>
</table>
Monitoring MC User Activity Using Audit Log

When an MC user makes changes on the MC interface, whether to an MC-managed database or to the MC itself, their action generates a log entry that records a timestamp, the MC user name, the database and client host (if applicable), and the operation the user performed. You monitor user activity on the Diagnostics > Audit Log page.

MC records the following types of user operations:

- User log-on/log-off activities
- Database creation
- Database connection through the console interface
- Start/stop a database
- Remove a database from the console view
- Drop a database
- Database rebalance across the cluster
- License activity views on a database, as well as new license uploads
- Workload Analyzer views on a database
- Database password changes
Database settings changes (individual settings are tracked in the audit record)
Syncing the database with the cluster (who clicked Sync on grid view)
Query detail viewings of a database
Closing sessions
Node changes (add, start, stop, replace)
User management (add, edit, enable, disable, delete)
LDAP authentication (enable/disable)
Management Console setting changes (individual settings are tracked in the audit record)
SSL certificate uploads
Message deletion and number deleted
Console restart from the browser interface
Factory reset from the browser interface
Upgrade MC from the browser interface

Background Cleanup of Audit Records

An internal MC job starts every day and, if required, clears audit records that exceed a specified timeframe and size. The default is 90 days and 2K in log size. MC clears whichever limit is first reached.

You can adjust the time and size limits by editing the following lines in the /opt/vconsole/config/console.properties file:

```properties
vertica.audit.maxDays=90
vertica.audit.maxRecords=2000
```

Filter and Export Results

You can manipulate the output of the audit log by sorting column headings, scrolling through the log, refining your search to a specific date/time and you can export audit contents to a file.

If you want to export the log, see Exporting the User Audit Log.
If You Perform a Factory Reset

If you perform a factory reset on MC's Diagnostics page (restore it to its pre-configured state), MC prompts you to export audit records before the reset occurs.

Monitoring External Data Sources in Management Console

By default, Management Console monitors a database using information from that database's Data Collector (DC) tables. MC can also monitor DC tables you have copied into Vertica tables, locally or remotely.

MC administrators provide mappings to local schemas or to an external database containing the corresponding DC data. MC can then render its charts and graphs from the new repository instead of from local DC tables. This offers the benefit of loading larger sets of data faster in MC, and retaining historical data long term.

Note: MC also offers External Monitoring, which allows you to set up a Vertica storage database through the MC interface, then use Kafka to stream your data to the storage database. You can use the Data Source mapping process below if you prefer to set up your own alternative data source, or do not plan to use Kafka streaming.

Map an Alternative Data Source

1. On the MC Settings page, navigate to the Data Source tab.
2. Select the database for which you are creating the data source mapping.
3. Choose the database user for which you want to create the mapping.
4. Set Repository Location to Local or Remote.
5. If Remote is selected, provide JDBC connection parameters for the remote database repository. Click Validate Connection Properties to confirm a successful connection.
6. Enter the schema mappings for v_internal and v_catalog. MC does not support mapping the v_monitor schema.
7. Input your table mappings in one of the following ways:
   - Click **Auto Discover**. MC retrieves the table mappings based on the database and schema mappings you provided.
   - Click **Manual Entry**. Manually input table mappings.
   - Click **Load Configurations**. If you previously saved a data source configuration for the database in a file, import the file to use that configuration for the currently selected user.

8. Optionally, click **Save Configurations** to export this configuration file. You can create a mapping for another database user with this configuration file later.

9. Click **Apply** to save and apply your configuration settings.

### Reports Using Unmapped Schemas

If a report in MC needs to access a locally stored schema or table that is unmapped, MC includes information from the local DC tables for that schema to complete the report.

For remote configurations, if a report depends on an unmapped schema or table, the entire report is run against the local DC tables. If the remote database is down when MC attempts to run a report against it, MC reruns the report against the local database.

When the MC runs a report, it records missing mappings in the MC log under the INFO severity level.

### Monitoring Depot Activity in MC

If your database is in Eon Mode, you can use the Depot Activity page to monitor query activity, churn, and settings for your database's depot. The depot (see [Eon Mode Architecture](#)) is a cache-like component on each node that improves query performance by preventing your queries from having to go to communal storage every time. Instead the queries access the depot, which contains local copies of your data.

To view the Depot Activity page, select the **Activity** tab at the bottom of your database's Overview page, then select **Depot Activity Monitoring** from the chart list. The **Depot Activity** page has two tabs:

- **At a Glance**: The default, described below
- **Depot Content**: Described in [Monitoring Depot Content in MC](#)

The Depot Activity Monitoring page is not available when the database is in Enterprise Mode. See [Using Eon Mode](#) for more about Vertica database modes.
At a Glance Tab

The At a Glance tab has three sections:

- Current Depot Usage and Depot Configuration (left pane)
- User Queries Depot Hits and Misses, Fetches and Evictions (upper-right pane)
- Communal Storage Access Calls (lower-right pane)

Current Depot Usage and Depot Configuration

Current Depot Usage on the left side of the page, displays the following statistics:

- **Overall**
  - **Depot Capacity**: Total depot capacity for all nodes in the database, added together.
  - **Depot in Use**: Total depot space currently in use, on all nodes in the database added together.
  - **Database Size**: Select Calculate to show the total size of the database, in GB.
  - **View More on Database Storage**: Click to see the Storage View tab, with details on the storage for this database.

- **Usage by Node**
  - Lists the number of bytes in the depot and percentage used, for each node in the database.
  - **View More**: Click to display depot usage for individual nodes.
• **Depot Configuration**

  • **Participating Nodes**: Number of nodes covered by these statistics.
  • **Max Depot Limit**: Total amount of depot space on all the participating nodes.
  • **Depot for Writes**: Whether the depot is Enabled or Disabled for write operations.
  • **Depot for Reads**: Whether the depot is Enabled or Disabled for read operations.
  • **Depot Operations for Query**: Displays the current value of the Eon Mode system parameter DepotOperationsForQuery. This parameter specifies whether the depot fetches a file required by query from communal storage because it is not in the depot. This parameter also determines whether the depot evicts other files to make space for the fetched file. Possible values are:
    • **ALL** (default): When a query reads files that are not in the depot, the depot fetches the files from communal storage, and, if necessary, evicts other files.
    • **FETCHES**: When a query reads files that are not in the depot, the depot fetches those files only if space is available without evicting other files.
    • **NONE**: When a query reads files that are not in the depot, the depot does not fetch the files.

• **View documentation on Depot configuration**: Displays documentation on Eon Mode parameters for depot configuration.
• Retention limits for monitoring depot activity.
• Click the following DC tables link to see the retention policies. The retention policies determine how long Vertica retains the monitoring information that the depot activity charts display. Consider increasing retention limits, such as that of Depot Reads, to display a longer history of activity.

**Monitor Queries Involving Depot Versus Communal Storage**

The User Queries Depot Hits and Misses chart shows how your queries are interacting with the depot over time:

**Query Depot Hits and Misses**

  • The color-coded graph lines show how many queries were accessing the depot or communal storage, or both, at any given time.
  • The left y-axis indicates the number of queries.
For optimal performance, the majority of queries should access your depot, which is local. To maximize depot access, size your depot so it fits your frequently accessed data.

When the depot size is more limited, queries access communal storage more often to retrieve all the necessary data. A more limited depot size may be necessary due to storage costs, but accessing communal storage can impact query performance.

**Depot Fetches and Evictions**

- The colored bars on the **User Queries Depot Hits and Misses** chart show the moments when your queries are causing data to be fetched to or evicted from the depot, as measured in megabytes.
- The right y-axis shows how much data was fetched or evicted.

Whenever a query fetches new data from communal storage because it is not in the depot, if the depot is full, Vertica makes space for the new data by evicting older data.

Use the fetches and evictions bars to monitor churn (how many files are getting pushed out of the depot), and how up-to-date your depot's data is. Churn occurs when, with a limited depot size, the depot must begin to fetch and evict data more frequently. If you observe that queries are consistently slower due to accessing communal storage, and notice the depot keeps experiences frequent churn, you might benefit from increasing your depot's size limit.

**For Details**

- Hover over a point on the query line to see details about the number of queries that ran.
- Hover over a Fetches or Evictions bar graph to see details about the number of bytes fetched or evicted.
- Click the line or bar to view the Query Details page, which provides information about every query that ran in the selected timespan.

**Monitor Communal Storage Access Calls**

The **Communal Storage Access Calls** chart in the lower pane of the At a Glance tab shows how many of each type of API call executed in each timespan of the chart.
Reasons to Monitor Your Depot in MC

If you are running an Eon Mode database on a cloud platform, for example AWS, monitoring your depot in MC may provide information that can help you to tune your database to:

- Improve query performance
- Reduce your cloud platform bill

The features MC provides for monitoring depot activity give you information that can help you with both kinds of tuning.

To access the depot monitoring capabilities, from the MC home page, navigate to Database > Activity > Depot Activity Monitoring. See Monitoring Depot Activity in MC.

How Often Do Your Queries Hit the Depot vs. the S3 Bucket?

The more often your queries access the data in the depot on the node, rather than in communal storage, the faster they will run.

See Monitoring Depot Activity in MC.

Is the Depot the Optimal Size?

To optimize your queries for speed, you may want to make your depot big enough to fit your query workload. This ensures that queries do not need to spend extra time fetching data from the communal repository on S3.

You can use ALTER_LOCATION_SIZE to change a node's depot size. For example, if you had two nodes, two commands like these would change the depot size to 80MB:

```
SELECT ALTER_LOCATION_SIZE('/vertica/data/VerticaDB/v_verticadb_node0001_depot', 'v_verticadb_node0001', '80M')
SELECT ALTER_LOCATION_SIZE('/vertica/data/VerticaDB/v_verticadb_node0002_depot', 'v_verticadb_node0002', '80M')
```
For an overview on sizing your Eon Mode database, see Sizing your Vertica Cluster for Eon Mode.

How Many API Calls Are Your Queries Executing on the S3 Bucket?

On the Depot Activity Monitoring screen, in the Communal Storage Access Calls chart, MC displays how many of each type of API call your queries executed in each timespan. To see details on which queries were running, click on any point on the chart.

What Is the Current Depot Usage on Each Node?

The Depot Content tab of the Depot Activity Monitoring page provides detailed information about how each table is using the depot space on the cluster nodes.
Are Your Projections and Partitions Tuned for Best Query Performance?

On the Depot Content tab, when you select a row, you are selecting the table depot content on a node. MC loads the details for that table for that node in the bottom section of the page, to show depot content for the selected table, broken down by either projections or partitions on a given node.

Query Hits and Misses in the Depot: Details

When you hover over any point on the User Queries Depot Hits and Misses chart, MC displays a capsule summary of the data represented by that point. Below are two examples. The first shows a depot size sufficient to run all queries in the depot. The second shows what happens when the depot is too small for ongoing query activity, so a number of queries are forced to fetch their data from communal storage.
If you click on any point on the line, MC opens a Query Detail window that shows:

- All the queries represented by that point
- Details for each query

**See Also**

Monitoring Depot Activity in MC

**Communal Storage Access Calls: Details**

The lower pane on the **MC Depot Monitoring > At a Glance** tab displays how many communal storage access calls (for example, AWS S3 API calls) of each type your database has executed in the timespan shown on the X axis.
• Data Reads (GET)
• Data Writes (PUT)
• Metadata Reads (LIST)
• Metadata Writes (POST, DELETE, COPY)

When you hover over any point on the Communal Storage Access Calls chart, MC displays a capsule summary of the data that the point represents. If your cluster is on AWS, for example, the summary lists how many of each AWS S3 API call type were executed in the selected timespan.

If you click on any point on the bar graph, MC opens a Detail window that shows:

• All the queries that ran during the selected timespan. These queries executed the API calls listed for that timespan on the Communal Storage Access Calls chart.
• Details for each query, as the example shows below.

Amazon S3 Pricing

Monitoring Depot Content in MC

You can monitor in detail how the nodes in your Eon database are using the depot:
Display a list of tables with the largest amount of data in the depot.
Use the filter fields to list the tables most frequently or most recently accessed in the depot.
Display details about how frequently the projections and partitions for a specific table access the depot, and the last time the depot was accessed.

The Depot Activity Monitoring > Depot Content tab opens showing a default list of the top 25 tables in the database, as ranked by each table's total bytes in the depot. The list shows all the nodes for each of those top tables. The nodes are sorted solely based on most bytes in depot, so the nodes for a given table do not necessarily appear together.

**Filter the List**

You can use the filter fields above the table to focus the list more narrowly. The filters let you select:

- The number of top tables
- Whether the tables are selected by most bytes in depot, the highest number of times their depot was accessed, or the most recent last access time
- Tables in all schemas, or only in a specific schema
- All tables, or only a specific table
- All nodes, or only a specific node

In the Schema, Table, and Node filter fields, you can enter a text string to select all items whose names include that text string.

**Select a Node to See the Breakdown of Depot Data in Projections and Partitions**

Select a row in the top table. MC then loads the details to show how that table's depot content is distributed across the projections and the partitions for that table, that are on that node. The Projection and Partition panes show these details for the selected node:

- **Projection:** Number of bytes of data for the selected table that each projection has in the depot on the selected node.
- **Partition:** If the table is partitioned, this pane shows the number of bytes of data for the selected table that each partition has in the depot on the selected node.

For each projection and each partition, MC also displays the total number of times, that the projection or partition has accessed the depot on that node, and the last access time.
For more information about projections, see Working with Projections.

For more information about partitions, see Partitioning Tables.

**Steps to Monitor Depot Content**

1. From the MC home page, open a database, select the Activity tab from the bottom menu, select Depot Activity Monitoring in the top selection box, and select the Depot Content tab. MC displays the top N tables (25 by default), ranked by the number of bytes of data each table has in the depot on all its nodes.

2. To narrow the list, use the filters at the top of the tab. You can show only the nodes in a certain schema and/or database, or display all the activity on a specific subgroup of nodes. Change the filters, then click Apply.
3. To select all items whose names contain a certain text string, enter that text string in a filter field. This example selects the nodes for the tables whose names contain the string "fact".

4. To display details on the projections and partitions for a specific table that are accessing the depot, select a row in the top pane of the **Depot Content** tab.

**See Also**

Monitoring Depot Activity in MC
Monitoring Depot Storage in MC

To display detailed storage monitoring information for your Eon database:

1. From the MC home page, select View Your Infrastructure.
2. On the Infrastructure page, select the Storage View tab. MC displays the Storage View screen, with details about the database storage and links to further detail screens:

3. To see the loaded size of the database, click Load Size.
4. To see communal storage details for the database, such as its location and size, and the IP addresses of the nodes, click Communal/Depot Storage.

5. To view the shard subscriptions for your Eon nodes, click Communal Storage Subscription. MC displays the shard type, how many nodes are subscribed to each shard, and the status of each shard subscription (Active, Inactive, Passive, Pending, Removing).
There are two views:

- **Sharding Subscription** displays how many nodes store each shard.
- **Node Subscription** displays how many shards are on each node.

Hover over a bar to display the details.

6. To display the depot details for all nodes in the database, click **View Depot Details by Nodes**. MC lists the nodes by node name, and for each node shows the number of bytes the node has in its depot, the total capacity of the depot, the percent used, and the path to the node's depot.

```
<table>
<thead>
<tr>
<th>Node Name</th>
<th>In Use</th>
<th>Depot Capacity</th>
<th>% Used</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_verticadb_node0001</td>
<td>82.98 MB</td>
<td>83.89 MB</td>
<td>98.9%</td>
<td>/vertica/data/VerticaDB/v_verticadb_node0001_depor</td>
</tr>
<tr>
<td>v_verticadb_node0002</td>
<td>81.28 MB</td>
<td>83.99 MB</td>
<td>96.9%</td>
<td>/vertica/data/VerticaDB/v_verticadb_node0002_depor</td>
</tr>
</tbody>
</table>
```

*Monitoring Depot Activity in MC*
Loading Data From Amazon S3 Using MC

You can use the Data Load Activity page in Management Console to import data from Amazon S3 storage to an existing table in Vertica.

When you use Amazon Web Services (AWS), MC uses the Vertica library for AWS to import data directly from Amazon S3 storage to Vertica. You do not need to use any third-party scripts or programs. When you run a loading job, Vertica appends rows to the target table you provide. If the job fails, or you cancel the job, Vertica commits no rows to the target table.

When you view your load history on the Instance tab, loading jobs initiated in MC using Amazon S3 have the name MC_S3_Load in the Stream Name column.

For more information about loading data from Amazon S3 storage to Vertica, see Export Data From Amazon S3 Using the AWS Library.

Prerequisites

To use the MC Load feature, you must have:

- Access to an Amazon S3 storage account.
- An existing table in your Vertica database to which you can copy your data. You must be the owner of the table.
- (For non-CloudFormation Template installs) An S3 gateway endpoint.

If you aren't using a CloudFormation Template (CFT) to install Vertica, you must create an S3 gateway endpoint in your VPC. For more information, see the AWS documentation.

For example, the Vertica CFT has the following VPC endpoint:

```json
"S3Enpoint" : {
    "Type" : "AWS::EC2::VPCEndpoint",
    "Properties" : {
        "PolicyDocument" : {
            "Version":"2012-10-17",
            "Statement":[
                {"Effect":"Allow",
                "Principal": "*",
                "Action": ["*"]},
            "Resource": ["*"],
            ]
    }
},
```
Create a Loading Job

To load data from an Amazon S3 bucket to an existing table in your target database:

1. On your target database's Management Console (MC) dashboard, click the Load tab at the bottom of the page to view the Data Load Activity page.
2. Click the Instance tab.
3. Click New S3 Data Load at the top-right of the tab. The Create New Amazon S3 Loading Job dialog box opens.
4. Enter your AWS account credentials and your target location information in the required fields, which are indicated by asterisks (*). Use the format S3:// for the bucket name.
5. (Optional) Specify additional options by completing the following fields:
   - Direct
   - COPY Parameters
   - Capture rejected data in a table
   - Reject max
   For more about using these fields, see About Configuring a Data Load from S3.

Cancel an Initiated Loading Job

If a loading job is in progress, you can cancel it using the Cancel option in the Load History tab's Cancel column. Click Cancel to cancel the loading job. When you cancel a job, Vertica rolls back all rows and does not commit any data to the target table.

- Integrating with Apache Kafka
- Export Data From Amazon S3 Using the AWS Library
- COPY
- COPY Parameters

About Configuring a Data Load from S3

When you create a new S3 Data Load using MC, you have the option of further configuring the job. You can optionally specify the following:

Load Data into ROS or WOS

You can use the Direct field to specify whether to load the data directly into ROS (Read Optimized Store) containers. This is the default setting, and best for large loads of 100MB or more. For smaller loads, deselect this option to load the data into WOS (Write Optimized Store).

Note:
For databases created in Vertica Enterprise 9.3 and later, Vertica ignores load options and hints, and defaults to a load method of DIRECT (loading directly to ROS). You can configure this behavior using the DMLTargetDirect configuration parameter.

Add COPY Parameters

MC performs the loading job using a COPY statement. You can use the COPY Parameters field to further configure the COPY statement, or leave it blank. Only parameters used after the SOURCE parameter in a COPY statement are valid in this field.

Note that if you use the FILTER and PARSER parameters, they must appear in that order and precede any other parameters you use in the COPY Parameters field.

Specify EXCEPTIONS only if you set the Capture rejected data in a table field to No (see below).
In the following example, you could use the DELIMITER and SKIP parameters in the COPY parameters field to separate columns with a comma and skip 1 record of input data.

```
DELIMITER ',' SKIP 1
```

To add comments in the COPY statement using this field, begin your comment with a forward slash followed by an asterisk (/*) and end it with an asterisk followed by a forward slash (*/). Using a double hyphen (--) does not work in this field.

If COPY rejects the maximum number of rows, Vertica rolls back the target table rows without committing any data.

**Capture Rejected Data in a Table**

Use the **Capture rejected data in a table** field to create a rejected data table. A rejected data table allows you to view details about rejections through MC. If you set this field to Yes, you will be able to view rejected row data in the Load History tab.

You must have CREATE privilege on the schema if the table doesn't already exist. When you invoke multiple load processes for the same target table, MC appends all rejections data to the same table. MC generates a table using the following naming convention: `schema.s3_load_rejections_target-table-name`.

For more information about capturing rejected data, see [Saving Rejected Data To a Table](#).

**Set a Rejected Records Maximum**

Use the Reject Max field to specify the maximum number of records that can be rejected before the load fails. If COPY rejects the maximum number of rows, Vertica rolls back the target table rows without committing any data.

**Configuration Options**

To further configure the loading job, you can use the following optional fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direct</td>
<td>Use the Direct option to indicate whether to load the data into WOS or ROS.</td>
</tr>
</tbody>
</table>

- **Selected (Default):** The data loads directly into ROS (Read)
<table>
<thead>
<tr>
<th>Field</th>
<th>Details</th>
</tr>
</thead>
</table>
|                               | **Optimized Store)** containers. Use this for large bulk loads (100MB or more).  

- **Deselected:** Data loads into **WOS (Write Optimized Store)**. Use this for smaller bulk loads.                                                                                                                                                                                                                                                                                                                                                     |
| **COPY Parameters**           | Use the COPY Parameters field to further configure the COPY statement that will load your data.  

Valid values:  

- FILTER  
- PARSER  
- DELIMITER  
- TRAILING NULLCOLS  
- NULL  
- ESCAPE (NO ESCAPE)  
- ENCLOSED  
- RECORD TERMINATOR  
- SKIP, SKIP BYTES  
- TRIM 'byte'  
- EXCEPTIONS 'path'  
- ENFORCELENGTH  
- ABORT ON ERROR  
- STORAGE  

For more information about COPY syntax, see **COPY** and **COPY Parameters**.                                                                                                                                                                                                                                                                                                                                                      |
| **Capture rejected data in a table** | Use this field to create a rejected data table.  

- **Yes:** MC generates a rejected data table.  

- **No:** MC does not save rejected rows to a table.  

For more information, see **Saving Rejected Data To a Table**.                                                                                                                                                                                                                                                                                                                                                     |
| **Reject max**                | Use this field to specify the maximum number of records that can be rejected before the load fails.

- **Export Data From Amazon S3 Using the AWS Library**  
- **COPY**  
- **COPY Parameters**
Viewing Load History

You can view a history of all your continuous and instance loading jobs in Vertica on the Data Load Activity page.

- **Continuous jobs**: Loading jobs that continuously monitor a source and stream data from the source.
- **Instance jobs**: Loading jobs that batch load from a source. Instance jobs are of a fixed length and shorter-term than continuous loads.

View Continuous Loads

The Continuous tab on the Data Load Activity page displays history of your database’s continuous loading jobs. For example, you can see loading jobs you create using the Vertica integration with Kafka (see Integrating with Apache Kafka). Additionally, if you enable the MC extended monitoring feature, the Continuous tab displays the continuous jobs that stream data from your monitored database to a storage database. (See Extended Monitoring for more on how MC can use Kafka to monitor databases externally.)

Use the Continuous tab to view details about continuous jobs, such as their source, target tables, and other microbatch configuration details.

If extended monitoring is enabled, jobs streaming to the MC storage database show mc_dc_kafka_config as the scheduler name. Deselect Show MC data collector monitoring streams at the top of the tab to remove these jobs from the display.

In the Continuous tab, click the labels in the Scheduler, Microbatch, and Errors Last Hour to view additional details about those loading jobs.
For more on continuous data streaming terminology, see Data Streaming Integration Terms.

**View Load Instances**

In the Instance tab, you can see a history of your database's one-time loading jobs. For example, you can view instance jobs you created using the COPY command in vsql (see COPY), or instance jobs you created in MC to copy data from an Amazon S3 bucket. (For more about initiating loading jobs in MC, see Loading Data From Amazon S3 Using MC.)

In the Instance tab, click the labels in the Status column and Rejected Rows column to view more details about completed jobs. For more about rejected rows, see Capturing Load Rejections and Exceptions.

The number of load history results on the Instance tab depends on the Data Collector retention policy for Requests Issued and Requests Completed. To change the retention policy, see Configuring Data Retention Policies.

Viewing Profile Data in MC

Management Console allows you to view profile data about a single query. You can:

- Review the profile data in multiple views
- View details about projection metadata, execution events, and optimizer events
- Identify how much time was spent in each phase of query execution and which phases took the most amount of time

After you select the database you want to use, you can view the profile data using Management Console in either of two ways:

- Focus on specific areas of database activity, such as spikes in CPU usage
- Review the profile data for a specific query

To focus on specific areas of database activity:

1. At the bottom of the Management Console window, click the Activity tab.
2. From the list at the top of the page, select Queries.
3. On the activity graph, click the data point that corresponds to the query you want to view.
4. In the View Plan column, click Profile next to the command for which you want to view the query plan. Only certain queries, like SELECT, INSERT, UPDATE, and DELETE, have profile data.
5. In The Explain Plan window, Vertica profiles the query.
6. You can view the output in Path Information view, Query Plan Drilldown view, Tree Path view, or Profile Analysis view. To do so, click the respective buttons on the left of the output box.

**To review the profile data for a specific query:**

1. In the **Explain** window, type or paste the query text into the text box. Additionally, you can monitor queries that are currently running. To do so, perform one of the following. In the **Find a Query By ID** input window:
   - Enter the query statement and transaction ID
   - Click the **Browse Running Queries** link

   **Caution:**
   If you enter more than one query, Management Console profiles only the first query.

2. To receive periodic updates about the query's progress and resources used, select the **Enable Monitoring** check box. As a best practice, avoid specifying an interval time of less than 60 seconds because doing so may slow your query's progress.

3. Click the **Profile** button.

   While Vertica is profiling the query, a **Cancel Query** button is enabled briefly, allowing you to cancel the query and profiling task. If the **Cancel Query** button is disabled, that means Management Console does not have the proper information to cancel the query or the query is no longer running in the database.

   When processing completes, the profile data and metrics display below the text box. You can view the output in Path Information view, Query Plan Drilldown view, Tree Path view, or Profile Analysis view. To do so, click the respective view buttons on the left of the output box.

**Viewing Different Profile Outputs**

Vertica Management Console allows you to examine the results of your query profile in multiple views. You can view your profile in the following formats:
- Path Information view
- Query Drilldown view
- Tree Path view
- Profile Analysis view

You can change the query profile output using the icons on the bottom portion of the Explain page.

The **Path Information** view displays the query plan path along with metric data. If you enable profile monitoring, the data will update at the specified interval. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata if it is available.

The **Query Plan Drilldown** view shows detailed counter information at the node and operator level.
For each path, the path number is listed along with statistical information on the node and operator level. This view allows you to see which nodes are acting as outliers. Click on any of the bars to expand details for that node.

The Tree Path details the query plan in the form of a tree. If you enable monitoring, the state of the path blocks will change depending on whether the path is running, done, or has not started. Metric information is displayed in each path block for the counters you specified in the Profile Settings.

The Profile Analysis view allows you to identify any resource outliers. You can compare the estimated rows produced count with the actual rows produced count, view execution time per path, and identify memory usage per path.
When you profile a query, you will also see a pie chart detailing the query phase duration. You can also view projection metadata, execution events, and optimizer events by clicking on the respective buttons next to the pie chart.

### Monitoring Profiling Progress

While loading profile data for a query, Management Console can provide updates about the query's progress and resources used.

To enable profiling progress updates, select the Enable Monitoring check box when profiling a query. See [Viewing Profile Data in Management Console](#).

The default interval time is 60 seconds. At the specified interval, Management Console displays an updated view of the query's progress. Note that interval times of less than 60 seconds may slow down your query.
**Viewing Updated Profile Metrics**

At every interval, Management Console displays a new set of profile metrics. You can view these metrics in Path Information view, Query Plan Drilldown view, or Tree view by clicking the respective view buttons on the left of the output box.

- A dark blue bar indicates the current metric percentage.
- When a metric bar has decreased, a dark blue line indicates the previous metric percentage.
- When a metric bar has increased, a light blue bar indicates the added percentage. The previous percentage appears as a dark blue bar.
- A metric bar highlighted in yellow indicates it has changed since the last interval.
- A metric bar highlighted in red indicates the absolute value of the metric has decreased. This typically means Vertica reported the previous value incorrectly, and has readjusted. (For example, if Vertica previously reported path's Time value as 75 seconds, then reports it as 50 seconds at the next interval, the metric bar turns red to indicate the decrease in absolute Time value.)

**Expanding and Collapsing Query Path Profile Data**

When you have a query on the EXPLAIN window, the profile data displays in the right-hand side of the lower half of the window. The query path information can be lengthy, so you can collapse path information that is uninteresting, or expand paths that you want to focus on.

- To collapse all the query paths, click **Collapse All**.
- To expand all the query paths, click **Expand All**.
To expand an individual query path so you can see details about that step in processing the query, click the first line of the path information. Click the first line again to collapse the path data.

For information about what the profile data means, see About Profile Data in Management Console.

About Profile Data in Management Console

After you profile a specific query, the Management Console Explain page displays profile data like query duration, projection metadata, execution events, optimizer events, and metrics in a pie chart.

See the following links for more information on the kinds of profile data you can review on the Management Console Explain page:

- Projection Metadata
- Query Phase Duration
- Profile Metrics
- Execution Events
- Optimizer Events

Projection Metadata

To view projection metadata for a specific projection, click the projection name in the EXPLAIN output. Metadata for that projection opens in a pop-up window.

To view projection data for all projections accessed by that query, click the View Projection Metadata button at the top of the Explain page. The metadata for all projections opens in a new browser window.

Note:
If the View Projection Metadata button is not enabled, click Profile to retrieve the profile data, including the projection metadata.

The projection metadata includes the following information:

- Projection ID
- Schema name
- Whether or not it is a superprojection
- Sort columns
- IDs of the nodes the projection is stored on
- Whether or not it is segmented
- Whether or not it is up to date
- Whether or not it has statistics
- Owner name
- Anchor table name

To display a SQL script that can recreate the projection on a different cluster, click **Click to get export data**. This script is identical to the output of the `EXPORT_OBJECTS` function. The SQL script opens in a pop-up window.

Copy and paste the command from this window, and click **Close**.

**Query Phase Duration**

This pie chart appears in the upper-right corner of the Query Plan window. It shows what percentage of total query processing was spent in each phase of processing the query.

The phases included in the pie chart (when applicable) are:

- Plan
- InitPlan
- SerializePlan
- PopulateVirtualProjection
- PreparePlan
- CompilePlan
- ExecutePlan
- AbandonPlan

Hover over the slices on the pie chart or over the names of the phases in the box to get additional information. You can see the approximate number of milliseconds (ms) and percentage used during each phase.

**Note:**
The time data in the profile metrics might not match the times in the query phase duration. These times can differ because the query phase duration graph uses the longest execution time for a given phase from all the nodes. Network latency can add more data, which is not taken into account in these calculations.
Profile Metrics

In the Path Information view, the area to the right of each query path contains profile metrics for that path.

- **Disk**—Bytes of data accessed from disk by each query path. If none of the query paths accessed the disk data, all the values are 0.
- **Memory**—Bytes of data accessed from memory by each query path.
- **Sent**—Bytes of data sent across the cluster by each query path.
- **Received**—Bytes of data received across the cluster by each query path.
- **Time**—Number of milliseconds (ms) that the query path took to process on a given node, shown on progress bars. The sum of this data does not match the total time required to execute the query. This mismatch occurs because many tasks are executed in parallel on different nodes.

Hover over the progress bars to get more information, such as total bytes and percentages.

**Note:**
The time data in the profile metrics might not match the times in the Query Phase Duration chart. These times can differ because the query phase duration graph uses the longest execution time for a given phase from all the nodes. Network latency can add more data, which is not taken into account in these calculations.

Execution Events

To help you monitor your database system, Vertica logs significant events that affect database performance and functionality. Click View Execution Events to see information about the events that took place while the query was executing.

If the View Execution Events button is not enabled, click Profile to retrieve the profile data, including the execution events.

The arrows on the header of each column allow you to sort the table in ascending or descending order of that column.

The execution events are described in the following table.
<table>
<thead>
<tr>
<th>Event Characteristic</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>Clock time when the event took place.</td>
</tr>
<tr>
<td>Node Name</td>
<td>Name of the node for which information is listed.</td>
</tr>
<tr>
<td>Session ID</td>
<td>Identifier of the session for which profile information is captured.</td>
</tr>
<tr>
<td>User ID</td>
<td>Identifier of the user who initiated the query.</td>
</tr>
<tr>
<td>Request ID</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>Event Type</td>
<td>Type of event processed by the execution engine. For a list of events and their descriptions, see Initial Process for Improving Query Performance.</td>
</tr>
<tr>
<td>Event Description</td>
<td>Generic description of the event.</td>
</tr>
<tr>
<td>Operator Name</td>
<td>Name of the Execution Engine component that generated the event. Examples include but are not limited to:</td>
</tr>
</tbody>
</table>
|                      | - DataSource  
|                      | - DataTarget  
|                      | - NetworkSend  
|                      | - NetworkRecv  
|                      | - StorageUnion  
|                      | Values from the Operator name and Path ID columns let you tie a query event back to a particular operator in the query plan. If the event did not come from a specific operator, then this column is NULL. |
| Path ID              | Unique identifier that Vertica assigns to a query operation or a path in a query plan. If the event did not come from a specific operator, this column is NULL. |
| Event OID            | A unique ID that identifies the specific event. |
| Event Details        | A brief description of the event and details pertinent to the specific situation. |
| Suggested Action     | Recommended actions (if any) to improve query processing. |
Optimizer Events

To help you monitor your database system, Vertica logs significant events that affect database performance and functionality. Click View Optimizer Events to see a table of the events that took place while the optimizer was planning the query.

If the View Optimizer Events button is not enabled, click Profile to retrieve the profile data, including the optimizer events.

The arrows on the header of each column allow you to sort the table in ascending or descending order of that column.

The following types of optimizer events may appear in the table:

<table>
<thead>
<tr>
<th>Event characteristic</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>Clock time when the event took place.</td>
</tr>
<tr>
<td>Node Name</td>
<td>Name of the node for which information is listed.</td>
</tr>
<tr>
<td>Session ID</td>
<td>Identifier of the session for which profile information is captured.</td>
</tr>
<tr>
<td>User ID</td>
<td>Identifier of the user who initiated the query.</td>
</tr>
<tr>
<td>Request ID</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>Event Type</td>
<td>Type of event processed by the optimizer.</td>
</tr>
<tr>
<td>Event Description</td>
<td>Generic description of the event.</td>
</tr>
<tr>
<td>Event OID</td>
<td>A unique ID that identifies the specific event.</td>
</tr>
<tr>
<td>Event Details</td>
<td>A brief description of the event and details pertinent to the specific situation.</td>
</tr>
<tr>
<td>Suggested Action</td>
<td>Recommended actions (if any) to improve query processing.</td>
</tr>
</tbody>
</table>
Clearing Query Data

After you finish reviewing the current query data, click Clear All to clear the query text and data. Alternatively, to display information about another query, enter the query text and click Explain or Profile.

Extended Monitoring

Enabling extended monitoring allows you to monitor a longer range of data through MC. This can offer insight into long-term trends in your database's health. MC can also continue to display your monitored database's dashboard while it is down.

Extended monitoring uses Kafka to stream monitoring data from your monitored databases to a single MC storage database. MC can query the storage database instead of your monitored database to render some of its charts, reducing impact on your monitored database's performance.

How Extended Monitoring Works

By default, MC monitors your database by querying it directly for monitoring data about system activities, performance, and resource utilization. Typically, the Data Collector stores all monitoring data in data collector (DC) tables. However, DC tables have limited retention periods. See Retaining Monitoring Information.

Extended monitoring stores your database's monitoring data in a dedicated storage database. Vertica streams data from your database's DC tables through Kafka servers to the storage database. To use extended monitoring, you must have access to a running Kafka server. For more how Vertica integrates with Kafka, see Integrating with Apache Kafka.

After you set up and enable extended monitoring for a monitored database, MC renders several of your database's charts and graphs by querying the MC storage database instead of directly querying the database you are monitoring.

You can enable extended monitoring for any, or all, of your monitored databases. The MC storage database provides a single repository for monitoring data from every database that uses enabled extended monitoring.

In the following example, Kafka streams system data from two monitored databases to the storage database. MC uses the storage database to render individual dashboards for each
monitored database. Be aware that MC always creates a dashboard that monitors the MC storage database.

Use Extended Monitoring

Important: To use extended monitoring, OpenText recommends installing Management Console on a host without any other Vertica databases.

When a database has extended monitoring enabled, the MC charts that use the feature display a rocket ship icon in the corner. You can use these charts to access longer-term data about your database's health or performance.

To view historical information in these charts, click the calendar icon to specify the timeframe to display. For example, if your database has been down for several hours, your charts do not display recent activity in your database. You could use the timeframe filter in the System Bottlenecks chart to see unusual resource usage occurred in your database in the hour it went down.

You can view a history of the Kafka streaming jobs loading data into the storage database. MC displays these jobs on the Load tab of your storage database's dashboard. See Viewing Load History.

Set Up Extended Monitoring

To set up extended monitoring, see Managing the Storage Database and Managing Extended Monitoring on a Database.
See Also

- Managing the Storage Database
- Managing Extended Monitoring on a Database
- Viewing Load History
- Integrating with Apache Kafka
- Retaining Monitoring Information

Managing the Storage Database

Extended Monitoring stores your Vertica database's monitoring data in a dedicated MC storage database.

To use Extended Monitoring, you must first set up the storage database and configure it for Kafka streaming. Then, turn on Extended Monitoring for any or all monitored databases.

MC automatically configures a schema for the storage database, named dcschema, which is synced with DC tables on your monitored databases.

Caution: Do not alter dcschema after MC has configured it. Altering it could cause the storage database to lose data or supply incorrect monitoring information to MC.

MC Preparation

First verify that MC is not installed on the same host as a Vertica database. When Extended Monitoring is enabled, MC sharing a host with a production database can affect performance.

You must also increase the allocation of memory for the MC application server, as described in the next section. Tune the memory allocation options based on:

- The demands of your database.
- The amount of monitoring data you plan to view in MC charts at the same time.

For example, MC requires more memory to display a week of data in a chart.
Modify Memory Allocation

To modify memory allocation:

1. In Management Console, select the Configuration tab on the MC Settings page.
2. Modify the following fields under Application Server JVM Settings to increase the allocation of memory for the JVM:
   - **Initial Heap Size**: For Extended Monitoring, a minimum value of 2 GB is recommended. (The default value is 1 GB.)
   - **Maximum Heap Size**: For Extended Monitoring, a minimum value of 4 GB is recommended. (The default value is 2 GB.)
3. Click Apply at the top right of the page. A prompt appears to restart MC.
4. Click OK to restart MC and save your changes.

Storage Database Requirements

To set up storage for Extended Monitoring, your system must meet the following prerequisites:

- An available host, or available database whose Vertica version is the same version or a higher version of the database you plan to monitor.
- Configured MC for Extended Monitoring (See MC Preparation.)
- Access to a deployed Kafka server (For details on installing Kafka, see the Apache Kafka site.)

Set Up the Storage Database

To configure the storage database for Extended Monitoring, on the MC Settings page, select the MC Storage DB Setup tab. Modify the settings in each of the three areas:

1) **Kafka Broker**

Enter the host name or IP addresses and ports for one or more of your deployed Kafka servers.
2) **MC External Storage Database**

Designate the storage database. You can create a new database or use an existing database.

- **Create a new database:** To create a new single node cluster on an available host using a Community Edition license of Vertica, choose this option. Doing so does not affect your normal Vertica license usage.
- **Use an existing database known to MC:** To designate a database you have already imported to MC, choose this option. If the schema 'dcschema' exists in the database, a dialog appears. Depending on your system needs, do one of the following:
  - To keep the existing schema's data, click **Append**. For example, if you have already used this database for Extended Monitoring storage and are reimporting it, you can use this option to retain its historical data for continued use.
  - To clear the existing schema from the database and create a fresh version of dcschema configured for Extended Monitoring storage, click **Remove**.

At the **Database name** prompt:

1. Select the database you want to use from the drop-down list.
2. To use that database for Extended Monitoring, click **Prepare MC Storage database**.

**Advanced Streaming Options:**

To change the value of the Scheduler Frame Duration, click **Advanced Streaming Options**. Management Console displays the **Streaming Options** window, which allows you to modify the Scheduler Frame Duration default that Management Console uses for Extended Monitoring.

The **Scheduler Frame Duration** is the amount of time given to the Kafka scheduler for each individual frame to process and run the COPY statements, after which KafkaSource terminates the COPY statements. Vertica must have enough time to complete COPY tasks within this duration.

If the frame duration is too small, you would see data loss, as the scheduler does not have sufficient time to process all the data. You may see errors or messages on Management Console’s Load page for microbatches that are not able to process the data.

On the contrary, if the frame duration is too large, the scheduler will have too much time to process the incoming data and after it has finished processing the data, it might wait for the frame duration to expire. In this case, you may see some latency in the data getting
processed. In addition, the charts in Management Console may not show the data in real time and may show some latency.

You can approximate the average available time per COPY using the following equation:

\[ TimePerCopy = \frac{(FrameDuration \times Parallelism)}{Microbatches} \]

This equation provides only a rough estimate. There are many factors that impact the amount of time that each COPY statement needs to run.

Vertica requires at least 100 milliseconds per COPY to function.

**Note:**
The Advanced Scheduler options button is enabled when the Streaming is turned off. If Kafka Streaming is enabled, the Advanced Scheduler options button is disabled.

### 3) Enable Extended Monitoring

Click Select database(s) for extended monitoring.

**Note:**
For more information, see Managing Extended Monitoring on a Database.

### Restart the Storage Database

If you stop the storage database while streaming is enabled, streaming to the storage database stops automatically. You must re-enable streaming on the MC Storage DB Setup tab after you restart the storage database.

If streaming to the MC storage database is disabled while Extended Monitoring on your database is on, the Kafka retention policy determines how long streaming can remain disabled without data loss. See Managing Streaming Services for Extended Monitoring.

### Discontinue the Storage Database

1. Select the Extended Monitoring tab in MC Settings.
2. Set Extended Monitoring for all databases to **OFF**.
3. Select the MC Storage DB Setup tab in MC Settings.
4. Click **Disable Streaming** in the MC External Storage Database section to de-activate your storage database.
5. Click **Remove** in the MC External Storage Database section to remove the MC Storage Database from MC.
6. Choose whether to keep or remove the data your storage database has collected:
   - **Keep Data**: Existing data will not removed. If you re-use this database for Extended Monitoring storage, you can choose to append new collected monitoring data to this existing data.
   - **Remove Data**: MC deletes its customized storage schema from the database.

### Configure Storage Database Memory Usage

On the Resource Pools tab of the storage database, you can optionally increase the memory size of SYSQUERY and KAFKA_DEFAULT_POOL. For setting resource pool parameters in MC, see [Configuring Resource Pools in Management Console](#).

- **SYSQUERY**: Reserved for temporary storage of intermediate results of queries against system monitoring and catalog tables. Default setting is 1G. For best performance for MC, set to 2G or higher.
- **KAFKA_DEFAULT_POOL**: Reserved for all queries executed by the Kafka scheduler. Default setting is 30%, which is the recommended setting. By default, queries spill to the general pool when they exceed the 30% memory size.

### Manage Disk Space

The storage database uses a customized schema, named dcschema. You can monitor these tables on MC, using the Table Utilization chart on the storage database's Activity tab. The Table Utilization chart lists all the tables in dcschema and their details, such as row counts and column properties. You can sort by row count to determine if certain tables use more disk space on your storage database. See [Monitoring Table Utilization and Projections](#).

You should regularly drop partitions from dcschema if you have limited disk space for the MC storage database. MC does not automatically drop partitions from the storage database. For more information on dropping partitions, see [Dropping Partitions](#).

The table dc_execution_engine_profiles is partitioned by day. Because this table typically contains the most rows, as a best practice you should drop partitions from this table more often. The following example shows how you can specify partition key 2016-08-22 to drop a partition from dc_execution_engine_profiles.
Other than `dc_execution_engine_profiles`, all other tables in `dcschema` are partitioned by week. The next example shows you how you can drop a partition from the table `dc_cpu_aggregate_by_minute`, specifying the thirty-fourth week of 2016.

```sql
=> SELECT DROP_PARTITION ('dcschema.dc_cpu_aggregate_by_minute', 201634, 201634);
```

**Manage Client Sessions**

By default Vertica allows 50 client sessions and an additional five administrator sessions per node. If you reach the limit on the storage database, MC switches back to default monitoring, and does not use Extended Monitoring data from the storage database.

You can optionally configure the maximum number of client sessions that can run on a single database cluster node on your MC storage database's Settings page:

1. On the storage database dashboard, click the **Settings** page.
2. Choose the **General** tab.
3. Enter a value in the **Maximum client sessions** field. Valid values are 0–1000.

For more details about managing client connections in MC, see **Managing Client Connections**.

**See Also**

- Create a Private Key File

**Managing Extended Monitoring on a Database**

When you enable extended monitoring on your Vertica database, monitoring data from your database streams through Kafka servers to the MC storage database.

You can enable streaming for any or all databases that MC monitors.
Extended Monitoring Prerequisites

Before you can enable extended monitoring, your system must meet these prerequisites:

- The versions of MC and Vertica must match.
- Deployed Kafka server(s)
- Configured MC for extended monitoring (See Managing the Storage Database)
- Deployed MC storage database (See Managing the Storage Database)

Enable Extended Monitoring

1. Select the Extended Monitoring tab on MC Settings.

   The Extended Monitoring page displays all databases monitored by MC.

2. In the Memory Limit field for the database of your choice, set the maximum amount of memory the database can use for streaming monitoring data. For more about the memory limit, see Managing Streaming Services for Extended Monitoring.

3. In the Extended Monitoring column, select ON to enable streaming for the database of your choice.

   The database begins streaming its monitoring data to the Kafka server.

User Access

When you change user permissions for a database using extended monitoring, the user access policy on the storage database does not automatically update. On the Extended Monitoring page, in the user access column for your database, click Refresh to sync the policy.

If you rename a Vertica user, you must re-map the user in MC Settings before refreshing the user access policy.

- Integrating with Apache Kafka
Managing Streaming Services for Extended Monitoring

When extended monitoring is enabled, Vertica streams data from your database through Kafka servers to the storage database.

For additional parameters that optimize the performance of Kafka with Vertica, see Kafka and Vertica Configuration Settings.

View Streaming Details in MC

Click the Load tab on your database's MC dashboard to see the Data Load Activity page. On this page, the Continuous tab displays details about all continuous loading jobs for extended monitoring. You can use this page to monitor whether your extended monitoring data is streaming successfully to the MC storage database.

See Viewing Load History for more about the Data Load Activity page.

Tip: If you do not see loading jobs for extended monitoring, verify that you have selected Show MC data collector monitoring streams at the top of the Continuous tab.

Prevent Data Loss

The Memory Limit buffer allows you to restart the Kafka server without data loss. Vertica queues the streamed data until you restart the Kafka server. When the Kafka server remains down for an extended period of time, data loss occurs when the queue of streamed data exceeds the buffer. You set the buffer size on the Extended Monitoring tab when you enable extended monitoring for a database. See Managing Extended Monitoring on a Database.

The Kafka retention policy determines when data loss occurs during the following scenarios:

- Restarting the MC storage database (see Managing the Storage Database)
- Disabling streaming on the MC storage database (see Managing the Storage
Database

- Restart a micro-batch (see Loading Data From Amazon S3 Using MC)

The Kafka retention policy can allow you to restart these extended monitoring components without data loss. The Kafka server retains the data while the listed components are disabled. Data loss occurs when the streamed data exceeds the Kafka retention policy's log size or retention time limits. See the Apache Kafka documentation for how to configure the retention policy.

Changing the Kafka Server

Be aware that when you change Kafka servers for extended monitoring on the MC Storage DB Setup page, you must disable all extended monitoring processes and re-configure the MC storage database. For storage database setup instructions, see Managing the Storage Database.

Welcome to the Vertica SQL Reference Manual. This guide provides an overview of Vertica Structured Query Language (SQL). It defines system limits, describes SQL Language elements and system tables. This guide also provides reference descriptions of SQL Data Types, SQL Functions, and SQL Statements.

This document assumes that you are familiar with the basic concepts and terminology of the SQL language and relational database management systems.

**SQL in Vertica**

Vertica offers a robust set of SQL elements that allow you to manage and analyze massive volumes of data quickly and reliably. Vertica uses the following:

**SQL language elements**, including:

- Keywords and Reserved Words
- Identifiers
- Literals
- Operators
- Expressions
- Predicates
- Hints

**SQL data types**, including:
SQL functions including Vertica-specific functions that take advantage of Vertica's unique column-store architecture. For example, call `ANALYZE_STATISTICS` to collect and aggregate a variable amount of sample data for statistical analysis.

SQL statements that let you write robust queries to quickly return large volumes of data.

## System Limits

This section describes the system limits on the size and number of objects in a Vertica database. In most cases, computer memory and disk drive are the limiting factors.

<table>
<thead>
<tr>
<th>Item</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes</td>
<td>Maximum 128 (without Vertica assistance)</td>
</tr>
<tr>
<td>Database size</td>
<td>Approximates the number of files times the file size on a platform, depending on the maximum disk configuration</td>
</tr>
<tr>
<td>Table size</td>
<td>The smaller of:</td>
</tr>
<tr>
<td></td>
<td>• $2^{64}$ rows per node</td>
</tr>
<tr>
<td></td>
<td>• $2^{63}$ bytes per column</td>
</tr>
<tr>
<td>Row size</td>
<td>32,768,000 bytes</td>
</tr>
<tr>
<td></td>
<td>Row size is approximately the sum of its maximum column sizes, where, for example, a VARCHAR(80) has a maximum size of 80 bytes.</td>
</tr>
<tr>
<td>Key size</td>
<td>Limited only by row size</td>
</tr>
<tr>
<td>Tables/projections per database</td>
<td>Limited by physical RAM, as the catalog must fit in memory.</td>
</tr>
<tr>

<td>128 bytes. Basic names include table names, column names, etc.</td>
</tr>
<tr>
<td>Query length</td>
<td>No limit</td>
</tr>
<tr>
<td>Depth of nesting subqueries</td>
<td>Unlimited in FROM, WHERE, and HAVING clauses</td>
</tr>
</tbody>
</table>

**SQL Language Elements**

The following topics provide detailed descriptions of the language elements and conventions of Vertica SQL.

**Keywords**

Keywords are words that have a specific meaning in the SQL language. Every SQL statement contains one or more keywords. Although SQL is not case-sensitive with respect to keywords, they are generally shown in uppercase letters throughout this documentation for readability purposes.

**Note:**

If you use a keyword as the name of an identifier or an alias in your SQL statements, you may have to qualify the keyword with AS or double-quotes.
Vertica requires AS or double-quotes for certain reserved and non-reserved words to prevent confusion with expression syntax, or where the use of a word would be ambiguous.

Reserved Words and Keywords

Many keywords are also reserved words.

Vertica recommends that you not use reserved words as names for objects, or as identifiers. Including reserved words can make your SQL statements confusing. Reserved words that are used as names for objects or identifiers must be enclosed in double-quotes.

Note:
All reserved words are also keywords, but Vertica can add reserved words that are not keywords. A reserved word can simply be a word that is reserved for future use.

Non-reserved Keywords

Non-reserved keywords have a special meaning in some contexts, but can be used as identifiers in others. You can use non-reserved keywords as aliases—for example, SOURCE:

```=> SELECT my_node AS SOURCE FROM nodes;```

Note:
Vertica uses several non-reserved keywords in directed queries to specify special join types. You can use these keywords as table aliases only if they are double-quoted; otherwise, double-quotes can be omitted:

- ANTI
- NULLAWARE
- SEMI
- SEMIALL
- UNI
Viewing the List of Reserved and Non-reserved Keywords

To view the current list of Vertica reserved and non-reserved words, query system table `KEYWORDS`. Vertica lists keywords alphabetically and identifies them as reserved (R) or non-reserved (N).

For example, the following query gets all reserved keywords that begin with B:

```sql
=> SELECT * FROM keywords WHERE reserved = 'R' AND keyword ilike 'B%';
```

<table>
<thead>
<tr>
<th>keyword</th>
<th>reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>BETWEEN</td>
<td>R</td>
</tr>
<tr>
<td>BIGINT</td>
<td>R</td>
</tr>
<tr>
<td>BINARY</td>
<td>R</td>
</tr>
<tr>
<td>BIT</td>
<td>R</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>R</td>
</tr>
<tr>
<td>BOTH</td>
<td>R</td>
</tr>
</tbody>
</table>

(6 rows)

Identifiers

Identifiers (names) of objects such as schema, table, projection, column names, and so on, can be up to 128 bytes in length.

Unquoted Identifiers

Unquoted SQL identifiers must begin with one of the following:

- Non-Unicode letters: A–Z or a–z
- Underscore (_)

Subsequent characters in an identifier can be any combination of the following:

- Non-Unicode letters: A–Z or a–z
- Underscore (_)
- Digits (0–9)
- Unicode letters (letters with diacriticals or not in the Latin alphabet), unsupported for model names
• Dollar sign ($), unsupported for model names

Caution:
The SQL standard does not support dollar sign in identifiers, so usage can cause application portability problems.

Quoted Identifiers

Note:
Quoted identifiers are not supported for model names

Identifiers enclosed in double quote (") characters can contain any character. If you want to include a double quote, you need a pair of them; for example "". You can use names that would otherwise be invalid—for example, names that include only numeric characters ("123") or contain space characters, punctuation marks, and SQL or Vertica-reserved keywords. For example:

```
CREATE SEQUENCE "my sequence!";
```

Double quotes are required for non-alphanumerics and SQL keywords such as "1time", "Next week" and "Select".

Case Sensitivity

Identifiers are not case-sensitive. Thus, identifiers "ABC", "Abc", and "aBc" are synonymous, as are ABC, Abc, and aBc.

Non-ASCII Characters

Vertica accepts non-ASCII UTF-8 Unicode characters for table names, column names, and other identifiers, extending the cases where upper/lower case distinctions are ignored (case-folded) to all alphabets, including Latin, Cyrillic, and Greek.

For example, the following CREATE TABLE statement uses the ß (German eszett) in the table name:

```
=> CREATE TABLE straße(x int, y int);
CREATE TABLE
```
### Identifiers Are Stored As Created

SQL identifiers, such as table and column names, are not converted to lowercase. They are stored as created, and references to them are resolved using case-insensitive compares. For example, the following statement creates table ALLCAPS.

```sql
=> CREATE TABLE ALLCAPS(c1 varchar(30));
=> INSERT INTO ALLCAPS values('upper case');
```

The following statements are variations of the same query:

```sql
=> SELECT * FROM ALLCAPS;
=> SELECT * FROM allcaps;
=> SELECT * FROM "allcaps";
```

The three queries all return the same result:

```
c1
---------
upper case
(1 row)
```

Note that Vertica returns an error if you try to create table AllCaps:

```sql
=> CREATE TABLE AllCaps(c1 varchar(30));
   ROLLBACK: table "AllCaps" already exists
```

See [QUOTE_IDENT](https://www.vertica.com/docs/9.3.x/EN-US/vdm_9_3_0.pdf) for additional information.
Literals

Literals are numbers or strings used in SQL as constants. Literals are included in the select-list, along with expressions and built-in functions and can also be constants.

Vertica provides support for number-type literals (integers and numerics), string literals, VARBINARY string literals, and date/time literals. The various string literal formats are discussed in this section.

Number-Type Literals

Vertica supports three types of numbers: integers, numerics, and floats.

- **Integers** are whole numbers less than 2^63 and must be digits.
- **Numerics** are whole numbers larger than 2^63 or that include a decimal point with a precision and a scale. Numerics can contain exponents. Numbers that begin with 0x are hexadecimal numerics.

Numeric-type values can also be generated using casts from character strings. This is a more general syntax. See the Examples section below, as well as Data Type Coercion Operators (CAST).

Syntax

```
digits
[digits].[digits] | [digits].digits
digits e[+][-]digits | [digits].digits e[+][-]digits | digits.[digits] e[+][-]digits
```

Parameters

| **digits** | One or more numeric characters, 0 through 9 |
| **e**      | Exponent marker                           |
Notes

- At least one digit must follow the exponent marker (e), if e is present.
- There cannot be any spaces or other characters embedded in the constant.
- Leading plus (+) or minus (−) signs are not considered part of the constant; they are unary operators applied to the constant.
- In most cases a numeric-type constant is automatically coerced to the most appropriate type depending on context. When necessary, you can force a numeric value to be interpreted as a specific data type by casting it as described in Data Type Coercion Operators (CAST).
- Floating point literals are not supported. If you specifically need to specify a float, you can cast as described in Data Type Coercion Operators (CAST).
- Vertica follows the IEEE specification for floating point, including NaN (not a number) and Infinity (Inf).
- A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.
- Dividing INTEGERS (x / y) yields a NUMERIC result. You can use the // operator to truncate the result to a whole number.

Examples

The following are examples of number-type literals:

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>42</td>
</tr>
<tr>
<td>3.5</td>
</tr>
<tr>
<td>4.</td>
</tr>
<tr>
<td>.001</td>
</tr>
<tr>
<td>5e2</td>
</tr>
<tr>
<td>1.925e-3</td>
</tr>
</tbody>
</table>

Scientific notation:

```sql
=> SELECT NUMERIC '1e10';
?column?
-------------
10000000000
(1 row)
```

BINARY scaling:
The following examples illustrated using the / and // operators to divide integers:

```sql
=> SELECT NUMERIC '1p10';
?column?
-----------
1024
(1 row)
=> SELECT FLOAT 'Infinity';
?column?
-----------
Infinity
(1 row)
```

Data Type Coercion
String Literals

String literals are string values surrounded by single or double quotes. Double-quoted strings are subject to the backslash, but single-quoted strings do not require a backslash, except for \' and \.\n
You can embed single quotes and backslashes into single-quoted strings.

To include other backslash (escape) sequences, such as \t (tab), you must use the double-quoted form.

Precede single-quoted strings with a space between the string and its preceding word, since single quotes are allowed in identifiers.

See Also

- SET ESCAPE_STRING_WARNING
- Internationalization Parameters
- Implement Locales for International Data Sets

Character String Literals

Character string literals are a sequence of characters from a predefined character set and are enclosed by single quotes. If the single quote is part of the sequence, it must be doubled as "'"'.

Syntax

'characters'

Parameters

| characters | Arbitrary sequence of characters bounded by single quotes (') |
Single Quotes in a String

The SQL standard way of writing a single-quote character within a string literal is to write two adjacent single quotes. For example:

```
=> SELECT 'Chester''s gorilla';
?column?
--------------
Chester's gorilla
(1 row)
```

Standard Conforming Strings and Escape Characters

Vertica uses standard conforming strings as specified in the SQL standard, which means that backslashes are treated as string literals, not escape characters.

**Note:**

Earlier versions of Vertica did not use standard conforming strings, and backslashes were always considered escape sequences. To revert to this older behavior, set the StandardConformingStrings parameter to '0', as described in Configuration Parameters in the Administrator's Guide.

Examples

```
=> SELECT 'This is a string';
?column?
-----------------
This is a string
(1 row)
=> SELECT 'This \is a string';
  WARNING: nonstandard use of escape in a string literal at character 8
  HINT: Use the escape string syntax for escapes, e.g., E'\r\n'.
?column?
-----------------
This is a string
(1 row)
vmartdb=> SELECT E'This \is a string';
  ?column?
-----------------
This is a string
(1 row)
vmartdb=> SELECT E'This is a \n new line';
  ?column?
-----------------
```
This is a new line

(1 row)

=> SELECT 'String''s characters';

---

String's characters

(1 row)

See Also

- SET STANDARD_CONFORMING_STRINGS
- SET ESCAPE_STRING_WARNING
- Internationalization Parameters
- Implement Locales for International Data Sets

**Dollar-Quoted String Literals**

Dollar-quoted string literals are rarely used, but are provided here for your convenience.

The standard syntax for specifying string literals can be difficult to understand. To allow more readable queries in such situations, Vertica SQL provides dollar quoting. Dollar quoting is not part of the SQL standard, but it is often a more convenient way to write complicated string literals than the standard-compliant single quote syntax.

**Syntax**

```
$$characters$$
```

**Parameters**

<table>
<thead>
<tr>
<th>characters</th>
<th>Arbitrary sequence of characters bounded by paired dollar signs ($)</th>
</tr>
</thead>
</table>

Dollar-quoted string content is treated as a literal. Single quote, backslash, and dollar sign characters have no special meaning within a dollar-quoted string.
Notes

A dollar-quoted string that follows a keyword or identifier must be separated from the preceding word by whitespace; otherwise, the dollar-quoted delimiting is taken as part of the preceding identifier.

Examples

```sql
=> SELECT $$Fred's

Fred's
(1 row)

ERROR: syntax error at or near "'" at character 21
LINE 1: SELECT 'SELECT 'fact'';

=> SELECT $$fact'';

SELECT $$fact
(1 row)

=> SELECT 'SELECT ''fact''';

SELECT 'fact';
(1 row)
```

Unicode String Literals

Syntax

U&'characters' [UESCAPE '<Unicode escape character>' ]

Parameters

| characters | Arbitrary sequence of UTF-8 characters bounded by single quotes ('') |
Using Standard Conforming Strings

With StandardConformingStrings enabled, Vertica supports SQL standard Unicode character string literals (the character set is UTF-8 only).

Before you enter a Unicode character string literal, enable standard conforming strings in one of the following ways.

- To enable for all sessions, update the StandardConformingStrings configuration parameter. See Configuration Parameters in the Administrator's Guide.
- To treat backslashes as escape characters for the current session, use the SET STANDARD_CONFORMING_STRINGS statement.

See also Extended String Literals.

Examples

To enter a Unicode character in hexadecimal, such as the Russian phrase for "thank you, use the following syntax:

```sql
=> SET STANDARD_CONFORMING_STRINGS TO ON;
=> SELECT U'\0441\043F\0430\0441\0438\0431\043E' as 'thank you';
    thank you
---------
  спасибо
(1 row)
```

To enter the German word mude (where u is really u-umlaut) in hexadecimal:

```sql
=> SELECT U'm\00fcde';
?column?
---------
müde
(1 row)
=> SELECT 'ü';
?column?
---------
ü
(1 row)
```

To enter the LINEAR B IDEOGRAPH B240 WHEELED CHARIOT in hexadecimal:
Note: Not all fonts support the wheeled chariot character.

See Also

- SET STANDARD_CONFORMING_STRINGS
- SET ESCAPE_STRING WARNING
- Internationalization Parameters
- Implement Locales for International Data Sets

**VARBINARY String Literals**

VARBINARY string literals allow you to specify hexadecimal or binary digits in a string literal.

**Syntax**

```sql
X'\hexadecimal digits''
B'\binary digits''
```

**Parameters**

<table>
<thead>
<tr>
<th>X or x</th>
<th>Specifies hexadecimal digits. The <code>&lt;hexadecimal digits&gt;</code> string must be enclosed in single quotes (').</th>
</tr>
</thead>
<tbody>
<tr>
<td>B or b</td>
<td>Specifies binary digits. The <code>&lt;binary digits&gt;</code> string must be enclosed in single quotes (').</td>
</tr>
</tbody>
</table>

**Examples**

```sql
=> SELECT E'xF0\x90\x83\x0C';
?column?
-------------
(wheeled chariot character)
(1 row)
```
---
\253\315
(1 row)
=> SELECT B'\101100';
?column?
---
(1 row)

**Extended String Literals**

**Syntax**

```
E 'characters'
```

**Parameters**

<table>
<thead>
<tr>
<th>characters</th>
<th>Arbitrary sequence of characters bounded by single quotes (')</th>
</tr>
</thead>
</table>

You can use C-style backslash sequence in extended string literals, which are an extension to the SQL standard. You specify an extended string literal by writing the letter E as a prefix (before the opening single quote); for example:

```
E 'extended character string\n'
```

Within an extended string, the backslash character (\) starts a C-style backslash sequence, in which the combination of backslash and following character or numbers represent a special byte value, as shown in the following list. Any other character following a backslash is taken literally; for example, to include a backslash character, write two backslashes (\\).

- \ is a backslash
- \b is a backspace
- \f is a form feed
- \n is a newline
- \r is a carriage return
- \t is a tab
- \x##, where ## is a 1 or 2-digit hexadecimal number; for example \x07 is a tab
- \###, where #### is a 1, 2, or 3-digit octal number representing a byte with the corresponding code.
When an extended string literal is concatenated across lines, write only E before the first opening quote:

```sql
=> SELECT E'first part o'
   'f a long line';
read only E before the first opening quote:
```

(1 row)

Two adjacent single quotes are used as one single quote:

```sql
=> SELECT 'Aren''t string literals fun?';
```

(1 row)

### Standard Conforming Strings and Escape Characters

When interpreting commands, such as those entered in `vsql` or in queries passed via JDBC or ODBC, Vertica uses standard conforming strings as specified in the SQL standard. In standard conforming strings, backslashes are treated as string literals (ordinary characters), not escape characters.

**Note:**

Text read in from files or streams (such as the data inserted using the `COPY` statement) are not treated as literal strings. The `COPY` command defines its own escape characters for the data it reads. See the `COPY` statement documentation for details.

The following options are available, but Vertica recommends that you migrate your application to use standard conforming strings at your earliest convenience, after warnings have been addressed.

- To treat back slashes as escape characters, set configuration parameter `StandardConformingStrings` to 0.
- To enable standard conforming strings permanently, set the `StandardConformingStrings` parameter to '1', as described [below](#).
- To enable standard conforming strings per session, use `SET STANDARD_CONFORMING_STRING TO ON`, which treats backslashes as escape characters for the current session only.
Identifying Strings That Are Not Standard Conforming

The following procedure can be used to identify nonstandard conforming strings in your application so that you can convert them into standard conforming strings:

1. Be sure the `StandardConformingStrings` parameter is off, as described in Internationalization Parameters.

```sql
=> ALTER DATABASE DEFAULT SET StandardConformingStrings = 0;
```

**Note:**
Vertica recommends that you migrate your application to use standard conforming strings.

2. If necessary, turn on the `EscapeStringWarning` parameter.

```sql
=> ALTER DATABASE DEFAULT SET EscapeStringWarning = 1;
```

Vertica now returns a warning each time it encounters an escape string within a string literal. For example, Vertica interprets the `\n` in the following example as a new line:

```sql
=> SELECT 'a\nb';
   WARNING: nonstandard use of escape in a string literal at character 8
   HINT: Use the escape string syntax for escapes, e.g., E'\r\n'.
?column?
----------
a
b
(1 row)
```

When `StandardConformingStrings` is ON, the string is interpreted as four characters: `a \ n b`.

Modify each string that Vertica flags by extending it as in the following example:

```sql
E'a\nb'
```

Or if the string has quoted single quotes, double them; for example, `'one'' double'`.

3. Turn on the `StandardConformingStrings` parameter for all sessions:

```sql
=> ALTER DATABASE DEFAULT SET StandardConformingStrings = 1;
```
Doubled Single Quotes

This section discusses vsql inputs that are not passed on to the server.

Vertica recognizes two consecutive single quotes within a string literal as one single quote character. For example, the following inputs, 'You''re here!' ignored the second consecutive quote and returns the following:

```
=> SELECT 'You''re here!';
    ?column?
    ----------------
    You're here!
    (1 row)
```

This is the SQL standard representation and is preferred over the form, 'You\'re here!', because backslashes are not parsed as before. You need to escape the backslash:

```
=> SELECT (E'You\'re here!');
    ?column?
    ----------------
    You're here!
    (1 row)
```

This behavior change introduces a potential incompatibility in the use of the vsql meta-command `\set`, which automatically concatenates its arguments. For example:

```
\set file '"'pwd'"/file.txt'"'"echo :file
```

vsql takes the four arguments and outputs the following:

```
'/home/vertica/file.txt'
```

Vertica parses the adjacent single quotes as follows:

```
\set file '"'pwd'/file.txt'"'"echo :file
 '/home/vertica/file.txt''
```

Note the extra single quote at the end. This is due to the pair of adjacent single quotes together with the backslash-quoted single quote.

The extra quote can be resolved either as in the first example above, or by combining the literals as follows:

```
\set file '"'pwd'/file.txt'"'"echo :file
 '/home/vertica/file.txt''
```
In either case the backslash-quoted single quotes should be changed to doubled single quotes as follows:

```
\set file "'pwd' '/file.txt'
```

### Additional Examples

```sql
=> SELECT 'This \
\is a string';
+---------------+
<table>
<thead>
<tr>
<th>This \is a string</th>
</tr>
</thead>
<tbody>
<tr>
<td>This \is a string</td>
</tr>
</tbody>
</table>

(1 row)

=> SELECT E'This \is a string';
+---------------+
<table>
<thead>
<tr>
<th>This is a string</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is a string</td>
</tr>
</tbody>
</table>

(1 row)

=> SELECT E'This is a \n new line';
+---------------+
<table>
<thead>
<tr>
<th>This is a new line</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is a new line</td>
</tr>
</tbody>
</table>

(1 row)

=> SELECT 'String's characters';
+---------------+
<table>
<thead>
<tr>
<th>String's characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>String's characters</td>
</tr>
</tbody>
</table>

(1 row)
```
Date/Time Literals

Date or time literal input must be enclosed in single quotes. Input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others.

Vertica handles date/time input more flexibly than the SQL standard requires. The exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones are described in Date/Time Expressions.

Time Zone Values

Vertica attempts to be compatible with the SQL standard definitions for time zones. However, the SQL standard has an odd mix of date and time types and capabilities. Obvious problems are:

- Although the DATE type does not have an associated time zone, the TIME/TIMETZ type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
- Vertica assumes your local time zone for any data type containing only date or time.
- The default time zone is specified as a constant numeric offset from UTC. It is therefore not possible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, OpenText recommends using Date/Time types that contain both date and time when you use time zones. OpenText recommends that you do not use the type TIME WITH TIME ZONE, even though it is supported it for legacy applications and for compliance with the SQL standard.

Time zones and time-zone conventions are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900's, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules.

Vertica currently supports daylight-savings rules over the time period 1902 through 2038, corresponding to the full range of conventional UNIX system time. Times outside that range are taken to be in "standard time" for the selected time zone, no matter what part of the year in which they occur.
<table>
<thead>
<tr>

</tbody>
</table>
**Interval Literal**

A literal that represents a time span.

**Syntax**

\[
[ @ ] [-] \{ \text{quantity} \ \text{subtype-unit} \}[..] \ [ \text{AGO} ]
\]

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@</td>
<td>Ignored</td>
</tr>
<tr>
<td>- (minus)</td>
<td>Specifies a negative interval value.</td>
</tr>
</tbody>
</table>

**quantity**

Integer **numeric constant**

**subtype-unit**

See Year-Month Subtype Units for valid values. Subtype units must be specified for *year-month* intervals; they are optional for *day-time* intervals.

**AGO**

Specifies a negative interval value. AGO and - (minus) are synonymous.

**Notes**

- The amounts of different units are implicitly added up with appropriate sign accounting.
- The boundaries of an interval constant are:
  - 9223372036854775807 usec to -9223372036854775807 usec
  - 296533 years 3 mons 21 days 04:00:54.775807 to -296533 years -3 mons -21 days -04:00:54.775807
- The range of an interval constant is +/- \(2^{63}\) – 1 microseconds.
- In Vertica, interval fields are additive and accept large floating-point numbers.

**Examples**

See Specifying Interval Input.
Interval Subtype Units

The following tables lists subtype units that you can specify in an interval literal, divided into major categories:

- Year-month subtype units
- Day-time subtype units

Year-Month Subtype Units

<table>

<td></td>
</tr>
<tr>
<td>Microsecond</td>
<td>us, usec, usecs, usecond, useconds, microseconds, microsecond</td>
<td></td>
</tr>
</tbody>
</table>

### Processing m Input

Vertica uses context to interpret the input unit m as months or minutes. For example, the following command creates a one-column table with an interval value:

```sql
=> CREATE TABLE int_test(i INTERVAL YEAR TO MONTH);
```

Given the following INSERT statement, Vertica interprets the interval literal `1y 6m` as 1 year 6 months:

```sql
=> INSERT INTO int_test VALUES('1y 6m');
OUTPUT
-------
1
(1 row)
=> COMMIT;
COMMIT
=> SET INTERVALSTYLE TO UNITS;
SET
```
SELECT * FROM int_test;

---

1 year 6 months
(1 row)

Tip: The SET INTERVALSTYLE statement changes interval output to include subtype unit identifiers. For details, see Setting Interval Unit Display.

The following ALTER TABLE statement adds a DAY TO MINUTE interval column to table int_test:

=> ALTER TABLE int_test ADD COLUMN x INTERVAL DAY TO MINUTE;

The next INSERT statement sets the first and second columns to 3y 20m and 1y 6m, respectively. In this case, Vertica interprets the m input literals in two ways:

- For column i, Vertica interprets the m input as months, and displays 4 years 8 months.
- For column x, Vertica interprets the m input as minutes. Because the interval is defined as DAY TO MINUTE, it converts the inserted input value 1y 6m to 365 days 6 minutes:

=> INSERT INTO int_test VALUES ('3y 20m', '1y 6m');

OUTPUT
-------

1
(1 row)

=> SELECT * FROM int_test;

---

i | x
---|---

1 year 6 months | 4 years 8 months | 365 days 6 mins
(2 rows)

Interval Qualifier

Specifies how to interpret and format an interval literal for output, and optionally sets precision. Interval qualifiers are composed of one or two units:

unit [ TO unit ] [ (p) ]

where:
• *unit* specifies a day-time or year-month subtype.
• *p* specifies precision, an integer between 0 and 6.

**Note:**
Precision only applies to SECOND units, specifying the number of decimal digits to show after the seconds value decimal point. The default precision for SECOND is 6.

When SECOND is the second unit of a qualifier—for example, DAY TO SECOND or MINUTE TO SECOND—it has a precision of 2 places before the decimal point.

For example:

```sql
=> SELECT INTERVAL '6 122.538987' MINUTE TO SECOND (5);
?column?
-----------------------
08:02.53899
(1 row)
```

For details, see [Specifying Interval Precision](#).

If an interval omits an interval qualifier, the default is DAY TO SECOND(6).

Interval qualifiers are divided into two categories:

• day-time
• year-month

**Day-time interval qualifiers**

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY</td>
<td>Unconstrained</td>
</tr>
<tr>
<td>DAY TO HOUR</td>
<td>Span of days and hours</td>
</tr>
<tr>
<td>DAY TO MINUTE</td>
<td>Span of days and minutes</td>
</tr>
<tr>
<td>DAY TO SECOND [(p)]</td>
<td>Span of days, hours, minutes, seconds, and fractions of a second.</td>
</tr>
<tr>
<td>HOUR</td>
<td>Hours within days</td>
</tr>
<tr>
<td>Qualifier</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>HOUR TO MINUTE</td>
<td>Span of hours and minutes</td>
</tr>
<tr>
<td>HOUR TO SECOND [(p)]</td>
<td>Span of hours and seconds</td>
</tr>
<tr>
<td>MINUTE</td>
<td>Minutes within hours</td>
</tr>
<tr>
<td>MINUTE TO SECOND [(p)]</td>
<td>Span of minutes and seconds</td>
</tr>
<tr>
<td>SECOND [(p)]</td>
<td>Seconds within minutes</td>
</tr>
</tbody>
</table>

### Year-month interval qualifiers

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>YEAR</td>
<td>Unconstrained</td>
</tr>
<tr>
<td>MONTH</td>
<td>Months within year</td>
</tr>
<tr>
<td>YEAR TO MONTH</td>
<td>Span of years and months</td>
</tr>
</tbody>
</table>

**Note:**
Vertica also supports INTERVALYM, which is an alias for INTERVAL YEAR TO MONTH. Thus, the following two statements are equivalent:

```
=> SELECT INTERVALYM '1 2';
?column?
--------
1-2
(1 row)
```

```
=> SELECT INTERVAL '1 2' YEAR TO MONTH;
?column?
--------
1-2
(1 row)
```

### Examples

See Controlling Interval Format.
Operators

Operators are logical, mathematical, and equality symbols used in SQL to evaluate, compare, or calculate values.

Bitwise Operators

Bitwise operators perform bit manipulations on INTEGER and BINARY/VARBINARY data types:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;</td>
<td>AND</td>
<td>12 &amp; 4</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>32</td>
<td>3</td>
</tr>
<tr>
<td>#</td>
<td>XOR</td>
<td>17 # 5</td>
<td>20</td>
</tr>
<tr>
<td>~</td>
<td>NOT</td>
<td>~1</td>
<td>-2</td>
</tr>
<tr>
<td>&lt;&lt; †</td>
<td>Bitwise shift left</td>
<td>1 &lt;&lt; 4</td>
<td>16</td>
</tr>
<tr>
<td>&gt;&gt; †</td>
<td>Bitwise shift right</td>
<td>8 &gt;&gt; 2</td>
<td>2</td>
</tr>
</tbody>
</table>

† Invalid for BINARY/VARBINARY data types

String Argument Handling

String arguments must be explicitly cast as BINARY or VARBINARY data types for all bitwise operators. For example:

```sql
=> SELECT 'xyz'::VARBINARY & 'zyx'::VARBINARY AS AND;
   AND
  -----
  xyx
(1 row)

=> SELECT 'xyz'::VARBINARY | 'zyx'::VARBINARY AS OR;
   OR
  -----
```
Bitwise operators treat all string arguments as equal in length. If the arguments have different lengths, the operator function right-pads the smaller string with one or more zero bytes to equal the length of the larger string.

For example, the following statement ANDs unequal strings `xyz` and `zy`. Vertica right-pads string `zy` with one zero byte. The last character in the result is represented accordingly, as `\000`:

```
=> SELECT 'xyz'::VARBINARY & 'zy'::VARBINARY AS AND;
AND
--------
xy\000
(1 row)
```

**Boolean Operators**

Vertica supports the following Boolean operators:

- AND
- OR
- NOT

Operators AND and OR are commutative, that is, you can switch left and right operands without affecting the result. However, the order of evaluation of sub-expressions is not defined. To force evaluation order, use a `CASE` construct.

**Caution:**
Do not confuse Boolean operators with the `Boolean predicate` or `Boolean` data type, which can have only two values: true and false.

**Logic**

SQL uses a three-valued Boolean logic where the NULL represents "unknown."
Comparison Operators

Comparison operators are available for all data types where comparison makes sense. All comparison operators are binary operators that return values of true, false, or NULL.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Binary function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;</code></td>
<td>less than</td>
<td>binary_lt</td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td>greater than</td>
<td>binary_gt</td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td>less than or equal to</td>
<td>binary_le</td>
</tr>
<tr>
<td><code>&gt;=</code></td>
<td>greater than or equal to</td>
<td>binary_ge</td>
</tr>
<tr>
<td><code>=</code></td>
<td>equal</td>
<td>binary_eq</td>
</tr>
<tr>
<td><code>&lt;&gt;</code></td>
<td>equal</td>
<td>binary_eq</td>
</tr>
<tr>
<td><code>!=</code></td>
<td>not equal (use in predicate subqueries not supported)</td>
<td>binary_ne</td>
</tr>
</tbody>
</table>
NULL Handling

Comparison operators return NULL if either or both operands are null. One exception applies: <=> returns true if both operands are NULL, and false if one operand is NULL.

Data Type Coercion Operators (CAST)

Data type coercion (casting) passes an expression value to an input conversion routine for a specified data type, resulting in a constant of the indicated type. In Vertica, data type coercion can be invoked by an explicit cast request that uses one of the following constructs:

Syntax

SELECT CAST ( expression AS data-type )
SELECT expression::data-type
SELECT data-type 'string'

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>An expression of any type</th>
</tr>
</thead>
<tbody>
<tr>
<td>data-type</td>
<td>An SQL data type that Vertica supports to convert expression.</td>
</tr>
</tbody>
</table>

Truncation

If a binary value is cast (implicitly or explicitly) to a binary type with a smaller length, the value is silently truncated. For example:

```sql
=> SELECT 'abcd'::BINARY(2);
?column?
--------
ab
(1 row)
```

Similarly, if a character value is cast (implicitly or explicitly) to a character value with a smaller length, the value is silently truncated. For example:
Binary Casting and Resizing

Vertica supports only casts and resize operations as follows:

- **BINARY** to and from **VARBINARY**
- **VARBINARY** to and from **LONG VARBINARY**
- **BINARY** to and from **LONG VARBINARY**

On binary data that contains a value with fewer bytes than the target column, values are right-extended with the zero byte '\0' to the full width of the column. Trailing zeros on variable-length binary values are not right-extended:

```sql
=> SELECT 'ab'::BINARY(4), 'ab'::VARBINARY(4), 'ab'::LONG VARBINARY(4);

+-----------------+-----------------+-----------------+
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ab\000\000</td>
<td>ab</td>
<td>ab</td>
</tr>
</tbody>
</table>
+-----------------+-----------------+-----------------+
(1 row)
```

Automatic Coercion

The explicit type cast can be omitted if there is no ambiguity as to the type the constant must be. For example, when a constant is assigned directly to a column, it is automatically coerced to the column's data type.

Examples

```sql
=> SELECT CAST((2 + 2) AS VARCHAR);

+--------+
<table>
<thead>
<tr>
<th>column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
</tbody>
</table>
+--------+
(1 row)

=> SELECT (2 + 2)::VARCHAR;

+--------+
<table>
<thead>
<tr>
<th>column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
</tbody>
</table>
+--------+
(1 row)
```
See Also

- Data Type Conversions
- Data Type Coercion Chart
- CAST Failures

Cast Failures

When you invoke data type coercion (casting) by an explicit cast and the cast fails, the result returns either an error or NULL. Cast failures commonly occur when you attempt to cast conflicting conversions, such as trying to convert a varchar expression that contains letters to an integer.

When a cast fails, the result returned depends on the data type.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Cast Failure Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date/Time</td>
<td>NULL</td>
</tr>
<tr>
<td>Literal</td>
<td>Error</td>
</tr>
<tr>
<td>All Other Types</td>
<td>Error</td>
</tr>
</tbody>
</table>
Enabling Strict Time Casts

You can enable all cast failures to result in an error, including those for Date/Time data types. Doing so allows you to see the reason why some or all of the cast failed. To return an error instead of NULL, use the `ALTER SESSION` statement with the SET parameter:

```
ALTER SESSION SET EnableStrictTimeCasts=1;
```

The following example shows a Date/Time cast failure that returns NULL:

```
=> CREATE TABLE mytable (a VARCHAR);
CREATE TABLE
=> INSERT INTO mytable VALUES('string');
OUTPUT
---------
1
(1 row)
=> INSERT INTO mytable VALUES('1');
OUTPUT
---------
1
(1 row)
=> SELECT a::time FROM mytable;
a
---

(2 rows)
```

When you specify EnableStrictTimeCasts, the cast failure returns an error:

```
=> ALTER SESSION SET EnableStrictTimeCasts=1;
ALTER SESSION
=> SELECT a::time FROM mytable;
ERROR 2005: Invalid input syntax for time: "1"
```

Returning All Cast Failures as NULL

To explicitly cast an expression to a requested data type, use the following construct:

```
SELECT expression::data_type
```

Using this command to cast any values to a conflicting data type returns the following error:

```
ERROR 2827: Could not convert "string" from column table.a to an int8
```
In addition to the `::` cast, Vertica supports the use of `::!`. Use `::!` instead of `::`, if you want to return:

- NULL instead of an error for any non-Date/Time data types
- NULL instead of an error after setting EnableStrictTimeCasts

Returning all cast failures as NULL allows those expressions that succeeded during the cast to appear in the result. Those expressions which failed during the cast, however, have a NULL value.

The following example shows a cast failure that returns an error:

```sql
=> CREATE TABLE mytable (a VARCHAR);
CREATE TABLE
=> INSERT INTO mytable VALUES('string');
OUTPUT
---------
1
(1 row)
=> INSERT INTO mytable VALUES('1');
OUTPUT
---------
1
(1 row)
=> SELECT a::int FROM mytable;
ERROR 2827: Could not convert "string" from column mytable.a to an int8
```

When you use `::!`, the cast fails for the "string" value and returns NULL. However, it succeeds for the "1" value and returns 1:

```sql
=> SELECT a::int FROM mytable;
a
---
1
(2 rows)
```

## Date/Time Operators

### Syntax

```
[ + | - | * | / ]
```

### Parameters

- Addition
- Subtraction
The operators described below that take TIME or TIMESTAMP inputs actually come in two variants: one that takes TIME WITH TIME ZONE or TIMESTAMP WITH TIME ZONE, and one that takes TIME WITHOUT TIME ZONE or TIMESTAMP WITHOUT TIME ZONE. For brevity, these variants are not shown separately.

The + and * operators come in commutative pairs (for example both DATE + INTEGER and INTEGER + DATE); only one of each such pair is shown.

<table>
<thead>
<tr>
<th>Example</th>
<th>Result Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE '2001-09-28' + INTEGER '7'</td>
<td>DATE</td>
<td>'2001-10-05'</td>
</tr>
<tr>
<td>DATE '2001-09-28' + INTERVAL '1 HOUR'</td>
<td>TIMESTAMP</td>
<td>'2001-09-28 01:00:00'</td>
</tr>
<tr>
<td>DATE '2001-09-28' + TIME '03:00'</td>
<td>TIMESTAMP</td>
<td>'2001-09-28 03:00:00'</td>
</tr>
<tr>
<td>INTERVAL '1 DAY' + INTERVAL '1 HOUR'</td>
<td>INTERVAL</td>
<td>'1 DAY 01:00:00'</td>

<td>2 + 3</td>
<td>5</td>
</tr>
<tr>
<td>-</td>
<td>Subtraction</td>
<td>2 − 3</td>
<td>−1</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication</td>
<td>2 * 3</td>
<td>6</td>
</tr>
<tr>
<td>/</td>
<td>Division (integer division produces NUMERIC results).</td>
<td>4 / 2</td>
<td>2.00...</td>
</tr>
<tr>
<td>//</td>
<td>With integer division, returns an INTEGER rather than a NUMERIC.</td>
<td>117.32 // 2.5</td>
<td>46</td>
</tr>
<tr>
<td>%</td>
<td>Modulo (remainder). For details, see MOD.</td>
<td>5 % 4</td>
<td>1</td>
</tr>
<tr>
<td>^</td>
<td>Exponentiation</td>
<td>2.0 ^ 3.0</td>
<td>8</td>
</tr>
<tr>
<td>/\</td>
<td>Square root</td>
<td>5/\ 25.0</td>
<td>5</td>
</tr>
<tr>
<td>/\</td>
<td>Cube root</td>
<td>5/\ 27.0</td>
<td>3</td>
</tr>
<tr>
<td>/!!</td>
<td>Factorial (prefix operator)</td>
<td>/!! 5</td>
<td>120</td>
</tr>
<tr>
<td>@</td>
<td>Absolute value</td>
<td>@ -5.0</td>
<td>5</td>
</tr>
</tbody>
</table>
**Factorial Operator Support**

Vertica supports use of factorial operators on positive and negative floating point (`DOUBLE PRECISION`) numbers and integers. For example:

```sql
=> SELECT 4.98!;
     column?
---------------------
115.978600750905
(1 row)
```

Factorial is defined in terms of the gamma function, where (-1) = Infinity and the other negative integers are undefined. For example:

```sql
(-4)! = NaN
-(4!) = -24
```

Factorial is defined as follows for all complex numbers $z$:

$$z! = \gamma(z+1)$$

For details, see [Abramowitz and Stegun: Handbook of Mathematical Functions](https://dlmf.nist.gov/).  

**NULL Operators**

To check whether a value is or is not NULL, use the constructs:

```
[expression IS NULL | expression IS NOT NULL]
```

Alternatively, use equivalent, but nonstandard, constructs:

```
[expression ISNULL | expression NOTNULL]
```

Do not write `expression = NULL` because NULL represents an unknown value, and two unknown values are not necessarily equal. This behavior conforms to the SQL standard.

**Note:**

Some applications might expect that `expression = NULL` returns true if `expression` evaluates to null. Vertica strongly recommends that these applications be modified to comply with the SQL standard.
String Concatenation Operators

To concatenate two strings on a single line, use the concatenation operator (two consecutive vertical bars).

Syntax

\texttt{string} \mid\mid \texttt{string}

Parameters

| \texttt{string} | Is an expression of type \texttt{CHAR} or \texttt{VARCHAR} |

Notes

- \mid\mid \text{ is used to concatenate expressions and constants. The expressions are cast to VARCHAR if possible, otherwise to VARBINARY, and must both be one or the other.}
- Two consecutive strings within a single SQL statement on separate lines are automatically concatenated

Examples

The following example is a single string written on two lines:

```sql
=> SELECT E'xx' \mid\mid '\';
?column?
----------
xx\n(1 row)
```

The following examples show two strings concatenated:

```sql
=> SELECT E'xx' \mid\mid '\';
?column?
----------
xx\n(1 row)
=> SELECT 'auto' \mid\mid 'mobile';
```
automobile
(1 row)
=> SELECT 'auto'-> 'mobile';
automobile
(1 row)
=> SELECT 1 || 2;
12
(1 row)

=> SELECT '1' || '2';
12
(1 row)
=> SELECT '1'-> '2';
12
(1 row)
Expressions

SQL expressions are the components of a query that compare a value or values against other values. They can also perform calculations. Expressions found inside any SQL command are usually in the form of a conditional statement.

Operator Precedence

The following table shows operator precedence in decreasing (high to low) order.

Note: When an expression includes more than one operator, Vertica recommends that you specify the order of operation using parentheses, rather than relying on operator precedence.

<table>
<thead>
<tr>
<th>Operator/Element</th>
<th>Associativity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>left</td>
<td>table/column name separator</td>
</tr>
<tr>
<td>::</td>
<td>left</td>
<td>typecast</td>

**Expression Evaluation Rules**

The order of evaluation of subexpressions is not defined. In particular, the inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order. To force evaluation in a specific order, use a **CASE** construct. For example, this is an untrustworthy way of trying to avoid division by zero in a **WHERE** clause:

```sql
=> SELECT x, y WHERE x <> 0 AND y/x > 1.5;
```

But this is safe:

```sql
=> SELECT x, y WHERE
   CASE
     WHEN x <> 0 THEN y/x > 1.5
     ELSE false
   END;
```

A **CASE** construct used in this fashion defeats optimization attempts, so use it only when necessary. (In this particular example, it would be best to avoid the issue by writing `y > 1.5*x` instead.)

**Limits to SQL Expressions**

There are some limits on the number of modifiers and recursions that you can make in an expression. There are two limits that you should be aware of:

- The first limit is based on the stack available to the expression. Vertica requires at least 100kb of free stack. If this limit is exceeded then the error “The query contains
an expression that is too complex to analyze" may be thrown. Adding additional physical memory and/or increasing the value of ulimit -s max increase the available stack and prevent the error.

- The second limit is the number of recursions possible in an analytic expression. The limit is 2000. If this limit is exceeded then the error "The query contains an expression that is too complex to analyze" may be thrown. This limit cannot be increased.

### Aggregate Expressions

An aggregate expression applies an aggregate function across the rows or groups of rows selected by a query.

An aggregate expression only can appear in the select list or HAVING clause of a SELECT statement. It is invalid in other clauses such as WHERE, because those clauses are evaluated before the results of aggregates are formed.

### Syntax

An aggregate expression has the following format:

```
aggregate-function ( [ * ] [ ALL | DISTINCT ] expression )
```

### Parameters

<table>
<thead>
<tr>
<th>aggregate-function</th>
<th>A Vertica function that aggregates data over groups of rows from a query result set.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ALL</strong></td>
<td>Specifies which input rows to process:</td>
</tr>
<tr>
<td><strong>DISTINCT</strong></td>
<td></td>
</tr>
<tr>
<td>ALL (default): Invokes aggregate-function across all input rows where expression evaluates to a non-null value.</td>
<td></td>
</tr>
<tr>
<td>DISTINCT: Invokes aggregate-function across all input rows where expression evaluates to a unique non-null value.</td>
<td></td>
</tr>
<tr>
<td>expression</td>
<td>A value expression that does not itself contain an aggregate expression.</td>
</tr>
</tbody>
</table>
Examples

The AVG aggregate function returns the average income from the customer_dimension table:

```sql
=> SELECT AVG(annual_income) FROM customer_dimension;
AVG
-----------
2104270.6485
(1 row)
```

The following example shows how to use the COUNT aggregate function with the DISTINCT keyword to return all distinct values of evaluating the expression $x+y$ for all inventory_fact records.

```sql
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
COUNT
-------
21560
(1 row)
```

CASE Expressions

The CASE expression is a generic conditional expression that can be used wherever an expression is valid. It is similar to CASE and IF/THEN/ELSE statements in other languages.

Syntax (form 1)

```sql
CASE
  WHEN condition THEN result
  [ WHEN condition THEN result ]
  ...
  [ ELSE result ]
END
```

Parameters

<table>
<thead>
<tr>
<th>condition</th>
<th>An expression that returns a Boolean (true/false) result. If the result is false, subsequent WHEN clauses are evaluated in the same way.</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Specifies the value to return when the associated condition is true.</td>
</tr>
<tr>
<td>ELSE result</td>
<td>If no condition is true then the value of the CASE expression is the result in the ELSE clause. If the ELSE clause is omitted and no condition matches, the result is NULL.</td>
</tr>
</tbody>
</table>

**Syntax (form 2)**

```sql
CASE expression
WHEN value THEN result
[ WHEN value THEN result ]
...
[ ELSE result ]
END
```

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>An expression that is evaluated and compared to all the value specifications in WHEN clauses until one is found that is equal.</td>
</tr>
<tr>
<td>value</td>
<td>Specifies a value to compare to the expression.</td>
</tr>
<tr>
<td>result</td>
<td>Specifies the value to return when the expression is equal to the specified value.</td>
</tr>
<tr>
<td>ELSE result</td>
<td>Specifies the value to return when the expression is not equal to any value; if no ELSE clause is specified, the value returned is null.</td>
</tr>
</tbody>
</table>

**Notes**

The data types of all result expressions must be convertible to a single output type.

**Examples**

The following examples show two uses of the CASE statement.

```sql
=> SELECT * FROM test;
a---
1 2 3
```
=> SELECT a,
   CASE WHEN a=1 THEN 'one'
       WHEN a=2 THEN 'two'
       ELSE 'other'
   END
FROM test;
a | case
---+-----
1 | one
2 | two
3 | other

=> SELECT a,
   CASE a WHEN 1 THEN 'one'
       WHEN 2 THEN 'two'
       ELSE 'other'
   END
FROM test;
a | case
---+-----
1 | one
2 | two
3 | other

**Special Example**

A CASE expression does not evaluate subexpressions that are not needed to determine the result. You can use this behavior to avoid division-by-zero errors:

=> SELECT x FROM T1 WHERE
    CASE WHEN x <> 0 THEN y/x > 1.5
    ELSE false
    END;

**Column References**

**Syntax**

[[[database.]schema.]table-name.]column-name

**Parameters**

<table>
<thead>
<tr>
<th>schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
</table>
If you specify a database, it must be the current database.

<table>
<thead>
<tr>
<th><strong>table-name</strong></th>
<th>One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Name of a table</td>
</tr>
<tr>
<td></td>
<td>• Table alias defined in the query’s FROM clause</td>
</tr>
</tbody>
</table>

| **column-name** | A column name that is unique among all queried tables. |

## Restrictions

A column reference cannot contain any spaces.

## Comments

A comment is an arbitrary sequence of characters beginning with two consecutive hyphen characters and extending to the end of the line. For example:

```sql
-- This is a standard SQL comment
```

A comment is removed from the input stream before further syntax analysis and is effectively replaced by white space.

Alternatively, C-style block comments can be used where the comment begins with `/*` and extends to the matching occurrence of `*/`.

```sql
/* multiline comment
 * with nesting: /* nested block comment */
 */
```

These block comments nest, as specified in the SQL standard. Unlike C, you can comment out larger blocks of code that might contain existing block comments.

## Date/Time Expressions

Vertica uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information might be in the field. Each field is interpreted and either assigned
a numeric value, ignored, or rejected. The parser contains internal lookup tables for all
textual fields, including months, days of the week, and time zones.

Vertica parses date/time type inputs as follows:

1. Break the input string into tokens and categorize each token as a string, time, time
zone, or number.
2. Numeric token contains:
   - colon (:) — Parse as a time string, include all subsequent digits and colons.
   - dash (-), slash (/), or two or more dots (.) — Parse as a date string which might
     have a text month.
   - Numeric only — Parse as a single field or an ISO 8601 concatenated date
     (19990113 for January 13, 1999) or time (141516 for 14:15:16).
3. Token starts with a plus (+) or minus (−): Parse as a time zone or a special field.
4. Token is a text string: match up with possible strings.
   - Perform a binary-search table lookup for the token as either a special string (for
     example, today), day (for example, Thursday), month (for example, January), or
     noise word (for example, at, on).
   - Set field values and bit mask for fields. For example, set year, month, day for
today, and additionally hour, minute, second for now.
   - If not found, do a similar binary-search table lookup to match the token with a
time zone.
   - If still not found, throw an error.
5. Token is a number or number field:
   - If eight or six digits, and if no other date fields were previously read, interpret
     as a "concatenated date" (19990118 or 990118). The interpretation is
     YYYYMMDD or YYMMDD.
   - If token is three digits and a year was already read, interpret as day of year.
   - If four or six digits and a year was already read, interpret as a time (HHMM or
     HHHHSS).
   - If three or more digits and no date fields were found yet, interpret as a year
     (this forces yy-mm-dd ordering of the remaining date fields).
   - Otherwise the date field ordering is assumed to follow the DateStyle setting:
     mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is
     found to be out of range.
6. If BC is specified: negate the year and add one for internal storage. (In the Vertica
   implementation, 1 BC = year zero.)
7. If BC is not specified, and year field is two digits in length: adjust the year to four
digits. If field is less than 70, add 2000, otherwise add 1900.

Tip:
Gregorian years AD 1–99 can be entered as 4 digits with leading zeros— for
example, 0099 = AD 99.
Month Day Year Ordering

For some formats, ordering of month, day, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields.

Special Date/Time Values

Vertica supports several special date/time values for convenience, as shown below. All of these values need to be written in single quotes when used as constants in SQL statements.

The values INFINITY and -INFINITY are specially represented inside the system and are displayed the same way. The others are simply notational shorthands that are converted to ordinary date/time values when read. (In particular, NOW and related strings are converted to a specific time value as soon as they are read.)

<table>
<thead>
<tr>
<th>String</th>
<th>Valid Data Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>epoch</td>
<td>DATE, TIMESTAMP</td>
<td>1970-01-01 00:00:00+00 (UNIX SYSTEM TIME ZERO)</td>
</tr>
<tr>
<td>INFINITY</td>
<td>TIMESTAMP</td>
<td>Later than all other time stamps</td>
</tr>
<tr>
<td>-INFINITY</td>
<td>TIMESTAMP</td>
<td>Earlier than all other time stamps</td>
</tr>
<tr>
<td>NOW</td>
<td>DATE, TIME, TIMESTAMP</td>
<td>Current transaction's start time</td>
</tr>
</tbody>
</table>

Note: NOW is not the same as the NOW function.

<table>
<thead>
<tr>
<th>String</th>
<th>Valid Data Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TODAY</td>
<td>DATE, TIMESTAMP</td>
<td>Midnight today</td>
</tr>
<tr>
<td>TOMORROW</td>
<td>DATE, TIMESTAMP</td>
<td>Midnight tomorrow</td>
</tr>
<tr>
<td>YESTERDAY</td>
<td>DATE, TIMESTAMP</td>
<td>Midnight yesterday</td>
</tr>
<tr>
<td>ALLBALLS</td>
<td>TIME</td>
<td>00:00:00.00 UTC</td>
</tr>
</tbody>
</table>

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type:

- CURRENT_DATE
- CURRENT_TIME
- CURRENT_TIMESTAMP
- LOCALTIME
- LOCALTIMESTAMP
The latter four accept an optional precision specification. (See Date/Time Functions.) However, these functions are SQL functions and are not recognized as data input strings.

## NULL Value

NULL is a reserved keyword used to indicate that a data value is unknown. It is the ASCII abbreviation for NULL characters (\0).

### Usage in Expressions

Vertica does not treat an empty string as a NULL value. An expression must specify NULL to indicate that a column value is unknown.

The following considerations apply to using NULL in expressions:

- NULL is not greater than, less than, equal to, or not equal to any other expression. Use the Boolean predicate to determine whether an expression value is NULL.
- You can write queries with expressions that contain the `<=>` operator for NULL=NULL joins. See Equi-Joins and Non Equi-Joins in Analyzing Data.
- Vertica accepts NULL characters ('\0') in constant strings and does not remove null characters from VARCHAR fields on input or output.

### Projection Ordering of NULL Data

Vertica sorts NULL values in projection columns as follows:

<table>
<thead>
<tr>
<th>Column data type</th>
<th>NULL values placed at...</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMERIC, INTEGER</td>
<td>Beginning of sorted column (NULLS FIRST)</td>
</tr>
<tr>
<td>DATE, TIME, TIMESTAMP</td>
<td></td>
</tr>
<tr>
<td>INTERVAL</td>
<td></td>
</tr>
<tr>
<td>FLOAT, STRING, BOOLEAN</td>
<td>End of sorted column (NULLS LAST)</td>
</tr>
</tbody>
</table>

NULL-handling Functions
Predicates

Predicates are truth-tests. If the predicate test is true, it returns a value. Each predicate is evaluated per row, so that when the predicate is part of an entire table SELECT statement, the statement can return multiple results.

Predicates consist of a set of parameters and arguments. For example, in the following example WHERE clause:

```sql
WHERE name = 'Smith';
```

- `name = 'Smith'` is the predicate
- `'Smith'` is an expression

**BETWEEN predicate**

The special BETWEEN predicate is available as a convenience.

**Syntax**

```sql
WHERE a BETWEEN x AND y
```

**Examples**

```sql
WHERE a BETWEEN x AND y
```

is equivalent to:

```sql
WHERE a >= x AND a <= y
```

Similarly:

```sql
WHERE a NOT BETWEEN x AND y
```

is equivalent to:

```sql
WHERE a < x OR a > y
```

You can use the BETWEEN predicate for date ranges:
CREATE TABLE t1 (c1 INT, c2 INT, c3 DATE);
COPY t1 FROM stdin DELIMITER '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2014-07-26</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>2014-07-27</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>2014-07-28</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>2014-07-29</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>2014-07-30</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
<td>2014-07-31</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>2014-08-01</td>
</tr>
<tr>
<td>8</td>
<td>9</td>
<td>2014-08-02</td>
</tr>
</tbody>
</table>

.  

=> SELECT* FROM t1 WHERE c3 BETWEEN DATE('2014-07-26') AND DATE('2014-07-30');

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2014-07-26</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>2014-07-27</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>2014-07-28</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>2014-07-29</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>2014-07-30</td>
</tr>
</tbody>
</table>

(5 rows)

You can also use the NOW and INTERVAL keywords to select from a date range:

=> SELECT * FROM t1 WHERE c3 BETWEEN NOW()-INTERVAL '1 week' AND NOW();

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
<th>c3</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>8</td>
<td>2014-08-01</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>2014-07-26</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>2014-07-27</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>2014-07-28</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>2014-07-29</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>2014-07-30</td>
</tr>
<tr>
<td>6</td>
<td>7</td>
<td>2014-07-31</td>
</tr>
</tbody>
</table>

(7 rows)

**Boolean predicate**

Retrieves rows where the value of an expression is true, false, or unknown (null).

**Syntax**

expression IS [NOT] TRUE
expression IS [NOT] FALSE
expression IS [NOT] UNKNOWN
Notes

- A null input is treated as the value UNKNOWN.
- IS UNKNOWN and IS NOT UNKNOWN are effectively the same as the NULL predicate, except that the input expression does not have to be a single column value. To check a single column value for NULL, use the NULL-predicate.
- Do not confuse the boolean-predicate with Boolean Operators or the Boolean data type, which can have only two values: true and false.

Column value predicate

Syntax

\[
\text{column-name} \text{ comparison-op constant-expression}
\]

Parameters

<table>
<thead>
<tr>
<th>column-name</th>
<th>A single column of one the tables specified in the FROM Clause.</th>
</tr>
</thead>
<tbody>
<tr>
<td>comparison-op</td>
<td>A Comparison Operators.</td>
</tr>
<tr>
<td>constant-expression</td>
<td>A constant value of the same data type as the column-name.</td>
</tr>
</tbody>
</table>

Notes

To check a column value for NULL, use the NULL predicate.

Examples

```sql
table.column1 = 2
table.column2 = 'Seafood'
table.column3 IS NULL
```
**IN predicate**

**Syntax**

\[(column-list) \[ \text{NOT} \] \text{IN} (values-list)\]

**Parameters**

<table>
<thead>
<tr>
<th>column-list</th>
<th>One or more comma-delimited columns in the queried tables.</th>
</tr>
</thead>
<tbody>
<tr>
<td>values-list</td>
<td>Comma-delimited list of constant values to find in the \textit{column-list} columns. Each values-list value maps to a \textit{column-list} column according to their order in values-list and column-list, respectively. Column/value pairs must have \textit{compatible} data types. You can specify multiple sets of values as follows: ((\text{values-list}), (\text{values-list})[,...])</td>
</tr>
</tbody>
</table>

**Examples**

The following SELECT statement queries all data in table \textit{t11}.

```sql
=> SELECT * FROM t11 ORDER BY pk;
<table>
<thead>
<tr>
<th>pk</th>
<th>col1</th>
<th>col2</th>
<th>SKIP_ME_FLAG</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>t</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>4</td>
<td>t</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>5</td>
<td>f</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>6</td>
<td>f</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>7</td>
<td>t</td>
</tr>
<tr>
<td>6</td>
<td></td>
<td>8</td>
<td>f</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td></td>
<td>t</td>
</tr>
</tbody>
</table>
(7 rows)
```

The following query specifies an IN predicate, to find all rows in \textit{t11} where columns \textit{col1} and \textit{col2} contain values of (2,3) or (6,7):
### INTERPOLATE

Used to join two **event series** together using some ordered attribute, event series joins let you compare values from two series directly, rather than having to normalize the series to the same measurement interval.

### Syntax

```
expression1 INTERPOLATE PREVIOUS VALUE expression2
```

### Parameters

<table>
<thead>
<tr>
<th>expression1</th>
<th>expression2</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>A column reference</strong> from one the tables specified in the FROM Clause.</td>
<td></td>
</tr>
</tbody>
</table>

The referenced columns are typically a DATE/TIME data type, often TIMESTAMP, inasmuch as you are joining data that represents an event series; however, the referenced columns can be of any type.

<table>
<thead>
<tr>
<th>PREVIOUS VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pads the non-preserved side with the previous values from relation when there is no match.</td>
</tr>
</tbody>
</table>

Input rows are sorted in ascending logical order of the join column.

**Note:**

An ORDER BY clause, if used, does not determine the input order but only determines query output order.

### Description

- An event series join is an extension of a regular outer join. Instead of padding the non-preserved side with null values when there is no match, the event series join pads the non-preserved side with the previous values from the table.
The difference between expressing a regular outer join and an event series join is the INTERPOLATE predicate, which is used in the ON clause. See the Examples section below Notes and Restrictions. See also Event Series Joins in Analyzing Data.

Data is logically partitioned on the table in which it resides, based on other ON clause equality predicates.

Interpolated values come from the table that contains the null, not from the other table.

Vertica does not guarantee that there will be no null values in the output. If there is no previous value for a mismatched row, that row will be padded with nulls.

Event series join requires that both tables be sorted on columns in equality predicates, in any order, followed by the INTERPOLATED column. If data is already sorted in this order, then an explicit sort is avoided, which can improve query performance. For example, given the following tables:

```
ask: exchange, stock, ts, price
bid: exchange, stock, ts, price
```

In the query that follows

- ask is sorted on exchange, stock (or the reverse), ts
- bid is sorted on exchange, stock (or the reverse), ts

```
SELECT ask.price - bid.price, ask.ts, ask.stock, ask.exchange
FROM ask FULL OUTER JOIN bid
ON ask.stock = bid.stock AND ask.exchange = bid.exchange AND ask.ts INTERPOLATE PREVIOUS VALUE bid.ts;
```

**Restrictions**

- Only one INTERPOLATE expression is allowed per join.
- INTERPOLATE expressions are used only with ANSI SQL-99 syntax (the ON clause), which is already true for full outer joins.
- INTERPOLATE can be used with equality predicates only.
- The AND operator is supported but not the OR and NOT operators.
- Expressions and implicit or explicit casts are not supported, but subqueries are allowed.

**Example**

The examples that follow use this simple schema.
CREATE TABLE t(x TIME);
CREATE TABLE t1(y TIME);
INSERT INTO t VALUES('12:40:23');
INSERT INTO t VALUES('14:40:25');
INSERT INTO t VALUES('14:45:00');
INSERT INTO t VALUES('14:49:55');
INSERT INTO t1 VALUES('12:40:23');
INSERT INTO t1 VALUES('14:00:00');
COMMIT;

Normal Full Outer Join

=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x = t1.y;

Notice the null rows from the non-preserved table:

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:40:23</td>
<td>12:40:23</td>
</tr>
<tr>
<td>14:40:25</td>
<td></td>
</tr>
<tr>
<td>14:45:00</td>
<td></td>
</tr>
<tr>
<td>14:49:55</td>
<td></td>
</tr>
<tr>
<td></td>
<td>14:00:00</td>
</tr>
</tbody>
</table>

(5 rows)

Full Outer Join with Interpolation

=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;

In this case, the rows with no entry point are padded with values from the previous row.

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:40:23</td>
<td>12:40:23</td>
</tr>
<tr>
<td>12:40:23</td>
<td>14:00:00</td>
</tr>
<tr>
<td>14:40:25</td>
<td>14:00:00</td>
</tr>
<tr>
<td>14:45:00</td>
<td>14:00:00</td>
</tr>
<tr>
<td>14:49:55</td>
<td>14:00:00</td>
</tr>
</tbody>
</table>

(5 rows)

Normal Left Outer Join

=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x = t1.y;

Again, there are nulls in the non-preserved table
Left Outer Join with Interpolation

```sql
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x INTERPOLATE
    PREVIOUS VALUE t1.y;
```

Nulls padded with interpolated values.

Inner Joins

For inner joins, there is no difference between a regular inner join and an event series inner join. Since null values are eliminated from the result set, there is nothing to interpolate.

A regular inner join returns only the single matching row at 12:40:23:

```sql
=> SELECT * FROM t INNER JOIN t1 ON t.x = t1.y;
```

An event series inner join finds the same single-matching row at 12:40:23:

```sql
=> SELECT * FROM t INNER JOIN t1 ON t.x INTERPOLATE
    PREVIOUS VALUE t1.y;
```
Semantics

When you write an event series join in place of normal join, values are evaluated as follows (using the schema in the above examples):

- \( t \) is the outer, preserved table
- \( t1 \) is the inner, non-preserved table
- For each row in outer table \( t \), the ON clause predicates are evaluated for each combination of each row in the inner table \( t1 \).
- If the ON clause predicates evaluate to true for any combination of rows, those combination rows are produced at the output.
- If the ON clause is false for all combinations, a single output row is produced with the values of the row from \( t \) along with the columns of \( t1 \) chosen from the row in \( t1 \) with the greatest \( t1.y \) value such that \( t1.y < t.x \); if no such row is found, pad with nulls.

Note:
\[ t \text{ LEFT OUTER JOIN} \ t1 \text{ is equivalent to} \ t1 \text{ RIGHT OUTER JOIN} \ t. \]

In the case of a full outer join, all values from both tables are preserved.

- Event Series Joins

Join predicate

Specifies the columns on which records from two or more tables are joined. You can connect multiple join predicates with logical operators AND, OR, and NOT.

Syntax

\[ \text{ON} \ \text{column-ref} = \text{column-ref} \ [\ \{\ AND \ | \ OR \ | \ NOT \}\ \text{column-ref} = \text{column-ref} \ ]\ldots \]
Parameters

| column-ref | Specifies a column in a queried table. For best performance, do not join on LONG VARBINARY and LONG VARCHAR columns. |

LIKE predicate

Retrieves rows where the string value of a column matches a specified pattern. The pattern can contain one or more wildcard characters.

Syntax

```
string-expression [ NOT ] { LIKE | ILIKE | LIKEB | ILIKEB } 'pattern' [ ESCAPE 'escape-character' ]
```

Parameters

<table>
<thead>
<tr>
<th>string-expression</th>
<th>The column values to search for pattern.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT</td>
<td>Returns true if LIKE returns false, and the reverse; equivalent to NOT string LIKE pattern.</td>
</tr>
<tr>
<td>pattern</td>
<td>Specifies what strings to match, typically containing one or both of the following wildcard characters:</td>
</tr>
<tr>
<td></td>
<td>• Underscore (_) matches any single character.</td>
</tr>
<tr>
<td></td>
<td>• Percent sign (%) matches any string of zero or more characters.</td>
</tr>
<tr>
<td>ESCAPE escape-character</td>
<td>Specifies an escape character, used in the to escape reserved characters underscore (_), percent (%), and the escape character itself. This is enforced only for non-default collations.</td>
</tr>
<tr>
<td></td>
<td>If you omit this parameter, you can use Vertica's default escape character, backslash (), which is valid for CHAR and VARCHAR strings.</td>
</tr>
</tbody>
</table>
Substitute Symbols

You can substitute the following symbols for LIKE and its variants:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Substitution</th>
</tr>
</thead>
<tbody>
<tr>
<td>~#</td>
<td>LIKEB</td>
</tr>
<tr>
<td>~~~</td>
<td>ILIKE</td>
</tr>
<tr>
<td>~#*</td>
<td>ILIKEB</td>
</tr>
<tr>
<td>!~~</td>
<td>NOT LIKE</td>
</tr>
<tr>
<td>!~#</td>
<td>NOT LIKEB</td>
</tr>
<tr>
<td>!~~*</td>
<td>NOT ILIKE</td>
</tr>
<tr>
<td>!~#*</td>
<td>NOT ILIKEB</td>
</tr>
</tbody>
</table>

Note: ESCAPE is not valid for the above symbols.

Pattern Matching

LIKE requires that the entire string expression match the pattern. To match a sequence of characters anywhere within a string, the pattern must start and end with a percent sign.

LIKE does not ignore trailing white space characters. If the data values to match end with an indeterminate amount of white space, append the wildcard character % to pattern.

LIKE Variants Compared

The LIKE predicate is compliant with the SQL standard. Vertica also supports several non-standard variants, notably ILIKE, which is equivalent to LIKE except it performs case-insensitive searches. The following differences pertain to LIKE and its variants:
• LIKE operates on UTF-8 character strings. Exact behavior depends on collation parameters such as strength. In particular, ILIKE works by setting S=2 (ignore case) in the current session locale.
• LIKE and ILIKE are stable for character strings, but immutable for binary strings, while LIKEB and ILIKEB are immutable for both cases.
• LIKEB and ILIKEB predicates do byte-at-a-time ASCII comparisons.

Locale Dependencies

In the default locale, LIKE and ILIKE handle UTF-8 character-at-a-time, locale-insensitive comparisons. ILIKE handles language-independent case-folding.

In non-default locales, LIKE and ILIKE perform locale-sensitive string comparisons, including some automatic normalization, using the same algorithm as the "=" operator on VARCHAR types.

ESCAPE expressions evaluate to exactly one octet—or one UTF-8 character for non-default locales.

Examples

The following example illustrates pattern matching in locales.

```
\locale default=> CREATE TABLE src(c1 VARCHAR(100));
=> INSERT INTO src VALUES (U8'\00DF'); --The sharp s (ß)
=> INSERT INTO src VALUES ('ss');
=> COMMIT;
```

Querying the src table in the default locale returns both ss and sharp s.

```
=> SELECT * FROM src;
c1
----
ß
ss
(2 rows)
```

The following query combines pattern-matching predicates to return the results from column c1:

```
=> SELECT c1, c1 = 'ss' AS equality, c1 LIKE 'ss'
   AS LIKE, c1 ILIKE 'ss' AS ILIKE FROM src;
c1 | equality | LIKE | ILIKE
----|----------|------|-------
ß  | f        | f    | f
```
The next query specifies unicode format for c1:

```sql
=> SELECT c1, c1 = U'\00DF' AS equality, 
c1 LIKE U'\00DF' AS LIKE, 
c1 ILIKE U'\00DF' AS ILIKE from src;
```

<table>
<thead>
<tr>
<th>equality</th>
<th>LIKE</th>
<th>ILIKE</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
</tbody>
</table>

(2 rows)

Now change the locale to German with a strength of 1 (ignore case and accents):

```sql
\locale LDE_S1
=> SELECT c1, c1 = 'ss' AS equality, 
c1 LIKE 'ss' AS LIKE, c1 ILIKE 'ss' AS ILIKE from src;
```

<table>
<thead>
<tr>
<th>equality</th>
<th>LIKE</th>
<th>ILIKE</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>t</td>
<td>t</td>
<td>t</td>
</tr>
</tbody>
</table>

(2 rows)

This example illustrates binary data types with pattern-matching predicates:

```sql
=> CREATE TABLE t (c BINARY(1));
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
=> SELECT TO_HEX(c) from t;
```

<table>
<thead>
<tr>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
</tr>
</tbody>
</table>

(2 rows)

```sql
=> SELECT c, c = \000, c LIKE \000, c ILIKE \000 from t;
```

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>\000</td>
<td>t</td>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>\377</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
</tbody>
</table>

(2 rows)

```sql
=> SELECT c, c = '\377', c LIKE '\377', c ILIKE '\377' from t;
```

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>\000</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>\377</td>
<td>t</td>
<td>t</td>
<td>t</td>
</tr>
</tbody>
</table>

(2 rows)
NULL predicate

Tests for null values.

Syntax

\( value\_expression \) IS [ NOT ] NULL

Parameters

\begin{tabular}{|l|}
\hline
\( value\_expression \) & A column name, literal, or function.
\hline
\end{tabular}

Examples

Column name:

\[
\Rightarrow \text{SELECT date_key FROM date_dimension WHERE date_key IS NOT NULL;}
\]

\[
\begin{array}{l}
\text{date_key} \\
\hline
1 \\
366 \\
1462 \\
1097 \\
2 \\
3 \\
6 \\
7 \\
8 \\
\ldots
\end{array}
\]

Function:

\[
\Rightarrow \text{SELECT MAX(household_id) IS NULL FROM customer_dimension;}
\]

\[
\begin{array}{l}
\text{?column?} \\
\hline
f \\
\hline
(1 \text{ row})
\end{array}
\]

Literal:

\[
\Rightarrow \text{SELECT 'a' IS NOT NULL;}
\]

\[
\begin{array}{l}
\text{?column?} \\
\hline
\end{array}
\]
Hints

Hints are directives that you embed within a query or directed query. They conform to the following syntax:

```sql
/*+ hint-name[, hint-name]... */
```

Hints are bracketed by comment characters /*+ and *//, which can enclose multiple comma-delimited hints. For example:

```sql
/*+ DIRECT, LABEL(myLabel) */
```

Restrictions

When embedding hints, be aware of the following restrictions:

- Do not embed spaces in the comment characters /* and */.
- In general, spaces are allowed before and after the plus (+) character and `hint-name`; however, some third-party tools do not support spaces embedded inside /*+.

Supported Hints

Vertica supports the following hints:

<table>
<thead>
<tr>
<th>General hints</th>
<th>ALLNODES</th>
<th>Qualifies an EXPLAIN statement to request a query plan that assumes all nodes are active.</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO</td>
<td></td>
<td>Specifies to initially load table data into WOS. This hint overrides the table's</td>
</tr>
<tr>
<td>Setting</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td><strong>load method.</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>DEPOT_FETCH</strong></td>
<td>Specifies whether a query fetches data to the depot from communal storage when the depot lacks data for this query.</td>
<td></td>
</tr>
<tr>
<td><strong>EARLY_MATERIALIZATION</strong></td>
<td>Specifies early materialization of a table for the current query.</td>
<td></td>
</tr>
<tr>
<td><strong>ENABLE_WITH_CLAUSE_MATERIALIZATION</strong></td>
<td>Enables and disables WITH clause materialization for a specific query.</td>
<td></td>
</tr>
<tr>
<td><strong>DIRECT</strong></td>
<td>Specifies to write data directly to disk (ROS); valid only for <code>CREATE [TEMPORARY] TABLE AS, INSERT, MERGE, and UPDATE</code> operations.</td>
<td></td>
</tr>
<tr>
<td><strong>LABEL</strong></td>
<td>Labels a query so you can identify it for profiling and debugging.</td>
<td></td>
</tr>
<tr>
<td><strong>SKIP_STATISTICS</strong></td>
<td>Directs the optimizer to produce a query plan that incorporates only minimal statistics.</td>
<td></td>
</tr>
<tr>
<td><strong>TRICKLE</strong></td>
<td>Specifies to load data only into WOS.</td>
<td></td>
</tr>
<tr>
<td><strong>Join hints</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>SYNTACTIC_JOIN</strong></td>
<td>Enforces join order and enables other join hints.</td>
<td></td>
</tr>
<tr>
<td><strong>DISTRIB</strong></td>
<td>Sets the input operations for a distributed join to broadcast, resegment,</td>
<td></td>
</tr>
</tbody>
</table>

**Join hints**

- **SYNTACTIC_JOIN**: Enforces join order and enables other join hints.
- **DISTRIB**: Sets the input operations for a distributed join to broadcast, resegment,
<table>
<thead>
<tr>
<th>Table hints</th>
<th>PROJS</th>
<th>Specifies one or more projections to use for a queried table.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>SKIP_PROJS</td>
<td>Specifies which projections to avoid using for a queried table.</td>
</tr>
<tr>
<td>Directed query hints</td>
<td>IGNORECONST</td>
<td>Maps an input query constant to one or more annotated query constants.</td>
</tr>
<tr>
<td></td>
<td>VERBATIM</td>
<td>Enforces execution of an annotated query exactly as written.</td>
</tr>
</tbody>
</table>

**ALLNODES**

Qualifies an EXPLAIN statement to request a query plan that assumes all nodes are active. If you omit this hint, the EXPLAIN statement produces a query plan that takes into account any nodes that are currently down.
Syntax

```sql
EXPLAIN /*+ ALLNODES */ ...
```

Examples

In the following example, the ALLNODES hint requests a query plan that assumes all nodes are active.

```
QUERY PLAN DESCRIPTION:
------------------------
Opt Vertica Options
------------------------
PLAN_ALL_NODES_ACTIVE

EXPLAIN /*+ALLNODES*/ select * from Emp_Dimension;

Access Path:
+STORAGE ACCESS for Emp_Dimension [Cost: 125, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
 | Projection: public.Emp_Dimension_b0
 | Execute on: All Nodes
```

AUTO

**Note:**

For databases created in Vertica releases ≥ 9.3, Vertica ignores load options and hints and defaults to a load method of DIRECT. You can configure this behavior with configuration parameter `DMLTargetDirect`.

In databases created in versions of Vertica prior to 9.3, AUTO loads table data initially into WOS until the space budgeted for the load is exceeded. Then the load switches and writes the remainder of the data to ROS. This hint overrides the table's load method.

The following statements support this hint:

- INSERT
- MERGE
• UPDATE
• CREATE [TEMPORARY] TABLE AS

For details, see Choosing a Load Method in the Administrator's Guide.

Syntax

statement-name /*+ AUTO */ ...

DEPOT_FETCH

Specifies whether a query fetches data to the depot from communal storage when the depot lacks data for this query. This hint overrides configuration parameter DepotOperationsForQuery. It is valid only for Eon mode, otherwise ignored.

Syntax

SELECT /*+ DEPOT_FETCH (option)*/ ...

Arguments

<table>
<thead>
<tr>
<th>option</th>
<th>Specifies behavior when the depot does not contain queried file data, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• ALL: Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.</td>
</tr>
<tr>
<td></td>
<td>• FETCHES: Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.</td>
</tr>
<tr>
<td></td>
<td>• NONE: Do not fetch file data to the depot, read the queried data directly from communal storage.</td>
</tr>
</tbody>
</table>
Examples

SELECT /*+DEPOT_FETCH(ALL)*/ count(*) FROM bar;
SELECT /*+DEPOT_FETCH(FETCHES)*/ count(*) FROM bar;
SELECT /*+DEPOT_FETCH(NULL)*/ count(*) FROM bar;

DIRECT

Note:
For databases created in Vertica releases ≥ 9.3, Vertica ignores load options and hints and defaults to a load method of DIRECT. You can configure this behavior with configuration parameter DMLTargetDirect.

Specifies to bypass memory (WOS) and write table data directly to disk (ROS).

The following statements support this hint:

- DELETE
- EXPORT TO VERTICA
- INSERT
- MERGE
- UPDATE
- CREATE [TEMPORARY] TABLE AS

For details, see Choosing a Load Method in the Administrator's Guide.

Syntax

`statement-name /*+ DIRECT */ ...`

Examples

The following CREATE statement's AS clause contains the load method hint /*+DIRECT*/ , which specifies to load the data queried from test_table1 into ROS:

```
=> SELECT * FROM test_table1;
  col1 | col2 | col3
----------
  4     5     6
```
CREATE TABLE test_table2 DIRECT AS SELECT /*+DIRECT*/ * FROM test_table1;
CREATE TABLE
SELECT EXPORT_TABLES ('','bar');
EXPORT_TABLES
CREATE TABLE public.test_table2
(
    col1 int,
    col2 int,
    col3 int )
DIRECT ;
(1 row)

DISTRIB

Specifies to the optimizer how to distribute join key data to implement a join.

Syntax

...JOIN /*+ DISTRIB(outer-join, inner-join) */

Arguments

<table>
<thead>
<tr>
<th>outer-join</th>
<th>inner-join</th>
<th>Specifies how to distribute data on the outer and inner joins:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• L (local): Inner and outer join keys are identically segmented on each node, join locally.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• R (resegment): Inner and outer join keys are not identically segmented. Resegment join-key data before implementing the join.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• B (broadcast): Inner and outer join keys are not identically segmented. Broadcast data of this join key to other nodes before implementing the join.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• F (filter): Join table is unsegmented. Filter data as needed by the other join key before implementing the join.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A (any): Let the optimizer choose the distribution method that it considers to be most cost-effective.</td>
</tr>
</tbody>
</table>
**Description**

The DISTRIB hint specifies to the optimizer how to distribute join key data in order to implement a join. If a specified distribution is not feasible, the optimizer ignores the hint and throws a warning.

The following requirements apply:

- Queries that include the DISTRIB hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the DISTRIB hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

**Examples**

In the following query, the join is qualified with a DISTRIB hint of /*+ DISTRIB(L,R)*/. This hint tells the optimizer to resegment data of join key stores.store_key before joining it to the sales.store_key data:

```sql
SELECT /*+ SYNTACTIC_JOIN */ sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date
FROM (store.storeSales AS sales JOIN /*+DISTRIB(L,R),JTYPE(H)*/ store.store_dimension AS stores ON (sales.store_key = stores.store_key))
WHERE (sales.sale_date = '2014-12-01'::date) ORDER BY sales.store_key, sales.sale_date;
```

**EARLY_MATERIALIZATION**

Specifies early materialization of a table for the current query. A query can include this hint for any number of tables. Typically, the query optimizer delays materialization until late in the query execution process. This hint overrides any choices that the optimizer otherwise would make.

This hint can be useful in cases where late materialization of join inputs precludes other optimizations—for example, pushing aggregation down the joins, or using live aggregate projections. In these cases, qualifying a join input with EARLY_MATERIALIZATION can enable the optimizations.

**Syntax**

```
table-name [ [AS] alias ] /*+ EARLY_MATERIALIZATION */
```
**ENABLE_WITH_CLAUSE_MATERIALIZATION**

Enables materialization of all queries in the current WITH clause. Otherwise, materialization is set by configuration parameter WithClauseMaterialization, by default set to 0 (disabled). If WithClauseMaterialization is disabled, materialization is automatically cleared when the primary query of the WITH clause returns. For details, see Materialization of WITH Clause.

**Syntax**

```sql
WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION*/
```

**GBYTYPE**

Specifies which algorithm—GROUPBY HASH or GROUPBY PIPELINED—the Vertica query optimizer should use to implement a GROUP BY clause. If both algorithms are valid for this query, the query optimizer chooses the specified algorithm over the algorithm that the query optimizer might otherwise choose in its query plan.

**Syntax**

```sql
...GROUP BY /*+ GBYTYPE( HASH | PIPE ) */
```

**Arguments**

<table>
<thead>
<tr>
<th>HASH</th>
<th>PIPE</th>
<th>Specifies the GROUP BY algorithm to use:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• HASH: GROUPBY HASH algorithm</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PIPE: GROUPBY PIPELINED algorithm</td>
</tr>
</tbody>
</table>

**Note:**

Vertica uses the GROUPBY PIPELINED algorithm only if the query and one of its projections comply with GROUP BY PIPELINED requirements. Otherwise, Vertica issues a warning and uses GROUPBY HASH.
For more information about both algorithms, see GROUP BY Implementation Options.

**Examples**

See Controlling GROUPBY Algorithm Choice in Analyzing Data.

**IGNORECONST**

In a directed query, maps an input query constant to one or more annotated query constants.

IGNORECONST lets you create directed queries that support input queries with various conditions. IGNORECONST requires an integer argument. This argument matches constants in input and annotated queries that you want the optimizer to ignore.

For details, see Ignoring Constants in Directed Queries in the Administrator's Guide.

**Syntax**

```sql
/*+ IGNORECONST(arg) */
```

**Examples**

In the following example a directed query is created where input and annotated queries set IGNORECONST hints on Employee_city and Employee_position:

```sql
=> SAVE QUERY SELECT Employee_first_name, Employee_last_name FROM EMP_Dimension
  WHERE Employee_city='somewhere'/*+IGNORECONST(1)*/
  AND Employee_position='somejob' /*+IGNORECONST(2)*/;
SAVE QUERY

=> CREATE DIRECTED QUERY CUSTOM 'findEmployees' SELECT Employee_first_name, Employee_last_name FROM
  EMP_Dimension /*+projs('public.Emp_Dimension_Unseg')*/
  WHERE Employee_city='somewhere'/*+IGNORECONST(1)*/
  AND Employee_position='somejob'/*+IGNORECONST(2)*/;
CREATE DIRECTED QUERY

IGNORECONST pairs two sets of constants:
• IGNORECONST(1) pairs input and annotated query settings for Employee_city.
• IGNORECONST(2) pairs input and annotated query settings for Employee_position.

**JFMT**

Specifies how to size VARCHAR column data when joining tables on those columns, and buffer that data accordingly. The JFMT hint overrides the default behavior that is set by configuration parameter [JoinDefaultTupleFormat](https://www.vertica.com/docs/9.3.x/EN-C17638/vdm/reference-manual/tables/JoinDefaultTupleFormat.html), which can be set at database and session levels.

For more information, see [Joining Variable Length String Data](https://www.vertica.com/docs/9.3.x/EN-C17638/vdm/reference-manual/tables/JoiningVariableLengthStringData.html).

**Syntax**

```sql
...JOIN /*+ JFMT(format-type) */
```

**Arguments**

<table>
<thead>
<tr>
<th>format-type</th>
<th>Specifies how to format VARCHAR column data when joining tables on those columns, and buffers the data accordingly. Set to one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>f (fixed)</td>
<td>Use join column metadata to size column data to a fixed length, and buffer accordingly.</td>
</tr>
<tr>
<td>v (variable)</td>
<td>Use the actual length of join column data, so buffer size varies for each join.</td>
</tr>
</tbody>
</table>

For example:

```sql
SELECT /*+ SYNTACTIC_JOIN */ s.store_region, SUM(e.vacation_days) TotalVacationDays
FROM public.employee_dimension e
JOIN /*+JFMT(f)*/ store.store_dimension s ON s.store_region=e.employee_region
GROUP BY s.store_region ORDER BY TotalVacationDays;
```
Requirements

- Queries that include the JFMT hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the JFMT hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

JTYPE

Specifies the join algorithm as hash or merge.

Use the JTYPE hint to specify the algorithm the optimizer uses to join table data. If specified algorithm is not feasible, the optimizer ignores the hint and throws a warning.

Syntax

```
...JOIN /*+ JTYPE(join-type) */
```

Arguments

<table>
<thead>
<tr>
<th>join-type</th>
<th>One of the following arguments:</th>
</tr>
</thead>
<tbody>
<tr>
<td>H</td>
<td>Hash join</td>
</tr>
<tr>
<td>M</td>
<td>Merge join, valid only if both join inputs are already sorted on the join columns, otherwise Vertica ignores it and throws a warning.</td>
</tr>
</tbody>
</table>

- FM: Forced merge join. Before performing the merge, the optimizer re-sorts the join inputs. Two restrictions apply:
  - This option is valid only for simple join conditions. For example:

```
SELECT /*+ SYNTACTIC_JOIN*/ * FROM x JOIN /*+JTYPE(FM)*/ y ON x.c1 = y.c1;
```
• Join columns must be of the same type and precision or scale. One exception applies: string columns can have different lengths.

**Requirements**

- Queries that include the JTYPE hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the JTYPE hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

**LABEL**

Assigns a label to a statement in order to identify it for profiling and debugging.

LABEL hints are valid in the following statements:

- DELETE
- INSERT
- MERGE
- SELECT
- UPDATE
- UNION: Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

**Syntax**

```
statement-name /*+ LABEL (label-string) */
```

**Arguments**

| label-string | A string that is up to 128 octets long. If enclosed with single quotes, label-string can contain embedded spaces. |

**Examples**

See Labeling Queries in the Administrator's Guide.
**PROJS**

Specifies one or more projections to use for a queried table.

**Syntax**

```sql
...FROM table-name /*+ PROJS( [[database.]schema.]projection[,...] ) */
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[database.]schema</code></td>
<td>Specifies a schema, by default public. If <code>schema</code> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td><code>projection</code></td>
<td>The projection to use. You can specify a list of comma-delimited projections.</td>
</tr>
</tbody>
</table>

**Description**

The PROJS hint can specify multiple projections; the optimizer determines which ones are valid and uses the one that is most cost-effective for the queried table. If no hinted projection is valid, the query returns a warning and ignores projection hints.

**Examples**

The following query includes a PROJS hint that specifies two projections:

```sql
=> EXPLAIN SELECT * FROM Emp_Dimension /*+PROJS('public.Emp_Dimension_Unseg', 'public.Emp_Dimension')*/;
```

The first projection `public.Emp_Dimension_Unseg` does not include all columns in the queried table `Emp_Dimension`, so the optimizer cannot use it. The second projection includes all table columns so the optimizer uses it, as verified by the following query plan:
**QUERY PLAN DESCRIPTION:**

```
explain SELECT * FROM Emp_Dimension /*+PROJS('public.Emp_Dimension_Unseg', 'public.Emp_Dimension')*/;
```

**Access Path:**

```
+-STORAGE ACCESS for Emp_Dimension [Cost: 125, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
    |  Projection: public.Emp_Dimension_b0
```

---

**SKIP_PROJS**

Specifies which projections to avoid using for a queried table.

**Syntax**

```
...FROM table-name /*+ SKIP_PROJS( [[database.]schema.]projection[, ...] ) */
```

**Arguments**

<table>
<thead>
<tr>
<th>[database.]schema</th>
<th>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td>projection</td>
<td>A projection to skip. You can specify a list of comma-delimited projections.</td>
</tr>
</tbody>
</table>

**Description**

The SKIP_PROJS specifies one or more projections that the optimizer should avoid using. If the SKIP_PROJS hint excludes all available projections that are valid for the query, the optimizer issues a warning and ignores the projection hints.
Examples

In this example, the EXPLAIN output shows that the optimizer uses the projection `public.Emp_Dimension_b0` for a given query:

```
QUERY PLAN DESCRIPTION:
-------------------------
EXPLAIN SELECT Employee_last_name, Employee_first_name, Employee_city, Employee_position FROM Emp_Dimension;
Access Path:
  +--STORAGE ACCESS for Emp_Dimension [Cost: 59, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
    |   Projection: public.Emp_Dimension_b0
```

You can use the `SKIP_PROJS` hint to avoid using this projection. If another projection is available that is valid for this query, the optimizer uses it instead:

```
QUERY PLAN DESCRIPTION:
-------------------------
EXPLAIN SELECT Employee_last_name, Employee_first_name, Employee_city, Employee_position FROM Emp_Dimension /*+SKIP_PROJS('public.Emp_Dimension')*/;
Access Path:
  +--STORAGE ACCESS for Emp_Dimension [Cost: 152, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
    |   Projection: public.Emp_Dimension_Unseg
```

**SKIP_STATISTICS**

Directs the optimizer to produce a query plan that incorporates only the minimal statistics that are collected by `ANALYZE_ROW_COUNT`. The optimizer ignores other statistics that would otherwise be used, that are generated by `ANALYZE_STATISTICS` and `ANALYZE_STATISTICS_PARTITION`. This hint is especially useful when used in queries on small tables, where the amount of time required to collect full statistics is often greater than actual execution time.

**Syntax**

```
SELECT /*+ SKIP_STATISTICS */ ...
```
EXPLAIN Output

EXPLAIN returns the following output for a query that includes SKIP_STATISTICS (using its shortened form SKIP_STATS):

```sql
=> EXPLAIN SELECT /*+ SKIP_STATS*/ customer_key, customer_name, customer_gender, customer_city||',
   '||customer_state, customer_age
   FROM customer_dimension WHERE customer_region = 'East' AND customer_age > 60;
```

**QUERY PLAN DESCRIPTION:**
```
EXPLAIN SELECT /*+ SKIP_STATS*/ customer_key, customer_name, customer_gender, customer_city||',
   '||customer_state, customer_age FROM customer_dimension WHERE customer_region = 'East' AND customer_age > 60;
```

**Access Path:**
```
+--STORAGE ACCESS for customer_dimension [Cost: 2K, Rows: 10K (STATISTICS SKIPPED)] (PATH ID: 1)
   | Project: public.customer_dimension_b0
   | Materialize: public.customer_dimension.customer_age, public.customer_dimension.customer_key,
   | public.customer_dimensi
   | on. customer_name, public.customer_dimension.customer_gender, public.customer_dimension.customer_city,
   | public.customer_di
   | mension.customer_state
   | Filter: (public.customer_dimension.customer_region = 'East')
   | Filter: (public.customer_dimension.customer_age > 60)
   | Execute on: All Nodes
```

SYNTACTIC_JOIN

Enforces join order and enables other join hints.

Syntax

```sql
SELECT /*+ SYNTACTIC_JOIN */ _
```

**Description**

In order to achieve optimal performance, the optimizer often overrides a query's specified join order. By including the SYNTACTIC_JOIN hint, you can ensure that the optimizer enforces the query's join order exactly as specified. One requirement applies: the join syntax must conform with ANSI SQL-92 conventions.
The SYNTACTIC_Join hint must immediately follow SELECT. If the annotated query includes another hint that must also follow SELECT, such as VERBATIM, combine the two hints together. For example:

```
SELECT /*+ syntactic_join,verbatim */ ... 
```

### Examples

In the following examples, the optimizer produces different plans for two queries that differ only by including or excluding the SYNTACTIC_Join hint.

#### Excludes SYNTACTIC_Join

```
EXPLAIN SELECT sales.store_key, stores.store_name, products.product_description, sales.sales_quantity, sales.sale_date
FROM (store.store_sales JOIN products ON sales.product_key = products.product_key)
JOIN store.store_dimension stores ON sales.store_key = stores.store_key
WHERE sales.sale_date = '2014-12-01' order by sales.store_key, sales.sale_date;
```

Access Path:

\(+\)-SORT [Cost: 14K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
  | Order: sales.store_key ASC, sales.sale_date ASC
  | Execute on: All Nodes
  | ----> JOIN HASH [Cost: 11K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND ROBIN) Inner (RESEGMENT)
  | | Join Cond: (sales.product_key = products.product_key)
  | | | Materialize at Input: sales.store_key, sales.product_key, sales_sale_date, sales.sales_quantity
  | | | Execute on: All Nodes
  | | | ----> Outer \(-\) JOIN HASH [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
  | | | | Join Cond: (sales.store_key = stores.store_key)
  | | | | Execute on: All Nodes
  | | | | ----> Outer \(-\) STORAGE ACCESS for sales [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
  | | | | | Projection: store.store_sales_b0
  | | | | | Materialize: sales.store_key
  | | | | | Filter: (sales.sale_date = '2014-12-01':date)
  | | | | | Execute on: All Nodes
  | | | | | Runtime Filter: (SIP1(HashJoin): sales.store_key)
  | | | | | ----> Inner \(-\) STORAGE ACCESS for stores [Cost: 34, Rows: 250] (PATH ID: 5)
  | | | | | | Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
  | | | | | | Materialize: stores.store_key, stores.store_name
  | | | | | | Execute on: All Nodes

  |  |  |  |  Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
  |  |  |  |  Materialize: stores.store_key, stores.store_name
  |  |  |  |  Execute on: All Nodes

TRICKLE

Note:
For databases created in Vertica releases ≥ 9.3, Vertica ignores load options and hints and defaults to a load method of DIRECT. You can configure this behavior with configuration parameter DMLTargetDirect.

In databases created in versions of Vertica prior to 9.3, TRICKLE loads data only into WOS. This hint overrides the table's load method.

The following statements support this hint:

- INSERT
- MERGE
- UPDATE
- CREATE [TEMPORARY] TABLE AS

For details, see Choosing a Load Method in the Administrator's Guide.
**Syntax**

```
statement-name /*+ TRICKLE */ ...
```

**UTYPE**

Specifies how to combine `UNION ALL` input.

**Syntax**

```
...UNION ALL /*+ UTYPE(union-type) */
```

**Arguments**

<table>
<thead>
<tr>
<th><code>union-type</code></th>
<th>One of the following arguments:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• U: Concatenates <code>UNION ALL</code> input (default).</td>
</tr>
<tr>
<td></td>
<td>• M: Merges <code>UNION ALL</code> input in the same sort order as the source query results. This option requires all input from the source queries to use the same sort order; otherwise, Vertica throws a warning and concatenates the <code>UNION ALL</code> input.</td>
</tr>
</tbody>
</table>

**Note:**
The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.

**Requirements**

Queries that include the UTYPE hint must also include the SYNTACTIC_Join hint. Otherwise, the optimizer ignores the UTYPE hint and throws a warning.

**VERBATIM**

Enforces execution of an annotated query exactly as written.
VERBATIM directs the optimizer to create a query plan that incorporates all hints in a annotated query. Furthermore, it directs the optimizer not to apply its own plan development processing on query plan components that pertain to those hints.

Usage of this hint varies between optimizer-generated and custom directed queries, as described below.

**Syntax**

```sql
SELECT /*+ VERBATIM */ ...
```

**Requirements**

The VERBATIM hint must immediately follow SELECT. If the annotated query includes another hint that must also follow SELECT, such as SYNTACTIC_JOIN, combine the two hints together. For example:

```sql
SELECT /*+ syntactic_join,verbatim */ ...
```

**Optimizer-Generated Directed Queries**

The optimizer always includes the VERBATIM hint in the annotated queries that it generates for directed queries. For example, given the following CREATE DIRECTED QUERY OPTIMIZER statement:

```sql
CREATE DIRECTED QUERY OPTIMIZER getStoreSales
SELECT sales.store_key, stores.store_name,
sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storeSales sales
JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-01' /*+IGNORECONST(1)*/ AND stores.store_name='Store1' /*+IGNORECONST(2)*/ ORDER BY sales.store_key, sales.sale_date;
CREATE DIRECTED QUERY
```

The optimizer generates an annotated query that includes the VERBATIM hint:

```sql
=> SELECT query_name, annotated_query FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name = 'getStoreSales';
-[ RECORD 1 ]----------
query_name | getStoreSales
annotated_query | SELECT /*+ syntactic_join,verbatim */ sales.store_key AS store_key, stores.store_name AS store_name, sales.product_description AS product_description, sales.sales_quantity AS sales_quantity, sales.sale_date AS sale_date
FROM (store.storeSales AS sales/*+projs('store.storeSales')*/ JOIN /*+Distrib(L,L),JType(H)*/ store.store_dimension AS stores/*+projs('store.store_dimension_DBD_10_rep_VMartDesign')*/ ON (sales.store_key = stores.store_key))
WHERE (sales.sale_date = '2014-12-01':date /*+IgnoreConst(1)*/) AND (stores.store_name =
```

Vertica Analytic Database (9.3.x)
When the optimizer uses this directed query, it produces a query plan that is equivalent to the query plan that it used when it created the directed query:

```sql
=> ACTIVATE DIRECTED QUERY getStoreSales;
ACTIVATE DIRECTED QUERY

=> EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key = stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;

QUERY PLAN DESCRIPTION:
---------------------------
EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key = stores.store_key WHERE sales_sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;

The following active directed query(query name: getStoreSales) is being executed:
SELECT /*+syntactic_join,verbatim*/ sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales/*+projs('store.storeSales')*/ JOIN /*+Distrib('L', 'L'), JType ('H')*/store.store_dimension stores /*+projs('store.store_dimension_DBD_10_rep_VMartDesign')*/ ON ((sales.store_key = stores.store_key)) WHERE ((sales_sale_date = '2014-12-04':::date) AND (stores.store_name = 'Store14':::varchar(7))) ORDER BY sales.store_key, sales.sale_date;

Access Path:
+--JOIN HASH [Cost: 463, Rows: 622 (NO STATISTICS)] (PATH ID: 2)
  | Join Cond: (sales.store_key = stores.store_key)
  | Materialize at Output: sales.sale_date, sales.sales_quantity, sales.product_description
  | Execute on: All Nodes
  | -- Outer --> STORAGE ACCESS for sales [Cost: 150, Rows: 155K (NO STATISTICS)] (PATH ID: 3)
  |   | Projection: store.storeSales_b0
  |   | Materialize: sales.store_key
  |   | Filter: (sales.sale_date = '2014-12-04':::date)
  |   | Execute on: All Nodes
  |   | Runtime Filter: (SIP1(HashJoin): sales.store_key)
  | -- Inner --> STORAGE ACCESS for stores [Cost: 35, Rows: 2] (PATH ID: 4)
  |   | Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
  |   | Materialize: stores.store_name, stores.store_key
  |   | Filter: (stores.store_name = 'Store14')
  |   | Execute on: All Nodes
```

## Custom Directed Queries

The VERBATIM hint is included in a custom directed query only if you explicitly include it in the annotated query that you write for that directed query. When the optimizer uses that directed query, it respects the VERBATIM hint and creates a query plan accordingly.
If you omit the VERBATIM hint when you create a custom directed query, the hint is not stored with the annotated query. When the optimizer uses that directed query, it applies its own plan development processing on the annotated query before it generates a query plan. This query plan might not be equivalent to the query plan that the optimizer would have generated for the Vertica version in which the directed query was created.

**SQL Data Types**

The following table summarizes the internal data types that Vertica supports. It also shows the default placement of null values in projections. The Size column lists uncompressed bytes.

External tables also support the **ROW**, which cannot be used for Vertica-managed tables.

<table>
<thead>
<tr>
<th>Data Type</th>

</table>

## Binary Data Types

Store raw-byte data, such as IP addresses, up to 65000 bytes. Data types BINARY and BINARY VARYING (VARBINARY) are collectively referred to as binary string types and the values of binary string types are referred to as binary strings. A binary string is a sequence of octets or bytes.

### Note:

BYTEA and RAW are synonyms for VARBINARY.

## Syntax

**BINARY**

BINARY ( Length )
VARBINARY

{ VARBINARY | BINARY VARYING | BYTEA | RAW } ( max-Length )

Parameters

| Length | max-Length | Specifies the length of the string or column width, in bytes (octets). |

BINARY and VARBINARY Data Types

BINARY and VARBINARY data types have the following attributes:

- **BINARY**: A fixed-width string of length bytes, where the number of bytes is declared as an optional specifier to the type. If length is omitted, the default is 1. Where necessary, values are right-extended to the full width of the column with the zero byte. For example:

  ```sql
  => SELECT TO_HEX('ab'::BINARY(4));
  to_hex
  ----------
  61620000
  ```

- **VARBINARY**: A variable-width string up to a length of max-length bytes, where the maximum number of bytes is declared as an optional specifier to the type. The default is the default attribute size, which is 80, and the maximum length is 65000 bytes. VARBINARY values are not extended to the full width of the column. For example:

  ```sql
  => SELECT TO_HEX('ab'::VARBINARY(4));
  to_hex
  -------
  6162
  ```

Input Formats

You can use several formats when working with binary values. The hexadecimal format is generally the most straightforward and is emphasized in Vertica documentation.

Binary values can also be represented in octal format by prefixing the value with a backslash '\'.

```sql
=> SELECT TO_HEX('ab'::BINARY(4));
```
Note:
If you use vsql, you must use the escape character (\) when you insert another backslash on input; for example, input '\141' as '\\141'.

You can also input values represented by printable characters. For example, the hexadecimal value '0x61' can also be represented by the symbol 'a'.

See Bulk-Loading Data in the Administrator's Guide.

On input, strings are translated from:

- Hexadecimal representation to a binary value using the function HEX_TO_BINARY.
- Bitstring representation to a binary value using the function BITSTRING_TO_BINARY.

Both functions take a VARCHAR argument and return a VARBINARY value.

Output Formats

Like the input format, the output format is a hybrid of octal codes and printable ASCII characters. A byte in the range of printable ASCII characters (the range [0x20, 0x7e]) is represented by the corresponding ASCII character, with the exception of the backslash (\), which is escaped as '\". All other byte values are represented by their corresponding octal values. For example, the bytes {97,92,98,99}, which in ASCII are {a,\b,c}, are translated to text as 'a\bc'.

Binary Operators and Functions

Binary operators &, ~, | and # have special behavior for binary data types, as described in Bitwise Operators.

The following aggregate functions are supported for binary data types:

- BIT_AND
- BIT_OR
- BIT_XOR
- MAX
- MIN

BIT_AND, BIT_OR, and BIT_XOR are bit-wise operations that are applied to each non-null value in a group, while MAX and MIN are byte-wise comparisons of binary values.

Like their binary operator counterparts, if the values in a group vary in length, the aggregate functions treat the values as though they are all equal in length by extending
shorter values with zero bytes to the full width of the column. For example, given a group containing the values 'ff', null, and 'f', a binary aggregate ignores the null value and treats the value 'f' as 'f0'. Also, like their binary operator counterparts, these aggregate functions operate on VARBINARY types explicitly and operate on BINARY types implicitly through casts. See Data Type Coercion Operators (CAST).

Binary Versus Character Data Types

Binary data types BINARY and VARBINARY are similar to character data types CHAR and VARCHAR, respectively. They differ as follows:

- Binary data types contain byte strings—a sequence of octets or bytes.
- Character data types contain character strings (text).
- The lengths of binary data types are measured in bytes, while character data types are measured in characters.

Examples

The following example shows VARBINARY HEX_TO_BINARY(VARCHAR) and VARCHAR TO_HEX(VARBINARY) usage.

Table t and its projection are created with binary columns:

```sql
=> CREATE TABLE t (c BINARY(1));
=> CREATE PROJECTION t_p (c) AS SELECT c FROM t;
```

Insert minimum byte and maximum byte values:

```sql
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
```

Binary values can then be formatted in hex on output using the TO_HEX function:

```sql
=> SELECT TO_HEX(c) FROM t;
to_hex
-------
00
ff
(2 rows)
```

The BIT_AND, BIT_OR, and BIT_XOR functions are interesting when operating on a group of values. For example, create a sample table and projections with binary columns:

The example that follows uses table t with a single column of VARBINARY data type:
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));

Query table t to see column c output:

=> SELECT TO_HEX(c) FROM t;
   TO_HEX
   --------
   ff00
   ffff
   f00f
   (3 rows)

Now issue the bitwise AND operation. Because these are aggregate functions, an implicit GROUP BY operation is performed on results using (ff00&ffff&f00f):

=> SELECT TO_HEX(BIT_AND(c)) FROM t;
   TO_HEX
   --------
   f000
   (1 row)

Issue the bitwise OR operation on (ff00|ffff|f00f):

=> SELECT TO_HEX(BIT_OR(c)) FROM t;
   TO_HEX
   --------
   ffff
   (1 row)

Issue the bitwise XOR operation on (ff00#ffff#f00f):

=> SELECT TO_HEX(BIT_XOR(c)) FROM t;
   TO_HEX
   --------
   f0f0
   (1 row)

Boolean Data Type

Vertica provides the standard SQL type BOOLEAN, which has two states: true and false. The third state in SQL boolean logic is unknown, which is represented by the NULL value.
**Syntax**

**BOOLEAN**

**Parameters**

Valid literal data values for input are:

<table>
<thead>
<tr>
<th>TRUE</th>
<th>'t'</th>
<th>'true'</th>
<th>'y'</th>
<th>'yes'</th>
<th>'1'</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>'f'</td>
<td>'false'</td>
<td>'n'</td>
<td>'no'</td>
<td>'0'</td>
<td>0</td>
</tr>
</tbody>
</table>

**Notes**

- Do not confuse the BOOLEAN data type with Boolean Operators or the Boolean predicate.
- The keywords TRUE and FALSE are preferred and are SQL-compliant.
- A Boolean value of NULL appears last (largest) in ascending order.
- All other values must be enclosed in single quotes.
- Boolean values are output using the letters t and f.

**See Also**

- **NULL Value**
- **Data Type Coercion Chart**

**Character Data Types**

Stores strings of letters, numbers, and symbols. Data types CHARACTER (CHAR) and CHARACTER VARYING (VARCHAR) are collectively referred to as **character string types**, and the values of character string types are known as **character strings**.

Character data can be stored as fixed-length or variable-length strings. Fixed-length strings are right-extended with spaces on output; variable-length strings are not extended.

String literals in SQL statements must be enclosed in single quotes.
Syntax

CHAR

{ CHAR | CHARACTER } [ (octet-length) ]

VARCHAR

{ VARCHAR | CHARACTER VARYING } ) [ (octet-length) ]

Parameters

<table>
<thead>
<tr>
<th>octet-Length</th>
<th>Specifies the length of the string or column width, declared in bytes (octets).</th>
</tr>
</thead>
<tbody>
<tr>

</table>

CHAR Versus VARCHAR Data Types

The following differences apply to CHAR and VARCHAR data:

- CHAR is conceptually a fixed-length, blank-padded string. Trailing blanks (spaces) are removed on input, and are restored on output. The default length is 1, and the maximum length is 65000 octets (bytes).
- VARCHAR is a variable-length character data type. The default length is 80, and the maximum length is 65000 octets. For string values longer than 65000, use Long Data Types. Values can include trailing spaces.

Normally, you use VARCHAR for all of string data. Use CHAR when you need fixed-width string output. For example, you can use CHAR columns for data to be transferred to a legacy system that requires fixed-width strings.

Setting Maximum Length

When you define character columns, specify the maximum size of any string to be stored in a column. For example, to store strings up to 24 octets in length, use one of the following definitions:
The maximum length parameter for VARCHAR and CHAR data types refers to the number of octets that can be stored in that field, not the number of characters (Unicode code points). When using multibyte UTF-8 characters, the fields must be sized to accommodate from 1 to 4 octets per character, depending on the data. If the data loaded into a VARCHAR/CHAR column exceeds the specified maximum size for that column, data is truncated on UTF-8 character boundaries to fit within the specified size. See COPY.

**Note:**
Remember to include the extra octets required for multibyte characters in the column-width declaration, keeping in mind the 65000 octet column-width limit.

Due to compression in Vertica, the cost of overestimating the length of these fields is incurred primarily at load time and during sorts.

## NULL Versus NUL

NULL and NUL differ as follows:

- NUL represents a character whose ASCII/Unicode code is 0, sometimes qualified "ASCII NUL".
- NULL means no value, and is true of a field (column) or constant, not of a character.

CHAR, LONG VARCHAR, and VARCHAR string data types accept ASCII NUL values.

NULL appears last (largest) in ascending order.

**Note:**
For additional information about NULL ordering, see NULL Sort Order.

The following example casts the input string containing NUL values to VARCHAR:

```sql
=> SELECT 'vert\0ica':CHARACTER VARYING AS VARCHAR;
VARCHAR
---------
vert\0ica
(1 row)
```

The result contains 9 characters:
If you use an extended string literal, the length is 8 characters:

```sql
=> SELECT LENGTH('vert\0ica'::CHARACTER VARYING);
   length
  --------
    9
(1 row)

=> SELECT E'vert\0ica'::CHARACTER VARYING AS VARCHAR;
   VARCHAR
  --------
   vertica
(1 row)

=> SELECT LENGTH(E'vert\0ica'::CHARACTER VARYING);
   length
  --------
    8
(1 row)
```
Date/Time Data Types

Vertica supports the full set of SQL date and time data types.

The following rules apply to all date/time data types:

- All have a size of 8 bytes.
- A date/time value of NULL is smallest relative to all other date/time values.
- Vertica uses Julian dates for all date/time calculations, which can correctly predict and calculate any date more recent than 4713 BC to far into the future, based on the assumption that the average length of the year is 365.2425 days.
- All the date/time data types accept the special literal value NOW to specify the current date and time. For example:

```sql
=> SELECT TIMESTAMP 'NOW';
```

```
2020-09-23 08:23:50.42325
```

- By default, Vertica rounds with a maximum precision of six decimal places. You can substitute an integer between 0 and 6 for p to specify your preferred level of precision.

The following table lists specific attributes of date/time data types:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>Dates only (no time of day)</td>
<td>~ 25e+15 BC</td>
<td>~ 25e+15 AD</td>
<td>1 day</td>
</tr>
<tr>
<td>TIME</td>
<td>Time of day only (no date)</td>

### Time Zone Abbreviations for Input

Vertica recognizes the files in /opt/vertica/share/timezonesets as date/time input values and defines the default list of strings accepted in the AT TIME ZONE zone parameter.
The names are not necessarily used for date/time output—output is driven by the official time zone abbreviations associated with the currently selected time zone parameter setting.

**DATE**

Consists of a month, day, and year.

**Syntax**

```sql
DATE
```

**Parameters/Limits**

<table>
<thead>
<tr>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>~ 25e+15 BC</td>
<td>~ 25e+15 AD</td>
<td>1 DAY</td>
</tr>
</tbody>
</table>

See [SET DATESTYLE](#) for information about ordering.

**Note:**

'0000-00-00' is not valid. If you try to insert that value into a DATE or TIMESTAMP field, an error occurs. If you copy '0000-00-00' into a DATE or TIMESTAMP field, Vertica converts the value to 0001-01-01 00:00:00 BC.

<table>

</tbody>
</table>

**DATETIME**

DATETIME is an alias for `TIMESTAMP/TIMESTAMPZ`.

**INTERVAL**

Measures the difference between two points in time. Intervals can be positive or negative. The INTERVAL data type is SQL:2008 compliant, and supports `interval qualifiers` that are divided into two major subtypes:

- **Year-month**: Span of years and months
- **Day-time**: Span of days, hours, minutes, seconds, and fractional seconds

Intervals are represented internally as some number of microseconds and printed as up to 60 seconds, 60 minutes, 24 hours, 30 days, 12 months, and as many years as necessary. You can control the output format of interval units with `SET INTERVALSTYLE` and `SET DATESTYLE`. 
Syntax

INTERVAL 'interval-literal' [ interval-qualifier ] [ (p) ]

Parameters

<table>
<thead>
<tr>
<th>interval-literal</th>
<th>A character string that expresses an interval, conforming to this format:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>[-] { quantity subtype-unit }[...] [ AGO ]</td>
</tr>
<tr>
<td></td>
<td>For details, see Interval Literal.</td>
</tr>
</tbody>
</table>

| interval-qualifier    | Optionally specifies how to interpret and format an interval literal for output, and, optionally, sets precision. If omitted, the default is DAY TO SECOND(6). For details, see Day-time interval qualifiers. |

| p                     | Specifies precision of the seconds field, where p is an integer between 0 - 6. For details, see Specifying Interval Precision. |
|                       | Default: 6                                                               |

Limits

<table>
<thead>
<tr>
<th>Name</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTERVAL DAY TO SECOND(15)</td>
<td>0106751991 days 00:00:00</td>
<td>04:00:54.775807</td>
<td>1 microsecond</td>
</tr>
<tr>
<td>INTERVAL YEAR TO MONTH</td>
<td>-768e15 yrs</td>
<td>~ 768e15 yrs</td>
<td>1 month</td>
</tr>
</tbody>
</table>

Setting Interval Unit Display

SET INTERVALSTYLE and SET DATESTYLE control the output format of interval units.
Important:
DATESTYLE settings supersede INTERVALSTYLE. If DATESTYLE is set to SQL, interval unit display always conforms to the SQL:2008 standard, which omits interval unit display. If DATESTYLE is set to ISO, you can use SET INTERVALSTYLE to omit or display interval unit display, as described below.

Omitting Interval Units

To omit interval units from the output, set INTERVALSTYLE to PLAIN. This is the default setting, which conforms with the SQL:2008 standard:

```sql
=> SET INTERVALSTYLE TO PLAIN;
SET
=> SELECT INTERVAL '3 2';
?column?
-----------
3 02:00
```

When INTERVALSTYLE is set to PLAIN, units are omitted from the output, even if the query specifies input units:

```sql
=> SELECT INTERVAL '3 days 2 hours';
?column?
-----------
3 02:00
```

If DATESTYLE is set to SQL, Vertica conforms with SQL:2008 standard and always omits interval units from output:

```sql
=> SET DATESTYLE TO SQL;
SET
=> SET INTERVALSTYLE TO UNITS;
SET
=> SELECT INTERVAL '3 2';
?column?
-----------
3 02:00
```

Displaying Interval Units

To enable display of interval units, DATESTYLE must be set to ISO. You can then display interval units by setting INTERVALSTYLE to UNITS:

```sql
=> SET DATESTYLE TO ISO;
SET
```
Checking INTERVALSTYLE and DATESTYLE Settings

Use SHOW statements to check INTERVALSTYLE and DATESTYLE settings:

```
=> SHOW INTERVALSTYLE;
   name | setting
---------------------
   intervalstyle | units
=> SHOW DATESTYLE;
   name | setting
---------------------
   datestyle | ISO, MDY
```

Specifying Interval Input

Interval values are expressed through interval literals. An interval literal is composed of one or more interval fields, where each field represents a span of days and time, or years and months, as follows:

```
[-] { quantity subtype-unit }[...] [AGO]
```

Using Subtype Units

Subtype units are optional for day-time intervals; they must be specified for year-month intervals.

For example, the first statement below implicitly specifies days and time; the second statement explicitly identifies day and time units. Both statements return the same result:

```
=> SET INTERVALSTYLE TO UNITS;
=> SELECT INTERVAL '1 12:59:10:05';
   ?column?
---------------------
3 days 2 hours
```
1 day 12:59:10.005
(1 row)

=> SELECT INTERVAL '1 day 12 hours 59 min 10 sec 5 milliseconds';
?column?
-----------------------
1 day 12:59:10.005
(1 row)

The following two statements add 28 days and 4 weeks to the current date, respectively. The intervals in both cases are equal and the statements return the same result. However, in the first statement, the interval literal omits the subtype (implicitly days); in the second statement, the interval literal must include the subtype unit weeks:

=> SELECT CURRENT_DATE;
?column?
-----------
2016-08-15
(1 row)

=> SELECT CURRENT_DATE + INTERVAL '28';
?column?
-----------
2016-09-12 00:00:00
(1 row)

dbadmin=> SELECT CURRENT_DATE + INTERVAL '4 weeks';
?column?
-----------
2016-09-12 00:00:00
(1 row)

An interval literal can include day-time and year-month fields. For example, the following statement adds an interval of 4 years, 4 weeks, 4 days and 14 hours to the current date. The years and weeks fields must include subtype units; the days and hours fields omit them:

> SELECT CURRENT_DATE + INTERVAL '4 years 4 weeks 4 14';
?column?
-----------------------
2020-09-15 14:00:00
(1 row)

**Omitting Subtype Units**

You can specify quantities of days, hours, minutes, and seconds without specifying units. Vertica recognizes colons in interval literals as part of the timestamp:

=> SELECT INTERVAL '1 4 5 6';
?column?
If Vertica cannot determine the units, it applies the quantity to any missing units based on the interval qualifier. In the next two examples, Vertica uses the default interval qualifier (DAY TO SECOND(6)) and assigns the trailing 1 to days, since it has already processed hours, minutes, and seconds in the output:

```sql
=> SELECT INTERVAL '1 day 04:5:6';
?column?
-----------------------
1 day 04:05:06
-----------------------
=> SELECT INTERVAL '1 day 4 hour 5 min 6 sec';
?column?
-----------------------
1 day 04:05:06
```

In the next two examples, Vertica recognizes 4:5 as hours:minutes. The remaining values in the interval literal are assigned to the missing units: 1 is assigned to days and 2 is assigned to seconds.

```sql
SELECT INTERVAL '4:5 1 2';
?column?
-----------------------
1 day 04:05:02
-----------------------
=> SELECT INTERVAL '1 4:5 2';
?column?
-----------------------
1 day 04:05:02
```

Specifying the interval qualifier can change how Vertica interprets 4:5:

```sql
=> SELECT INTERVAL '4:5' MINUTE TO SECOND;
?column?
-----------------------
00:04:05
```

---

**Controlling Interval Format**

*Interval qualifiers* specify a range of options that Vertica uses to interpret and format an *interval literal*. The interval qualifier can also specify precision. Each interval qualifier is
composed of one or two units:

\[ \text{unit}[p] \ [ \text{TO} \ \text{unit}[p] ] \]

where:

- \( \text{unit} \) specifies a day-time or year-month subtype.
- \( p \) specifies precision, an integer between 0 and 6. In general, precision only applies to SECOND units. The default precision for SECOND is 6. For details, see Specifying Interval Precision.

If an interval omits an interval qualifier, Vertica uses the default \text{DAY TO SECOND(6)}.

### Interval Qualifier Categories

Interval qualifiers belong to one of the following categories:

- **Year-month**: Span of years and months
- **Day-time**: Span of days, hours, minutes, seconds, and fractional seconds

---

**Note:**
All examples below assume that \text{INTERVALSTYLE} is set to plain.

---

### Year-Month

Vertica supports two year-month subtypes: YEAR and MONTH.

In the following example, \text{YEAR TO MONTH} qualifies the interval literal 1 2 to indicate a span of 1 year and two months:

```sql
=> SELECT interval '1 2' YEAR TO MONTH;

| ?column?
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>
```

If you omit the qualifier, Vertica uses the default interval qualifier \text{DAY TO SECOND(6)} and returns a different result:

```sql
=> SELECT interval '1 2';

| ?column?
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1 02:00</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>
```
The following example uses the interval qualifier YEAR. In this case, Vertica extracts only the year from the interval literal \texttt{1y 10m}:

```sql
=> SELECT INTERVAL '1y 10m' YEAR;
?column?
--------
1
(1 row)
```

In the next example, the interval qualifier MONTH converts the same interval literal to months:

```sql
=> SELECT INTERVAL '1y 10m' MONTH;
?column?
--------
22
(1 row)
```

## Day-Time

Vertica supports four day-time subtypes: DAY, HOUR, MINUTE, and SECOND.

In the following example, the interval qualifier \texttt{DAY TO SECOND(4)} qualifies the interval literal \texttt{1h 3m 6s 5msecs 57us}. The qualifier also sets precision on seconds to 4:

```sql
=> SELECT INTERVAL '1h 3m 6s 5msecs 57us' DAY TO SECOND(4);
?column?
----------
01:03:06.0051
(1 row)
```

If no interval qualifier is specified, Vertica uses the default subtype \texttt{DAY TO SECOND(6)}, regardless of how you specify the interval literal. For example, as an extension to SQL:2008, both of the following commands return 910 days:

```sql
=> SELECT INTERVAL '2-6';
?column?
--------
910
=> SELECT INTERVAL '2 years 6 months';
?column?
--------
910
```

An interval qualifier can extract other values from the input parameters. For example, the following command extracts the \texttt{HOUR} value from the interval literal \texttt{3 days 2 hours}:
The primary day/time (DAY TO SECOND) and year/month (YEAR TO MONTH) subtype ranges can be restricted to more specific range of types by an interval qualifier. For example, HOUR TO MINUTE is a limited form of day/time interval, which can be used to express time zone offsets.

hh:mm:ss and hh:mm formats are used only when at least two of the fields specified in the interval qualifier are non-zero and there are no more than 23 hours or 59 minutes:

Specifying Interval Precision

In general, interval precision only applies to seconds. If no precision is explicitly specified, Vertica rounds precision to a maximum of six decimal places. For example:

Vertica lets you specify interval precision in two ways:
After the INTERVAL keyword
After the SECOND unit of an interval qualifier, one of the following:
- DAY TO SECOND
- HOUR TO SECOND
- MINUTE TO SECOND
- SECOND

For example, the following statements use both methods to set precision, and return identical results:

```sql
=> SELECT INTERVAL(4) '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;
?column?
------------------
02:04:03.7094
(1 row)

=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND(4);
?column?
------------------
02:04:03.7094
(1 row)
```

If the same statement specifies precision more than once, Vertica uses the lesser precision. For example, the following statement specifies precision twice: the INTERVAL keyword specifies precision of 1, while the interval qualifier SECOND specifies precision of 2. Vertica uses the lesser precision of 1:

```sql
=> SELECT INTERVAL(1) '1.2467' SECOND(2);
?column?
--------
1.2 secs
```

### Setting Precision on Interval Table Columns

If you create a table with an interval column, the following restrictions apply to the column definition:

- You can set precision on the INTERVAL keyword only if you omit specifying an interval qualifier. If you try to set precision on the INTERVAL keyword and include an interval qualifier, Vertica returns an error.
- You can set precision only on the last unit of an interval qualifier. For example:
If you specify precision on another unit, Vertica discards it when it saves the table definition.

**Fractional Seconds in Interval Units**

Vertica supports intervals in milliseconds (hh:mm:ss:ms), where 01:02:03:25 represents 1 hour, 2 minutes, 3 seconds, and 025 milliseconds. Milliseconds are converted to fractional seconds as in the following example, which returns 1 day, 2 hours, 3 minutes, 4 seconds, and 25.5 milliseconds:

```sql
=> SELECT INTERVAL '1 02:03:04:25.5';
?column?
-------------
 1 day 02:03:04.0255
```

Vertica allows fractional minutes. The fractional minutes are rounded into seconds:

```sql
=> SELECT INTERVAL '10.5 minutes';
?column?
-------------
00:10:30
=> select interval '10.659 minutes';
?column?
-------------
00:10:39.54
=> select interval '10.3333333333333 minutes';
?column?
-------------
00:10:20
```

**Considerations**

- An INTERVAL can include only the subset of units that you need; however, year/month intervals represent calendar years and months with no fixed number of days, so year/month interval values cannot include days, hours, minutes. When year/month values are specified for day/time intervals, the intervals extension assumes 30 days per month and 365 days per year. Since the length of a given month or year varies, day/time intervals are never output as months or years, only as days, hours, minutes, and so on.
Day/time and year/month intervals are logically independent and cannot be combined with or compared to each other. In the following example, an interval-literal that contains DAYS cannot be combined with the YEAR TO MONTH type:

```sql
=> SELECT INTERVAL '1 2 3' YEAR TO MONTH;
ERROR 3679: Invalid input syntax for interval year to month: "1 2 3"
```

Vertica accepts intervals up to $2^{63} - 1$ microseconds or months (about 18 digits). INTERVAL YEAR TO MONTH can be used in an analytic RANGE window when the ORDER BY column type is TIMESTAMP/TIMESTAMP WITH TIMEZONE, or DATE. Using TIME/TIME WITH TIMEZONE are not supported.

You can use INTERVAL DAY TO SECOND when the ORDER BY column type is TIMESTAMP/TIMESTAMP WITH TIMEZONE, DATE, and TIME/TIME WITH TIMEZONE.

## Examples

Examples in this section assume that INTERVALSTYLE is set to PLAIN, so results omit subtype units. Interval values that omit an interval qualifier use the default to DAY TO SECOND(6).

<tr>
<td>SELECT FLOOR((TIMESTAMP '2005-01-17 10:00' - TIMESTAMP '2005-01-01') / INTERVAL '7');</td>
<td>2</td>
</tr>
</tbody>
</table>

**Processing Signed Intervals**

In the SQL:2008 standard, a minus sign before an interval-literal or as the first character of the interval-literal negates the entire literal, not just the first component. In Vertica, a leading minus sign negates the entire interval, not just the first component. The following commands both return the same value:

```sql
=> SELECT INTERVAL '-'-1 month - 1 second';
?column?
----------
-29 days 23:59:59

=> SELECT INTERVAL -'1 month - 1 second';
?column?
----------
-29 days 23:59:59
```

Use one of the following commands instead to return the intended result:

```sql
=> SELECT INTERVAL -'1 month 1 second';
?column?
```
Two negatives together return a positive:

=> SELECT INTERVAL -'1 month - 1 second';
?column?
----------
29 days 23:59:59

=> SELECT INTERVAL -'1 month 1 second';
?column?
----------
30 days 1 sec

You can use the year-month syntax with no spaces. Vertica allows the input of negative months but requires two negatives when paired with years.

=> SELECT INTERVAL '3-3' YEAR TO MONTH;
?column?
----------
3 years 3 months

=> SELECT INTERVAL '3--3' YEAR TO MONTH;
?column?
----------
2 years 9 months

When the interval-literal looks like a year/month type, but the type is day/second, or vice versa, Vertica reads the interval-literal from left to right, where number-number is years-months, and number <space> <signed number> is whatever the units specify. Vertica processes the following command as (–) 1 year 1 month = (–) 365 + 30 = –395 days:

=> SELECT INTERVAL '-1-1' DAY TO HOUR;
?column?
----------
-395 days

If you insert a space in the interval-literal, Vertica processes it based on the subtype DAY TO HOUR: (–) 1 day – 1 hour = (–) 24 – 1 = –23 hours:

=> SELECT INTERVAL -1 -1' DAY TO HOUR;
?column?
----------
-23 hours

Two negatives together returns a positive, so Vertica processes the following command as (–) 1 year – 1 month = (–) 365 – 30 = –335 days:
If you omit the value after the hyphen, Vertica assumes 0 months and processes the following command as 1 year 0 month –1 day = 365 + 0 – 1 = –364 days:

```sql
=> SELECT INTERVAL '-1-1' DAY TO HOUR;
?column? ----------------
-335 days
```

### Casting with Intervals

You can use CAST to convert strings to intervals, and vice versa.

#### String to Interval

You cast a string to an interval as follows:

```sql
CAST( [ INTERVAL[(p)] ] [-] ] interval-literal AS INTERVAL[(p)] interval-qualifier )
```

For example:

```sql
=> SELECT CAST('3700 sec' AS INTERVAL);
?column? ----------------
01:01:40
```

You can cast intervals within day-time or the year-month subtypes but not between them:

```sql
=> SELECT CAST(INTERVAL '4440' MINUTE as INTERVAL);
?column? ----------------
3 days 2 hours
=> SELECT CAST(INTERVAL '-01:15' as INTERVAL MINUTE);
?column? ----------------
-75 mins
```

#### Interval to String

You cast an interval to a string as follows:

```sql
CAST( (SELECT interval ) AS VARCHAR[(n)] )
```
For example:

```sql
=> SELECT CONCAT('Tomorrow at this time: ',
    CAST((SELECT INTERVAL '24 hours') + CURRENT_TIMESTAMP(0) AS VARCHAR) AS VARCHAR));
                        -----------------------------------------------
Tomorrow at this time: 2016-08-17 08:41:23-04
(1 row)
```

**Operations with Intervals**

If you divide an interval by an interval, you get a FLOAT:

```sql
=> SELECT INTERVAL '28 days 3 hours' HOUR(4) / INTERVAL '27 days 3 hours' HOUR(4);
                ?column?
              -----------
                1.036866359447
```

An INTERVAL divided by FLOAT returns an INTERVAL:

```sql
=> SELECT INTERVAL '3' MINUTE / 1.5;
                ?column?
              -----------
                  2 mins
```

**INTERVAL MODULO (remainder) INTERVAL** returns an INTERVAL:

```sql
=> SELECT INTERVAL '28 days 3 hours' HOUR % INTERVAL '27 days 3 hours' HOUR;
                ?column?
              -----------
                  24 hours
```

If you add INTERVAL and TIME, the result is TIME, modulo 24 hours:

```sql
=> SELECT INTERVAL '1' HOUR + TIME '1:30';
                ?column?
              -----------
                  02:30:00
```

**SMALLDATETIME**

SMALLDATETIME is an alias for `TIMESTAMP/TIMESTAMPZ`. 
**TIME/TIMETZ**

Stores the specified time of day. TIMETZ is the same as TIME WITH TIME ZONE: both data types store the UTC offset of the specified time.

**Syntax**

**TIME**

```
TIME [(p)] [ { WITHOUT | WITH } TIME ZONE ] 'input-string' [ AT TIME ZONE zone ]
```

**TIMETZ**

```
TIME [(p)] 'input-string' [ AT TIME ZONE zone ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(p)</td>
<td>Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.</td>
</tr>
<tr>
<td>WITHOUT TIME ZONE</td>
<td>Specifies whether to include a time zone with the stored value:</td>
</tr>
<tr>
<td>WITH TIME ZONE</td>
<td>• WITHOUT TIME ZONE (default): Specifies that input-string does not include a time zone. If the input string contains a time zone, Vertica ignores this qualifier. Instead, it conforms to WITH TIME ZONE behavior.</td>
</tr>
<tr>
<td></td>
<td>• WITH TIME ZONE: Specifies to convert input-string to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is configured for your system.</td>
</tr>
<tr>
<td>input-string</td>
<td>See Input String below.</td>
</tr>
</tbody>
</table>
**TIME versus TIMETZ**

TIMETZ and TIMESTAMPTZ are not parallel SQL constructs. TIMESTAMPTZ records a time and date in GMT, converting from the specified TIME_ZONE. TIMETZ records the specified time and the specified time zone, in minutes, from GMT.

### Limits

<table>
<thead>
<tr>
<th>Name</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME [p]</td>
<td>00:00:00.00</td>
<td>23:59:60.999999</td>
<td>1 µs</td>
</tr>
<tr>
<td>TIME [p] WITH TIME ZONE</td>
<td>00:00:00.00+14</td>
<td>23:59:59.999999-14</td>
<td>1 µs</td>
</tr>
</tbody>
</table>

### Input String

A TIME input string can be set to any of the formats shown below:

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>04:05:06.789</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05:06</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>040506</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05 AM</td>
<td>Same as 04:05; AM does not affect value</td>
</tr>
<tr>
<td>04:05 PM</td>
<td>Same as 16:05</td>
</tr>
<tr>
<td>04:05:06.789-8</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05:06-08:00</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05-08:00</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>040506-08</td>
<td>ISO 8601</td>
</tr>
</tbody>
</table>
Data Type Coercion

You can cast a TIME or TIMETZ interval to a TIMESTAMP. This returns the local date and time as follows:

```sql
=> SELECT (TIME '3:01am')::TIMESTAMP;
?column? 2012-08-30 03:01:00 ------------------
(1 row)
```

Casting the same TIME or TIMETZ interval to a TIMESTAMPTZ returns the local date and time, appended with the UTC offset—in this example, -05:

```sql
=> SELECT (TIMETZ '3:01am')::TIMESTAMPTZ;
?column? 2012-08-22 03:01:00-05 ------------------
(1 row)
```

TIME AT TIME ZONE

Converts the specified TIME to the time in another time zone.

Syntax

```
TIME [WITH TIME ZONE] 'input-string' AT TIME ZONE 'zone'
```

Parameters

| WITH TIME ZONE | Converts the input string to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica |
uses the UTC offset of the time zone that is configured for your system, and converts the input string accordingly.

**zone**

Specifies the time zone to use in the conversion, either as a literal or interval that specifies UTC offset:

- AT TIME ZONE INTERVAL 'utc-offset'
- AT TIME ZONE 'time-zone-literal'

For details, see [Specifying Time Zones](#) below.

**Note:**
Vertica treats literals TIME ZONE and TIMEZONE as synonyms.

---

## Specifying Time Zones

You can specify time zones in two ways:

- A string literal such as America/Chicago or PST
- An interval that specifies a UTC offset—for example, INTERVAL ' -08:00'

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is -04, both queries return the same results:

```
=> SELECT CURRENT_TIME(0) "EDT";
    EDT
   --------------
    12:34:35-04
    (1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE 'America/Denver' "Mountain Time";
  Mountain Time
               ------------
    10:34:35-06
    (1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
  Mountain Time
               ------------
    10:34:35-06
    (1 row)
```
If you issue a use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to -07—otherwise, Vertica returns a different (and erroneous) result:

```sql
=> SELECT CURRENT_TIME(0) "EST";
           EST
----------
14:18:22-05
(1 row)
```

```sql
=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
       Mountain Time
----------
13:18:22-06
(1 row)
```

You can show and set the session's time zone with `SHOW TIMEZONE` and `SET TIME ZONE`, respectively:

```sql
=> SHOW TIMEZONE;
    name         | setting
---------------------
    timezone       | America/New_York
(1 row)

=> SELECT CURRENT_TIME(0) "Eastern Daylight Time";
       Eastern Daylight Time
---------------------
12:18:24-04
(1 row)

=> SET TIMEZONE 'America/Los_Angeles';
SET

=> SELECT CURRENT_TIME(0) "Pacific Daylight Time";
       Pacific Daylight Time
---------------------
09:18:24-07
(1 row)
```

## Time Zone Literals

To view the default list of valid literals, see the files in the following directory:

```
opt/vertica/share/timezonesets
```

For example:

```
$ cat Antarctica.txt
...
# src/timezone/tznames/Antarctica.txt
#
```
Examples

The following example assumes that local time is EST (Eastern Standard Time). The query converts the specified time to MST (mountain standard time):

```sql
=> SELECT CURRENT_TIME(0);
    timezone
----------
  10:10:56-05
(1 row)

=> SELECT '10:10:56' AT TIME ZONE 'America/Denver' "Denver Time";
        Denver Time
----------------
    08:10:56-07
(1 row)
```

The next example adds a time zone literal to the input string—in this case, Europe/Vilnius—and converts the time to MST:

```sql
=> SELECT '09:56:13 Europe/Vilnius' AT TIME ZONE 'America/Denver';
       Denver Time
--------------
   00:56:13-07
(1 row)
```

TIMESTAMP/TIMESTAMPTZ

Stores the specified date and time. TIMESTAMPTZ is the same as TIMESTAMP WITH TIME ZONE: both data types store the UTC offset of the specified time.

TIMESTAMP is an alias for DATETIME and SMALLDATETIME.

Syntax

TIMESTAMP

\[
\text{TIMESTAMP} \ [\ (p) \ ] \ [\ \{\ \text{WITHOUT} \ | \ \text{WITH}\ \} \ \text{TIME ZONE} \ ] \ 'input-string' \ [\ \text{AT TIME ZONE} \ zone \ ]
\]

TIMESTAMPTZ

\[
\text{TIMESTAMPTZ} \ [\ (p) \ ] \ 'input-string' \ [\ \text{AT TIME ZONE} \ zone \ ]
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( p )</td>
<td>Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.</td>
</tr>
</tbody>
</table>

WITHOUT TIME ZONE

WITH TIME ZONE

- **WITHOUT TIME ZONE** (default): Specifies that \textit{input-string} does not include a time zone. If the input string contains a time zone, Vertica ignores this qualifier. Instead, it conforms to WITH TIME ZONE behavior.
- **WITH TIME ZONE**: Specifies to convert \textit{input-string} to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is configured for your system.

| \textit{input-string} | See Input String below. |
| \textit{AT TIME ZONE} zone | See TIMESTAMP AT TIME ZONE. |
Limits

In the following table, values are rounded. See Date/Time Data Types for more detail.

<table>
<thead>
<tr>
<th>Name</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIMESTAMP [ (p) ] [ WITHOUT TIME ZONE ]</td>
<td>290279 BC</td>
<td>294277 AD</td>
<td>1 µs</td>
</tr>
<tr>
<td>TIMESTAMP [ (p) ] WITH TIME ZONE</td>
<td>290279 BC</td>
<td>294277 AD</td>
<td>1 µs</td>
</tr>
</tbody>
</table>

Input String

The date/time input string concatenates a date and a time. The input string can include a time zone, specified as a literal such as America/Chicago, or as a UTC offset.

The following list represents typical date/time input variations:

- 1999-01-08 04:05:06
- 1999-01-08 04:05:06 -8:00
- January 8 04:05:06 1999 PST

Note:

0000-00-00 is invalid input. If you try to insert that value into a DATE or TIMESTAMP field, an error occurs. If you copy 0000-00-00 into a DATE or TIMESTAMP field, Vertica converts the value to 0001-01-01 00:00:00 BC.

The input string can also specify the calendar era, either AD (default) or BC. If you omit the calendar era, Vertica assumes the current calendar era (AD). The calendar era typically follows the time zone; however, the input string can include it in various locations. For example, the following queries return the same results:

```sql
=> SELECT TIMESTAMP WITH TIME ZONE 'March 1, 44 12:00 CET BC' "Caesar's Time of Death EST";
Caesar's Time of Death EST
--------------------------
0044-03-01 06:00:00-05 BC
(1 row)

=> SELECT TIMESTAMP WITH TIME ZONE 'March 1, 44 12:00 BC CET' "Caesar's Time of Death EST";
Caesar's Time of Death EST
--------------------------
0044-03-01 06:00:00-05 BC
(1 row)
```
Examples: TIMESTAMP Computation

<table>
<thead>
<tr>
<th>Statement</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-'</td>
<td>10</td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-'</td>
<td>08:571429</td>
</tr>
<tr>
<td>SELECT TIMESTAMP '2009-05-29 15:21:00.456789' - TIMESTAMP</td>
<td>120960.2457</td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2009-05-29 15:21:00.456789' - TIMESTAMP</td>
<td>(3);</td>
</tr>
<tr>
<td>SELECT '2017-03-18 07:00':TIMESTAMPTZ(0) + INTERVAL '120000.000' 19:00:00-04</td>
<td></td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-'</td>
<td>86-01' day;</td>
</tr>
<tr>
<td>SELECT cast((TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-'</td>
<td>'2014-01-01') day as integer</td>
</tr>
<tr>
<td>SELECT floor((TIMESTAMP '2014-01-17 10:00' - TIMESTAMP</td>
<td>'2014-01-01') / interval '120000.000' second;</td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2012-05-29 15:21:00.456789' - TIMESTAMP</td>
<td>'2009-01-01') year;</td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2012-05-29 15:21:00.456789' - TIMESTAMP</td>
<td>'2009-01-01') month;</td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2012-05-29 15:21:00.456789' - TIMESTAMP</td>
<td>'2009-01-01') year to month;</td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2012-05-29 15:21:00.456789' - TIMESTAMP</td>
<td>'2009-01-01') second(3);</td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2012-05-29 15:21:00.456789' - TIMESTAMP</td>
<td>'2009-01-01') minute;</td>
</tr>
<tr>
<td>SELECT (TIMESTAMP '2012-05-29 15:21:00.456789' - TIMESTAMP</td>
<td>'2009-01-01') minute to second(3);</td>
</tr>
<tr>
<td>SELECT TIMESTAMP 'infinity';</td>
<td>infinity</td>
</tr>
</tbody>
</table>

TIMESTAMP AT TIME ZONE

Converts the specified TIMESTAMP or TIMESTAMPTZ (TIMESTAMP WITH TIMEZONE) to another time zone. Vertica executes AT TIME ZONE differently, depending on whether the date input is a TIMESTAMP or TIMESTAMPTZ. See TIMESTAMP Versus TIMESTAMPTZ Behavior below.
Syntax

\[ \text{timestamp-clause} \text{ AT TIME ZONE \textquotesingle zone\textquotesingle} \]

Parameters

| timestamp-clause | Specifies the timestamp to convert, either TIMESTAMP or TIMESTAMPTZ.  
                      For details, see TIMESTAMP/TIMESTAMPTZ. |
|------------------|------------------------------------------------------------------------------------------------------|
| AT TIME ZONE zone | Specifies the time zone to use in the timestamp conversion, where \textit{zone} is a literal or interval that specifies a UTC offset:  
                                - AT TIME ZONE INTERVAL \textquotesingle utc-offset\textquotesingle  
                                - AT TIME ZONE \textquotesingle time-zone-literal\textquotesingle  
                      For details, see Specifying Time Zones below. |

**Note:** Vertica treats literals TIME ZONE and TIMEZONE as synonyms.

**TIMESTAMP Versus TIMESTAMPTZ Behavior**

How Vertica interprets AT TIME ZONE depends on whether the date input is a TIMESTAMP or TIMESTAMPTZ:

<table>
<thead>
<tr>
<th>Date input</th>
<th>Action</th>
</tr>
</thead>
</table>
| TIMESTAMP  | If the input string specifies no time zone, Vertica performs two actions:  
                                1. Converts the input string to the time zone of the AT TIME ZONE argument.  
                                2. Returns the time for the current session's time zone.  
                      If the input string includes a time zone, Vertica implicitly casts it to a |
TIMESTAMP and converts it accordingly (see TIMESTAMPTZ below).

For example, the following statement specifies a TIMESTAMP with no time zone. Vertica executes the statement as follows:

1. Converts the input string to PDT (Pacific Daylight Time).
2. Returns that time in the local time zone, which is three hours later:

```sql
=> SHOW TIMEZONE;
  name | setting
--------------------
timezone | America/New_York
(1 row)
SELECT TIMESTAMP '2017-3-14 5:30' AT TIME ZONE 'PDT';
timezone
--------------------
2017-03-14 08:30:00-04
(1 row)
```

TIMESTAMPTZ

Vertica converts the input string to the time zone of the AT TIME ZONE argument and returns that time.

For example, the following statement specifies a TIMESTAMPTZ data type. The input string omits any time zone expression, so Vertica assumes the input string to be in local time zone (America/New_York) and returns the time of the AT TIME ZONE argument:

```sql
=> SHOW TIMEZONE;
  name | setting
--------------------
timezone | America/New_York
(1 row)
=> SELECT TIMESTAMP '2001-02-16 20:38:40' AT TIME ZONE 'America/Denver';
timezone
--------------------
2001-02-16 18:38:40
(1 row)
```

The input string in the next statement explicitly specifies a time zone, so Vertica coerces the TIMESTAMP to a TIMESTAMPTZ and returns the time of the AT TIME ZONE argument:

```sql
=> SELECT TIMESTAMP '2001-02-16 20:38:40 America/Mexico_City' AT TIME ZONE 'Asia/Tokyo';
```
Specifying Time Zones

You can specify time zones in two ways:

- A string literal such as America/Chicago or PST
- An interval that specifies a UTC offset—for example, INTERVAL '-08:00'

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is -04, both queries return the same results:

```sql
=> SELECT TIMESTAMPTZ '2017-03-16 09:56:13' AT TIME ZONE 'America/Denver' "Denver Time";
Denver Time
----------------------
2017-03-16 07:56:13
(1 row)
```

```sql
=> SELECT TIMESTAMPTZ '2017-03-16 09:56:13' AT TIME ZONE INTERVAL '-06:00' "Denver Time";
Denver Time
----------------------
2017-03-16 07:56:13
(1 row)
```

If you issue a use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to -07—otherwise, Vertica returns a different (and erroneous) result:

```sql
=> SELECT TIMESTAMPTZ '2017-01-16 09:56:13' AT TIME ZONE 'America/Denver' "Denver Time";
Denver Time
----------------------
2017-01-16 07:56:13
(1 row)
```

```sql
=> SELECT TIMESTAMPTZ '2017-01-16 09:56:13' AT TIME ZONE INTERVAL '-06:00' "Denver Time";
Denver Time
----------------------
2017-01-16 08:56:13
(1 row)
```
You can show and set the session's time zone with `SHOW TIMEZONE` and `SET TIME ZONE`, respectively:

```sql
=> SHOW TIMEZONE;
   name | setting
------------------------
timezone | America/New_York
(1 row)

=> SELECT CURRENT_TIMESTAMP('Eastern Daylight Time');
Eastern Daylight Time
------------------------
2017-03-20 12:18:24-04
(1 row)

=> SET TIMEZONE 'America/Los_Angeles';
SET

=> SELECT CURRENT_TIMESTAMP('Pacific Daylight Time');
Pacific Daylight Time
------------------------
2017-03-20 09:18:24-07
(1 row)
```

**Time Zone Literals**

To view the default list of valid literals, see the files in the following directory:

`opt/vertica/share/timezonesets`

For example:

```bash
$ cat Antarctica.txt
...
# src/timezone/tznames/Antarctica.txt
#
AWST 28800  # Australian Western Standard Time
   # (Antarctica/Cassey)
   # (Australia/Perth)
...
NZST 43200  # New Zealand Standard Time
   # (Antarctica/McMurdo)
   # (Pacific/Auckland)
ROTT -10800 # Rothera Time
   # (Antarctica/Rothera)
SYOT 10800  # Syowa Time
   # (Antarctica/Syowa)
VOST 21600  # Vostok time
   # (Antarctica/Vostok)
```

- Sources for Time Zone and Daylight Saving Time Data

Long Data Types

Store data up to 32000000 octets. Vertica supports two long data types:

- LONG VARBINARY: Variable-length raw-byte data, such as spatial data. LONG VARBINARY values are not extended to the full width of the column.
- LONG VARCHAR: Variable-length strings, such as log files and unstructured data. LONG VARCHAR values are not extended to the full width of the column.

Use LONG data types only when you need to store data greater than the maximum size of VARBINARY and VARCHAR data types (65 KB). Long data can include unstructured data, online comments or posts, or small log files.

Flex tables have a default LONG VARBINARY _raw__ column, with a NOT NULL constraint. For more information, see Using Flex Tables.

Syntax

LONG VARBINARY

LONG VARBINARY (max-length)

LONG VARCHAR

LONG VARCHAR (octet-length)

Parameters

| max-Length | Specifies the length of the byte string or column width, declared in |
bytes (octets).
Maximum value: 32000000
Default value: 1 MB

<table>
<thead>
<tr>
<th>octet-Length</th>
<th>Specifies the length of the string or column width, declared in bytes (octets).</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Maximum value: 32000000</td>
</tr>
<tr>
<td></td>
<td>Default value: 1 MB</td>
</tr>
</tbody>
</table>

**Optimized Performance**

For optimal performance of LONG data types, Vertica recommends that you:

- Use the LONG data types as *storage only* containers; Vertica supports operations on the content of LONG data types, but does not support all the operations that VARCHAR and VARBINARY take.
- Use VARBINARY and VARCHAR data types, instead of their LONG counterparts, whenever possible. VARBINARY and VARCHAR data types are more flexible and have a wider range of operations.
- Do not sort, segment, or partition projections on LONG data type columns.
- Do not add constraints, such as a primary key, to any LONG VARBINARY or LONG VARCHAR columns.
- Do not join or aggregate any LONG data type columns.

**Example**

The following example creates a table `user_comments` with a LONG VARCHAR column and inserts data into it:

```sql
=> CREATE TABLE user_comments
  (id INTEGER,
   username VARCHAR(200),
   time_posted TIMESTAMP,
   comment_text LONG VARCHAR(200000));
=> INSERT INTO user_comments VALUES
  (1,
   'User1',
   'The weather tomorrow will be cold and rainy and then on the day after, the sun will come and the temperature will rise dramatically.');
```
Numeric Data Types

Numeric data types are numbers stored in database columns. These data types are typically grouped by:

- **Exact** numeric types, values where the precision and scale need to be preserved. The exact numeric types are INTEGER, BIGINT, DECIMAL, NUMERIC, NUMBER, and MONEY.
- **Approximate** numeric types, values where the precision needs to be preserved and the scale can be floating. The approximate numeric types are DOUBLE PRECISION, FLOAT, and REAL.

Implicit casts from INTEGER, FLOAT, and NUMERIC to VARCHAR are not supported. If you need that functionality, write an explicit cast using one of the following forms:

\[
\text{CAST}(\text{numeric-expression} \ AS \ \text{data-type})
\]

\[
\text{numeric-expression::data-type}
\]

For example, you can cast a float to an integer as follows:

```
=> SELECT (FLOAT '123.5')::INT;
?column?
---------
 124
(1 row)
```

String-to-numeric data type conversions accept formats of quoted constants for scientific notation, binary scaling, hexadecimal, and combinations of numeric-type literals:

- **Scientific notation**:

```
=> SELECT FLOAT '1e10';
?column?
-----------
10000000000
(1 row)
```

- **BINARY scaling**:

```
=> SELECT NUMERIC '1p10';
?column?
--------
   1024
(1 row)
```

- **hexadecimal**: 

Vertica supports the numeric data type DOUBLE PRECISION, which is the IEEE-754 8-byte floating point type, along with most of the usual floating point operations.

Syntax

[ DOUBLE PRECISION | FLOAT | FLOAT(n) | FLOAT8 | REAL ]

Parameters

Note:
On a machine whose floating-point arithmetic does not follow IEEE-754, these values probably do not work as expected.

Double precision is an inexact, variable-precision numeric type. In other words, some values cannot be represented exactly and are stored as approximations. Thus, input and output operations involving double precision might show slight discrepancies.

- All of the DOUBLE PRECISION data types are synonyms for 64-bit IEEE FLOAT.
- The n in FLOAT(n) must be between 1 and 53, inclusive, but a 53-bit fraction is always used. See the IEEE-754 standard for details.
- For exact numeric storage and calculations (money for example), use NUMERIC.
- Floating point calculations depend on the behavior of the underlying processor, operating system, and compiler.
- Comparing two floating-point values for equality might not work as expected.
- While Vertica treats decimal values as FLOAT internally, if a column is defined as FLOAT then you cannot read decimal values from ORC and Parquet files. In those formats, FLOAT and DECIMAL are different types.

Values

COPY accepts floating-point data in the following format:
Optional leading white space
An optional plus ("+") or minus sign ("-"
A decimal number, a hexadecimal number, an infinity, a NAN, or a null value

**Decimal Number**

A decimal number consists of a non-empty sequence of decimal digits possibly containing a radix character (decimal point "."), optionally followed by a decimal exponent. A decimal exponent consists of an "E" or "e", followed by an optional plus or minus sign, followed by a non-empty sequence of decimal digits, and indicates multiplication by a power of 10.

**Hexadecimal Number**

A hexadecimal number consists of a "0x" or "0X" followed by a non-empty sequence of hexadecimal digits possibly containing a radix character, optionally followed by a binary exponent. A binary exponent consists of a "P" or "p", followed by an optional plus or minus sign, followed by a non-empty sequence of decimal digits, and indicates multiplication by a power of 2. At least one of radix character and binary exponent must be present.

**Infinity**

An infinity is either INF or INFINITY, disregarding case.

**NaN (Not A Number)**

A NaN is NAN (disregarding case) optionally followed by a sequence of characters enclosed in parentheses. The character string specifies the value of NAN in an implementation-dependent manner. (The Vertica internal representation of NAN is 0xffff800000000000LL on x86 machines.)

When writing infinity or NAN values as constants in a SQL statement, enclose them in single quotes. For example:

```
=> UPDATE table SET x = 'Infinity'
```

**Note:**

Vertica follows the IEEE definition of NaNs (IEEE 754). The SQL standards do not specify how floating point works in detail.

IEEE defines NaNs as a set of floating point values where each one is not equal to anything, even to itself. A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.
However, for the purpose of sorting data, NaN values must be placed somewhere in the result. The value generated 'NaN' appears in the context of a floating point number matches the NaN value generated by the hardware. For example, Intel hardware generates (0xfff8000000000000LL), which is technically a Negative, Quiet, Non-signaling NaN.

Vertica uses a different NaN value to represent floating point NULL (0x7fffffffffffffffLL). This is a Positive, Quiet, Non-signaling NaN and is reserved by Vertica.

A NaN example follows.

```sql
=> SELECT CBRT('Nan'); -- cube root
   CBRT
   ------
    NaN
     (1 row)
=> SELECT 'Nan' > 1.0;
   ?column?
   --------
    f
     (1 row)
```

**Null Value**

The load file format of a null value is user defined, as described in the `COPY` command. The Vertica internal representation of a null value is 0x7fffffffffffffffLL. The interactive format is controlled by the `vsqll` printing option null. For example:

```
\pset null '(null)'
```

The default option is not to print anything.

**Rules**

- -0 == +0
- 1/0 = Infinity
- 0/0 == Nan
- NaN != anything (even NaN)

To search for NaN column values, use the following predicate:

```
... WHERE column != column
```

This is necessary because WHERE `column = 'Nan'` cannot be true by definition.
Sort Order (Ascending)

- NaN
- -Inf
- numbers
- +Inf
- NULL

Notes

- NULL appears last (largest) in ascending order.
- All overflows in floats generate +/-infinity or NaN, per the IEEE floating point standard.

INTEGER

A signed 8-byte (64-bit) data type.

Syntax

```
[ INTEGER | INT | BIGINT | INT8 | SMALLINT | TINYINT ]
```

Parameters

INT, INTEGER, INT8, SMALLINT, TINYINT, and BIGINT are all synonyms for the same signed 64-bit integer data type. Automatic compression techniques are used to conserve disk space in cases where the full 64 bits are not required.

Notes

- The range of values is $-2^{63}+1$ to $2^{63}-1$.
- $2^{63} = 9,223,372,036,854,775,808$ (19 digits).
- The value $-2^{63}$ is reserved to represent NULL.
- NULL appears first (smallest) in ascending order.
Vertica does not have an explicit 4-byte (32-bit integer) or smaller types. Vertica's encoding and compression automatically eliminate the storage overhead of values that fit in less than 64 bits.

**Restrictions**

- The JDBC type INTEGER is 4 bytes and is not supported by Vertica. Use BIGINT instead.
- Vertica does not support the SQL/JDBC types NUMERIC, SMALLINT, or TINYINT.
- Vertica does not check for overflow (positive or negative) except in the aggregate function `SUM()`. If you encounter overflow when using `SUM`, use `SUM_FLOAT()`, which converts to floating point.

**See Also**

[Data Type Coercion Chart](#)

**NUMERIC**

Numeric data types store fixed-point numeric data. For example, a value of $123.45$ can be stored in a `NUMERIC(5,2)` field. Note that the first number, the precision, specifies the total number of digits.

**Syntax**

```
numeric-type [ ( precision[, scale] ) ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>numeric-type</strong></td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• NUMERIC</td>
</tr>
<tr>
<td></td>
<td>• DECIMAL</td>
</tr>
<tr>
<td></td>
<td>• NUMBER</td>
</tr>
<tr>
<td></td>
<td>• MONEY</td>
</tr>
<tr>
<td><strong>precision</strong></td>
<td>An unsigned integer that specifies the total number of significant digits.</td>
</tr>
</tbody>
</table>
digits that the data type stores, where `precision` is ≤ 1024. If omitted, the default precision depends on numeric type that you specify. If you assign a value that exceeds `precision`, Vertica returns an error.

If a data type's precision is ≤ 18, performance is equivalent to an INTEGER data type, regardless of scale. When possible, Vertica recommends using a precision ≤ 18.

### Scale

`scale` An unsigned integer that specifies the maximum number of digits to the right of the decimal point to store. `scale` must be ≤ `precision`. If omitted, the default scale depends on numeric type that you specify. If you assign a value with more decimal digits than `scale`, the scale is rounded to `scale` digits.

When using ALTER to modify the data type of a numeric column, `scale` cannot be changed.

**Note:** When using `ALTER TABLE...ALTER COLUMN` to modify the data type of a NUMERIC column, `scale` cannot be changed.

## Default Precision and Scale

NUMERIC, DECIMAL, NUMBER, and MONEY differ in their default precision and scale values:

<table>
<thead>
<tr>
<th>Type</th>
<th>Precision</th>
<th>Scale</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMERIC</td>
<td>37</td>
<td>15</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>37</td>
<td>15</td>
</tr>
<tr>
<td>NUMBER</td>
<td>38</td>
<td>0</td>
</tr>
<tr>
<td>MONEY</td>
<td>18</td>
<td>4</td>
</tr>
</tbody>
</table>

## Supported Encoding

Vertica supports the following encoding for numeric data types:

- Precision ≤ 18: AUTO, BLOCK_DICT, BLOCK_DICT_COMP, COMMONDELTA_COMP, DELTAVAL, GCDDELTA, and RLE
• Precision > 18: AUTO, BLOCK_DICT, BLOCKDICT_COMP, RLE

For details, see Encoding Types.

### Numeric Versus Integer and Floating Data Types

Numeric data types are *exact* data types that store values of a specified precision and scale, expressed with a number of digits before and after a decimal point. This contrasts with the Vertica integer and floating data types:

- **DOUBLE PRECISION (FLOAT)** supports ~15 digits, variable exponent, and represents numeric values approximately. It can be less precise than NUMERIC data types.
- **INTEGER** supports ~18 digits, whole numbers only.

The NUMERIC data type is preferred for non-integer constants, because it is always exact. For example:

```sql
=> SELECT 1.1 + 2.2 = 3.3;
?column?
--------
t
(1 row)

=> SELECT 1.1::float + 2.2::float = 3.3::float;
?column?
--------
f
(1 row)
```

### Numeric Operations

Supported numeric operations include the following:

<table>
<thead>
<tr>
<th>Basic math</th>
<th>+</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td></td>
<td>*</td>
</tr>
<tr>
<td></td>
<td>/</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Aggregation</th>
<th><strong>SUM</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>MIN</strong></td>
</tr>
<tr>
<td></td>
<td><strong>MAX</strong></td>
</tr>
<tr>
<td></td>
<td><strong>COUNT</strong></td>
</tr>
</tbody>
</table>
Comparison

| <  | <= | =  | => | <> | => |

- NUMERIC divide operates directly on numeric values, without converting to floating point. The result has at least 18 decimal places and is rounded.
- NUMERIC mod (including %) operates directly on numeric values, without converting to floating point. The result has the same scale as the numerator and never needs rounding.
- Some complex operations used with numeric data types result in an implicit cast to FLOAT. When using SQRT, STDDEV, transcendental functions such as LOG, and TO_CHAR/TO_NUMBER formatting, the result is always FLOAT.

Examples

The following series of commands creates a table that contains a numeric data type and then performs some mathematical operations on the data:

```sql
=> CREATE TABLE num1 (id INTEGER, amount NUMERIC(8,2));
```

Insert some values into the table:

```sql
=> INSERT INTO num1 VALUES (1, 123456.78);
```

Query the table:

```sql
=> SELECT * FROM num1;
   id  | amount
    ---|--------
       | 123456.78
(1 row)
```

The following example returns the NUMERIC column, amount, from table num1:

```sql
=> SELECT amount FROM num1;
   amount
    ------
   123456.78
(1 row)
```

The following syntax adds one (1) to the amount:
=> SELECT amount+1 AS 'amount' FROM num1;
amount
-----------
 123457.78
(1 row)

The following syntax multiplies the amount column by 2:

=> SELECT amount*2 AS 'amount' FROM num1;
amount
-----------
246913.56
(1 row)

The following syntax returns a negative number for the amount column:

=> SELECT -amount FROM num1;
?column?
-----------
-123456.78
(1 row)

The following syntax returns the absolute value of the amount argument:

=> SELECT ABS(amount) FROM num1;
ABS
-----------
123456.78
(1 row)

The following syntax casts the NUMERIC amount as a FLOAT data type:

=> SELECT amount::float FROM num1;
amount
-----------
 123456.78
(1 row)

Mathematical Functions
Numeric Data Type Overflow

Vertica does not check for overflow (positive or negative) except in the aggregate function `SUM()`. If you encounter overflow when using `SUM`, use `SUM_FLOAT()` which converts to floating point.

For a detailed discussion of how Vertica handles overflow when you use the functions `SUM`, `SUM_FLOAT`, and `AVG` with numeric data types, see Numeric Data Type Overflow with `SUM`, `SUM_FLOAT`, and `AVG`. The discussion includes directives for turning off silent numeric overflow and setting precision for numeric data types.

Dividing by zero returns an error:

```sql
=> SELECT 0/0;
ERROR 3117: Division by zero

=> SELECT 0.0/0;
ERROR 3117: Division by zero

=> SELECT 0.0::float/0;
NaN

== SELECT 0.0::float//0;
NaN
```

Dividing zero as a FLOAT by zero returns NaN:

```sql
=> SELECT 2.0::float/0;
Infinity

=> SELECT 200.0::float//0;
Infinity
```

Dividing a non-zero FLOAT by zero returns Infinity:
Add, subtract, and multiply operations ignore overflow. Sum and average operations use 128-bit arithmetic internally. `SUM()` reports an error if the final result overflows, suggesting the use of `SUM_FLOAT(INT)`, which converts the 128-bit sum to a FLOAT. For example:

```sql
=> CREATE TEMP TABLE t (i INT);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> SELECT SUM(i) FROM t;
   ERROR: sum() overflowed
   HINT: try sum_float() instead
=> SELECT SUM_FLOAT(i) FROM t;
   ---
   2.30584300921369e+19
```

### Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG

When you use the functions SUM, SUM_FLOAT, and AVG with a NUMERIC data type, be aware that overflow can occur and how Vertica responds to that overflow.

This discussion applies to both the aggregate and analytic functions.

For queries, when using the functions SUM, SUM_FLOAT, and AVG with a NUMERIC data type, Vertica allows for silent overflow if you exceed your specified precision.

Vertica also allows numeric overflow when you use the SUM or SUM_FLOAT functions with LAPs.

### Default Overflow Handling

With NUMERIC data types, Vertica internally works with multiples of 18 digits. If your specified precision is less than 18 (for example, `x(12,0)`), Vertica allows for an overflow up to and including the first multiple of 18. In some situations, if you sum a column (`SUM(x)`), you can exceed the number of digits Vertica internally reserves for the result. In this case, Vertica allows a silent overflow.
**Turning Off Silent Numeric Overflow**

You can turn off silent numeric overflow and instruct Vertica to implicitly include extra digit places. Specifying extra spaces allows Vertica to consistently return your expected results, even when you exceed the precision specified in your DDL.

You turn off silent numeric overflow by setting the parameter `AllowNumericOverflow` to 0 (false).

When you set the parameter to 0, Vertica considers the value of a corresponding parameter, `NumericSumExtraPrecisionDigits`.

The `NumericSumExtraPrecisionDigits` parameter defaults to 6, meaning that Vertica internally add six places beyond your DDL-specified precision. Adding extra precision digits can allow Vertica to consistently return results that overflow your DDL-specified precision. However, there can be a performance impact for crossing into the second multiple of 18 internally.

An example:

- Suppose your DDL specifies 11 (for example, `x(11, 0)`) and you accept the default of `NumericSumExtraPrecisionDigits` (6). In this case, Vertica internally stays within the first multiple of 18 digits and no additional performance impact occurs.
- Given the same example, if you set `NumericSumExtraPrecisionDigits` to 10, Vertica internally crosses a threshold into the second multiple of 18. Performance-wise, if (hypothetically) the first example is performance “a,” then the second is “2a,” substantially increasing the performance impact. Beyond the second multiple of 18, the performance impact continues to be "2a."

This sample representation shows how Vertica responds internally when you set `AllowNumericOverflow` to 0 (false).
Vertica recommends that you turn off silent numeric overflow and set the parameter NumericSumExtraPrecisionDigits if you expect to exceed the precision specified in your DDL. Crossing into the second multiple of 18 can affect performance. Therefore, consider carefully before setting NumericSumExtraPrecisionDigits to a number higher than what you need for returning the SUM of your numeric columns.

Be aware that, if you turn off AllowNumericOverflow, and you exceed the number of extra precision digits set by NumericSumExtraPrecisionDigits, Vertica returns an error.

**Impact on Live Aggregate Projections (LAPs)**

For LAPs, Vertica also allows silent numeric overflow if your LAP uses the SUM or SUM_FLOAT functions. To turn off silent numeric overflow for LAPs:

1. Set the parameter AllowNumericOverflow to 0.
2. Set the parameter NumericSumExtraPrecisionDigits to the number of implicit digits you want. Alternatively, use the default setting of 6.
3. Drop and re-create your LAPs.

If you turn off silent numeric overflow, be aware of the following scenarios where an overflow causes a roll back or error message. In these examples, AllowNumericOverflow is set to 0 (false), and each LAP uses the SUM or SUM_FLOAT function.

When numeric overflow is off:
• A load can roll back upon overflow.
  
  Vertica aggregates data before loading in into a LAP. If you are inserting, copying, or merging data, and an overflow occurs during load as Vertica is aggregating the data, Vertica rolls back the load.

• An overflow can occur after load as Vertica sums existing data.

  Vertica computes the sum of existing data separately from the computation that it does during data load. If your LAP selects a column using SUM or SUM_FLOAT and an overflow occurs, Vertica produces an error message. This response is similar to the way Vertica produces an error for a query using the SUM or SUM_FLOAT function.

• An overflow can occur during merge-out.

  Vertica logs a message during merge-out if an overflow occurs as Vertica computes a final sum during the tuple mover operation. If an error occurs, Vertica marks the LAP as out-of-date. Vertica no longer runs tuple mover operations with the out-of-date LAP.

**Spatial Data Types**

Vertica supports two spatial data types. These data types store two- and three-dimensional spatial objects in a table column:

• **GEOMETRY**: Spatial object with coordinates expressed as \((x,y)\) pairs, defined in the Cartesian plane. All calculations use Cartesian coordinates.

• **GEOGRAPHY**: Spatial object defined as on the surface of a perfect sphere, or a spatial object in the WGS84 coordinate system. Coordinates are expressed in longitude/latitude angular values, measured in degrees. All calculations are in meters. For perfect sphere calculations, the sphere has a radius of 6371 kilometers, which approximates the shape of the earth.

  **Note:**
  
  Some spatial programs use an ellipsoid to model the earth, resulting in slightly different data.
The maximum size of a GEOMETRY or GEOGRAPHY data type is 10,000,000 bytes (10 MB). You cannot use either data type as a table's primary key.

**Syntax**

**GEOMETRY**

GEOMETRY [ (Length) ]

**GEOGRAPHY**

GEOGRAPHY [ (Length) ]

**Parameters**

<table>
<thead>
<tr>
<th>Length</th>
<th>The maximum amount of spatial data that a GEOMETRY or GEOGRAPHY column can store.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Maximum value: 10 MB</td>
</tr>
<tr>
<td></td>
<td>Default value: 1 MB</td>
</tr>
</tbody>
</table>

**UUID Data Type**

Stores universally unique identifiers (UUIDs). UUIDs are 16-byte (128-bit) numbers used to uniquely identify records. To generate UUIDs, Vertica provides the function `UUID_GENERATE`, which returns UUIDs based on high-quality randomness from `/dev/urandom`.

**Syntax**

UUID

**UUID Input and Output Formats**

UUIDs support input of case-insensitive string literal formats, as specified by [RFC 4122](https://tools.ietf.org/html/rfc4122). In general, a UUID is written as a sequence of hexadecimal digits, in several groups optionally separated by hyphens, for a total of 32 digits representing 128 bits.
The following input formats are valid:

6bbf0744-74b4-46b9-bb05-53905d4538e7
(6bbf0744-74b4-46b9-bb05-53905d4538e7)
6BF074474B446B9B0553905D4538E7
6BBF-0744-74B4-46B9-BB05-5390-5D45-38E7

On output, Vertica always uses the following format:

xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx

For example, the following table defines column cust_id as a UUID:

```sql
=> CREATE TABLE public.Customers
  (  
cust_id uuid,
   lname varchar(36),
   fname varchar(24)
);
```

The following input for cust_id uses several valid formats:

```sql
=> COPY Customers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {cede66b7-3d29-4da6-b700-871fc8ac57be}|Kearney|Thomas
>> 34462732ed5649838f3be735b0c32d50|Pham|Duc
>> 9fb0-1de0-1d63-4d09-9415-90e0-b4e9-3b9a|Steinberg|Jeremy
>> .
```

On querying this table, Vertica formats all cust_id data in the same way:

```sql
=> SELECT cust_id, fname, lname FROM Customers;

cust_id | fname | lname
---------+-------+-------
9fb01de0-1d63-4d09-9415-90e0b4e93b9a | Jeremy | Steinberg
34462732ed5649838f3be735b0c32d50 | Duc | Pham
cede66b7-3d29-4da6-b700-871fc8ac57be | Thomas | Kearney

(3 rows)
```

**Generating UUIDs**

You can use the Vertica function `UUID_GENERATE` to automatically generate UUIDs that uniquely identify table records. For example:

```sql
=> INSERT INTO Customers SELECT UUID_GENERATE(),'Rostova','Natasha';
OUTPUT
--------
1
(1 row)
=> COMMIT;
COMMIT
```
The following string is reserved as NULL for UUID columns:

0000000-0000-0000-0000-000000000000

Vertica always renders NULL as blank.

The following COPY statements insert NULL values into the UUID column, explicitly and implicitly:

```sql
=> COPY Customers FROM STDIN NULL AS 'null';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> null|Jane
>> 0000000-0000-0000-0000-000000000000|Man|Nowhere
>> \.
=> COPY Customers FROM STDIN;
>> |Doe|John
>> \.
```

In all cases, Vertica renders NULL as blank:

```sql
=> SELECT cust_id, fname, lname FROM Customers WHERE cust_id IS NULL;
cust_id | fname | lname
---------|-------|--------
| Nowhere | Man   |
| Jane    | Doe   |
| John    | Doe   |
(3 rows)
```

Usage Restrictions

UUID data types only support relational operators and functions that are also supported by CHAR and VARCHAR data types—for example, `MIN`, `MAX`, and `COUNT`. UUID data types do not support mathematical operators or functions, such as `SUM` and `AVG`. 
Data Type Coercion

Vertica supports two types of data type casting:

- *Implicit casting*: The expression automatically converts the data from one type to another.
- *Explicit casting*: An SQL statement specifies the target data type for the conversion.

Implicit Casting

The ANSI SQL-92 standard supports implicit casting among similar data types:

- Number types
- CHAR, VARCHAR, LONG VARCHAR
- BINARY, VARBINARY, LONG VARBINARY

Vertica supports two types of nonstandard implicit casts:

- From CHAR to FLOAT, to match the one from VARCHAR to FLOAT. The following example converts the CHAR '3' to a FLOAT so it can add the number 4.33 to the FLOAT result of the second expression:

  ```sql
  => SELECT '3':CHAR + 4.33::FLOAT;
  7.33
  (1 row)
  ```

- Between DATE and TIMESTAMP. The following example DATE to a TIMESTAMP and calculates the time 6 hours, 6 minutes, and 6 seconds back from 12:00 AM:

  ```sql
  => SELECT DATE('now') - INTERVAL '6:6:6';
  2013-07-30 17:53:54
  (1 row)
  ```

When there is no ambiguity about the data type of an expression value, it is implicitly coerced to match the expected data type. In the following command, the quoted string constant '2' is implicitly coerced into an INTEGER value so that it can be the operand of an arithmetic operator (addition):

```sql
=> SELECT 2::INTEGER + 4.33::FLOAT;
7.33
(1 row)
```
A concatenate operation explicitly takes arguments of any data type. In the following example, the concatenate operation implicitly coerces the arithmetic expression 2 + 2 and the INTEGER constant 2 to VARCHAR values so that they can be concatenated.

```sql
=> SELECT 2 + '2';
?column?
--------
 4
(1 row)
```

Another example is to first get today's date:

```sql
=> SELECT DATE 'now';
?column?
--------
2013-07-31
(1 row)
```

The following command converts DATE to a TIMESTAMP and adds a day and a half to the results by using INTERVAL:

```sql
=> SELECT DATE 'now' + INTERVAL '1 12:00:00';
?column?
-----------------
2013-07-31 12:00:00
(1 row)
```

Most implicit casts stay within their relational family and go in one direction, from less detailed to more detailed. For example:

- DATE to TIMESTAMP/TZ
- INTEGER to NUMERIC to FLOAT
- CHAR to FLOAT
- CHAR to VARCHAR
- CHAR and/or VARCHAR to FLOAT
- CHAR to LONG VARCHAR
- VARCHAR to LONG VARCHAR
- BINARY to VARBINARY
- BINARY to LONG VARBINARY
- VARBINARY to LONG VARBINARY

More specifically, data type coercion works in this manner in Vertica:
<table>
<thead>
<tr>
<th>Type</th>
<th>Direction</th>
<th>Type</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT8</td>
<td>&gt;</td>
<td>FLOAT8</td>
<td>Implicit, can lose significance</td>
</tr>
<tr>
<td>FLOAT8</td>
<td>&gt;</td>
<td>INT8</td>
<td>Explicit, rounds</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>&lt;-&gt;</td>
<td>CHAR</td>
<td>Implicit, adjusts trailing spaces</td>
</tr>
<tr>
<td>VARBINARY</td>
<td>&lt;-&gt;</td>
<td>BINARY</td>
<td>Implicit, adjusts trailing NULs</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>&gt;</td>
<td>LONG VARCHAR</td>
<td>Implicit, adjusts trailing spaces</td>
</tr>
<tr>
<td>VARBINARY</td>
<td>&gt;</td>
<td>LONG VARBINARY</td>
<td>Implicit, adjusts trailing NULs</td>
</tr>
</tbody>
</table>

No other types cast to or from LONGVARBINARY, VARBINARY, or BINARY. In the following list, <any> means one these types: INT8, FLOAT8, DATE, TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, INTERVAL.

- <any> -> VARCHAR—implicit
- VARCHAR -> <any>—explicit, except that VARCHAR->FLOAT is implicit
- <any> <-> CHAR—explicit
- DATE -> TIMESTAMP/TZ—implicit
- TIMESTAMP/TZ -> DATE—explicit, loses time-of-day
- TIME -> TIMETZ—implicit, adds local timezone
- TIMETZ -> TIME—explicit, loses timezone
- TIME -> INTERVAL—implicit, day to second with days=0
- INTERVAL -> TIME—explicit, truncates non-time parts
- TIMESTAMP <-> TIMESTAMPTZ—implicit, adjusts to local timezone
- TIMESTAMP/TZ -> TIME—explicit, truncates non-time parts
- TIMESTAMPTZ -> TIMETZ—explicit
- VARBINARY -> LONG VARBINARY—implicit
- LONG VARBINARY -> VARBINARY—explicit
- VARCHAR -> LONG VARCHAR—implicit
- LONG VARCHAR -> VARCHAR—explicit

**Important:**
Implicit casts from INTEGER, FLOAT, and NUMERIC to VARCHAR are not supported. If you need that functionality, write an explicit cast:

```
CAST(x AS data-type-name)
```

or

```
x::data-type-name
```

The following example casts a FLOAT to an INTEGER:
String-to-numeric data type conversions accept formats of quoted constants for scientific notation, binary scaling, hexadecimal, and combinations of numeric-type literals:

- **Scientific notation:**

  ```sql
  => SELECT FLOAT '123.5':INT;
  ?column?  
  -------
  124
  (1 row)
  ```

- **BINARY scaling:**

  ```sql
  => SELECT NUMERIC '1p10';
  ?column?  
  -------
  1024
  (1 row)
  ```

- **hexadecimal:**

  ```sql
  => SELECT NUMERIC '0x0abc';
  ?column?  
  -------
  2748
  (1 row)
  ```

## Examples

The following example casts three strings as NUMERICs:

```sql
=> SELECT NUMERIC '12.3e3', '12.3p10':NUMERIC, CAST('0x12.3p-10e3' AS NUMERIC);
---------|---------|---------
 12300 | 12595.2 | 17.76123046875000
(1 row)
```

This example casts a VARBINARY string into a LONG VARBINARY data type:

```sql
=> SELECT B'101111000':LONG VARBINARY;
?column?  
---------
\001x
(1 row)
```
The following example concatenates a CHAR with a LONG VARCHAR, resulting in a LONG VARCHAR:

```sql
=> \$ s '``cat longfile.txt``'
=> SELECT length ('a' || s :: LONG VARCHAR);
   length
  ---------
   65002
(1 row)
```

The following example casts a combination of NUMERIC and INTEGER data into a NUMERIC result:

```sql
=> SELECT (18. + 3./16)/1024*1000;
      ?column?
-------------
  17.76123046875000000000000000000000
(1 row)
```

**Note:**
In SQL expressions, pure numbers between \(-2^{63}–1\) and \(2^{63}–1\) are INTEGRERS. Numbers with decimal points are NUMERIC.

**Conversion Types**

The following table defines all possible type conversions that Vertica supports. The data types in the first column of the table are the inputs to convert, while data types listed across the second heading row indicate the resultant assignments.
<table>
<thead>
<tr>

* CHAR length ≥ 36
### Implicit and Explicit Conversion

Vertica supports data type conversion of values without explicit casting, such as `NUMERIC(10,6) -> NUMERIC(18,4)`. Implicit data type conversion occurs automatically when converting values of different, but compatible, types to the target column's data type. For example, when adding values, `(INTEGER + NUMERIC)`, the result is implicitly cast to a `NUMERIC` type to accommodate the prominent type in the statement. Depending on the input data types, different precision and scale can occur.

An explicit type conversion must occur when the source data cannot be cast implicitly to the target column’s data type.

### Assignment Conversion

In data assignment conversion, coercion implicitly occurs when values are assigned to database columns in an `INSERT` or `UPDATE...SET` statement. For example, in a statement that includes `INSERT...VALUES('2.5')`, where the target column data type is `NUMERIC(18,5)`, a cast from `VARCHAR` to the column data type is inferred.
In an assignment without numeric meaning, the value is subject to CHAR/VARCHAR/LONG VARCHAR comparisons.

**See Also**

- Data Type Coercion
- Data Type Coercion Operators (CAST)

**External Types**

External types are types found in certain external file formats that Vertica can read. The types in this section are supported only when defining or querying external tables using Parquet files.

**ARRAY**

Represents array data in external tables in the Parquet format only. Arrays must use only primitive types (and nested arrays, for multi-dimensionality). Arrays may not contain other complex types. For more information, see Reading Structs.

**Syntax for Direct Construction**

You can use the keyword ARRAY to construct an array type inside of a query. For example, to create an array of INT, you would do the following:

```sql
=> SELECT array_max(ARRAY[1,2,3]);
```

A two-dimensional array of INT would be declared as:

```sql
=> SELECT array_dims(ARRAY[[1,3,5],[2,4,6]]);
```
Array Input Format for Column Definition

Use "ARRAY[data_type]" to declare an array column in a table. The following example defines an external table for customers (abbreviated as cust):

```sql
=> CREATE EXTERNAL TABLE cust
(  cust_custkey int,
  cust_custname varchar(50),
  cust_custstaddress ARRAY[varchar(100)],
  cust_custaddressln2 ARRAY[varchar(100)],
  cust_custcity ARRAY[varchar(50)],
  cust_custstate ARRAY[char(2)],
  cust_custzip ARRAY[int],
  cust_email varchar(50),
  cust_phone varchar(30)
) AS COPY FROM '...' PARQUET;
```

To declare a multi-dimensional array, use nesting. For example, ARRAY[ARRAY[int]] specifies a two-dimensional array.

Array Output Format

A query reading arrays from external tables results in the following output:

```sql
=> SELECT cust_custkey,cust_custstaddress,cust_custcity,cust_custstate from cust;
cust_custkey | cust_custstaddress | cust_custcity | cust_custstate
------------- | ----------------- | ------------- | -------------
342176       | ["668 SW New Lane","518 Main Ave","7040 Campfire Dr"] | ["Winchester","New Hyde Park","Massapequa"] | ["VA","NY","NY"]
342799       | ["2400 Hearst Avenue","3 Cypress Street"] | ["Berkeley","San Antonio"] | ["CA","TX"]
342845       | ["336 Boylston Street","180 Clarkhill Rd"] | ["Boston","Amherst"] | ["MA","MA"]
342321       | ["95 Fawn Drive"] | ["Allen Park"] | ["MI"]
342989       | ["5 Thompson St"] | ["Massillon"] | ["OH"]
(5 rows)
```

Element Access

You can access (dereference) elements from an array by index (zero-based):
To specify a range, use the format start:end. The end of the range is non-inclusive.

```sql
=> SELECT (ARRAY['a','b','c','d','e'])[1];
array
-------
"b"
(1 row)
```

Out-of-bound index references return NULL.

### Restrictions

- Arrays support only data of primitive types, for example, int, UUID, and so on.
- Arrays are supported only for external tables using Parquet data.
- Arrays are 0-indexed. The first element's ordinal position is 0, second is 1, and so on.
- Array dimensionality is enforced. A column cannot contain arrays of varying dimensions. For example, a column that contains a three-dimensional array can only contain other three-dimensional arrays; it cannot simultaneously include a one-dimensional array. However, the arrays in a column can vary in size, where one array can contain four elements while another contains ten.
- Out-of-bound indexes into arrays return NULL.

### Null Handling

Null semantics for arrays are consistent with normal columns. See [NULL Sort Order](#) for more information on null-handling.

### Functions and Operators

See [Array Functions](#) for a comprehensive list of functions that can be used to manipulate arrays.
**MAP**

Represents map data in external tables in the Parquet format only. Maps must use only primitive types and may not contain other complex types.

You can define maps in order to read Parquet files that contain them, but you cannot query map columns.

### Syntax

In column definitions:

```
MAP<key,value>
```

### Map Input Format for Column Definition

In a column definition in an external table, a MAP consists of a key-value pair, specified as types. The table in the following example defines a map of product IDs to names.

```sql
=> CREATE EXTERNAL TABLE store (storeID INT, inventory MAP<INT,VARCHAR(100)>) AS COPY FROM ...
   PARQUET;
```

**ROW**

Represents structured data (structs) in external tables in the Parquet format only. Rows must use only primitive types and nested rows. Rows may not contain other complex types.

For more information, see Reading Structs as Inline Types.

### Syntax

In column definitions:

```
ROW(field type[, ...])
```

In literals:

```
ROW(value[, ...])
```
Row Input Format for Column Definition

In a column definition in an external table, a ROW consists of one or more comma-separated pairs of field names and types. This syntax is similar to that for columns in table definitions. The following example defines a ROW to represent an address struct in the data.

```sql
=> CREATE EXTERNAL TABLE customers (name VARCHAR,
       address ROW(street VARCHAR, city VARCHAR, zipcode INT))
       AS COPY FROM '...' PARQUET;
```

ROWs can be nested; a field can have a type of ROW:

```sql
=> CREATE EXTERNAL TABLE employees(
       employeeID INT,
       personal ROW(
           name VARCHAR,
           address ROW(street VARCHAR, city VARCHAR, zipcode INT),
           taxID INT),
       department VARCHAR)
       AS COPY FROM '...' PARQUET;
```

The primitive types in the table definition must match those in the data. By default the ROW structure must also match; a ROW must contain all and only the fields in the struct in the data. You can violate the ROW schema match by passing `skip_strong_schema_match='true'` in the PARQUET clause.

ROW columns have several restrictions:

- The maximum nesting depth is 10.
- The maximum number of total columns and fields in a table is 1600. The ROW itself is not counted, just its fields.
- ROW columns cannot use any constraints (such as NOT NULL) or defaults.
- ROW fields cannot be auto_increment or setof.
- A ROW definition must include at least one field.
- "Row" is a reserved keyword within a ROW definition, but is permitted as the name of a table or column.
- ROW columns cannot be modified using ALTER TABLE...ALTER COLUMN. You must drop and recreate the external table to change a ROW column.
- External tables containing ROW columns cannot also contain identity, auto-increment, or sequence columns.
Vertica Documentation
SQL Reference Manual

Row Input Format for Literals
In a literal, such as a value in a comparison operation, a ROW consists of one or more
values. Omit field names; Vertica generates them automatically. If you do not coerce types,
Vertica infers the types from the data values.
=> SELECT ROW('Amy',2,false);
row
-------------------------------------------{"field0":"Amy","field1":2,"field2":false}
(1 row)

You can coerce types explicitly:
=> SELECT ROW('Amy',2.5::int,false::varchar);
row
-----------------------------------------{"field0":"Amy","field1":3,"field2":"f"}
(1 row)

Supported Operators and Predicates
The ROW type supports the following query operators and predicates:
l
l
l
l
l
l

INNER and OUTER JOIN
Comparison, IN, BETWEEN (non-nullable filters only)
IS NULL, IS NOT NULL
CASE (only in outer SELECT)
GROUP BY, ORDER BY
SELECT DISTINCT

The following operators and predicates are not supported for ROW columns:
l
l
l
l
l
l
l

Math operators
Type coercion
BITWISE, LIKE
MLA (ROLLUP, CUBE, GROUPING SETS)
Aggregate functions including MAX, MIN, and SUM
Set operators including UNION, UNION ALL, MINUS, and INTERSECT
Subqueries and views with structs in SELECT output; however, you can include
individual fields using rowname.fieldname notation

Vertica Analytic Database (9.3.x)

Page 2381 of 6246


In comparison operations (including implicit comparisons like ORDER BY), a ROW is treated as the sequence of its field values. For example, the following two statements are equivalent:

GROUP BY ROW(zipcode, city)
GROUP BY zipcode, city

### NULL Inputs

A ROW in which each field is null is equivalent to a null ROW:

```sql
=> SELECT ROW(null, null, null) IS NULL;
?column?
---------
t
(1 row)
```

### Row Output Format

ROW values read from external tables are output in JSON format as in the following example.

```sql
=> CREATE EXTERNAL TABLE customers (name VARCHAR,
    address ROW(street VARCHAR, city VARCHAR, zipcode INT))
    AS COPY FROM '...'
    PARQUET;

=> SELECT address FROM customers WHERE address.city = 'Pasadena';
    address

{"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001}
{"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001}
{"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001}
{"street":"15 Raymond Dr","city":"Pasadena","zipcode":91003}
(4 rows)
```

The following table specifies the mappings from Vertica data types to JSON data types.

<table>
<thead>
<tr>
<th>Vertica Type</th>
<th>JSON Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>Integer</td>
</tr>
<tr>
<td>Float</td>
<td>Numeric</td>
</tr>
<tr>
<td>Numeric</td>
<td>Numeric</td>
</tr>
<tr>
<td>Boolean</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
Escape single quotes in literal inputs using single quotes, as in the following example:

```
=> SELECT ROW('Howard''s house',2,false);

ROW
("field0":"Howard's house","field1":2,"field2":false)
(1 ROW)
```

## SQL Functions

Functions return information from the database. Except for Vertica-specific functions, you can use a function anywhere an expression is allowed.

This chapter describes each function that Vertica supports. The Behavior Type section of these descriptions categorizes the function's return behavior as one of the following:

**Immutable (invariant)**
When run with a given set of arguments, immutable functions such as `AVG()` always produce the same result, regardless of environment or session settings such as locale.

**Stable**
When run with a given set of arguments, stable functions produce the same result within a single query or scan operation. However, a stable function can produce different results when issued under different environments or at different times, such as change of locale and time zone—for example, `SYSDATE()` and 'today'.

**Volatile**
Regardless of their arguments or environment, volatile functions can return a different result with each invocation—for example, `UUID_GENERATE()`.

**Note:**
All Vertica-specific functions are volatile; thus, the descriptions of these functions omit a Behavior Type section.
Aggregate Functions

**Note:**
All functions in this section that have an analytic function counterpart are appended with [Aggregate] to avoid confusion between the two.

Aggregate functions summarize data over groups of rows from a query result set. The groups are specified using the `GROUP BY` clause. They are allowed only in the select list and in the `HAVING` and `ORDER BY` clauses of a `SELECT` statement (as described in Aggregate Expressions).

**Notes**

- Except for COUNT, these functions return a null value when no rows are selected. In particular, SUM of no rows returns NULL, not zero.
- In some cases you can replace an expression that includes multiple aggregates with an single aggregate of an expression. For example `SUM(x) + SUM(y)` can be expressed as `SUM(x+y)` (where x and y are NOT NULL).
- Vertica does not support nested aggregate functions.

You can also use some of the simple aggregate functions as analytic (window) functions. See Analytic Functions for details. See also SQL Analytics in Analyzing Data.

**APPROXIMATE_COUNT_DISTINCT**

Returns the number of distinct non-NULL values in a data set.

**Behavior Type**

**Immutable**

**Syntax**

```
APPROXIMATE_COUNT_DISTINCT ( expression[, error-tolerance ] )
```
Parameters

<table>
<thead>
<tr>
<th><strong>expression</strong></th>
<th>Value to be evaluated using any data type that supports equality comparison.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>error-tolerance</strong></td>
<td>Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation. You can set error-tolerance to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance. If you omit this argument, Vertica uses an error tolerance of 1.25 (%).</td>
</tr>
</tbody>
</table>

Restrictions

APPROXIMATE_COUNT_DISTINCT and DISTINCT aggregates cannot be in the same query block.

Error Tolerance

APPROXIMATE_COUNT_DISTINCT(x, error-tolerance) returns a value equal to COUNT(DISTINCT x), with an error that is lognormally distributed with standard deviation.

Parameter error-tolerance is optional. Supply this argument to specify the desired standard deviation. error-tolerance is defined as 2.17 standard deviations, which corresponds to a 97 percent confidence interval:

\[
\text{standard-deviation} = \frac{\text{error tolerance}}{2.17}
\]

For example:

- \text{error-tolerance} = 1
  The default setting, corresponds to a standard deviation. 97 percent of the time, APPROXIMATE_COUNT_DISTINCT(x, 5) returns a value between:
COUNT(DISTINCT x) * 0.99
COUNT(DISTINCT x) * 1.01

**error-tolerance = 5**
97 percent of the time, APPROXIMATE_COUNT_DISTINCT(x) returns a value between:

COUNT(DISTINCT x) * 0.95
COUNT(DISTINCT x) * 1.05

A 99 percent confidence interval corresponds to 2.58 standard deviations. To set error-tolerance confidence level corresponding to 99 (instead of a 97) percent, multiply error-tolerance by 2.17 / 2.58 = 0.841.

For example, if you specify error-tolerance as 5 * 0.841 = 4.2, APPROXIMATE_COUNT_DISTINCT(x,4.2) returns values 99 percent of the time between:

COUNT (DISTINCT x) * 0.95
COUNT (DISTINCT x) * 1.05

**Examples**

Count the total number of distinct values in column product_key from table store.store_sales_fact:

```sql
=> SELECT COUNT(DISTINCT product_key) FROM store.store_sales_fact;

COUNT
-------
19982
(1 row)
```

Count the approximate number of distinct values in product_key with various error tolerances. The smaller the error tolerance, the closer the approximation:

```sql
=> SELECT APPROXIMATE_COUNT_DISTINCT(product_key,5) AS five_pct_accuracy,
               APPROXIMATE_COUNT_DISTINCT(product_key,1) AS one_pct_accuracy,
               APPROXIMATE_COUNT_DISTINCT(product_key,.88) AS point_eighteight_pct_accuracy
FROM store.store_sales_fact;

five_pct_accuracy | one_pct_accuracy | point_eighteight_pct_accuracy
--------------------|------------------|---------------------------
     19431          |       19921      |                   19921
(1 row)
```
**See Also**

- Approximate Count Distinct Functions
- APPROXIMATE_COUNT_DISTINCT_SYNOPSIS
- APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS
- COUNT [Aggregate]

**APPROXIMATE_COUNT_DISTINCT_SYNOPSIS**

Summarizes the information of distinct non-NULL values and materializes the result set in a VARBINARY or LONG VARBINARY *synopsis* object. The calculated result is within a specified range of error tolerance. You save the synopsis object in a Vertica table for use by APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS.

**Behavior Type**

Immutable

**Syntax**

`APPROXIMATE_COUNT_DISTINCT_SYNOPSIS ( expression[, error-tolerance] )`

**Parameters**

<table>
<thead>
<tr>
<th><strong>expression</strong></th>
<th>Value to evaluate using any data type that supports equality comparison.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>error-tolerance</strong></td>
<td>Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation. You can set <em>error-tolerance</em> to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance. If you omit this argument, Vertica uses an error tolerance of 1.25 (%).</td>
</tr>
</tbody>
</table>
Restrictions

APPROXIMATE_COUNT_DISTINCT_SYNOPSIS and DISTINCT aggregates cannot be in the same query block.

Example

See APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS.

See Also

Approximate Count Distinct Functions

APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE

Aggregates multiple synopses into one new synopsis. This function is similar to APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS but returns one synopsis instead of the count estimate. The benefit of this function is that it speeds up final estimation when calling APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS.

For example, if you need to regularly estimate count distinct of users for a long period of time (such as several years) you can pre-accumulate synopses of days into one synopsis for a year.

Behavior Type

Immutable

Syntax

APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE ( synopsis-obj [, error-tolerance] )
**Parameters**

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>synopsis-obj</strong></td>
<td>An expression that can be evaluated to one or more synopses. Typically a <strong>synopsis-obj</strong> is generated as a binary string by either the APPROXIMATE_COUNT_DISTINCT or APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE function and is stored in a table column of type VARBINARY or LONG VARBINARY.</td>
</tr>
<tr>
<td><strong>error-tolerance</strong></td>
<td>Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation. You can set <strong>error-tolerance</strong> to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance. If you omit this argument, Vertica uses an error tolerance of 1.25 (%). For more details, see <a href="#">APPROXIMATE_COUNT_DISTINCT</a>.</td>
</tr>
</tbody>
</table>

**Example**

See [Approximate Count Distinct Functions](#).

### APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS

Calculates the number of distinct non-NULL values from the synopsis objects created by [APPROXIMATE_COUNT_DISTINCT_SYNOPSIS](#).

**Behavior Type**

*Immutable*
Syntax

APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS ( synopsis-obj[, error-tolerance ] )

Parameters

<table>
<thead>
<tr>
<th>synopsis-obj</th>
<th>A synopsis object created by APPROXIMATE_COUNT_DISTINCT_SYNOPSIS.</th>
</tr>
</thead>
<tbody>
<tr>
<td>error-tolerance</td>
<td>Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation. You can set error-tolerance to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance. If you omit this argument, Vertica uses an error tolerance of 1.25 (%). For more details, see APPROXIMATE_COUNT_DISTINCT.</td>
</tr>
</tbody>
</table>

Restrictions

APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS and DISTINCT aggregates cannot be in the same query block.

Examples

The following examples review and compare different ways to obtain a count of unique values in a table column:

Return an exact count of unique values in column product_key, from table store.store_sales_fact:

=> \timing
Timing is on.
=> SELECT COUNT(DISTINCT product_key) from store.store_sales_fact;
count
--------
Return an approximate count of unique values in column **product_key**:

```sql
=> SELECT APPROXIMATE_COUNT_DISTINCT(product_key) as unique_product_keys
    FROM store.store_sales_fact;
unique_product_keys
----------------- 19921
(1 row)
```

Time: First fetch (1 row): 394.562 ms. All rows formatted: 394.600 ms

Create a synopsis object that represents a set of **store.store_sales_fact** data with unique **product_key** values, store the synopsis in the new table **my_summary**:

```sql
=> CREATE TABLE my_summary AS SELECT APPROXIMATE_COUNT_DISTINCT_SYNOPSIS (product_key) syn
    FROM store.store_sales_fact;
CREATE TABLE
```

Time: First fetch (0 rows): 582.662 ms. All rows formatted: 582.682 ms

Return a count from the saved synopsis:

```sql
=> SELECT APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(syn) FROM my_summary;
ApproxCountDistinctOfSynopsis
----------------------------- 19921
(1 row)
```

Time: First fetch (1 row): 105.295 ms. All rows formatted: 105.335 ms

**See Also**

Approximate Count Distinct Functions

**APPROXIMATE_MEDIAN [Aggregate]**

Computes the approximate median of an expression over a group of rows. The function returns a FLOAT value.

APPROXIMATE_MEDIAN is an alias of APPROXIMATE_PERCENTILE [Aggregate] with a parameter of 0.5.
Note: This function is best suited for large groups of data. If you have a small group of data, use the exact MEDIAN [Analytic] function.

Behavior Type

Immutable

Syntax

APPROXIMATE_MEDIAN ( expression )

Parameters

expression | Any FLOAT or INTEGER data type. The function returns the approximate middle value or an interpolated value that would be the approximate middle value once the values are sorted. Null values are ignored in the calculation.

Examples

Tip:
For optimal performance when using GROUP BY in your query, verify that your table is sorted on the GROUP BY column.

The following examples uses this table:

```sql
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Calculate the approximate median of all sales in this table:

```sql
=> SELECT APPROXIMATE_MEDIAN (sales) FROM allsales;
APPROXIMATE_MEDIAN
---------------------
```

Vertica Analytic Database (9.3.x)
Modify the query to group sales by state, and obtain the approximate median for each one:

```sql
=> SELECT state, APPROXIMATE_MEDIAN(sales) FROM allsales GROUP BY state;
```

<table>
<thead>
<tr>
<th>state</th>
<th>APPROXIMATE_MEDIAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>35</td>
</tr>
<tr>
<td>NY</td>
<td>20</td>
</tr>
</tbody>
</table>

(2 rows)

**See Also**

- MEDIAN [Analytic]
- PERCENTILE_CONT [Analytic]
- APPROXIMATE_PERCENTILE [Aggregate]
- SQL Analytics

**APPROXIMATE_PERCENTILE [Aggregate]**

Computes the approximate percentile of an expression over a group of rows. This function returns a FLOAT value. Nulls are ignored.

**Note:** This function is best suited for large groups of data. If you have a small group of data, use the exact PERCENTILE_CONT [Analytic] function.

**Behavior Type**

Immutable

**Syntax**

```sql
APPROXIMATE_PERCENTILE ( expression USING PARAMETERS percentile = number )
```
**Parameters**

<table>
<thead>
<tr>
<th>expression</th>
<th>Any FLOAT or INTEGER data type. Null values are ignored.</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>Percentile value, which must be a FLOAT constant ranging from 0 to 1 (inclusive).</td>
</tr>
</tbody>
</table>

**Examples**

**Tip:**
For optimal performance when using GROUP BY in your query, verify that your table is sorted on the GROUP BY column.

The following example uses this table:

```sql
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Calculate the approximate percentile for sales in each state:

```sql
=> SELECT state, APPROXIMATE_PERCENTILE(sales USING PARAMETERS percentile=0.5) AS median FROM allsales GROUP BY state;
```

```
<table>
<thead>
<tr>
<th>state</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>35</td>
</tr>
<tr>
<td>NY</td>
<td>20</td>
</tr>
</tbody>
</table>
```

See Also

- MEDIAN [Analytic]
- PERCENTILE_CONT [Analytic]
- SQL Analytics
**AVG [Aggregate]**

Computes the average (arithmetic mean) of an expression over a group of rows. AVG always returns a DOUBLE PRECISION value.

The AVG aggregate function differs from the AVG analytic function, which computes the average of an expression over a group of rows within a window.

**Behavior Type**

Immutable

**Syntax**

```
AVG ( [ ALL | DISTINCT ] expression )
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Invokes the aggregate function for all rows in the group (default).</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Invokes the aggregate function for all distinct non-null values of the expression found in the group.</td>
</tr>
<tr>
<td>expression</td>
<td>The value whose average is calculated over a set of rows, any expression that can have a DOUBLE PRECISION result.</td>
</tr>
</tbody>
</table>

**Overflow Handling**

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG.

**Examples**

The following query returns the average income from the `customer` table:
See Also

- COUNT [Aggregate]
- SUM [Aggregate]
- Numeric Data Types

**BIT_AND**

Takes the bitwise AND of all non-null input values. If the input parameter is NULL, the return value is also NULL.

**Behavior Type**

Immutable

**Syntax**

BIT_AND ( expression )

**Parameters**

| expression | The BINARY or VARBINARY input value to evaluate. BIT_AND operates on VARBINARY types explicitly and on BINARY types implicitly through casts. |

**Returns**

BIT_AND returns:

- The same value as the argument data type.
- 1 for each bit compared, if all bits are 1; otherwise 0.
If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values ff, null, and f, BIT_AND ignores the null value and extends the value f to f0.

**Example**

The example that follows uses table t with a single column of VARBINARY data type:

```sql
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table t to see column c output:

```sql
=> SELECT TO_HEX(c) FROM t;
  TO_HEX
  -----
  ff00
  ffff
  f00f
(3 rows)
```

Query table t to get the AND value for column c:

```sql
=> SELECT TO_HEX(BIT_AND(c)) FROM t;
  TO_HEX
  -----
  f000
(1 row)
```

The function is applied pairwise to all values in the group, resulting in f000, which is determined as follows:

1. ff00 (record 1) is compared with ffff (record 2), which results in ff00.
2. The result from the previous comparison is compared with f00f (record 3), which results in f000.

**See Also**

Binary Data Types
BIT_OR

Takes the bitwise OR of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior Type

Immutable

Syntax

BIT_OR ( expression )

Parameters

| expression | The [BINARY | VARBINARY] input value to be evaluated. BIT_OR() operates on VARBINARY types explicitly and on BINARY types implicitly through casts. |

Returns

BIT_OR returns:

- The same value as the argument data type.
- 1 for each bit compared, if any bit is 1; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values ff, null, and f, the function ignores the null value and extends the value f to f0.

Example

The example that follows uses table t with a single column of VARBINARY data type:
CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));

Query table t to see column c output:

=> SELECT TO_HEX(c) FROM t;
 TO_HEX
-------
 ff00
 ffff
 f00f
 (3 rows)

Query table t to get the OR value for column c:

=> SELECT TO_HEX(BIT_OR(c)) FROM t;
 TO_HEX
 -------
 ffff
 (1 row)

The function is applied pairwise to all values in the group, resulting in ffff, which is determined as follows:

1. ff00 (record 1) is compared with ffff, which results in ffff.
2. The ff00 result from the previous comparison is compared with f00f (record 3), which results in ffff.

See Also
Binary Data Types

BIT_XOR

Takes the bitwise XOR of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior Type
Immutable
Syntax

BIT_XOR ( expression )

Parameters

| expression  | The BINARY or VARBINARY input value to evaluate. BIT_XOR operates on VARBINARY types explicitly and on BINARY types implicitly through casts. |

Returns

BIT_XOR returns:

- The same value as the argument data type.
- 1 for each bit compared, if there are an odd number of arguments with set bits; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values ff, null, and f, the function ignores the null value and extends the value f to f0.

Example

First create a sample table and projections with binary columns:

The example that follows uses table t with a single column of VARBINARY data type:

```sql
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table t to see column c output:

```sql
=> SELECT TO_HEX(c) FROM t;
  TO_HEX
  --------
  ff00
  ffff
```
Query table t to get the XOR value for column c:

```sql
=> SELECT TO_HEX(BIT_XOR(c)) FROM t;
    TO_HEX
--------
      f0f0
(1 row)
```

See Also

Binary Data Types

BOOL_AND [Aggregate]

Processes Boolean values and returns a Boolean value result. If all input values are true, BOOL_AND returns t. Otherwise it returns f (false).

Behavior Type

Immutable

Syntax

```sql
BOOL_AND ( expression )
```

Parameters

| expression | A Boolean data type or any non-Boolean data type that can be implicitly coerced to a Boolean data type. |

Examples

The following example shows how to use aggregate functions BOOL_AND, BOOL_OR, and BOOL_XOR. The sample table mixers includes columns for models and colors.
CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'advanced', 'green'
UNION ALL
SELECT 'advanced', 'blue'
UNION ALL
SELECT 'professional', 'blue'
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
```

Query the table. The result shows models that have two blue (BOOL_AND), one or two blue (BOOL_OR), and specifically not more than one blue (BOOL_XOR) mixer.

```
=> SELECT model,
   BOOL_AND(colors= 'blue')AS two,
   BOOL_OR(colors= 'blue')AS one_or_two,
   BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one
FROM mixers
GROUP BY model;
```

<table>
<thead>
<tr>
<th>model</th>
<th>two</th>
<th>one_or_two</th>
<th>specifically_not_more_than_one</th>
</tr>
</thead>
<tbody>
<tr>
<td>advanced</td>
<td>f</td>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>beginner</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>intermediate</td>
<td>t</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>professional</td>
<td>f</td>
<td>t</td>
<td>t</td>
</tr>
</tbody>
</table>

(4 rows)

See Also

- BOOL_XOR [Aggregate]
- Boolean Data Type
BOOL_OR [Aggregate]

Processes Boolean values and returns a Boolean value result. If at least one input value is true, BOOL_OR returns \( t \). Otherwise, it returns \( f \).

**Behavior Type**

Immutable

**Syntax**

```
BOOL_OR ( expression )
```

**Parameters**

| expression | A [Boolean data type] or any non-Boolean data type that can be implicitly coerced to a Boolean data type. |

**Examples**

The following example shows how to use aggregate functions BOOL_AND, BOOL_OR, and BOOL_XOR. The sample table `mixers` includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'advanced', 'green'
UNION ALL
SELECT 'advanced', 'blue'
UNION ALL
SELECT 'professional', 'blue'
```

```
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
```

8
(1 row)

Query the table. The result shows models that have two blue (BOOL_AND), one or two blue (BOOL_OR), and specifically not more than one blue (BOOL_XOR) mixer.

```
=> SELECT model,
    BOOL_AND(colors = 'blue')AS two_blue,
    BOOL_OR(colors = 'blue')AS one_or_two_blue,
    BOOL_XOR(colors = 'blue')AS specifically_not_more_than_one_blue
FROM mixers
GROUP BY model;
```

<table>
<thead>
<tr>
<th>model</th>
<th>two_blue</th>
<th>one_or_two_blue</th>
<th>specifically_not_more_than_one_blue</th>
</tr>
</thead>
<tbody>
<tr>
<td>advanced</td>
<td>t</td>

**BOOL_XOR [Aggregate]**

Processes Boolean values and returns a Boolean value result. If specifically only one input value is true, BOOL_XOR returns t. Otherwise, it returns f.

**Behavior Type**

**Immutable**
**Syntax**

`BOOL_XOR ( expression )`

**Parameters**

| expression | A Boolean data type or any non-Boolean data type that can be implicitly coerced to a Boolean data type. |

**Examples**

The following example shows how to use aggregate functions `BOOL_AND`, `BOOL_OR`, and `BOOL_XOR`. The sample table `mixers` includes columns for models and colors.

```sql
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```sql
=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'

- Boolean Data Type

CORR

Returns the DOUBLE PRECISION coefficient of correlation of a set of expression pairs. CORR eliminates expression pairs where either expression in the pair is NULL. If no rows remain, the function returns NULL.

The approach CORR uses for calculating the correlation is Pearson Correlation Coefficient.

Syntax

CORR ( expression1, expression2 )

Parameters

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>
Example

```sql
=> SELECT CORR (Annual_salary, Employee_age) FROM employee_dimension;

CORR
-0.00719153413192422
(1 row)
```

COUNT [Aggregate]

Returns as a BIGINT the number of rows in each group where the expression is not NULL. If the query has no GROUP BY clause, COUNT returns the number of table rows.

The COUNT aggregate function differs from the COUNT analytic function, which returns the number over a group of rows within a window.

Behavior Type

Immutable

Syntax

```sql
COUNT ( [ * ] [ ALL | DISTINCT ] expression )
```

Parameters

<table>
<thead>
<tr>
<th>*</th>
<th>Specifies to count all rows in the specified table or each group.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>DISTINCT</td>
</tr>
<tr>
<td></td>
<td>• ALL (default): Counts all rows where expression evaluates to a non-null value.</td>
</tr>
<tr>
<td></td>
<td>• DISTINCT: Counts all rows where expression evaluates to a distinct non-null value.</td>
</tr>
</tbody>
</table>

expression The column or expression whose non-null values are counted.
Examples

The following query returns the number of distinct values in the primary_key column of the date_dimension table:

```
=> SELECT COUNT (DISTINCT date_key) FROM date_dimension;
   COUNT
   ------
     1826
(1 row)
```

This example returns all distinct values of evaluating the expression x+y for all inventory_fact records.

```
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
   COUNT
   ------
     21560
(1 row)
```

You can create an equivalent query using the LIMIT keyword to restrict the number of rows returned:

```
=> SELECT COUNT(date_key + product_key) FROM inventory_fact GROUP BY date_key LIMIT 10;
   COUNT
   ------
     173 31 321 113 286 84 244 238 145 202
(10 rows)
```

This query returns the number of distinct values of date_key in all records with the specific distinct product_key value.

```
=> SELECT product_key, COUNT (DISTINCT date_key) FROM inventory_fact GROUP BY product_key LIMIT 10;
   product_key | count
   -------------
       1 |    12
       2 |    18
       3 |    13
       4 |    17
```
This query counts each distinct product_key value in inventory_fact table with the constant 1.

```
=> SELECT product_key, COUNT(DISTINCT product_key) FROM inventory_fact
         GROUP BY product_key LIMIT 10;

<table>
<thead>
<tr>
<th>product_key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
</tr>
</tbody>
</table>
```

This query selects each distinct date_key value and counts the number of distinct product_key values for all records with the specific product_key value. It then sums the qty_in_stock values in all records with the specific product_key value and groups the results by date_key.

```
=> SELECT date_key, COUNT(DISTINCT product_key), SUM(qty_in_stock) FROM inventory_fact
         GROUP BY date_key LIMIT 10;

<table>
<thead>
<tr>
<th>date_key</th>
<th>count</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>173</td>
<td>88953</td>
</tr>
<tr>
<td>2</td>
<td>31</td>
<td>16315</td>
</tr>
<tr>
<td>3</td>
<td>318</td>
<td>156003</td>
</tr>
<tr>
<td>4</td>
<td>113</td>
<td>53341</td>
</tr>
<tr>
<td>5</td>
<td>285</td>
<td>148380</td>
</tr>
<tr>
<td>6</td>
<td>84</td>
<td>42421</td>
</tr>
<tr>
<td>7</td>
<td>241</td>
<td>119315</td>
</tr>
<tr>
<td>8</td>
<td>238</td>
<td>122380</td>
</tr>
<tr>
<td>9</td>
<td>142</td>
<td>70151</td>
</tr>
<tr>
<td>10</td>
<td>202</td>
<td>95274</td>
</tr>
</tbody>
</table>
```

This query selects each distinct product_key value and then counts the number of distinct date_key values for all records with the specific product_key value. It also counts the number of distinct warehouse_key values in all records with the specific product_key value.
```sql
=> SELECT product_key, COUNT(DISTINCT date_key), COUNT(DISTINCT warehouse_key) FROM inventory_fact
   GROUP BY product_key LIMIT 15;
```

<table>
<thead>
<tr>
<th>product_key</th>
<th>count</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>12</td>
<td>12</td>
</tr>
<tr>
<td>2</td>
<td>18</td>
<td>18</td>
</tr>
<tr>
<td>3</td>
<td>13</td>
<td>12</td>
</tr>
<tr>
<td>4</td>
<td>17</td>
<td>18</td>
</tr>
<tr>
<td>5</td>
<td>11</td>
<td>9</td>
</tr>
<tr>
<td>6</td>
<td>14</td>
<td>13</td>
</tr>
<tr>
<td>7</td>
<td>13</td>
<td>13</td>
</tr>
<tr>
<td>8</td>
<td>17</td>
<td>15</td>
</tr>
<tr>
<td>9</td>
<td>15</td>
<td>14</td>
</tr>
<tr>
<td>10</td>
<td>12</td>
<td>12</td>
</tr>
<tr>
<td>11</td>
<td>11</td>
<td>11</td>
</tr>
<tr>
<td>12</td>
<td>13</td>
<td>12</td>
</tr>
<tr>
<td>13</td>
<td>9</td>
<td>7</td>
</tr>
<tr>
<td>14</td>
<td>13</td>
<td>13</td>
</tr>
<tr>
<td>15</td>
<td>18</td>
<td>17</td>
</tr>
</tbody>
</table>

(15 rows)

This query selects each distinct `product_key` value, counts the number of distinct `date_key` and `warehouse_key` values for all records with the specific `product_key` value, and then sums all `qty_in_stock` values in records with the specific `product_key` value. It then returns the number of `product_version` values in records with the specific `product_key` value.

```sql
=> SELECT product_key, COUNT(DISTINCT date_key),
       COUNT(DISTINCT warehouse_key),
       SUM(qty_in_stock),
       COUNT(product_version)
FROM inventory_fact GROUP BY product_key LIMIT 15;
```

(15 rows)

The following example returns the number of warehouses from the `warehouse` dimension table:
=> SELECT COUNT(warehouse_name) FROM warehouse_dimension;

COUNT
-------
100
(1 row)

This next example returns the total number of vendors:

=> SELECT COUNT(*) FROM vendor_dimension;

COUNT
-------
50
(1 row)

**COVAR_POP**

Returns the population covariance for a set of expression pairs. The return value is of type DOUBLE PRECISION. COVAR_POP eliminates expression pairs where either expression in the pair is NULL. If no rows remain, the function returns NULL.

**Syntax**

```
SELECT COVAR_POP ( expression1, expression2 )
```

**Parameters**

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>
Example

```sql
=> SELECT COVAR_POP (Annual_salary, Employee_age)
    FROM employee_dimension;
```

<table>
<thead>
<tr>
<th>SELECT COVAR_POP (Annual_salary, Employee_age)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FROM employee_dimension;</td>
</tr>
<tr>
<td>COVAR_POP</td>
</tr>
<tr>
<td>------------------------------------------------</td>
</tr>
<tr>
<td>-9032.34810730019</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>

COVAR_SAMP

Returns the sample covariance for a set of expression pairs. The return value is of type DOUBLE PRECISION. COVAR_SAMP eliminates expression pairs where either expression in the pair is NULL. If no rows remain, the function returns NULL.

Syntax

```sql
SELECT COVAR_SAMP ( expression1, expression2 )
```

Parameters

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>

Example

```sql
=> SELECT COVAR_SAMP (Annual_salary, Employee_age)
    FROM employee_dimension;
```

<table>
<thead>
<tr>
<th>SELECT COVAR_SAMP (Annual_salary, Employee_age)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FROM employee_dimension;</td>
</tr>
<tr>
<td>COVAR_SAMP</td>
</tr>
<tr>
<td>------------------------------------------------</td>
</tr>
<tr>
<td>-9033.25143244343</td>
</tr>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>
GROUP_ID

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. This function returns one or more integers, starting with zero (0), as identifiers.

For the number of duplicates $n$ for a particular grouping, GROUP_ID returns a range of sequential numbers, $0$ to $n-1$. For the first each unique group it encounters, GROUP_ID returns the value $0$. If GROUP_ID finds the same grouping again, the function returns $1$, then returns $2$ for the next found grouping, and so on.

**Note:**

Use GROUP_ID only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING SETS, and ROLLUP.

**Behavior Type**

Immutable

**Syntax**

GROUP_ID ()

**Examples**

This example shows how GROUP_ID creates unique identifiers when a query produces duplicate groupings. For an expenses table, the following query groups the results by category of expense and year and rolls up the sum for those two columns. The results have duplicate groupings for category and NULL. The first grouping has a GROUP_ID of $0$, and the second grouping has a GROUP_ID of $1$.

```sql
=> SELECT Category, Year, SUM(Amount), GROUPING_ID(Category, Year),
    GROUP_ID() FROM expenses GROUP BY Category, ROLLUP(Category, Year)
    ORDER BY Category, Year, GROUPING_ID(Category, Year);
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING_ID</th>
<th>GROUP_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>99.96</td>
<td>1</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Books</td>
<td>99.96</td>
<td>1</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

- GROUPING_ID
- GROUPING SETS Aggregate
- GROUP BY Clause
- ROLLUP Aggregate

GROUPING

Disambiguates the use of NULL values when GROUP BY queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. Such NULL values from the original data can also occur in rows. GROUPING returns 1, if the value of expression is:

- NULL, representing an aggregated value
- 0 for any other value, including NULL values in rows

Note:

Use GROUPING only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING SETS, and ROLLUP.

Behavior Type

Immutable

Syntax

GROUPING ( expression )
Parameters

expression | An expression in the GROUP BY clause

Examples

The following query uses the GROUPING function, taking one of the GROUP BY expressions as an argument. For each row, GROUPING returns one of the following:

- 0: The column is part of the group for that row
- 1: The column is not part of the group for that row

The 1 in the GROUPING(Year) column for electricity and books indicates that these values are subtotals. The right-most column values for both GROUPING(Category) and GROUPING(Year) are 1. This value indicates that neither column contributed to the GROUP BY. The final row represents the total sales.

```sql
=> SELECT Category, Year, SUM(Amount),
     GROUPING(Category), GROUPING(Year)
FROM expenses
GROUP BY ROLLUP(Category, Year)
ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

- GROUP BY Clause
- ROLLUP Aggregate
GROUPING_ID

Concatenates the set of Boolean values generated by the GROUPING function into a bit vector. GROUPING_ID treats the bit vector as a binary number and returns it as a base-10 value that identifies the grouping set combination.

By using GROUPING_ID you avoid the need for multiple, individual GROUPING functions. GROUPING_ID simplifies row-filtering conditions, because rows of interest are identified using a single return from GROUPING_ID = n. Use GROUPING_ID to identify grouping combinations.

Note:
Use GROUPING_ID only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING_SETS, and ROLLUP.

Behavior Type
Immutable

Syntax

GROUPING_ID ( [expression[,..] ] )

expression | An expression that matches one of the expressions in the GROUP BY clause.
If the GROUP BY clause includes a list of expressions, GROUPING_ID returns a number corresponding to the GROUPING bit vector associated with a row.

Examples

This example shows how calling GROUPING_ID without an expression returns the GROUPING bit vector associated with a full set of multilevel aggregate expressions. The GROUPING_ID value is comparable to GROUPING_ID(a,b) because GROUPING_ID() includes all columns in the GROUP BY ROLLUP:

=> SELECT a,b,COUNT(*), GROUPING_ID() FROM T GROUP BY ROLLUP(a,b);
In the following query, the GROUPING(Category) and GROUPING(Year) columns have three combinations:

- 0,0
- 0,1
- 1,1

```sql
=> SELECT Category, Year, SUM(Amount), GROUPING(Category), GROUPING(Year) FROM expenses GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2008</td>
<td>449.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

GROUPING_ID converts these values as follows:

<table>
<thead>
<tr>
<th>Binary Set Values</th>
<th>Decimal Equivalents</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>3</td>
</tr>
<tr>
<td>0</td>
<td>Category, Year</td>
</tr>
</tbody>
</table>

The following query returns the single number for each GROUP BY level that appears in the gr_id column:

```sql
=> SELECT Category, Year, SUM(Amount), GROUPING(Category), GROUPING(Year), GROUPING_ID(Category,Year) AS gr_id FROM expenses GROUP BY ROLLUP(Category, Year);
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
<th>gr_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>449.96</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

The gr_id value determines the GROUP BY level for each row:
<table>
<thead>
<tr>
<th>GROUP BY Level</th>
<th>GROUP BY Row Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Total sum</td>
</tr>
<tr>
<td>1</td>
<td>Category</td>
</tr>
<tr>
<td>0</td>
<td>Category, year</td>
</tr>
</tbody>
</table>

You can also use the `DECODE` function to give the values more meaning by comparing each search value individually:

```sql
=> SELECT Category, Year, SUM(AMOUNT), DECODE(GROUPING_ID(Category, Year),
   3, 'Total',
   1, 'Category',
   0, 'Category,Year')
   AS GROUP_NAME FROM expenses GROUP BY ROLLUP(Category, Year);
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUP_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>Category</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>Category,Year</td>
</tr>
</tbody>
</table>

**LISTAGG**

Transforms non-null values from a group of rows into a list of values that are delimited by a configurable separator. LISTAGG can be used to denormalize rows into a string of comma-separated values or other human-readable formats.
Behavior Type

Volatile

Syntax

LISTAGG ( [ DISTINCT ] column-expression
[ WITH PARAMETERS [max_length=integer-expr]
[, separator='char']
[, on_overflow=('ERROR' | 'TRUNCATE')] ] )

Arguments

| column-expression | A table column or column expression to select from the source table or view. |

LISTAGG does not support spatial data types directly. In order to pass column data of this type, convert the data to strings with the geospatial function ST_AsText.

Caution: Converted spatial data frequently contains commas. LISTAGG uses comma as the default separator character. To avoid ambiguous output, override this default by setting the function's separator parameter to another character.

Parameter Settings

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Set to...</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_length</td>
<td>An integer or integer expression that specifies in bytes the maximum length of the result, up to 32M.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> 1024</td>
</tr>
<tr>
<td>separator</td>
<td>Separator character.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> Comma (,)</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Set to...</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>on_overflow</td>
<td>Specifies behavior when the result overflows the max_length setting, one of the following strings:</td>
</tr>
<tr>
<td></td>
<td>• ERROR (default): Return an error when overflow occurs.</td>
</tr>
<tr>
<td></td>
<td>• TRUNCATE: Remove any characters that exceed max_length setting from the query result, and return the truncated string.</td>
</tr>
</tbody>
</table>

**Privileges**

None

**Examples**

```sql
=> SELECT customer_region Region,
    LISTAGG (DISTINCT customer_city||customer_state USING PARAMETERS max_length=80, on_overflow='TRUNCATE') CityState
FROM customer_dimension
GROUP BY Region;
```

<table>
<thead>
<tr>
<th>Region</th>
<th>CityState</th>
</tr>
</thead>
<tbody>
<tr>
<td>West</td>

</tr>
<tr>
<td>East</td>
<td>ManchesterNH,StamfordCT,CambridgeMA,EriePA,ElizabethNJ,olumbiaSC,WashingtonDC,F</td>
</tr>
</tbody>
</table>

(6 rows)

**MAX [Aggregate]**

Returns the greatest value of an expression over a group of rows. The return value has the same type as the expression data type.

The **MAX analytic function** function differs from the aggregate function, in that it returns the maximum value of an expression over a group of rows within a window.

Aggregate functions MIN and MAX can operate with Boolean values. MAX can act upon a **Boolean data type** or a value that can be implicitly converted to a Boolean. If at least one input value is true, MAX returns `t` (true). Otherwise, it returns `f` (false). In the same scenario, MIN returns `t` (true) if all input values are true. Otherwise it returns `f`. 
Behavior Type

Immutable

Syntax

MAX ( expression )

Parameters

| expression | Any expression for which the maximum value is calculated, typically a column reference. |

Examples

The following query returns the largest value in column sales_dollar_amount.

```
=> SELECT MAX(sales_dollar_amount) AS highest_sale FROM store.store_sales_fact;
  highest_sale
  ------------
  600
  (1 row)
```

The following example shows you the difference between the MIN and MAX aggregate functions when you use them with a Boolean value. The sample creates a table, adds two rows of data, and shows sample output for MIN and MAX.

```
=> CREATE TABLE min_max_functions (torf BOOL);
=> INSERT INTO min_max_functions VALUES (1);
=> INSERT INTO min_max_functions VALUES (0);

=> SELECT * FROM min_max_functions;
  torf
  ------
  t
  f
  (2 rows)

=> SELECT min(torf) FROM min_max_functions;
  min
  ------
  f
  (1 row)
```
See Also

Data Aggregation

MIN [Aggregate]

Returns the smallest value of an expression over a group of rows. The return value has the same type as the expression data type.

The MIN analytic function differs from the aggregate function, in that it returns the minimum value of an expression over a group of rows within a window.

Aggregate functions MIN and MAX can operate with Boolean values. MAX can act upon a Boolean data type or a value that can be implicitly converted to a Boolean. If at least one input value is true, MAX returns t (true). Otherwise, it returns f (false). In the same scenario, MIN returns t (true) if all input values are true. Otherwise it returns f.

Behavior Type

Immutable

Syntax

MIN (expression)

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Any expression for which the minimum value is calculated, typically a column reference.</th>
</tr>
</thead>
</table>
Examples

The following query returns the lowest salary from the employee dimension table.

This example shows how you can query to return the lowest salary from the employee dimension table.

```sql
=> SELECT MIN(annual_salary) AS lowest_paid FROM employee_dimension;

<table>
<thead>
<tr>
<th>lowest_paid</th>
</tr>
</thead>
<tbody>
<tr>
<td>1200</td>
</tr>
</tbody>
</table>

(1 row)
```

The following example shows you the difference between the MIN and MAX aggregate functions when you use them with a Boolean value. The sample creates a table, adds two rows of data, and shows sample output for MIN and MAX.

```sql
=> CREATE TABLE min_max_functions (torf BOOL);
=> INSERT INTO min_max_functions VALUES (1);
=> INSERT INTO min_max_functions VALUES (0);

=> SELECT * FROM min_max_functions;
  torf  
  ------
     t
     f
(2 rows)

=> SELECT min(torf) FROM min_max_functions;
  min  
  ------
     f
(1 row)

=> SELECT max(torf) FROM min_max_functions;
  max  
  ------
     t
(1 row)
```

See Also

Data Aggregation
**REGR_AVGX**

Returns the DOUBLE PRECISION average of the independent expression in an expression pair. REGR_AVGX eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_AVGX returns NULL.

**Syntax**

```
SELECT REGR_AVGX ( expression1, expression2 )
```

**Parameters**

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>

**Example**

```
=> SELECT REGR_AVGX (Annual_salary, Employee_age)
   FROM employee_dimension;
REGR_AVGX
----------
 39.321
(1 row)
```

**REGR_AVGY**

Returns the DOUBLE PRECISION average of the dependent expression in an expression pair. The function eliminates expression pairs where either expression in the pair is NULL. If no rows remain, the function returns NULL.

**Syntax**

```
REGR_AVGY ( expression1, expression2 )
```
Parameters

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE  PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE  PRECISION expression</td>
</tr>
</tbody>
</table>

Example

=> SELECT REGR_AVGY (Annual_salary, Employee_age)  
   FROM employee_dimension;  
   REGR_AVGY  
   --------  
   58354.4913  
   (1 row)

REGR_COUNT

Returns the count of all rows in an expression pair. The function eliminates expression pairs where either expression in the pair is NULL. If no rows remain, the function returns 0.

Syntax

SELECT REGR_COUNT (expression1, expression2)

Parameters

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE  PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE  PRECISION expression</td>
</tr>
</tbody>
</table>

Example

=> SELECT REGR_COUNT (Annual_salary, Employee_age)  
   FROM employee_dimension;  
   REGR_COUNT  
   --------  
   10000  
   (1 row)
**REGR_INTERCEPT**

Returns the y-intercept of the regression line determined by a set of expression pairs. The return value is of type DOUBLE PRECISION. REGR_INTERCEPT eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_INTERCEPT returns NULL.

**Syntax**

```
SELECT REGR_INTERCEPT ( expression1, expression2 )
```

**Parameters**

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT REGR_INTERCEPT (Annual_salary, Employee_age) FROM employee_dimension;
    REGR_INTERCEPT
-----------------------
      59929.5490163437
(1 row)
```

**REGR_R2**

Returns the square of the correlation coefficient of a set of expression pairs. The return value is of type DOUBLE PRECISION. REGR_R2 eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_R2 returns NULL.

**Syntax**

```
SELECT REGR_R2 ( expression1, expression2 )
```
**Parameters**

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT REGR_R2 (Annual_salary, Employee_age) FROM employee_dimension;

---
5.17181631706311e-05
(1 row)
```

**REGR_SLOPE**

Returns the slope of the regression line, determined by a set of expression pairs. The return value is of type DOUBLE PRECISION. REGR_SLOPE eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_SLOPE returns NULL.

**Syntax**

```sql
SELECT REGR_SLOPE ( expression1, expression2 )
```

**Parameters**

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT REGR_SLOPE (Annual_salary, Employee_age) FROM employee_dimension;

---
-48.056400383749
```
**REGR_SXX**

Returns the sum of squares of the difference between the independent expression \( (expression2) \) and its average.

That is, REGR_SXX returns: \[ \sum((expression2 - \text{average}(expression2))(expression2 - \text{average}(expression2))) \]

The return value is of type DOUBLE PRECISION. REGR_SXX eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_SXX returns NULL.

**Syntax**

```sql
SELECT REGR_SXX (expression1, expression2)
```

**Parameters**

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT REGR_SXX (Annual_salary, Employee_age) FROM employee_dimension;
REGR_SXX
-----------
2254907.59
(1 row)
```

**REGR_SXY**

Returns the sum of products of the difference between the dependent expression \( (expression1) \) and its average and the difference between the independent expression \( (expression2) \) and its average.
That is, REGR_SXY returns: \[ \sum((\text{expression1} - \text{average(expression1)})(\text{expression2} - \text{average(expression2)})) \]

The return value is of type DOUBLE PRECISION. REGR_SXY eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_SXY returns NULL.

**Syntax**

```sql
SELECT REGR_SXY (expression1, expression2)
```

**Parameters**

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT REGR_SXY (Annual_salary, Employee_age) FROM employee_dimension;

-90323481.0730019

(1 row)
```

**REGR_SYY**

Returns the sum of squares of the difference between the dependent expression (expression1) and its average.

That is, REGR_SYY returns: \[ \sum((\text{expression1} - \text{average(expression1)})(\text{expression1} - \text{average(expression1)})) \]

The return value is of type DOUBLE PRECISION. REGR_SYY eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_SYY returns NULL.

**Syntax**

```sql
SELECT REGR_SYY (expression1, expression2)
```
Parameters

<table>
<thead>
<tr>
<th>expression1</th>
<th>The dependent DOUBLE PRECISION expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression2</td>
<td>The independent DOUBLE PRECISION expression</td>
</tr>
</tbody>
</table>

Example

```
=> SELECT REGR_SYY (Annual_salary, Employee_age) FROM employee_dimension;
       REGR_SYY
------------------------
  69956728794707.2
(1 row)
```

STDDEV [Aggregate]

Evaluates the statistical sample standard deviation for each member of the group. The return value is the same as the square root of VAR_SAMP:

```
STDDEV(expression) = SQRT(VAR_SAMP(expression))
```

Behavior Type

Immutable

Syntax

```
STDDEV ( expression )
```

Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. STDDEV returns the same data type as expression. |
**Related Functions**

- Nonstandard function STDDEV is provided for compatibility with other databases. It is semantically identical to `STDDEV_SAMP`.
- This aggregate function differs from analytic function `STDDEV`, which computes the statistical sample standard deviation of the current row with respect to the group of rows within a `window`.
- When `VAR_SAMP` returns NULL, STDDEV returns NULL.

**Examples**

The following example returns the statistical sample standard deviation for each household ID from the customer_dimension table of the VMart example database:

```sql
=> SELECT STDDEV(household_id) FROM customer_dimension;
STDDEV
-----------
8651.5084240071
```

**STDDEV_POP [Aggregate]**

Evaluates the statistical population standard deviation for each member of the group.

**Behavior Type**

*Immutable*

**Syntax**

```sql
STDDEV_POP ( expression )
```

**Parameters**

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. STDDEV_POP returns the same data type as expression. |
Related Functions

- This function differs from the analytic function `STDDEV_POP`, which evaluates the statistical population standard deviation for each member of the group of rows within a window.
- `STDDEV_POP` returns the same value as the square root of `VAR_POP`:
  \[
  STDDEV_POP(expression) = \sqrt{VAR_POP(expression)}
  \]
- When `VAR_SAMP` returns NULL, this function returns NULL.

Examples

The following example returns the statistical population standard deviation for each household ID in the `customer` table.

```sql
=> SELECT STDDEV_POP(household_id) FROM customer_dimension;

  STDDEV_POP
  ------------
  8651.41895973367

(1 row)
```

See Also

- Analytic Functions
- SQL Analytics

STDDEV_SAMP [Aggregate]

Evaluates the statistical sample standard deviation for each member of the group. The return value is the same as the square root of `VAR_SAMP`:

\[
STDDEV_SAMP(expression) = \sqrt{VAR_SAMP(expression)}
\]

Behavior Type

Immutable
Syntax

STDDEV_SAMP ( expression )

Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. STDDEV_SAMP returns the same data type as expression. |

Related Functions

- STDDEV_SAMP is semantically identical to nonstandard function STDDEV, which is provided for compatibility with other databases.
- This aggregate function differs from analytic function STDDEV_SAMP, which computes the statistical sample standard deviation of the current row with respect to the group of rows within a window.
- When VAR_SAMP returns NULL, STDDEV_SAMP returns NULL.

Examples

The following example returns the statistical sample standard deviation for each household ID from the customer dimension table.

```sql
=> SELECT STDDEV_SAMP(household_id) FROM customer_dimension;

stddev_samp
------------------
 8651.50842400771

(1 row)
```

SUM [Aggregate]

Computes the sum of an expression over a group of rows. SUM returns a DOUBLE PRECISION value for a floating-point expression. Otherwise, the return value is the same as the expression data type.
The SUM aggregate function differs from the SUM analytic function, which computes the sum of an expression over a group of rows within a window.

**Behavior Type**

*Immutable*

**Syntax**

```
SUM ( [ ALL | DISTINCT ] expression )
```

**Parameters**

<table>
<thead>
<tr>
<th>ALL</th>
<th>Invokes the aggregate function for all rows in the group (default)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISTINCT</td>
<td>Invokes the aggregate function for all distinct non-null values of the expression found in the group</td>
</tr>
</tbody>
</table>

**Overflow Handling**

If you encounter data overflow when using SUM(), use SUM_FLOAT which converts the data to a floating point. By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG.

**Example**

The following query returns the total sum of the product_cost column.

```sql
=> SELECT SUM(product_cost) AS cost FROM product_dimension;

<table>
<thead>
<tr>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>9042850</td>
</tr>
</tbody>
</table>
```

(1 row)
See Also

- AVG [Aggregate]
- COUNT [Aggregate]

SUM_FLOAT [Aggregate]

Computes the sum of an expression over a group of rows and returns a DOUBLE PRECISION value.

Behavior Type

Immutable

Syntax

SUM_FLOAT ( [ ALL | DISTINCT ] expression )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Invokes the aggregate function for all rows in the group (default).</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Invokes the aggregate function for all distinct non-null values of the expression found in the group.</td>
</tr>
<tr>
<td>expression</td>
<td>Any expression whose result is type DOUBLE PRECISION.</td>
</tr>
</tbody>
</table>

Overflow Handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG.
Example

The following query returns the floating-point sum of the average price from the product table:

```
=> SELECT SUM_FLOAT(average_competitor_price) AS cost FROM product_dimension;

   cost
---
18181102

(1 row)
```

VAR_POP [Aggregate]

Evaluates the population variance for each member of the group. This is defined as the sum of squares of the difference of `expression` from the mean of `expression`, divided by the number of remaining rows:

\[
\frac{(\sum(expression*expression) - \sum(expression)\times\sum(expression))}{\text{COUNT(expression)}} / \text{COUNT(expression)}
\]

Behavior Type

Immutable

Syntax

`VAR_POP ( expression )`

Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. VAR_POP returns the same data type as `expression`. |

Related Functions

This aggregate function differs from analytic function `VAR_POP`, which computes the population variance of the current row with respect to the group of rows within a window.
**Examples**

The following example returns the population variance for each household ID in the customer table.

```sql
=> SELECT VAR_POP(household_id) FROM customer_dimension;

<table>
<thead>
<tr>
<th>var_pop</th>
</tr>
</thead>
<tbody>
<tr>
<td>74847050.0168393</td>
</tr>
</tbody>
</table>

(1 row)
```

**VAR_SAMP [Aggregate]**

Evaluates the sample variance for each row of the group. This is defined as the sum of squares of the difference of `expression` from the mean of `expression` divided by the number of remaining rows minus 1:

\[
\frac{(\text{SUM}(\text{expression}^2) - \text{SUM}(\text{expression}) \times \text{SUM}(\text{expression}) \div \text{COUNT}(\text{expression})) \div (\text{COUNT}(\text{expression}) - 1)}{}
\]

**Behavior Type**

Immutable

**Syntax**

`VAR_SAMP ( expression )`

**Parameters**

| `expression` | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. VAR_SAMP returns the same data type as expression. |
Related Functions

- VAR_SAMP is semantically identical to nonstandard function VARIANCE, which is provided for compatibility with other databases.
- This aggregate function differs from analytic function VAR_SAMP, which computes the sample variance of the current row with respect to the group of rows within a window.

Examples

The following example returns the sample variance for each household ID in the customer table.

```
=> SELECT VAR_SAMP(household_id) FROM customer_dimension;
    var_samp
------------
  74848998.0106764
(1 row)
```

See Also

VARIANCE [Aggregate]

VARIANCE [Aggregate]

Evaluates the sample variance for each row of the group. This is defined as the sum of squares of the difference of expression from the mean of expression divided by the number of remaining rows minus 1.

```
(SUM(expression*expression) - SUM(expression) *SUM(expression) /COUNT(expression)) / (COUNT(expression) -1)
```

Behavior Type

Immutable
Syntax

VARIANCE ( expression )

Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. VARIANCE returns the same data type as expression. |

Related Functions

The nonstandard function VARIANCE is provided for compatibility with other databases. It is semantically identical to VAR_SAMP.

This aggregate function differs from analytic function VARIANCE, which computes the sample variance of the current row with respect to the group of rows within a window.

Examples

The following example returns the sample variance for each household ID in the customer table.

```sql
=> SELECT VARIANCE(household_id) FROM customer_dimension;

<table>
<thead>
<tr>
<th>variance</th>
</tr>
</thead>
<tbody>
<tr>
<td>74848598.0106764</td>
</tr>
</tbody>
</table>

(1 row)
```

- VAR_SAMP [Aggregate]
- SQL Analytics
Analytic Functions

Note:
All analytic functions in this section with an aggregate counterpart are appended with [Analytics] in the heading to avoid confusion between the two function types.

Vertica analytics are SQL functions based on the ANSI 99 standard. These functions handle complex analysis and reporting tasks—for example:

- Rank the longest-standing customers in a particular state.
- Calculate the moving average of retail volume over a specified time.
- Find the highest score among all students in the same grade.
- Compare the current sales bonus that salespersons received against their previous bonus.

Analytic functions return aggregate results but they do not group the result set. They return the group value multiple times, once per record. You can sort group values, or partitions, using a window ORDER BY clause, but the order affects only the function result set, not the entire query result set.

Syntax

General

```sql
analytic-function ( arguments ) OVER(
    [ window-partition-clause ]
    [ window-order-clause [ window-frame-clause ] ]
)
```

With named window

```sql
analytic-function ( arguments ) OVER(
    [ named-window [ window-frame-clause ] ]
)
```

Parameters

<p>| analytic-function (arguments) | A Vertica analytic function and its arguments. |</p>
<table>
<thead>
<tr>
<th>Clause</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>OVER</strong></td>
<td>Specifies how to partition, sort, and window frame function input with respect to the current row. The input data is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses. An empty OVER clause provides the best performance for single threaded queries on a single node.</td>
</tr>
<tr>
<td><strong>window-partition-clause</strong></td>
<td>Groups input rows according to one or more columns or expressions. If you omit this clause, no grouping occurs and the analytic function processes all input rows as a single partition.</td>
</tr>
<tr>
<td><strong>window-order-clause</strong></td>
<td>Optionally specifies how to sort rows that are supplied to the analytic function. If the OVER clause also includes a partition clause, rows are sorted within each partition.</td>
</tr>
<tr>
<td><strong>window-frame-clause</strong></td>
<td>Only valid for some analytic functions, specifies as input a set of rows relative to the row that is currently being evaluated by the analytic function. After the function processes that row and its window, Vertica advances the current row and adjusts the window boundaries accordingly.</td>
</tr>
<tr>
<td><strong>named-window</strong></td>
<td>The name of a window that you define in the same query with a <a href="https://vertica.com/docs/analytic/9.3/en/sql-ref/topics/window-frame-clause.html">window name clause</a>. This definition encapsulates window partitioning and sorting. Named windows are useful when the query invokes multiple analytic functions with similar OVER clauses. A window name clause cannot specify a window frame clause. However, you can qualify the named window in an OVER clause with a window frame clause.</td>
</tr>
</tbody>
</table>

**Requirements**

The following requirements apply to analytic functions:
All require an OVER clause. Each function has its own OVER clause requirements. For example, you can supply an empty OVER clause for some analytic aggregate functions such as SUM. For other functions, window frame and order clauses might be required, or might be invalid.

Analytic functions can be invoked only in a query's SELECT and ORDER BY clauses.

Analytic functions cannot be nested. For example, the following query is not allowed:

```sql
=> SELECT MEDIAN(RANK() OVER(ORDER BY sal)) OVER().
```

WHERE, GROUP BY and HAVING operators are technically not part of the analytic function. However, they determine input to that function.

**See Also**

- SQL Analytics
- GROUP BY Queries

**Window Partition Clause**

When specified, a window partition clause divides the rows of the function input based on user-provided expressions. If no expression is provided, the partition clause can improve query performance by using parallelism.

Window partitioning is similar to the GROUP BY clause except that it returns only one result row per input row. If you omit specifying a window partition clause, all input rows are treated as a single partition.

When used with analytic functions, results are computed per partition and start over again (reset) at the beginning of each subsequent partition.

**Syntax**

```
{ PARTITION BY expression[,...] | PARTITION BEST | PARTITION NODES }
```

**Parameters**

<p>| PARTITION BY | Expression on which to sort the partition, where expression |</p>
<table>
<thead>
<tr>
<th>expression</th>
<th>can be a column, constant, or an arbitrary expression formed on columns. Use PARTITION BY for analytic functions with specific partitioning requirements.</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARTITION BEST</td>
<td>Use parallelism to improve performance for multi-threaded queries across multiple nodes.</td>
</tr>
</tbody>
</table>

OVER(PARTITION BEST) provides the best performance on multi-threaded queries across multiple nodes.

The following considerations apply to using PARTITION BEST:

- Use PARTITION BEST for analytic functions that have no partitioning requirements and are thread safe—for example, a one-to-many transform.
- Do not use PARTITION BEST on user-defined transform functions (UDTFs) that are not thread-safe. Doing so can produce an error or incorrect results. If a UDTF is not thread safe, use PARTITION NODES.

<table>
<thead>
<tr>
<th>PARTITION NODES</th>
<th>Use parallelism to improve performance for single-threaded queries across multiple nodes.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>OVER(PARTITION NODES) provides the best performance on single-threaded queries across multiple nodes.</td>
</tr>
</tbody>
</table>

**Examples**

See Window Partitioning in Analyzing Data.

**Window Order Cause**

Specifies how to sort rows that are supplied to the analytic function. If the OVER clause also includes a window partition clause, rows are sorted within each partition.

The window order clause only specifies order within a window result set. The query can have its own ORDER BY clause outside the OVER clause. This has precedence over the window order clause and orders the final result set.

An window order clause also creates a default window frame if none is explicitly specified.
Syntax

ORDER BY { expression[ sort-qualifiers ] } [,…]

dot-qualifiers =

[ ASC | DESC ]
[ NULLS { FIRST | LAST | AUTO } ]

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>A column, constant, or arbitrary expression formed on columns, on which to sort input rows.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASC</td>
<td>DESC</td>
</tr>
</tbody>
</table>
| NULLS {FIRST | LAST | AUTO}    | Specifies whether to position null values first or last. Default positioning depends on whether the sort order is ascending or descending:
  - Ascending default: NULLS LAST
  - Descending default: NULLS FIRST

If you specify NULLS AUTO, Vertica chooses the positioning that is most efficient for this query, either either NULLS FIRST or NULLS LAST.

If you omit all sort qualifiers, Vertica uses ASC NULLS LAST.

For more information, see:

- NULL Sort Order
- Runtime Sorting of NULL Values in Analytic Functions

Examples

See Window Ordering in Analyzing Data.
Window Frame Clause

Specifies a window frame, which comprises a set of rows relative to the row that is currently being evaluated by the analytic function. After the function processes that row and its window, Vertica advances the current row and adjusts the window boundaries accordingly. If the OVER clause also specifies a partition, Vertica also checks that window boundaries do not cross partition boundaries. This process repeats until the function evaluates the last row of the last partition.

Syntax

\[
\begin{align*}
\{ \text{ROWS} \mid \text{RANGE} \} \\
\{ \text{BETWEEN} \ \text{start-point} \ \text{AND} \ \text{end-point} \} \mid \text{start-point} \\
\text{start-point} / \ \text{end-point} = \\
\{ \text{UNBOUNDED} \ \{ \text{PRECEDING} \mid \text{FOLLOWING} \} \\
\mid \text{CURRENT \ ROW} \\
\mid \text{constant-value} \ \{ \text{PRECEDING} \mid \text{FOLLOWING} \}
\}
\end{align*}
\]

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWS</td>
<td>RANGE</td>
</tr>
<tr>
<td>BETWEEN</td>
<td>start-point</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Specifies that the window frame extends to the current partition's first row.

If ROWS or RANGE specifies only a start point, Vertica uses the current row as the end point and creates the window frame accordingly. In this case, **start-point** must resolve to a row that is less than or equal to the current row.

Specifies that the window frame extends to the current partition's last row.

Specifies the current row or value as the window's start or end point.

Specifies a constant value or expression that evaluates to a constant value. The value specifies a physical or logical offset from the current row, depending on whether you specify ROWS or RANGE.

Other dependencies also pertain, depending whether you specify ROWS and RANGE. See **ROWS versus RANGE** below for details.

### Requirements

In order to specify a window frame, the OVER must also specify a **window order (ORDER BY) clause**. If the OVER clause omits specifying a window frame, the function creates a default window that extends from the current row to the first row in the current partition. This is equivalent to the following clause:

```
RANGE UNBOUNDED PRECEDING AND CURRENT ROW
```

### ROWS versus RANGE

The window frame's offset from the current row can be physical or logical:

- **ROWS** specifies the window's **start-point** and **end-point** as a number of rows relative to the current row. If **start-point** and **end-point** are expressed as constant values, the value must evaluate to a positive integer.
• RANGE specifies the window as a logical offset such as time. The range value must match the window order (ORDER BY) clause data type: NUMERIC, DATE/TIME, FLOAT or INTEGER.

Use of ROWS or RANGE imposes specific requirements on setting the window's start and end points as constant values:

**Setting constant values for ROWS**
The constant must evaluate to a positive INTEGER.

**Setting constant values for RANGE**
The following requirements apply:

- The constant must evaluate to a positive numeric value or INTERVAL literal.
- If the constant evaluates to a NUMERIC value, the ORDER BY column type must be a NUMERIC data type.
- If the constant evaluates to an INTERVAL DAY TO SECOND subtype, the ORDER BY column type must be one of the following: TIMESTAMP, TIME, DATE, or INTERVAL DAY TO SECOND.
- If the constant evaluates to an INTERVAL YEAR TO MONTH, the ORDER BY column type must be one of the following: TIMESTAMP, DATE, or INTERVAL YEAR TO MONTH.
- The window order clause can specify only one expression.

**Examples**

See Window Framing in Analyzing Data

**Window Name Clause**

Defines a named window that specifies window partition and order clauses for an analytic function. This window is specified in the function's OVER clause. Named windows can be useful when you write queries that invoke multiple analytic functions with similar OVER clauses—for example, they use the same partition (PARTITION BY) clauses.

**Syntax**

WINDOW window-name AS ( window-partition-clause [window-order-clause] )
Parameters

<table>
<thead>
<tr>
<th>WINDOW window-name</th>
<th>Specifies the window name. All window names must be unique within the same query.</th>
</tr>
</thead>
<tbody>
<tr>
<td>window-partition-clause [window-order-clause]</td>
<td>Clauses to invoke when an OVER clause references this window. If the window definition omits a window order clause, the OVER clause can specify its own order clause.</td>
</tr>
</tbody>
</table>

Requirements

- A WINDOW clause cannot include a window frame clause.
- Each WINDOW clause within the same query must have a unique name.
- A WINDOW clause can reference another window that is already named. For example, the following query names window w1 before w2. Thus, the WINDOW clause that defines w2 can reference w1:

  \[
  \text{SELECT RANK() OVER(w1 ORDER BY sal DESC), RANK() OVER w2} \\
  \text{FROM EMP WINDOW w1 AS (PARTITION BY deptno), w2 AS (w1 ORDER BY sal);} \\
  \]

Examples

See Named Windows in Analyzing Data.

See Also

Analytic Functions

AVG [Analytic]

Computes an average of an expression in a group within a window. AVG returns the same data type as the expression's numeric data type.

The AVG analytic function differs from the AVG aggregate function, which computes the average of an expression over a group of rows.
Behavior Type

Immutable

Syntax

\[
\text{AVG} \left( \text{expression} \right) \text{ OVER} \left( \ldots \left[ \text{window-partition-clause} \right] \ldots \left[ \text{window-order-clause} \right] \ldots \left[ \text{window-frame-clause} \right] \right)
\]

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Any data that can be implicitly converted to a numeric data type.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OVER()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>

Overflow Handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG.

Examples

The following query finds the sales for that calendar month and returns a running/cumulative average (sometimes called a moving average) using the default window of RANGE UNBOUNDED PRECEDING AND CURRENT ROW:

```sql
=> SELECT calendar_month_number_in_year Mo, SUM(product_price) Sales, 
    AVG(SUM(product_price)) OVER (ORDER BY calendar_month_number_in_year)::<INTEGER> Average 
    FROM product_dimension pd, date_dimension dm, inventory_fact if 
    WHERE dm.date_key = if.date_key AND pd.product_key = if.product_key GROUP BY Mo;
```

<table>
<thead>
<tr>
<th>Mo</th>
<th>Sales</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>23869547</td>
<td>23869547</td>
</tr>
<tr>
<td>2</td>
<td>19684661</td>
<td>21737104</td>
</tr>
<tr>
<td>3</td>
<td>22877913</td>
<td>22117374</td>
</tr>
<tr>
<td>4</td>
<td>22901263</td>
<td>22313346</td>
</tr>
<tr>
<td>5</td>
<td>23670676</td>
<td>22584812</td>
</tr>
<tr>
<td>6</td>
<td>22507600</td>
<td>22571943</td>
</tr>
<tr>
<td>7</td>
<td>21514089</td>
<td>22420821</td>
</tr>
</tbody>
</table>
To return a moving average that is not a running (cumulative) average, the window can specify \texttt{ROWS BETWEEN 2 PRECENDING AND 2 FOLLOWING}:

```sql
=> SELECT calendar_month_number_in_year Mo,
    SUM(product_price) Sales,
    AVG(SUM(product_price)) OVER (ORDER BY calendar_month_number_in_year
    ROWS BETWEEN 2 PRECENDING AND 2 FOLLOWING)::INTEGER Average
FROM product_dimension pd,
     date_dimension dm,
     inventory_fact if
WHERE dm.date_key = if.date_key AND pd.product_key = if.product_key
GROUP BY Mo;
```

<table>
<thead>
<tr>
<th>Mo</th>
<th>Sales</th>
<th>Average</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>23869547</td>
<td>22117374</td>
</tr>
<tr>
<td>2</td>
<td>19684661</td>
<td>22313346</td>
</tr>
<tr>
<td>3</td>
<td>22877913</td>
<td>22584812</td>
</tr>
<tr>
<td>4</td>
<td>22901263</td>
<td>22312423</td>
</tr>
<tr>
<td>5</td>
<td>23678676</td>
<td>22694308</td>
</tr>
<tr>
<td>6</td>
<td>22587600</td>
<td>23090862</td>
</tr>
<tr>
<td>7</td>
<td>21514089</td>
<td>22848169</td>
</tr>
<tr>
<td>8</td>
<td>24860684</td>
<td>22843818</td>
</tr>
<tr>
<td>9</td>
<td>21687795</td>
<td>22790236</td>
</tr>
<tr>
<td>10</td>
<td>23648921</td>
<td>23204325</td>
</tr>
<tr>
<td>11</td>
<td>21115910</td>
<td>22790236</td>
</tr>
<tr>
<td>12</td>
<td>24708317</td>
<td>23157716</td>
</tr>
</tbody>
</table>

(12 rows)

See Also

- \texttt{COUNT [Analytic]}
- \texttt{SUM [Analytic]}
- \texttt{SQL Analytics}

\textbf{BOOL_AND [Analytic]}

Returns the Boolean value of an expression within a \texttt{window}. If all input values are true, \texttt{BOOL_AND} returns \texttt{t}. Otherwise, it returns \texttt{f}.

\textbf{Behavior Type}

\textit{Immutable}
Syntax

BOOL_AND ( expression ) OVER ( ... [ window-partition-clause ] ... [ window-order-clause ] ... [ window-frame-clause ] )

Parameters

| expression | A Boolean Data Type or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value. |
| OVER()     | See Analytic Functions. |

Examples

The following example illustrates how you can use the BOOL_AND, BOOL_OR, and BOOL_XOR analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```sql
=> CREATE TABLE employee(emptype VARCHAR, yearspaid VARCHAR);
CREATE TABLE

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```sql
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
```
SELECT 'contractor5', '2016';

Query the table. The result shows employees that were paid twice in 2014 (BOOL_AND), once or twice in 2014 (BOOL_OR), and specifically not more than once in 2014 (BOOL_XOR).

```
=> SELECT DISTINCT emptype, 
    BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptype) AS paidtwicein2014, 
    BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidonceortwicein2014, 
    BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidjustoncein2014 
FROM employee;

 emptype   | paidtwicein2014 | paidonceortwicein2014 | paidjustoncein2014 
-----------|-----------------|-----------------------|---------------------
 contractor1| t               | t                     | f                   
 contractor2| f               | t                     | t                   
 contractor3| f               | t                     | t                   
 contractor4| t               | t                     | f                   
 contractor5| f               | f                     | f                   
```

See Also

- BOOL_AND [Aggregate]
- BOOL_OR [Analytic]
- BOOL_XOR [Analytic]
- Boolean Data Type

**BOOL_OR [Analytic]**

Returns the Boolean value of an expression within a window. If at least one input value is true, BOOL_OR returns t. Otherwise, it returns f.

**Behavior Type**

Immutable
Syntax

BOOL_OR ( expression ) OVER ( 
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )

Parameters

| expression | A Boolean Data Type or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value. |
| OVER()     | See Analytic Functions. |

Examples

The following example illustrates how you can use the BOOL_AND, BOOL_OR, and BOOL_XOR analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```sql
=> CREATE TABLE employee(emptype VARCHAR, yearspaid VARCHAR);
CREATE TABLE

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
```
SELECT 'contractor5', '2016';
OUTPUT
----------
10
(1 row)

Query the table. The result shows employees that were paid twice in 2014 (BOOL_AND), once or twice in 2014 (BOOL_OR), and specifically not more than once in 2014 (BOOL_XOR).

```sql
=> SELECT DISTINCT emptype,
    BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptype) AS paidtwicein2014,
    BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidonceortwicein2014,
    BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidjustoncein2014
FROM employee;
```

<table>
<thead>
<tr>
<th>emptype</th>
<th>paidtwicein2014</th>
<th>paidonceortwicein2014</th>
<th>paidjustoncein2014</th>
</tr>
</thead>
<tbody>
<tr>
<td>contractor1</td>
<td>t</td>
<td>t</td>
<td>f</td>

CONDITIONAL_CHANGE_EVENT [Analytic]

Assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row.

Behavior Type

Immutable
Syntax

CONDITIONAL_CHANGE_EVENT ( expression ) OVER ( ...
... [ window-partition-clause ]
... window-order-clause )

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>SQL scalar expression that is evaluated on an input record. The result of expression can be of any data type.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OVER()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>

Notes

The analytic window-order-clause is required but the window-partition-clause is optional.

Example

=> SELECT CONDITIONAL_CHANGE_EVENT(bid)
   OVER (PARTITION BY symbol ORDER BY ts) AS cce
   FROM TickStore;

The system returns an error when no ORDER BY clause is present:

=> SELECT CONDITIONAL_CHANGE_EVENT(bid)
   OVER (PARTITION BY symbol) AS cce
   FROM TickStore;

ERROR: conditional_change_event must contain an ORDER BY clause within its analytic clause

For more examples, see Event-Based Windows in Analyzing Data.

See Also

- CONDITIONAL_TRUE_EVENT [Analytic]
- ROW_NUMBER [Analytic]
• Time Series Analytics
• Event-Based Windows

**CONDITIONAL_TRUE_EVENT [Analytic]**

Assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true. For example, given a sequence of values for column a, as follows:

```
( 1, 2, 3, 4, 5, 6 )
```

CONDITIONAL_TRUE_EVENT(a > 3) returns 0, 0, 0, 1, 2, 3.

**Behavior Type:**

*Immutable*

**Syntax**

```
CONDITIONAL_TRUE_EVENT ( boolean-expression ) OVER ...
" window-partition-clause ]
" window-order-clause  )
```

**Parameters**

<table>
<thead>
<tr>
<th>boolean-expression</th>
<th>SQL scalar expression that is evaluated on an input record, type BOOLEAN.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OVER()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>

**Notes**

The analytic *window-order-clause* is required but the *window-partition-clause* is optional.
Example

```
> SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6)
    OVER(PARTITION BY bid ORDER BY ts) AS cte
FROM Tickstore;
```

The system returns an error if the ORDER BY clause is omitted:

```
> SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6)
    OVER(PARTITION BY bid) AS cte
FROM Tickstore;
```

ERROR: conditional_true_event must contain an ORDER BY clause within its analytic clause

For more examples, see Event-Based Windows in Analyzing Data.

COUNT [Analytic]

Counts occurrences within a group within a window. If you specify * or some non-null constant, COUNT() counts all rows.

Behavior Type

Immutable

Syntax

```
COUNT ( expression ) OVER ( ...
    [ window-partition-clause ]
    [ window-order-clause ]
    [ window-frame-clause ]
)```

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Returns the number of rows in each group for which the expression is not null. Can be any expression resulting in BIGINT.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OVER()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>

Example

Using the schema defined in Window Framing in Analyzing Data, the following COUNT function omits window order and window frame clauses; otherwise Vertica would treat it as a window aggregate. Think of the window of reporting aggregates as UNBOUNDED PRECEDING and UNBOUNDED FOLLOWING.

```sql
=> SELECT deptno, sal, empno, COUNT(sal) OVER (PARTITION BY deptno) AS count FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>11</td>
<td>6</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Using ORDER BY sal creates a moving window query with default window: RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW.

```sql
=> SELECT deptno, sal, empno, COUNT(sal) OVER (PARTITION BY deptno ORDER BY sal) AS count FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>6</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>
Using the VMart schema, the following query finds the number of employees who make less than or equivalent to the hourly rate of the current employee. The query returns a running/cumulative average (sometimes called a moving average) using the default window of RANGE UNBOUNDED PRECEDING AND CURRENT ROW:

```
=> SELECT employee_last_name AS "last_name", hourly_rate, COUNT(*)
    OVER (ORDER BY hourly_rate) AS moving_count from employee_dimension;
```

<table>
<thead>
<tr>
<th>last_name</th>
<th>hourly_rate</th>
<th>moving_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gauthier</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>Taylor</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>Jefferson</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>Nielson</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>McNulty</td>
<td>6.01</td>
<td>11</td>
</tr>
<tr>
<td>Robinson</td>
<td>6.01</td>
<td>11</td>
</tr>
<tr>
<td>Dobisz</td>
<td>6.01</td>
<td>11</td>
</tr>
<tr>
<td>Williams</td>
<td>6.01</td>
<td>11</td>
</tr>
<tr>
<td>Kramer</td>
<td>6.01</td>
<td>11</td>
</tr>
<tr>
<td>Miller</td>
<td>6.01</td>
<td>11</td>
</tr>
<tr>
<td>Wilson</td>
<td>6.01</td>
<td>11</td>
</tr>
<tr>
<td>Vogel</td>
<td>6.02</td>
<td>14</td>
</tr>
<tr>
<td>Moore</td>
<td>6.02</td>
<td>14</td>
</tr>
<tr>
<td>Vogel</td>
<td>6.02</td>
<td>14</td>
</tr>
<tr>
<td>Carcetti</td>
<td>6.03</td>
<td>19</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To return a moving average that is not also a running (cumulative) average, the window should specify ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING:

```
=> SELECT employee_last_name AS "last_name", hourly_rate, COUNT(*)
    OVER (ORDER BY hourly_rate ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING)
    AS moving_count from employee_dimension;
```

See Also

- COUNT [Aggregate]
- AVG [Analytic]
- SUM [Analytic]
- SQL Analytics
CUME_DIST [Analytic]

Calculates the cumulative distribution, or relative rank, of the current row with regard to other rows in the same partition within a window.

CUME_DIST() returns a number greater then 0 and less then or equal to 1, where the number represents the relative position of the specified row within a group of n rows. For a row x (assuming ASC ordering), the CUME_DIST of x is the number of rows with values lower than or equal to the value of x, divided by the number of rows in the partition. For example, in a group of three rows, the cumulative distribution values returned would be 1/3, 2/3, and 3/3.

Note: Because the result for a given row depends on the number of rows preceding that row in the same partition, you should always specify a window-order-clause when you call this function.

Behavior Type

Immutable

Syntax

CUME_DIST() OVER (
    ...
    [ window-partition-clause ]
    ...
    window-order-clause
)

Parameters

OVER() See Analytic Functions.

Examples

The following example returns the cumulative distribution of sales for different transaction types within each month of the first quarter.
SELECT calendar_month_name AS month, tender_type, SUM(sales_quantity),
    CUME_DIST()
OVER (PARTITION BY calendar_month_name ORDER BY SUM(sales_quantity)) AS CUME_DIST
FROM store.store_sales_fact JOIN date_dimension
USING(date_key) WHERE calendar_month_name IN ('January','February','March')
AND tender_type NOT LIKE 'Other'
GROUP BY calendar_month_name, tender_type;

<table>
<thead>
<tr>
<th>month</th>
<th>tender_type</th>
<th>SUM</th>
<th>CUME_DIST</th>
</tr>
</thead>
<tbody>
<tr>
<td>March</td>
<td>Credit</td>
<td>469858</td>
<td>0.25</td>
</tr>
<tr>
<td>March</td>
<td>Cash</td>
<td>470449</td>
<td>0.5</td>
</tr>
<tr>
<td>March</td>
<td>Check</td>
<td>473033</td>
<td>0.75</td>
</tr>
<tr>
<td>March</td>
<td>Debit</td>
<td>475103</td>
<td>1</td>
</tr>
<tr>
<td>January</td>
<td>Cash</td>
<td>441730</td>
<td>0.25</td>
</tr>
<tr>
<td>January</td>
<td>Debit</td>
<td>443922</td>
<td>0.5</td>
</tr>
<tr>
<td>January</td>
<td>Check</td>
<td>446297</td>
<td>0.75</td>
</tr>
<tr>
<td>January</td>
<td>Credit</td>
<td>450994</td>
<td>1</td>
</tr>
<tr>
<td>February</td>
<td>Check</td>
<td>425665</td>
<td>0.25</td>
</tr>
<tr>
<td>February</td>
<td>Debit</td>
<td>426726</td>
<td>0.5</td>
</tr>
<tr>
<td>February</td>
<td>Credit</td>
<td>430818</td>
<td>0.75</td>
</tr>
<tr>
<td>February</td>
<td>Cash</td>

- PERCENT_RANK [Analytic]
- PERCENTILE_DISC [Analytic]
- SQL Analytics

DENSE_RANK [Analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's ORDER BY clause. A DENSE_RANK function returns a sequence of ranking numbers without any gaps.

DENSE_RANK executes as follows:

1. Sorts partition rows as specified by the ORDER BY clause.
2. Compares the ORDER BY values of the preceding row and current row and ranks the current row as follows:
   - If ORDER BY values are the same, the current row gets the same ranking as the preceding row.

   **Note:** Null values are considered equal. For detailed information on...
how null values are sorted, see NULL Sort Order.

- If the ORDER BY values are different, DENSE_RANK increments or decrements the current row's ranking by 1, depending whether sort order is ascending or descending.

DENSE_RANK always changes the ranking by 1, so no gaps appear in the ranking sequence. The largest rank value is the number of unique ORDER BY values returned by the query.

**Behavior Type**

Immutable

**Syntax**

```
DENSE_RANK() OVER(
  ... [ window-partition-clause ]
  ... window-order-clause )
```

**Parameters**

<table>
<thead>
<tr>
<th>OVER()</th>
<th>See Analytic Functions.</th>
</tr>
</thead>
</table>

See Analytic Functions

**Compared with RANK**

RANK leaves gaps in the ranking sequence, while DENSE_RANK does not. The example below compares the behavior of the two functions.

**Example**

The following query invokes RANK and DENSE_RANK to rank customers by annual income. The two functions return different rankings, as follows:

- If annual_salary contains duplicate values, RANK() inserts duplicate rankings and then skips one or more values—for example, from 4 to 6 and 7 to 9.
• In the parallel column Dense_Rank, DENSE_RANK() also inserts duplicate rankings, but leaves no gaps in the rankings sequence:

```sql
=> SELECT employee_region region, employee_key, annual_salary,
     RANK() OVER (PARTITION BY employee_region ORDER BY annual_salary) Rank,
     DENSE_RANK() OVER (PARTITION BY employee_region ORDER BY annual_salary) "Dense Rank"
FROM employee_dimension;
```

<table>
<thead>
<tr>
<th>region</th>
<th>employee_key</th>
<th>annual_salary</th>
<th>Rank</th>
<th>Dense Rank</th>
</tr>

SQL Analytics

**EXPONENTIAL_MOVING_AVERAGE [Analytic]**

Calculates the exponential moving average (EMA) of expression \( E \) with smoothing factor \( X \). An EMA differs from a simple moving average in that it provides a more stable picture of changes to data over time.

The EMA is calculated by adding the previous EMA value to the current data point scaled by the smoothing factor, as in the following formula:
\[ EMA = EMA_0 + (X \times (E - EMA_0)) \]

where:

- \( E \) is the current data point
- \( EMA_0 \) is the previous row's EMA value.
- \( X \) is the smoothing factor.

This function also works at the row level. For example, EMA assumes the data in a given column is sampled at uniform intervals. If the users' data points are sampled at non-uniform intervals, they should run the time series gap filling and interpolation (GFI) operations before EMA().

**Behavior Type**

Immutable

**Syntax**

```
EXPONENTIAL_MOVING_AVERAGE (E, X) OVER ( ... [ window-partition-clause ] ... window-order-clause )
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( E )</td>
<td>The value whose average is calculated over a set of rows. Can be INTEGER, FLOAT or NUMERIC type and must be a constant.</td>
</tr>
<tr>
<td>( X )</td>
<td>A positive FLOAT value between 0 and 1 that is used as the smoothing factor.</td>
</tr>
<tr>
<td>OVER ()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>

**Examples**

The following example uses time series gap filling and interpolation (GFI) first in a subquery, and then performs an EXPONENTIAL_MOVING_AVERAGE operation on the subquery result.

Create a simple four-column table:
Insert some data, including nulls, so GFI can do its interpolation and gap filling:

```sql
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:00', 'ABC', 60.45, 60.44);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:01', 'ABC', 60.49, 65.12);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:02', 'ABC', 57.78, 59.25);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:03', 'ABC', null, 65.12);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:04', 'ABC', 67.88, null);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:00', 'XYZ', 47.55, 40.15);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:01', 'XYZ', 44.35, 46.78);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:02', 'XYZ', 71.56, 75.78);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:03', 'XYZ', 85.55, 70.21);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:04', 'XYZ', 45.55, 58.65);
=> COMMIT;
```

**Note:**
During gap filling and interpolation, Vertica takes the closest non null value on either side of the time slice and uses that value. For example, if you use a linear interpolation scheme and you do not specify `IGNORE NULLS`, and your data has one real value and one null, the result is null. If the value on either side is null, the result is null. See [When Time Series Data Contains Nulls](#) in Analyzing Data for details.

Query the table that you just created to you can see the output:

```sql
=> SELECT * FROM ticker;
```

<table>
<thead>
<tr>
<th>time</th>
<th>symbol</th>
<th>bid1</th>
<th>bid2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-07-12 03:00:00</td>
<td>ABC</td>
<td>60.45</td>
<td>60.44</td>

</table>

(10 rows)

The following query processes the first and last values that belong to each 2-second time slice in table `trades`' column a. The query then calculates the exponential moving average of expression `fv` and `lv` with a smoothing factor of 50%:

```sql
SELECT symbol, slice_time, fv, lv,
    EXPONENTIAL_MOVING_AVERAGE(fv, 0.5)
    OVER (PARTITION BY symbol ORDER BY slice_time) AS ema_first,
    EXPONENTIAL_MOVING_AVERAGE(lv, 0.5)
    OVER (PARTITION BY symbol ORDER BY slice_time) AS ema_last
FROM (SELECT symbol, slice_time,
            TS_FIRST_VALUE(bid1 IGNORE NULLS) as fv,
            TS_LAST_VALUE(bid2 IGNORE NULLS) AS lv
    FROM ticker TIMESERIES slice_time AS '2 seconds'
    OVER (PARTITION BY symbol ORDER BY slice_time) ) AS sq;
```

<table>
<thead>
<tr>
<th>symbol</th>
<th>slice_time</th>
<th>fv</th>
<th>lv</th>
<th>ema_first</th>

**FIRST_VALUE [Analytic]**

Let's you select the first value of a table or partition (determined by the `window-order-clause`) without having to use a self join. This function is useful when you want to use the first value as a baseline in calculations.

Use `FIRST_VALUE()` with the `window-order-clause` to produce deterministic results. If no `window` is specified for the current row, the default window is **UNBOUNDED PRECEDING AND CURRENT ROW**.

**Behavior Type**

*Immutable*
**Syntax**

FIRST_VALUE (expression [ IGNORE NULLS ]) OVER ( ...
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )

**Parameters**

<table>
<thead>
<tr>
<th>expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>Expression to evaluate—or example, a constant, column, nonanalytic function, function expression, or expressions involving any of these.</td>
</tr>
<tr>
<td>IGNORE NULLS</td>
<td>Specifies to return the first non-null value in the set, or NULL if all values are NULL. If you omit this option and the first value in the set is null, the function returns NULL.</td>
</tr>
<tr>
<td>OVER()</td>
<td>See <a href="#">Analytic Functions</a>.</td>
</tr>
</tbody>
</table>

**Examples**

The following query asks for the first value in the partitioned day of week, and illustrates the potential nondeterministic nature of FIRST_VALUE():

```sql
=> SELECT calendar_year, date_key, day_of_week, full_date_description,
    FIRST_VALUE(full_date_description)
    OVER(PARTITION BY calendar_month_number_in_year ORDER BY day_of_week)
    AS "first_value"
FROM date_dimension
WHERE calendar_year=2003 AND calendar_month_number_in_year=1;
```

The first value returned is January 31, 2003; however, the next time the same query is run, the first value might be January 24 or January 3, or the 10th or 17th. This is because the analytic ORDER BY column `day_of_week` returns rows that contain ties (multiple Fridays). These repeated values make the ORDER BY evaluation result nondeterministic, because rows that contain ties can be ordered in any way, and any one of those rows qualifies as being the first value of `day_of_week`.

<table>
<thead>
<tr>
<th>calendar_year</th>
<th>date_key</th>
<th>day_of_week</th>
<th>full_date_description</th>
<th>first_value</th>
</tr>
</thead>
</table>
Note:
The day_of_week results are returned in alphabetical order because of
lexical rules. The fact that each day does not appear ordered by the 7-day
week cycle (for example, starting with Sunday followed by Monday,
Tuesday, and so on) has no affect on results.

To return deterministic results, modify the query so that it performs its analytic ORDER BY
operations on a unique field, such as date_key:

=> SELECT calendar_year, date_key, day_of_week, full_date_description,
   FIRST_VALUE(full_date_description) OVER
   (PARTITION BY calendar_month_number_in_year ORDER BY date_key) AS "first_value"
   FROM date_dimension WHERE calendar_year=2003;

FIRST_VALUE() returns a first value of January 1 for the January partition and the first
value of February 1 for the February partition. Also, the full_date_description
column contains no ties:
<table>
<thead>
<tr>
<th>Year</th>
<th>Week</th>
<th>Day</th>
<th>First Day</th>
<th>Last Day</th>
</tr>
</thead>
<tbody>
<tr>
<td>2003</td>

**LAG [Analytic]**

Returns the value of the input expression at the given offset before the current row within a window. This function lets you access more than one row in a table at the same time. This is useful for comparing values when the relative positions of rows can be reliably known. It also lets you avoid the more costly self join, which enhances query processing speed.

For information on getting the rows that follow, see LEAD.
Behavior Type

Immutable

Syntax

LAG ( expression[, offset ][, default ] ) OVER ( ... [ window-partition-clause ] ... window-order-clause )

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>The expression to evaluate—for example, a constant, column, non-analytic function, function expression, or expressions involving any of these.</th>
</tr>
</thead>
<tbody>
<tr>
<td>offset</td>
<td>Indicates how great is the lag. The default value is 1 (the previous row). This parameter must evaluate to a constant positive integer.</td>
</tr>
<tr>
<td>default</td>
<td>The value returned if offset falls outside the bounds of the table or partition. This value must be a constant value or an expression that can be evaluated to a constant; its data type is coercible to that of the first argument.</td>
</tr>
<tr>
<td>OVER()</td>
<td>See Analytic Functions</td>
</tr>
</tbody>
</table>

Examples

This example sums the current balance by date in a table and also sums the previous balance from the last day. Given the inputs that follow, the data satisfies the following conditions:

- For each some_id, there is exactly 1 row for each date represented by month_date.
- For each some_id, the set of dates is consecutive; that is, if there is a row for February 24 and a row for February 26, there would also be a row for February 25.
- Each some_id has the same set of dates.

```sql
=> CREATE TABLE balances ( month_date DATE,
```
current_bal INT,  
some_id INT);  
=> INSERT INTO balances values ('2009-02-24', 10, 1);  
=> INSERT INTO balances values ('2009-02-25', 10, 1);  
=> INSERT INTO balances values ('2009-02-26', 10, 1);  
=> INSERT INTO balances values ('2009-02-24', 20, 2);  
=> INSERT INTO balances values ('2009-02-25', 20, 2);  
=> INSERT INTO balances values ('2009-02-26', 20, 2);  
=> INSERT INTO balances values ('2009-02-24', 30, 3);  
=> INSERT INTO balances values ('2009-02-25', 30, 3);  
=> INSERT INTO balances values ('2009-02-26', 30, 3);  
Now run the LAG() function to sum the current balance for each date and sum the previous balance from the last day:

=> SELECT month_date,  
    SUM(current_bal) as current_bal_sum,
    SUM(previous_bal) as previous_bal_sum FROM
    (SELECT month_date, current_bal,
        LAG(current_bal, 1, 0) OVER
        (PARTITION BY some_id ORDER BY month_date)
        AS previous_bal FROM balances) AS subQ
    GROUP BY month_date ORDER BY month_date;

<table>
<thead>
<tr>
<th>month_date</th>
<th>current_bal_sum</th>
<th>previous_bal_sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-02-24</td>
<td>60</td>
<td>0</td>
</tr>
<tr>
<td>2009-02-25</td>
<td>50</td>
<td>60</td>
</tr>
<tr>
<td>2009-02-26</td>
<td>60</td>
<td>50</td>
</tr>
</tbody>
</table>

(3 rows)

Using the same example data, the following query would not be allowed because LAG() is nested inside an aggregate function:

=> SELECT month_date,  
    SUM(current_bal) as current_bal_sum,
    SUM(LAG(current_bal, 1, 0) OVER
    (PARTITION BY some_id ORDER BY month_date)) AS previous_bal_sum
    FROM some_table GROUP BY month_date ORDER BY month_date;

The following example uses the Vmart database. LAG first returns the annual income from the previous row, and then it calculates the difference between the income in the current row from the income in the previous row:

=> SELECT occupation, customer_key, customer_name, annual_income,
    LAG(annual_income, 1, 0) OVER (PARTITION BY occupation
    ORDER BY annual_income) AS prev_income, annual_income -
    LAG(annual_income, 1, 0) OVER (PARTITION BY occupation
    ORDER BY annual_income) AS difference
    FROM customer_dimension ORDER BY occupation, customer_key LIMIT 20;

<table>
<thead>
<tr>
<th>occupation</th>
<th>customer_key</th>
<th>customer_name</th>
<th>annual_income</th>
<th>prev_income</th>
<th>difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accountant</td>
<td>15</td>
<td>Midori V. Peterson</td>
<td>692610</td>
<td>692535</td>
<td>75</td>
</tr>
<tr>
<td>Accountant</td>
<td>43</td>
<td>Midori S. Rodriguez</td>
<td>282359</td>
<td>280976</td>
<td>1383</td>
</tr>
</tbody>
</table>
The next example uses both LEA and LAG to return the third row after the salary in the current row and fifth salary before the salary in the current row:

```sql
=> SELECT hire_date, employee_key, employee_last_name, 
    LEAD(hire_date, 1) OVER (ORDER BY hire_date) AS "next_hired", 
    LAG(hire_date, 1) OVER (ORDER BY hire_date) AS "last_hired"
FROM employee dimension ORDER BY hire_date, employee_key;
```

**LAST_VALUE [Analytic]**

Let's you select the last value of a table or partition (determined by the `window-order-clause`) without having to use a self join. LAST_VALUE takes the last record from the
partition after the window order clause. The function then computes the expression against the last record, and returns the results. This function is useful when you want to use the last value as a baseline in calculations.

Use LAST_VALUE() with the window-order-clause to produce deterministic results. If no window is specified for the current row, the default window is UNBOUNDED PRECEDING AND CURRENT ROW.

**Tip:**
Due to default window semantics, LAST_VALUE does not always return the last value of a partition. If you omit Window Frame Clause from the analytic clause, LAST_VALUE operates on this default window. Although results can seem non-intuitive by not returning the bottom of the current partition, it returns the bottom of the window, which continues to change along with the current input row being processed. If you want to return the last value of a partition, use UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING. See examples below.

**Behavior Type**
Immutable

**Syntax**

```
LAST_VALUE ( expression [ IGNORE NULLS ] ) OVER ( ...
    [ window-partition-clause ]
    [ window-order-clause ]
    [ window-frame-clause ]
)
```

**Parameters**

<table>
<thead>
<tr>
<th>expression</th>
<th>Expression to evaluate—for example, a constant, column, nonanalytic function, function expression, or expressions involving any of these.</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGNORE NULLS</td>
<td>Specifies to return the last non-null value in the set, or NULL if all values are NULL. If you omit this option and the last value in the set is null, the function returns NULL.</td>
</tr>
<tr>
<td>OVER()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>
Example

Using the schema defined in Window Framing in Analyzing Data, the following query does not show the highest salary value by department; instead it shows the highest salary value by department by salary.

```sql
=> SELECT deptno, sal, empno, LAST_VALUE(sal)
    OVER (PARTITION BY deptno ORDER BY sal) AS lv
FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>lv</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>101</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>104</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>100</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>109</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>109</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>109</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>110</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>110</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>102</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>103</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>105</td>
</tr>
</tbody>
</table>

If you include the window frame clause ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING, LAST_VALUE() returns the highest salary by department, an accurate representation of the information:

```sql
=> SELECT deptno, sal, empno, LAST_VALUE(sal)
    OVER (PARTITION BY deptno ORDER BY sal
         ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>lv</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>104</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>104</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>110</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>110</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>110</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>110</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>110</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>110</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>105</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>105</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>105</td>
</tr>
</tbody>
</table>

For more examples, see FIRST_VALUE().

LEAD [Analytic]

Returns values from the row after the current row within a **window**, letting you access more than one row in a table at the same time. This is useful for comparing values when the relative positions of rows can be reliably known. It also lets you avoid the more costly self join, which enhances query processing speed.

Behavior Type

Immutable

Syntax

LEAD ( *expression* [, *offset* ] [, *default* ] ) OVER ( ...
  [ *window-partition-clause* ]
  ...
  *window-order-clause* )

Parameters

<table>
<thead>
<tr>
<th><strong>expression</strong></th>
<th>The expression to evaluate—for example, a constant, column, non-analytic function, function expression, or expressions involving any of these.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>offset</strong></td>
<td>Is an optional parameter that defaults to 1 (the next row). This parameter must evaluate to a constant positive integer.</td>
</tr>
<tr>
<td><strong>default</strong></td>
<td>The value returned if <em>offset</em> falls outside the bounds of the table or partition. This value must be a constant value or an expression that can be evaluated to a constant; its data type is coercible to that of the first argument.</td>
</tr>
</tbody>
</table>
Examples

LEAD finds the hire date of the employee hired just after the current row:

```sql
=> SELECT employee_region, hire_date, employee_key, employee_last_name,
    LEAD(hire_date, 1) OVER (PARTITION BY employee_region ORDER BY hire_date) AS "next_hired"
FROM employee_dimension ORDER BY employee_region, hire_date, employee_key;
```

<table>
<thead>
<tr>
<th>employee_region</th>
<th>hire_date</th>
<th>employee_key</th>
<th>employee_last_name</th>
<th>next_hired</th>
</tr>
</thead>
<tbody>

<td>1958-09-18</td>
<td>9678</td>
<td>Sanchez</td>
<td>1958-11-10</td>
</tr>
</tbody>
</table>
```

The next example uses LEAD and LAG to return the third row after the salary in the current row and fifth salary before the salary in the current row.

```sql
=> SELECT hire_date, employee_key, employee_last_name,
    LEAD(hire_date, 1) OVER (ORDER BY hire_date) AS "next_hired",
    LAG(hire_date, 1) OVER (ORDER BY hire_date) AS "last_hired"
FROM employee_dimension ORDER BY hire_date, employee_key;
```

<table>
<thead>
<tr>
<th>hire_date</th>
<th>employee_key</th>
<th>employee_last_name</th>
<th>next_hired</th>
<th>last_hired</th>
</tr>
</thead>
<tbody>
<tr>
<td>1956-04-11</td>
<td>2694</td>
<td>Farmer</td>
<td>1956-05-12</td>
<td></td>
</tr>
<tr>

<td>3874</td>
<td>Martin</td>
<td>1958-02-06</td>
<td>1957-11-11</td>
</tr>
</tbody>
</table>
```

The following example returns employee name and salary, along with the next highest and lowest salaries.

```sql
=> SELECT employee_last_name, annual_salary,
    NVL(LEAD(annual_salary) OVER (ORDER BY annual_salary),
    MIN(annual_salary) OVER()) "Next Highest",
    NVL(LAG(annual_salary) OVER (ORDER BY annual_salary),
    MAX(annual_salary) OVER()) "Next Lowest"
FROM employee_dimension;
```
The next example returns, for each assistant director in the employees table, the hire date of the director hired just after the director on the current row. For example, Jackson was hired on 2016-12-28, and the next director hired was Bauer:

```sql
=> SELECT employee_last_name, hire_date,
    LEAD(hire_date, 1) OVER (ORDER BY hire_date DESC) as "NextHired"
FROM employee_dimension WHERE job_title = 'Assistant Director';
```

### Results

- [SQL Analytics]

### MAX [Analytic]

Returns the maximum value of an expression within a window. The return value has the same type as the expression data type.

The analytic functions MIN() and MAX() can operate with Boolean values. The MAX() function acts upon a Boolean Data Type or a value that can be implicitly converted to a Boolean value. If at least one input value is true, MAX() returns t (true). Otherwise, it returns f (false). In the same scenario, the MIN() function returns t (true) if all input values are true. Otherwise, it returns f.
Behavior Type

Immutable

Syntax

MAX(expression) OVER(
... [window-partition-clause]
... [window-order-clause]
... [window-frame-clause]
)

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Any expression for which the maximum value is calculated, typically a column reference.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OVER()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>

Examples

The following query computes the deviation between the employees' annual salary and the maximum annual salary in Massachusetts:

```sql
SELECT employee_state, annual_salary, MAX(annual_salary)
OVER(PARTITION BY employee_state ORDER BY employee_key) max,
annual_salary - MAX(annual_salary)
OVER(PARTITION BY employee_state ORDER BY employee_key) diff
FROM employee_dimension
WHERE employee_state = 'MA';
```

<table>
<thead>
<tr>
<th>employee_state</th>
<th>annual_salary</th>
<th>max</th>
<th>diff</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>1918</td>
<td>995533</td>
<td>-993615</td>
</tr>
<tr>
<td>MA</td>
<td>2058</td>

<td>2664</td>
<td>995533</td>
<td>-992869</td>
</tr>
</tbody>
</table>

(10 rows)
The following example shows you the difference between the MIN and MAX analytic functions when you use them with a Boolean value. The sample creates a table with two columns, adds two rows of data, and shows sample output for MIN and MAX.

```
CREATE TABLE min_max_functions (emp VARCHAR, torf BOOL);

INSERT INTO min_max_functions VALUES ('emp1', 1);
INSERT INTO min_max_functions VALUES ('emp1', 0);

SELECT DISTINCT emp,
    min(torf) OVER (PARTITION BY emp) AS worksasbooleanand,
    Max(torf) OVER (PARTITION BY emp) AS worksasbooleanor
FROM min_max_functions;
```

<table>
<thead>
<tr>
<th>emp</th>
<th>worksasbooleanand</th>
<th>worksasbooleanor</th>
</tr>
</thead>
<tbody>
<tr>
<td>emp1</td>
<td>f</td>
<td>t</td>
</tr>
</tbody>
</table>

(1 row)

**MEDIAN [Analytic]**

For each row, returns the median value of a value set within each partition. MEDIAN determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

MEDIAN is an alias of PERCENTILE_CONT [Analytic] with an argument of 0.5 (50%).

**Behavior Type**

Immutable

**Syntax**

```
MEDIAN ( expression ) OVER ( [ window-partition-clause ] )
```
Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the middle value or an interpolated value that would be the middle value once the values are sorted. Null values are ignored in the calculation. |
| OVER() | If the OVER clause specifies window-partition-clause, MEDIAN groups input rows according to one or more columns or expressions. If this clause is omitted, no grouping occurs and MEDIAN processes all input rows as a single partition. |

Examples

See Calculating a Median Value

See Also

- PERCENTILE_CONT [Analytic]
- SQL Analytics

MIN [Analytic]

Returns the minimum value of an expression within a window. The return value has the same type as the expression data type.

The analytic functions MIN() and MAX() can operate with Boolean values. The MAX() function acts upon a Boolean Data Type or a value that can be implicitly converted to a Boolean value. If at least one input value is true, MAX() returns t (true). Otherwise, it returns f (false). In the same scenario, the MIN() function returns t (true) if all input values are true. Otherwise, it returns f.

Behavior Type

Immutable
### Syntax

```
MAX ( expression ) OVER (  
  ... [ window-partition-clause ]  
  ... [ window-order-clause ]  
  ... [ window-frame-clause ]  
)
```

### Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Any expression for which the minimum value is calculated, typically a column reference.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OVER()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>

### Examples

The following example shows how you can query to determine the deviation between the employees' annual salary and the minimum annual salary in Massachusetts:

```
=> SELECT employee_state, annual_salary,
    MIN(annual_salary)
    OVER(PARTITION BY employee_state ORDER BY employee_key) min,
    annual_salary- MIN(annual_salary)  
    OVER(PARTITION BY employee_state ORDER BY employee_key) diff
FROM employee_dimension
WHERE employee_state = 'MA';
```

<table>
<thead>
<tr>
<th>employee_state</th>
<th>annual_salary</th>
<th>min</th>
<th>diff</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>1918</td>
<td>1204</td>
<td>714</td>
</tr>
<tr>
<td>MA</td>
<td>2058</td>
<td>1204</td>
<td>854</td>
</tr>
<tr>
<td>MA</td>
<td>2586</td>
<td>1204</td>
<td>1382</td>
</tr>
<tr>
<td>MA</td>
<td>2500</td>
<td>1204</td>
<td>1296</td>
</tr>
<tr>
<td>MA</td>
<td>1318</td>
<td>1204</td>
<td>114</td>
</tr>
<tr>
<td>MA</td>
<td>2072</td>
<td>1204</td>
<td>868</td>
</tr>
<tr>
<td>MA</td>
<td>2656</td>
<td>1204</td>
<td>1452</td>
</tr>
<tr>
<td>MA</td>
<td>2148</td>
<td>1204</td>
<td>944</td>
</tr>
<tr>
<td>MA</td>
<td>2366</td>
<td>1204</td>
<td>1162</td>
</tr>
<tr>
<td>MA</td>
<td>2664</td>
<td>1204</td>
<td>1460</td>
</tr>
</tbody>
</table>

(10 rows)

NTILE [Analytic]

Equally divides an ordered data set (partition) into a \{value\} number of subsets within a window, where the subsets are numbered 1 through the value in parameter constant-value. For example, if constant-value= 4 and the partition contains 20 rows, NTILE divides the partition rows into four equal subsets of five rows. NTILE assigns each row to a subset by giving row a number from 1 to 4. The rows in the first subset are assigned 1, the next five are assigned 2, and so on.

If the number of partition rows is not evenly divisible by the number of subsets, the rows are distributed so no subset is more than one row larger than any other subset, and the lowest subsets have extra rows. For example, if constant-value= 4 and the number of rows = 21, the first subset has six rows, the second subset has five rows, and so on.

If the number of subsets is greater than the number of rows, then a number of subsets equal to the number of rows is filled, and the remaining subsets are empty.

Behavior Type

Immutable
Syntax

```
NTILE ( constant-value ) OVER ( ...
    ... [ window-partition-clause ]
    ...
    window-order-clause )
```

Parameters

<table>
<thead>
<tr>
<th>constant-value</th>
<th>Specifies the number of subsets, where constant-value must resolve to a positive constant for each partition.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OVER()</td>
<td>See Analytic Functions.</td>
</tr>
</tbody>
</table>

Examples

The following query assigns each month's sales total into one of four subsets:

```sql
=> SELECT calendar_month_name AS MONTH, SUM(sales_quantity),
       NTILE(4) OVER (ORDER BY SUM(sales_quantity)) AS NTILE
FROM store.store_sales_fact JOIN date_dimension
USING(date_key)
GROUP BY calendar_month_name
ORDER BY NTILE;
```

<table>
<thead>
<tr>
<th>MONTH</th>
<th>SUM</th>
<th>NTILE</th>
</tr>
</thead>
<tbody>
<tr>
<td>November</td>
<td>2840726</td>
<td>1</td>
</tr>
<tr>
<td>June</td>
<td>2888528</td>
<td>1</td>
</tr>
<tr>
<td>February</td>

<td>2417239</td>
<td>4</td>
</tr>
<tr>
<td>May</td>
<td>2492182</td>
<td>4</td>
</tr>
<tr>
<td>December</td>
<td>2531842</td>
<td>4</td>
</tr>
</tbody>
</table>

(12 rows)

See Also

- PERCENTILE_CONT [Analytic]
- WIDTH_BUCKET
- SQL Analytics
NTH_VALUE [Analytic]

Returns the value evaluated at the row that is the \( n \)th row of the window (counting from 1). If the specified row does not exist, NTH_VALUE returns NULL.

**Behavior Type**

*Immutable*

**Syntax**

\[
\text{NTH\_VALUE}( \text{expression}, \text{row-number} \ [ \text{IGNORE NULLS} ] ) \ \text{OVER}( \ldots [ \text{window-frame-clause} ] \ldots [ \text{Window Order Cause} ] \ldots [ \text{window-frame-clause} ] )
\]

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{expression} )</td>
<td>Expression to evaluate. The expression can be a constant, column name, nonanalytic function, function expression, or expressions that include any of these.</td>
</tr>
<tr>
<td>( \text{row-number} )</td>
<td>Specifies the row to evaluate, where ( \text{row-number} ) evaluates to an integer ( \geq 1 ).</td>
</tr>
<tr>
<td>\text{IGNORE NULLS}</td>
<td>Specifies to return the first non-NULL value in the set, or NULL if all values are NULL.</td>
</tr>
<tr>
<td>\text{OVER()}</td>
<td>See <a href="https://vertica.com/documentation/analytic.html">Analytic Functions</a>.</td>
</tr>
</tbody>
</table>

**Example**

In the following example, for each tuple (current row) in table \( t1 \), the window frame clause defines the window as follows:

```
ORDER BY b ROWS BETWEEN 3 PRECEDING AND CURRENT ROW
```

For each window, \( n \) for \( n \)th value is \( a+1 \). \( a \) is the value of column \( a \) in the tuple.
NTH_VALUE returns the result of the expression b+1, where b is the value of column b in the nth row, which is the a+1 row within the window.

```sql
=> SELECT * FROM t1 ORDER BY a;
 a | b
------
 1 | 10
 2 | 20
 2 | 21
 3 | 30
 4 | 40
 5 | 50
 6 | 60
(7 rows)

=> SELECT NTH_VALUE(b+1, a+1) OVER
   (ORDER BY b ROWS BETWEEN 3 PRECEDING AND CURRENT ROW) FROM t1;
?column?
------
 22
 31
(7 rows)
```

**PERCENT_RANK [Analytic]**

Calculates the relative rank of a row for a given row in a group within a window by dividing that row’s rank less 1 by the number of rows in the partition, also less 1. PERCENT_RANK always returns values from 0 to 1 inclusive. The first row in any set has a PERCENT_RANK of 0. The return value is NUMBER.

\[
\frac{\text{rank} - 1}{\text{[rows] - 1}}
\]

In the preceding formula, rank is the rank position of a row in the group and rows is the total number of rows in the partition defined by the OVER() clause.

**Behavior Type**

Immutable

**Syntax**

\[
\text{PERCENT_RANK () OVER (}
\quad \text{[window-partition-clause]}
\text{)}
\]
... window-order-clause  )

Parameters

OVER()  See Analytic Functions

Examples

The following example finds the percent rank of gross profit for different states within each month of the first quarter:

```sql
-> SELECT calendar_month_name AS MONTH, store_state,
   SUM(gross_profit_dollar_amount),
   PERCENT_RANK() OVER (PARTITION BY calendar_month_name
   ORDER BY SUM(gross_profit_dollar_amount)) AS PERCENT_RANK
FROM store.store_sales_fact JOIN date_dimension
USING(date_key)
JOIN store.store_dimension
USING (store_key)
WHERE calendar_month_name IN ('January','February','March')
AND store_state IN ('OR','IA','DC','NV','WI')
GROUP BY calendar_month_name, store_state
ORDER BY calendar_month_name, PERCENT_RANK;
```

<table>
<thead>
<tr>
<th>MONTH</th>
<th>store_state</th>

- CUME_DIST [Analytic]
- SQL Analytics

PERCENTILE_CONT [Analytic]

An inverse distribution function where, for each row, PERCENTILE_CONT returns the value that would fall into the specified percentile among a set of values in each partition within a window. For example, if the argument to the function is 0.5, the result of the function is the median of the data set (50th percentile). PERCENTILE_CONT assumes a continuous distribution data model. NULL values are ignored.
PERCENTILE_CONT computes the percentile by first computing the row number where the percentile row would exist. For example:

\[
\text{row-number} = 1 + \text{percentile-value} \times (\text{num-partition-rows} - 1)
\]

If \( \text{row-number} \) is a whole number (within an error of 0.00001), the percentile is the value of row \( \text{row-number} \).

Otherwise, Vertica interpolates the percentile value between the value of the CEILING \( (\text{row-number}) \) row and the value of the FLOOR \( (\text{row-number}) \) row. In other words, the percentile is calculated as follows:

\[
(\text{CEILING}(\text{row-number}) - \text{row-number}) \times (\text{Value of FLOOR(row-number) row}) \\
+ (\text{row-number} - \text{FLOOR(row-number)}) \times (\text{Value of CEILING(row-number) row})
\]

**Note:**

If the percentile value is 0.5, PERCENTILE_CONT returns the same result set as the function MEDIAN.

**Behavior Type**

Immutable

**Syntax**

PERCENTILE_CONT (\(\text{percentile}\)) WITHIN GROUP (ORDER BY \(\text{expression}\) [ASC | DESC]) OVER (...

**Parameters**

<table>
<thead>
<tr>
<th>(\text{percentile})</th>
<th>Percentile value, a FLOAT constant that ranges from 0 to 1 (inclusive).</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\text{WITHIN GROUP (ORDER BY expression)})</td>
<td>Specifies how to sort data within each group. ORDER BY takes only one column/expression that must be INTEGER, FLOAT, INTERVAL, or NUMERIC data type. NULL values are discarded.</td>
</tr>
<tr>
<td></td>
<td>The WITHIN GROUP (ORDER BY) clause does not guarantee the order of the SQL result. To order the final result, use the SQL ORDER BY clause set.</td>
</tr>
<tr>
<td>ASC</td>
<td>DESC</td>
</tr>
</tbody>
</table>
Specifying ASC or DESC in the WITHIN GROUP clause affects results as long as the percentile is not 0.5.

```sql
SELECT customer_state, customer_key, annual_income,
       PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY annual_income)
OVER (PARTITION BY customer_state) AS PERCENTILE_CONT
FROM customer_dimension
WHERE customer_state IN ('DC', 'WI')
AND customer_key < 300
ORDER BY customer_state, customer_key;
```

This query computes the median annual income per group for all customers in Wisconsin and the District of Columbia.

```sql
=> SELECT customer_state, customer_key, annual_income,
       PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY annual_income)
OVER (PARTITION BY customer_state) AS PERCENTILE_CONT
FROM customer_dimension
WHERE customer_state IN ('DC', 'WI')
ORDER BY customer_state, customer_key;
```

Examples

This query computes the median annual income per group for the first 300 customers in Wisconsin and the District of Columbia.

```
<table>
<thead>
<tr>
<th>customer_state</th>
<th>customer_key</th>
<th>annual_income</th>
<th>PERCENTILE_CONT</th>

</tbody>
</table>
```
PERCENTILE_DISC [Analytic]

An inverse distribution function where, for each row, PERCENTILE_DISC returns the value that would fall into the specified percentile among a set of values in each partition within a window. PERCENTILE_DISC() assumes a discrete distribution data model. NULL values are ignored.

PERCENTILE_DISC examines the cumulative distribution values in each group until it finds one that is greater than or equal to the specified percentile. Vertica computes the percentile where, for each row, PERCENTILE_DISC outputs the first value of the WITHIN GROUP(ORDER BY) column whose CUME_DIST (cumulative distribution) value is $\geq$ the argument FLOAT value—for example, 0.4:

```
PERCENTILE_DIST(0.4) WITHIN GROUP (ORDER BY salary) OVER(PARTITION BY deptno)...
```

Given the following query:

```
SELECT CUME_DIST() OVER(ORDER BY salary) FROM table-name;
```

The smallest CUME_DIST value that is greater than 0.4 is also the PERCENTILE_DISC.

Behavior Type

Immutable
Syntax

```sql
PERCENTILE_DISC (percentile) WITHIN GROUP (...
    ORDER BY expression [ ASC | DESC ] ) OVER (...
    [ window-partition-clause ] )
```

Parameters

<table>
<thead>
<tr>
<th>percentile</th>
<th>Percentile value, a FLOAT constant that ranges from 0 to 1 (inclusive).</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>WITHIN GROUP (ORDER BY expression)</strong> Specifies how to sort data within each group. ORDER BY takes only one column/expression that must be INTEGER, FLOAT, INTERVAL, or NUMERIC data type. NULL values are discarded. The WITHIN GROUP (ORDER BY) clause does not guarantee the order of the SQL result. To order the final result, use the SQL ORDER BY clause set.</td>
</tr>
<tr>
<td>ASC</td>
<td>DESC</td>
</tr>
<tr>
<td>OVER()</td>
<td>See Analytic Functions</td>
</tr>
</tbody>
</table>

Example

This query computes the 20th percentile annual income by group for first 300 customers in Wisconsin and the District of Columbia.

```sql
=> SELECT customer_state, customer_key, annual_income,
    PERCENTILE_DISC(.2) WITHIN GROUP(ORDER BY annual_income)
OVER (PARTITION BY customer_state) AS PERCENTILE_DISC
FROM customer_dimension
WHERE customer_state IN ('DC', 'WI')
AND customer_key < 300
ORDER BY customer_state, customer_key;
```

<table>
<thead>
<tr>
<th>customer_state</th>
<th>customer_key</th>
<th>annual_income</th>
<th>PERCENTILE_DISC</th>
</tr>
</thead>
<tbody>
<tr>
<td>DC</td>
<td>104</td>
<td>658383</td>
<td>417092</td>
</tr>
<tr>
<td>DC</td>
<td>168</td>
<td>417092</td>
<td>417092</td>
</tr>
<tr>
<td>DC</td>
<td>245</td>
<td>670205</td>
<td>417092</td>
</tr>
<tr>
<td>WI</td>
<td>106</td>
<td>227279</td>
<td>227279</td>
</tr>
<tr>
<td>WI</td>
<td>127</td>
<td>783889</td>
<td>227279</td>
</tr>
<tr>
<td>WI</td>
<td>209</td>
<td>458607</td>
<td>227279</td>
</tr>
</tbody>
</table>

RANK [Analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's ORDER BY clause.

RANK executes as follows:

1. Sorts partition rows as specified by the ORDER BY clause.
2. Compares the ORDER BY values of the preceding row and current row and ranks the current row as follows:
   - If ORDER BY values are the same, the current row gets the same ranking as the preceding row.
   - If the ORDER BY values are different, DENSE_RANK increments or decrements the current row's ranking by 1, plus the number of consecutive duplicate values in the rows that precede it.

The largest rank value is the equal to the total number of rows returned by the query.

Behavior Type

Immutable

Syntax

RANK() OVER(
  ...
  [ window-partition-clause ]
  ...
  window-order-clause )
Parameters

OVER() See Analytic Functions

Compared with DENSE_RANK

RANK can leave gaps in the ranking sequence, while DENSE_RANK does not. For more information, see DENSE_RANK.

Examples

The following query ranks by state all company customers that have been customers since 2007. In rows where the customer_since dates are the same, RANK assigns the rows equal ranking. When the customer_since date changes, RANK skips one or more rankings—for example, within CA, from 12 to 14, and from 17 to 19.

```sql
=> SELECT customer_state, customer_name, customer_since,
    RANK() OVER (PARTITION BY customer_state ORDER BY customer_since) AS rank
FROM customer_dimension WHERE customer_type='Company' AND customer_since > '01/01/2007'
ORDER BY customer_state;
```

<table>
<thead>
<tr>
<th>customer_state</th>
<th>customer_name</th>
<th>customer_since</th>
<th>rank</th>
</tr>

SQL Analytics
**ROW_NUMBER [Analytic]**

Assigns a sequence of unique numbers, starting from 1, to each row in a window partition. Use the optional window partition clause to group data into partitions before operating on it. For example:

```sql
SUM OVER (PARTITION BY col1, col2, ...)
```

**Notes:**

- `ROW_NUMBER()` is a Vertica extension, not part of the SQL-99 standard.
- `ROW_NUMBER` and `RANK` are generally interchangeable. `ROW_NUMBER` differs from `RANK` in that it assigns a unique ordinal number to each row in the ordered set, starting with 1.

**Behavior Type**

*Immutable*

**Syntax**

```sql
ROW_NUMBER () OVER (  
... [ window-partition-clause ]  
... window-order-clause  )
```

**Parameters**

<table>
<thead>
<tr>
<th>OVER()</th>
<th>See Analytic Functions</th>
</tr>
</thead>
</table>

**Examples**

The following query partitions customers in the VMart table `customer_dimension` by occupation. It then ranks those customers according to the ordered set specified by the window partition clause.
=> SELECT occupation, customer_key, customer_since, annual_income,  
    ROW_NUMBER() OVER (PARTITION BY occupation) AS customer_since_row_num  
FROM public.customer_dimension  
ORDER BY occupation, customer_since_row_num;

<table>
<thead>
<tr>
<th>occupation</th>
<th>customer_key</th>
<th>customer_since</th>
<th>annual_income</th>
<th>customer_since_row_num</th>
</tr>

See Also

- RANK [Analytic]
- SQL Analytics

STDDEV [Analytic]

Computes the statistical sample standard deviation of the current row with respect to the group within a window. STDDEV_SAMP returns the same value as the square root of the variance defined for the VAR_SAMP function:
STDDEV(expression) = SQRT(VAR_SAMP(expression))

When VAR_SAMP returns NULL, this function returns NULL.

**Note:**
The nonstandard function STDDEV is provided for compatibility with other databases. It is semantically identical to STDDEV_SAMP.

**Behavior Type**

Immutable

**Syntax**

STDDEV(expression) OVER ( 
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ]
)

**Parameters**

<table>
<thead>
<tr>
<th>expression</th>
<th>Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OVER()</td>
<td>See Analytic Functions</td>
</tr>
</tbody>
</table>

**Example**

The following example returns the standard deviations of salaries in the employee dimension table by job title Assistant Director:

```sql
=> SELECT employee_last_name, annual_salary, 
    STDDEV(annual_salary) OVER (ORDER BY hire_date) as "stddev"
FROM employee_dimension 
WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary | stddev
-------------------|---------------|-------
Bauer              | 85003         | NaN   |
Reyes              | 91051         | 4276.58181261624 |
Overstreet         | 53296         | 20278.6923394976 |
Gauthier           | 97216         | 19543.7184537642 |
```

STDDEV_POP [Analytic]

Computes the statistical population standard deviation and returns the square root of the population variance within a window. The STDDEV_POP() return value is the same as the square root of the VAR_POP() function:

\[
\text{STDDEV\_POP}( \text{expression} ) = \sqrt{\text{VAR\_POP}( \text{expression} )}
\]

When VAR_POP returns null, STDDEV_POP returns null.

Behavior Type

Immutable

Syntax

```
STDDEV_POP ( expression ) OVER ( ... [ window-partition-clause ] )
```

Vertica Analytic Database (9.3.x)
### Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument. |
| OVER() | See Analytic Functions. |

### Examples

The following example returns the population standard deviations of salaries in the employee dimension table by job title Assistant Director:

```sql
=> SELECT employee_last_name, annual_salary,
    STDDEV_POP(annual_salary) OVER (ORDER BY hire_date) as "stddev_pop"
FROM employee_dimension WHERE job_title = 'Assistant Director';
```

### STDDEV_SAMP [Analytic]

Computes the statistical sample standard deviation of the current row with respect to the group within a window. STDDEV_SAMP's return value is the same as the square root of the variance defined for the VAR_SAMP function:

$$ \text{STDDEV}( \text{expression} ) = \sqrt{\text{VAR}_\text{SAMP}( \text{expression} )} $$
When VAR_SAMP returns NULL, STDDEV_SAMP returns NULL.

**Note:**
STDDEV_SAMP() is semantically identical to the nonstandard function, STDDEV().

**Behavior Type**

Immutable

**Syntax**

STDDEV_SAMP ( expression ) OVER ( ...
[ window-partition-clause ]
...
[ window-order-clause ]
...
[ window-frame-clause ] )

**Parameters**

- **expression**
  Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

- **OVER()**
  See Analytic Functions

**Examples**

The following example returns the sample standard deviations of salaries in the employee dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
   STDDEV(annual_salary) OVER (ORDER BY hire_date) as "stddev_samp"
FROM employee_dimension WHERE job_title = 'Assistant Director';

<table>
<thead>
<tr>
<th>employee_last_name</th>
<th>annual_salary</th>
<th>stddev_samp</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bauer</td>
<td>85003</td>
<td>NaN</td>
</tr>
<tr>
<td>Reyes</td>
<td>91051</td>
<td>4276.58181261624</td>
</tr>

- STDDEV_SAMP [Aggregate]
- SQL Analytics

SUM [Analytic]

Computes the sum of an expression over a group of rows within a window. It returns a DOUBLE PRECISION value for a floating-point expression. Otherwise, the return value is the same as the expression data type.

Behavior Type

Immutable

Syntax

```sql
SUM ( expression ) OVER ( ...
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ]
)
```

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.</th>
</tr>
</thead>
</table>
Overflow Handling

If you encounter data overflow when using SUM, use `SUM_FLOAT` which converts data to a floating point. By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG.

Examples

The following query returns the cumulative sum all of the returns made to stores in January:

```sql
=> SELECT calendar_month_name AS month, transaction_type, sales_quantity,
    SUM(sales_quantity)
    OVER (PARTITION BY calendar_month_name ORDER BY date_dimension.date_key) AS SUM
FROM store.store_sales_fact JOIN date_dimension
USING(date_key) WHERE calendar_month_name IN ('January')
AND transaction_type='return';
```

<table>
<thead>
<tr>
<th>month</th>
<th>transaction_type</th>
<th>sales_quantity</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>

- SQL Analytics

VAR_POP [Analytic]

Returns the statistical population variance of a non-null set of numbers (nulls are ignored) in a group within a window. Results are calculated by the sum of squares of the difference of expression from the mean of expression, divided by the number of rows remaining:

\[
\frac{\text{SUM}( \text{expression} \times \text{expression} ) - \text{SUM}( \text{expression} ) \times \text{SUM}( \text{expression} ) / \text{COUNT}( \text{expression} )}{\text{COUNT}( \text{expression} )}
\]

Behavior Type

Immutable

Syntax

VAR_POP ( expression ) OVER ( ...
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ]
)

Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument |
| OVER()     | See Analytic Functions |
Examples

The following example calculates the cumulative population in the store orders fact table of sales in January 2007:

```sql
=> SELECT date_ordered,
    VAR_POP(SUM(total_order_cost))
    OVER (ORDER BY date_ordered) "var_pop"
FROM store.store_orders_fact s
WHERE date_ordered BETWEEN '2007-01-01' AND '2007-01-31'
GROUP BY s.date_ordered;
```

<table>
<thead>
<tr>
<th>date_ordered</th>
<th>var_pop</th>
</tr>
</thead>
<tbody>
<tr>
<td>2007-01-01</td>
<td>0</td>
</tr>
<tr>
<td>2007-01-02</td>
<td>89870400</td>
</tr>
<tr>
<td>2007-01-03</td>
<td>3470302472</td>
</tr>
<tr>
<td>2007-01-04</td>
<td>4466755450.6875</td>
</tr>

- SQL Analytics

VAR_SAMP [Analytic]

Returns the sample variance of a non-NULL set of numbers (NULL values in the set are ignored) for each row of the group within a window. Results are calculated as follows:

```sql
(SUM( expression * expression ) - SUM( expression ) * SUM( expression ) / COUNT( expression ) ) / ( COUNT( expression ) - 1 )
```

This function and VARIANCE differ in one way: given an input set of one element, VARIANCE returns 0 and VAR_SAMP returns NULL.

Behavior Type

Immutable
Syntax

```
VAR_SAMP ( expression ) OVER ( ... [ window-partition-clause ] ... [ window-order-clause ] ... [ window-frame-clause ] )
```

Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument |
| OVER() | See Analytic Functions |

Null Handling

- VAR_SAMP returns the sample variance of a set of numbers after it discards the NULL values in the set.
- If the function is applied to an empty set, then it returns NULL.

Examples

The following example calculates the sample variance in the store orders fact table of sales in December 2007:

```
=> SELECT date Ordered, 
    VAR_SAMP(SUM(total_order_cost)) 
    OVER (ORDER BY date_ordered) "var_samp" 
FROM store.store_orders_fact s 
WHERE date_ordered BETWEEN '2007-12-01' AND '2007-12-31' 
GROUP BY s.date_ordered;
```

```
<table>
<thead>
<tr>
<th>date_ordered</th>
<th>var_samp</th>
</tr>
</thead>
<tbody>
<tr>
<td>2007-12-01</td>
<td>NaN</td>
</tr>
<tr>
<td>2007-12-02</td>
<td>90642601088</td>
</tr>
<tr>
<td>2007-12-03</td>
<td>48030548449.3359</td>
</tr>
<tr>
<td>2007-12-04</td>
<td>32740062504.2461</td>
</tr>
<tr>
<td>2007-12-05</td>
<td>32100319112.6992</td>
</tr>
<tr>
<td>2007-12-06</td>
<td>26274166814.668</td>
</tr>

- VAR_SAMP [Aggregate]
- SQL Analytics

VARIANCE [Analytic]

Returns the sample variance of a non-NULL set of numbers (NULL values in the set are ignored) for each row of the group within a window. Results are calculated as follows:

\[
\frac{\left( \sum (expression * expression) - \sum(expression) * \sum(expression) / \text{COUNT}(expression) \right) / \text{COUNT}(expression) - 1}{(\text{COUNT}(expression)}
\]

VARIANCE returns the variance of expression, which is calculated as follows:

- 0 if the number of rows in expression = 1
- VAR_SAMP if the number of rows in expression > 1

Note:
The nonstandard function VARIANCE is provided for compatibility with other databases. It is semantically identical to VAR_SAMP.

Behavior Type

Immutable

Syntax

VAR_SAMP (expression) OVER ( 
... [window-partition-clause]
... [window-order-clause]
... [window-frame-clause] )
Parameters

| expression | Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument. |
| OVER()     | See Analytic Functions |

Examples

The following example calculates the cumulative variance in the store orders fact table of sales in December 2007:

```sql
=> SELECT date_ordered,
    VARIANCE(SUM(total_order_cost))
    OVER (ORDER BY date_ordered) "variance"
FROM store.store_orders_fact s
WHERE date_ordered BETWEEN '2007-12-01' AND '2007-12-31'
GROUP BY s.date_ordered;
```

<table>
<thead>
<tr>
<th>date_ordered</th>
<th>variance</th>
</tr>
</thead>

Array Functions

Array functions operate on array values that are used in external tables. These functions allow you to access, compare and aggregate arrays.

In addition to these functions, arrays support comparison operators (\(=\), \(<\), and \(>\)) and can be dereferenced by index (ARRAY[index]).

Notes

- Array functions are supported only for external tables containing Parquet files.
- Arrays are 0-indexed. The first element's ordinal position is 0, second is 1, and so on.
- These functions operate on one-dimensional (1D) arrays, except array dereference and array slice. To use multidimensional arrays, you must first dereference to a 1D array type.
- Null semantics for arrays are consistent with normal columns. See NULL Sort Order for more information on null-handling.

ARRAY_AVG

Returns average of all elements in an array with numeric values.

Behavior Type

Immutable

Syntax

ARRAY_AVG(array)
**Supported Data Types**

1D arrays of:

- INTEGER
- FLOAT
- NUMERIC

**Null-Handling**

The following cases return NULL:

- if the input array is NULL
- if the input array only contains null values
- if the input array is empty

If the input array contains a mix of null and non-null elements, only the non-null values are considered in the calculation of the average.

**Example**

```sql
g=> SELECT array_avg(ARRAY[1,2.4,5,6]);
array_avg
----------
3.6
(1 row)
```

**See also**

- `ARRAY_SUM`

**ARRAY_CAT**

Concatenates two one-dimensional arrays.
**Behavior Type**

**Immutable**

**Syntax**

ARRAY_CAT(array1,array2)

**Supported Data Types**

1D arrays of:

- BOOLEAN
- INTEGER
- FLOAT
- NUMERIC
- STRING/VARCHAR
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL

**Null-Handling**

- Null arguments are ignored. If one of the inputs is null, the function returns the non-null input. In other words, an argument of NULL is equivalent to ARRAY[].
- If both inputs are null, the function returns null.

**Example**

```sql
=> SELECT array_cat(ARRAY[1,2], ARRAY[3,4,5.9]);
array_cat
---------------------
[1.0,2.0,3.0,4.0,5.9]
(1 row)
```
See also

- ARRAY_SLICE

ARRAY_CONTAINS

Returns true if the specified element is found in the array, false otherwise.

Behavior Type

Immutable

Syntax

ARRAY_CONTAINS(array, val_to_test)

Supported Data Types

1D array of:

- BOOLEAN
- INTEGER
- NUMERIC
- STRING/VARCHAR
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL
**Example**

```sql
=> SELECT array_contains(array[1,2,3,4],2);
array_contains
-----------
t
(1 row)
```

**See Also**

- [ARRAY_FIND](#)

**ARRAY_COUNT**

Returns the total number of non-null elements in an array. To count all elements including nulls, use [ARRAY_LENGTH](#).

**Behavior Type**

Immutable

**Syntax**

```sql
ARRAY_COUNT(array)
```

**Supported Data Types**

1D arrays of:

- BOOLEAN
- INTEGER
- FLOAT
- NUMERIC
- STRING/VARCHAR
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL

**Null-Handling**

Null values are not included in the count.

**Example**

```sql
=> SELECT array_count(ARRAY[1.2,NULL,3,7.6,8,5]);
array_count
----------
5
(1 row)
```

**ARRAY_DIMS**

Returns the dimensionality of the input array.

**Behavior Type**

**Immutable**

**Syntax**

```
ARRAY_DIMS(array)
```
**Supported Data Types**

- BOOLEAN
- INTEGER
- FLOAT
- NUMERIC
- STRING/VARCHAR
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL

**Example**

```sql
=> SELECT array_dims(ARRAY[[1,2],[2,3]]);
array_dims
--------
   2
(1 row)
```

**ARRAY_FIND**

Returns the ordinal position of a specified element in an array, or NULL if not found.

**Behavior Type**

**Immutable**

**Syntax**

```sql
ARRAY_FIND(array, val_to_find)
```
**Supported Data Types**

1D arrays of:

- BOOLEAN
- INTEGER
- NUMERIC
- STRING/VARCHAR
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL

**Example**

```sql
=> SELECT array_find(array[1,2,3],2);
array_find
-----------
  1
(1 row)
```

The function returns the first occurrence of the specified element. However, nothing ensures that value is unique in the array.

```sql
=> SELECT array_find(ARRAY[1,2,7,5,7],7);
array_find
-----------
  2
(1 row)
```

The function returns NULL if the specified element is not found.

```sql
=> SELECT array_find(ARRAY[1,3,5,7],4);
array_find
-----------
(1 row)
```

**See Also**

- ARRAY_CONTAINS
**ARRAY_LENGTH**

Returns the total number of elements in an array, including NULLs. To count only non-null values, use **ARRAY_COUNT**

*Behavior Type*

**Immutable**

*Syntax*

`ARRAY_LENGTH(array)`

*Supported Data Types*

1D arrays of:

- BOOLEAN
- INTEGER
- FLOAT
- NUMERIC
- STRING/VARCHAR
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL

*Null-Handling*

This function counts all members, including nulls.

An empty array (ARRAY[]) has a length of 0. An array containing a single null (ARRAY[null]) has a length of 1.
**Examples**

```sql
=> SELECT array_length(ARRAY[1.2, NULL, 3, 7.6, 8, 5]);
array_length
-------------
  6
(1 row)

=> SELECT array_length(ARRAY[null]);
array_length
-------------
   1
(1 row)

=> SELECT array_length(NULL);
array_length
-------------
    NULL
(1 row)
```

**ARRAY_MAX**

Returns the largest element in an array.

**Behavior Type**

*Immutable*

**Syntax**

```
ARRAY_MAX(array)
```

**Supported Data Types**

1D arrays of:
- INTEGER
- NUMERIC
- FLOAT
- STRING/VARCHAR
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL

**Null-Handling**

Null semantics for arrays are consistent with normal columns. See [NULL Sort Order](#) for more information on null-handling.

**Example**

```sql
=> SELECT array_max(ARRAY[1,3.4,15]);
array_max
---------
  15.0
(1 row)
```

**See Also**

- [ARRAY_MIN](#)

**ARRAY_MIN**

Returns the smallest element in an array.

**Behavior Type**

Immutable
Syntax

ARRAY_MIN(array)

Supported Data Types

1D arrays of:

- INTEGER
- NUMERIC
- FLOAT
- STRING/VARCHAR
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL

Null-Handling
Null semantics for arrays are consistent with normal columns. See NULL Sort Order for more information on null-handling.

Example

```sql
=> SELECT array_min(ARRAY[1,3.4,15]);
array_min
---------
   1.0
(1 row)
```

See Also

- ARRAY_MAX
**ARRAY_SUM**

Computes the sum of all elements in an array.

**Behavior Type**

*Immutable*

**Syntax**

`ARRAY_SUM(array)`

**Supported Data Types**

1D arrays of:

- INTEGER
- FLOAT
- NUMERIC
- TIMESTAMP
- TIMESTAMPTZ
- UUID
- INTERVAL

**Null-Handling**

The following cases return NULL:

- if the input array is NULL
- if the input array only contains null values
- if the input array is empty
**Example**

```sql
=> SELECT array_sum(ARRAY[12.5,3,4,1]);
array_sum
--------
 20.5
(1 row)
```

**STRING_TO_ARRAY**

Splits a string on a specified delimiter character and returns an array. The string must be bounded by brackets. The output does not include the "ARRAY" keyword.

The delimiter must be a single character. If you specify a multi-character string, the results are undefined.

This function returns array elements as strings. The function does not support casting to other types; instead, cast the elements to other types when operating on the returned array.

**Behavior**

*Immutable*

**Syntax**

`STRING_TO_ARRAY(string,delim_char)`

**Supported Data Types**

- STRING/VARCHAR
Examples

```sql
=> SELECT STRING_TO_ARRAY('[1,3,5]', ',');
STRING_TO_ARRAY
------------------
["1","3","5"]
(1 row)

=> SELECT STRING_TO_ARRAY('['t|t|f|t']','|');
STRING_TO_ARRAY
------------------
["t","t","f","t"]
(1 row)

=> SELECT STRING_TO_ARRAY('[]','>');
STRING_TO_ARRAY
------------------
[null]
(1 row)
```

Current Load Source

The current load source function returns the source file name.

**CURRENT_LOAD_SOURCE**

Returns the file name used during the COPY statement.

*Behavior Type*

**Stable**

*Syntax*

CURRENT_LOAD_SOURCE()
**Behavior**

- If the function is called outside of the context of a COPY statement, it returns NULL.
- If the function is called by a UDL that does not set the source, it returns the string `<unknown>`.
- This function is not supported for COPY LOCAL.

**Examples**

This example creates a table and populates column c3 with the names of the two separate files being loaded.

```sql
=> CREATE TABLE t (c1 integer, c2 varchar(50), c3 varchar(200));
CREATE TABLE
=> COPY t (c1, c2, c3 AS CURRENT_LOAD_SOURCE()) FROM '/home/load_file_1' ON exampledb_node02, '/home/load_file_2' ON exampledb_node03 DELIMITER ',';
Rows Loaded
------------
5 (1 row)
=> SELECT * FROM t;
c1 | c2     | c3
--- | ------- | ---
2  | dogs    | load_file_1
1  | cats    | load_file_1
4  | superheroes | load_file_2
3  | birds   | load_file_1
5  | whales  | load_file_2
(5 rows)
```

**See Also**

- COPY
Date/Time Functions

Date and time functions perform conversion, extraction, or manipulation operations on date and time data types and can return date and time information.

Usage

Functions that take TIME or TIMESTAMP inputs come in two variants:

- TIME WITH TIME ZONE or TIMESTAMP WITH TIME ZONE
- TIME WITHOUT TIME ZONE or TIMESTAMP WITHOUT TIME ZONE

For brevity, these variants are not shown separately.

The + and * operators come in commutative pairs; for example, both DATE + INTEGER and INTEGER + DATE. We show only one of each such pair.

Daylight Savings Time Considerations

When adding an INTERVAL value to (or subtracting an INTERVAL value from) a TIMESTAMP WITH TIME ZONE value, the days component advances (or decrements) the date of the TIMESTAMP WITH TIME ZONE by the indicated number of days. Across daylight saving time changes (with the session time zone set to a time zone that recognizes DST), this means INTERVAL '1 day' does not necessarily equal INTERVAL '24 hours'.

For example, with the session time zone set to CST7CDT:

```
TIMESTAMP WITH TIME ZONE '2014-04-02 12:00-07' + INTERVAL '1 day'
```

produces

```
TIMESTAMP WITH TIME ZONE '2014-04-03 12:00-06'
```

Adding INTERVAL '24 hours' to the same initial TIMESTAMP WITH TIME ZONE produces

```
TIMESTAMP WITH TIME ZONE '2014-04-03 13:00-06',
```
This result occurs because there is a change in daylight saving time at 2014-04-03 02:00 in time zone CST7CDT.

### Date/Time Functions in Transactions

Certain date/time functions such as `CURRENT_TIMESTAMP` and `NOW` return the start time of the current transaction; for the duration of that transaction, they return the same value. Other date/time functions such as `TIMEOFDAY` always return the current time.

### See Also

Template Patterns for Date/Time Formatting

### ADD_MONTHS

Adds the specified number of months to a date and returns the sum as a `DATE`. In general, `ADD_MONTHS` returns a date with the same day component as the start date. For example:

```sql
=> SELECT ADD_MONTHS ('2015-09-15':date, -2) "2 Months Ago"

2 Months Ago
----------
2015-07-15
(1 row)
```

Two exceptions apply:

- If the start date's day component is greater than the last day of the result month, `ADD_MONTHS` returns the last day of the result month. For example:

```sql
=> SELECT ADD_MONTHS ('31-Jan-2016':TIMESTAMP, 1) "Leap Month"

Leap Month
-----------
2016-02-29
(1 row)
```

- If the start date's day component is the last day of that month, and the result month has more days than the start date month, `ADD_MONTHS` returns the last day of the result month. For example:

```sql
=> SELECT ADD_MONTHS ('2015-09-30':date,-1) "1 Month Ago"

1 Month Ago
```
Behavior Type

- **Immutable** if the `start-date` argument is a `TIMESTAMP` or `DATE`
- **Stable** if the `start-date` argument is a `TIMESTAMPTZ`

Syntax

```sql
ADD_MONTHS ( start-date, num-months );
```

Parameters

<table>
<thead>
<tr>
<th><code>start-date</code></th>
<th>The date to process, an expression that evaluates to one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• DATE</td>
</tr>
<tr>
<td></td>
<td>• <code>TIMESTAMP</code></td>
</tr>
<tr>
<td></td>
<td>• <code>TIMESTAMPTZ</code></td>
</tr>
</tbody>
</table>

| `num-months` | An integer expression that specifies the number of months to add to or subtract from `start-date`. |

Examples

Add one month to the current date:

```sql
=> SELECT CURRENT_DATE Today;
  ------------
  2016-05-05
  (1 row)
```

VMart=> SELECT ADD_MONTHS(CURRENT_TIMESTAMP,1);

```
ADD_MONTHS
  ------------
  2016-06-05
  (1 row)
```

Subtract four months from the current date:

```sql
```
Add one month to January 31, 2016:

```sql
=> SELECT ADD_MONTHS(CURRENT_TIMESTAMP, -4);
ADD_MONTHS
-----------
2016-01-05
(1 row)
```

Leap Month - 2016-02-29 (1 row)

The following example sets the timezone to EST; it then adds 24 months to a TIMESTAMPTZ that specifies a PST time zone, so ADD_MONTHS takes into account the time change:

```sql
=> SET TIME_ZONE 'America/New_York';
SET
VMart=> SELECT ADD_MONTHS('2008-02-29 23:30 PST'::TIMESTAMPTZ, 24);
ADD_MONTHS
-----------
2010-03-01
(1 row)
```

**AGE_IN_MONTHS**

Returns the difference in months between two dates, expressed as an integer.

**Behavior Type**

- **Immutable** if both date arguments are of data type TIMESTAMP
- **Stable** if either date is a TIMESTAMPTZ or only one argument is supplied

**Syntax**

```sql
AGE_IN_MONTHS ([ date1, ] date2)
```

**Parameters**

- `date1` - Specify the boundaries of the period to measure. If you supply only one argument, Vertica sets `date2` to the current date. Both parameters must
evaluate to one of the following data types:

- DATE
- TIMESTAMP
- TIMESTAMPTZ

If $date1 < date2$, AGE_IN_MONTHS returns a negative value.

**Examples**

Get the age in months of someone born March 2 1972, as of June 21 1990:

```
=> SELECT AGE_IN_MONTHS('1990-06-21'::TIMESTAMP, '1972-03-02'::TIMESTAMP);
     AGE_IN_MONTHS
---------------
           219
(1 row)
```

If the first date is less than the second date, AGE_IN_MONTHS returns a negative value

```
=> SELECT AGE_IN_MONTHS('1972-03-02'::TIMESTAMP, '1990-06-21'::TIMESTAMP);
     AGE_IN_MONTHS
---------------
          -220
(1 row)
```

Get the age in months of someone who was born November 21 1939, as of today:

```
=> SELECT AGE_IN_MONTHS ('1939-11-21'::DATE);
     AGE_IN_MONTHS
---------------
             930
(1 row)
```

**AGE_IN_YEARS**

Returns the difference in years between two dates, expressed as an integer.

**Behavior Type**

- **Immutable** if both date arguments are of data type TIMESTAMPTZ
- **Stable** if either date is a TIMESTAMPTZ or only one argument is supplied
**Syntax**

```plaintext
AGE_IN_YEARS( [ date1, ] date2 )
```

**Parameters**

<table>
<thead>
<tr>
<th>date1</th>
<th>date2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the boundaries of the period to measure. If you supply only one argument, Vertica sets <code>date1</code> to the current date. Both parameters must evaluate to one of the following data types:</td>
<td></td>
</tr>
<tr>
<td>• DATE</td>
<td></td>
</tr>
<tr>
<td>• TIMESTAMP</td>
<td></td>
</tr>
<tr>
<td>• TIMESTAMPTZ</td>
<td></td>
</tr>
</tbody>
</table>

If `date1 < date2`, `AGE_IN_YEARS` returns a negative value.

**Examples**

Get the age of someone born March 2 1972, as of June 21 1990:

```sql
=> SELECT AGE_IN_YEARS('1990-06-21'::TIMESTAMP, '1972-03-02'::TIMESTAMP);
AGE_IN_YEARS
---------
18
(1 row)
```

If the first date is earlier than the second date, `AGE_IN_YEARS` returns a negative number:

```sql
=> SELECT AGE_IN_YEARS('1972-03-02'::TIMESTAMP, '1990-06-21'::TIMESTAMP);
AGE_IN_YEARS
---------
-19
(1 row)
```

Get the age of someone who was born November 21 1939, as of today:

```sql
=> SELECT AGE_IN_YEARS('1939-11-21'::DATE);
AGE_IN_YEARS
---------
77
(1 row)
```
CLOCK_TIMESTAMP

Returns a value of type TIMESTAMP WITH TIMEZONE that represents the current system-clock time.

CLOCK_TIMESTAMP uses the date and time supplied by the operating system on the server to which you are connected, which should be the same across all servers. The value changes each time you call it.

Behavior Type

Volatile

Syntax

CLOCK_TIMESTAMP()

Examples

The following command returns the current time on your system:

```sql
SELECT CLOCK_TIMESTAMP() "Current Time";
Current Time
------------------
2010-09-23 11:41:23.33772-04
(1 row)
```

Each time you call the function, you get a different result. The difference in this example is in microseconds:

```sql
SELECT CLOCK_TIMESTAMP() "Time 1", CLOCK_TIMESTAMP() "Time 2";
 Time 1 | Time 2
---------|---------
2010-09-23 11:41:55.369201-04 | 2010-09-23 11:41:55.369202-04
(1 row)
```

See Also

- STATEMENT_TIMESTAMP
- TRANSACTION_TIMESTAMP
**CURRENT_DATE**

Returns the date (date-type value) on which the current transaction started.

**Behavior Type**

*Stable*

**Syntax**

CURRENT_DATE()

**Note:**
You can call this function without parentheses.

**Examples**

```sql
SELECT CURRENT_DATE;
?column?
--------------
2010-09-23
(1 row)
```

**CURRENT_TIME**

Returns a value of type TIME WITH TIMEZONE that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to CURRENT_TIME within the same transaction return the same timestamp.

**Behavior Type**

*Stable*
Syntax

CURRENT_TIME  [ ( precision ) ]

Note:
If you specify a column label without precision, you must also omit parentheses.

Parameters

<table>
<thead>
<tr>
<th>precision</th>
<th>An integer value between 0-6, specifies to round the seconds fraction field result to the specified number of digits.</th>
</tr>
</thead>
</table>

Examples

```sql
=> SELECT CURRENT_TIME(1) AS Time;
           Time
----------
  06:51:45.2-07
(1 row)
=> SELECT CURRENT_TIME(5) AS Time;
           Time
----------
  06:51:45.18435-07
(1 row)
```

CURRENT_TIMESTAMP

Returns a value of type TIME WITH TIMEZONE that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to CURRENT_TIMESTAMP within the same transaction return the same timestamp.

Behavior Type

Stable
Syntax

CURRENT_TIMESTAMP ( precision )

Parameters

| precision | An integer value between 0-6, specifies to round the seconds fraction field result to the specified number of digits. |

Examples

```
=> SELECT CURRENT_TIMESTAMP(1) AS time;
   time
--------------
2017-03-27 06:50:49.7-07
(1 row)
=> SELECT CURRENT_TIMESTAMP(5) AS time;
   time
--------------
2017-03-27 06:50:49.69967-07
(1 row)
```

DATE_PART

Extracts a sub-field such as year or hour from a date/time expression, equivalent to the SQL-standard function EXTRACT.

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or INTERVAL
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

```
DATE_PART ( 'field', date )
```
## Parameters

<table>
<thead>
<tr>
<th><strong>field</strong></th>
<th>A constant value that specifies the sub-field to extract from <em>date</em> (see Field Values below).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>date</strong></td>
<td>The date to process, an expression that evaluates to one of the following data types:</td>
</tr>
</tbody>
</table>
|           | • **DATE** (cast to TIMESTAMP)  
|           | • **TIMESTAMP/TIMESTAMPZ**  
|           | • **INTERVAL** |

## Field Values

| **CENTURY** | The century number.  
The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from –1 to 1. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DAY</strong></td>
<td>The day (of the month) field (1–31).</td>
</tr>
<tr>
<td><strong>DECADE</strong></td>
<td>The year field divided by 10.</td>
</tr>
</tbody>
</table>
| **DOQ**     | The day within the current quarter.  
|             | DOQ recognizes leap year days. |
| **DOW**     | Zero-based day of the week, where Sunday=0.  
|             | **Note:** EXTRACT's day of week numbering differs from the function **TO_CHAR**. |
| **DOY**     | The day of the year (1–365/366) |
| **EPOCH**   | Specifies to return one of the following:  
|             | • For **DATE** and **TIMESTAMP** values: the number of seconds before or since 1970-01-01 00:00:00-00 (if before, a negative number). |
### For INTERVAL values
- The total number of seconds in the interval.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOUR</td>
<td>The hour field (0–23).</td>
</tr>
<tr>
<td>ISODOW</td>
<td>The ISO day of the week, an integer between 1 and 7 where Monday is 1.</td>
</tr>
<tr>
<td>ISOWEEK</td>
<td>The ISO week of the year, an integer between 1 and 53.</td>
</tr>
<tr>
<td>ISOYEAR</td>
<td>The ISO year.</td>
</tr>
<tr>
<td>MICROSECONDS</td>
<td>The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.</td>
</tr>
<tr>
<td>MILLENNIUM</td>
<td>The millennium number, where the first millennium is 1 and each millennium starts on 01-01-001. For example, millennium 2 starts on 01-01-1001.</td>
</tr>
<tr>
<td>MILISECONDS</td>
<td>The seconds field, including fractional parts, multiplied by 1000. This includes full seconds.</td>
</tr>
<tr>
<td>MINUTE</td>
<td>The minutes field (0 - 59).</td>
</tr>
<tr>
<td>MONTH</td>
<td>For TIMESTAMP values, the number of the month within the year (1 - 12); for interval values the number of months, modulo 12 (0 - 11).</td>
</tr>
<tr>
<td>QUARTER</td>
<td>The calendar quarter of the specified date as an integer, where the January-March quarter is 1, valid only for TIMESTAMP values.</td>
</tr>
<tr>
<td>SECOND</td>
<td>The seconds field, including fractional parts, 0–59, or 0-60 if the operating system implements leap seconds.</td>
</tr>
<tr>
<td>TIME ZONE</td>
<td>The time zone offset from UTC, in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.</td>
</tr>
<tr>
<td>TIMEZONE_HOUR</td>
<td>The hour component of the time zone offset.</td>
</tr>
<tr>
<td>TIMEZONE_MINUTE</td>
<td>The minute component of the time zone offset.</td>
</tr>
<tr>
<td>WEEK</td>
<td>The number of the week of the calendar year that the day is in.</td>
</tr>
</tbody>
</table>
**YEAR**

The year field. There is no 0 AD, so subtract BC years from AD years accordingly.

**Notes**

According to the ISO-8601 standard, the week starts on Monday, and the first week of a year contains January 4. Thus, an early January date can sometimes be in the week 52 or 53 of the previous calendar year. For example:

```sql
=> SELECT YEAR_ISO('01-01-2016'::DATE), WEEK_ISO('01-01-2016'), DAYOFWEEK_ISO('01-01-2016');

<table>
<thead>
<tr>
<th>YEAR_ISO</th>
<th>WEEK_ISO</th>
<th>DAYOFWEEK_ISO</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015</td>
<td>53</td>
<td>5</td>
</tr>
</tbody>
</table>
```

(1 row)

**Examples**

Extract the day value:

```sql
SELECT DATE_PART('DAY', TIMESTAMP '2009-02-24 20:38:40') "Day";

Day
---
24
```

(1 row)

Extract the month value:

```sql
SELECT DATE_PART('MONTH', '2009-02-24 20:38:40'::TIMESTAMP) "Month";

Month
------
2
```

(1 row)

Extract the year value:

```sql
SELECT DATE_PART('YEAR', '2009-02-24 20:38:40'::TIMESTAMP) "Year";

Year
----
2009
```

(1 row)

Extract the hours:

```sql
SELECT DATE_PART('HOUR', '2009-02-24 20:38:40'::TIMESTAMP) "Hour";

Hour
-----
```

(1 row)
Extract the minutes:

```sql
SELECT DATE_PART('MINUTES', '2009-02-24 20:38:40'::TIMESTAMP) "Minutes";
```

Minutes
--------
38
(1 row)

Extract the day of quarter (DOQ):

```sql
SELECT DATE_PART('DOQ', '2009-02-24 20:38:40'::TIMESTAMP) "DOQ";
```

DOQ
----
55
(1 row)

See Also

TO_CHAR

DATE

Converts the input value to a DATE data type.

Behavior Type

- **Immutable** if the input value is a TIMESTAMP, DATE, VARCHAR, or integer
- **Stable** if the input value is a TIMESTAMPTZ

Syntax

```sql
DATE ( value )
```

Parameters

<table>
<thead>
<tr>
<th>value</th>
<th>The value to convert, one of the following:</th>
</tr>
</thead>
</table>
• TIMESTAMP, TIMESTAMPTZ, VARCHAR, or another DATE.
• Integer: Vertica treats the integer as the number of days since 01/01/0001 and returns the date.

Examples

=> SELECT DATE (1);
   DATE
   ____________
   0001-01-01
   (1 row)

=> SELECT DATE (734260);
   DATE
   ____________
   2011-05-03
   (1 row)

=> SELECT DATE('TODAY');
   DATE
   ____________
   2016-12-07
   (1 row)

See Also

• TO_DATE
• TO_TIMESTAMPTZ
• TO_TIMESTAMPTZ_TZ

DATE_TRUNC

Truncates date and time values to the specified precision. The return value is the same data type as the input value. All fields that are less than the specified precision are set to 0, or to 1 for day and month.

Behavior Type

Stable
**Syntax**

```
DATE_TRUNC( precision, trunc-target )
```

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>precision</td>
<td>A string constant that specifies precision for the truncated value. See Precision Field Values below. The precision must be valid for the <code>trunc-target</code> date or time.</td>
</tr>
<tr>
<td>trunc-target</td>
<td>Valid date/time expression.</td>
</tr>
</tbody>
</table>

**Precision Field Values**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MILLENNIUM</td>
<td>The millennium number.</td>
</tr>
<tr>
<td>CENTURY</td>
<td>The century number.</td>
</tr>
<tr>
<td></td>
<td>The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries.</td>
</tr>
<tr>
<td>DECADE</td>
<td>The year field divided by 10.</td>
</tr>
<tr>
<td>YEAR</td>
<td>The year field. Keep in mind there is no 0 AD, so subtract BC years from AD years with care.</td>
</tr>
<tr>
<td>QUARTER</td>
<td>The calendar quarter of the specified date as an integer, where the January-March quarter is 1.</td>
</tr>
<tr>
<td>MONTH</td>
<td>For timestamp values, the number of the month within the year (1–12); for interval values the number of months, modulo 12 (0–11).</td>
</tr>
<tr>
<td>WEEK</td>
<td>The number of the week of the year that the day is in.</td>
</tr>
<tr>
<td></td>
<td>According to the ISO-8601 standard, the week starts on Monday, and the first week of a year contains January 4. Thus, an early January date can sometimes be in the week 52 or 53 of the previous calendar year. For example:</td>
</tr>
</tbody>
</table>

```sql
=> SELECT YEAR_ISO('01-01-2016': DATE), WEEK_ISO('01-01-2016'), DAYOFWEEK_
```
DAY The day (of the month) field (1–31).
HOUR The hour field (0–23).
MINUTE The minutes field (0–59).
SECOND The seconds field, including fractional parts (0–59) (60 if leap seconds are implemented by the operating system).
MILLISECONDS The seconds field, including fractional parts, multiplied by 1000. Note that this includes full seconds.
MICROSECONDS The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.

Examples

The following example sets the field value as hour and returns the hour, truncating the minutes and seconds:

```sql
=> SELECT DATE_TRUNC('HOUR', TIMESTAMP '2012-02-24 13:38:40') AS HOUR;
  HOUR
-------------------
  2012-02-24 13:00:00
(1 row)
```

The following example returns the year from the input timestampz '2012-02-24 13:38:40'. The function also defaults the month and day to January 1, truncates the hour:minute:second of the timestamp, and appends the time zone (-05):

```sql
=> SELECT DATE_TRUNC('YEAR', TIMESTAMPTZ '2012-02-24 13:38:40') AS YEAR;
  YEAR
-------------------
  2012-01-01 00:00:00-05
(1 row)
```

The following example returns the year and month and defaults day of month to 1, truncating the rest of the string:
SELECT DATE_TRUNC('MONTH', TIMESTAMP '2012-02-24 13:38:40') AS MONTH;

---

2012-02-01 00:00:00
(1 row)

**DATEDIFF**

Returns the time span between two dates, in the intervals specified. DATEDIFF excludes the start date in its calculation.

**Behavior Type**

- **Immutable** if start and end dates are TIMESTAMP, DATE, TIME, or INTERVAL
- **Stable** if start and end dates are TIMESTAMPTZ

**Syntax**

DATEDIFF (datepart, start, end);

**Parameters**

<table>
<thead>
<tr>
<th><strong>datepart</strong></th>
<th>Specifies the type of date or time intervals that DATEDIFF returns. If datepart is an expression, it must be enclosed in parentheses: DATEDIFF((expression), start, end; datepart must evaluate to one of the following string literals, either quoted or unquoted:</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>yy</td>
</tr>
<tr>
<td>quarter</td>
<td>qq</td>
</tr>
<tr>
<td>month</td>
<td>mm</td>
</tr>
<tr>
<td>day</td>
<td>dy</td>
</tr>
<tr>
<td>dayofyear</td>
<td>dd</td>
</tr>
<tr>
<td>week</td>
<td>wk</td>
</tr>
<tr>
<td>hour</td>
<td>hh</td>
</tr>
<tr>
<td>minute</td>
<td>mi</td>
</tr>
<tr>
<td>second</td>
<td>ss</td>
</tr>
<tr>
<td>millisecond</td>
<td>ms</td>
</tr>
<tr>
<td>microsecond</td>
<td>mcs</td>
</tr>
</tbody>
</table>
**start, end**
Specify the start and end dates, where `start` and `end` evaluate to one of the following data types:

- `TIMESTAMP/TIMESTAMPTZ`
- `DATE`
- `TIME/TIMETZ`
- `INTERVAL`

If `end < start`, `DATEDIFF` returns a negative value.

**Note:**
`TIME` and `INTERVAL` data types are invalid for start and end dates if `datepart` is set to year, quarter, or month.

---

**Compatible Start and End Date Data Types**

The following table shows which data types can be matched as start and end dates:

<table>
<thead>
<tr>
<th></th>
<th>DATE</th>
<th>TIMESTAMP</th>
<th>TIMESTAMPTZ</th>
<th>TIME</th>
<th>INTERVAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>•</td>
<td>•</td>
<td>•</td>
<td>•</td>
<td></td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>•</td>
<td>•</td>
<td>•</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TIMESTAMPTZ</td>
<td>•</td>
<td>•</td>
<td>•</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TIME</td>
<td>•</td>
<td>•</td>
<td>•</td>
<td></td>
<td>•</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>•</td>
<td>•</td>
<td>•</td>
<td>•</td>
<td></td>
</tr>
</tbody>
</table>

For example, if you set the start date to an `INTERVAL` data type, the end date must also be an `INTERVAL`, otherwise Vertica returns an error:

```
SELECT DATEDIFF(day, INTERVAL '26 days', INTERVAL '1 month ');
```

datediff
--------
4
(1 row)
Date Part Intervals

DATEDIFF uses the *datepart* argument to calculate the number of intervals between two dates, rather than the actual amount of time between them. DATEDIFF uses the following cutoff points to calculate those intervals:

- **year**: January 1
- **quarter**: January 1, April 1, July 1, October 1
- **month**: the first day of the month
- **week**: Sunday at midnight (24:00)

For example, if *datepart* is set to year, DATEDIFF uses January 01 to calculate the number of years between two dates. The following DATEDIFF statement sets *datepart* to year, and specifies a time span 01/01/2005 - 06/15/2008:

```sql
SELECT DATEDIFF(year, '01-01-2005'::date, '12-31-2008'::date);
```

```
<table>
<thead>
<tr>
<th>datdiff</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
```

DATEDIFF always excludes the start date when it calculates intervals—in this case, 01/01/2005. DATEDIFF considers only calendar year starts in its calculation, so in this case it only counts years 2006, 2007, and 2008. The function returns 3, although the actual time span is nearly four years.

If you change the start and end dates to 12/31/2004 and 01/01/2009, respectively, DATEDIFF also counts years 2005 and 2009. This time, it returns 5, although the actual time span is just over four years:

```sql
=> SELECT DATEDIFF(year, '12-31-2004'::date, '01-01-2009'::date);
```

```
<table>
<thead>
<tr>
<th>datdiff</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
</tr>
</tbody>
</table>
```

Similarly, DATEDIFF uses month start dates when it calculates the number of months between two dates. Thus, given the following statement, DATEDIFF counts months February through September and returns 8:

```sql
=> SELECT DATEDIFF(month, '01-31-2005'::date, '09-30-2005'::date);
```

```
<table>
<thead>
<tr>
<th>datdiff</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
</tr>
</tbody>
</table>
```
See Also

TIMESTAMPDIFF

DAY

Returns as an integer the day of the month from the input value.

Behavior Type

- **Immutable** if the input value is a TIMESTAMP, DATE, VARCHAR, or INTEGER
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

```
DAY ( value )
```

Parameters

| value | The value to convert, one of the following: TIMESTAMP, TIMESTAMPTZ, INTERVAL, VARCHAR, or INTEGER. |

Examples

```
=> SELECT DAY (6);
DAY
-----
6
(1 row)

=> SELECT DAY(TIMESTAMP 'sep 22, 2011 12:34');
DAY
-----
22
(1 row)

=> SELECT DAY('sep 22, 2011 12:34');
DAY
-----
```
DAYOFMONTH

Returns the day of the month as an integer.

**Behavior Type**

- **Immutable** if the target date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the target date is a TIMESTAMPTZ

**Syntax**

```sql
DAYOFMONTH ( date )
```

**Parameters**

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- VARCHAR</td>
</tr>
<tr>
<td></td>
<td>- DATE</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT DAYOFMONTH (TIMESTAMP 'sep 22, 2011 12:34');
DAYOFMONTH
----------
  22
(1 row)
```
DAYOFWEEK

Returns the day of the week as an integer, where Sunday is day 1.

Behavior Type

- **Immutable** if the target date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the target date is a TIMESTAMPTZ

Syntax

DAYOFWEEK( date )

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• DATE</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

Example

```sql
=> SELECT DAYOFWEEK (TIMESTAMP 'sep 17, 2011 12:34');
DAYOFWEEK
----------
  7
(1 row)
```

DAYOFWEEK_ISO

Returns the ISO 8061 day of the week as an integer, where Monday is day 1.
Behavior Type

- **Immutable** if the target date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the target date is a TIMESTAMPTZ

Syntax

`DAYOFWEEK_ISO ( date )`

Parameters

<table>
<thead>
<tr>
<th><code>date</code></th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• DATE</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

Examples

```sql
=> SELECT DAYOFWEEK_ISO(TIMESTAMP 'Sep 22, 2011 12:34');

DAYOFWEEK_ISO
------------------
        4
(1 row)
```

The following example shows how to combine the DAYOFWEEK_ISO, WEEK_ISO, and YEAR_ISO functions to find the ISO day of the week, week, and year:

```sql
=> SELECT DAYOFWEEK_ISO('Jan 1, 2000'), WEEK_ISO('Jan 1, 2000'), YEAR_ISO('Jan1,2000');

<table>
<thead>
<tr>
<th>DAYOFWEEK_ISO</th>
<th>WEEK_ISO</th>
<th>YEAR_ISO</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>52</td>
<td>1999</td>
</tr>
</tbody>
</table>
(1 row)
```

See Also

- WEEK_ISO
- DAYOFWEEK_ISO
DAYOFYEAR

Returns the day of the year as an integer, where January 1 is day 1.

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

```
DAYOFYEAR ( date )
```

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• DATE</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

Example

```
=> SELECT DAYOFYEAR (TIMESTAMP 'SEPT 22,2011 12:34');
DAYOFYEAR
---------
265
(1 row)
```

DAYS

Returns the integer value of the specified date, where 1 AD is 1. If the date precedes 1 AD, DAYS returns a negative integer.

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

```
DAYS (date)
```

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- VARCHAR</td>
</tr>
<tr>
<td></td>
<td>- DATE</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

Example

```sql
=> SELECT DAYS (DATE '2011-01-22');
   DAYS
   --------
   734159
   (1 row)

=> SELECT DAYS (DATE 'March 15, 0044 BC');
   DAYS
   --------
   -15997
   (1 row)
```

EXTRACT

Retrieves sub-fields such as year or hour from date/time values and returns values of type NUMERIC. EXTRACT is intended for computational processing, rather than for formatting date/time values for display.
Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or INTERVAL
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

```sql
EXTRACT (field FROM date)
```

Parameters

<table>
<thead>
<tr>
<th>field</th>
<th>A constant value that specifies the sub-field to extract from <code>date</code> (see Field Values below).</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date to process, an expression that evaluates to one of the following data types:</td>
</tr>
<tr>
<td></td>
<td>• DATE (cast to TIMESTAMP)</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ/TIMESTAMPTZ</td>
</tr>
<tr>
<td></td>
<td>• INTERVAL</td>
</tr>
</tbody>
</table>

Field Values

<table>
<thead>
<tr>
<th>CENTURY</th>
<th>The century number.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from −1 to 1.</td>
</tr>
<tr>
<td>DAY</td>
<td>The day (of the month) field (1–31).</td>
</tr>
<tr>
<td>DECADE</td>
<td>The year field divided by 10.</td>
</tr>
<tr>
<td>DOQ</td>
<td>The day within the current quarter.</td>
</tr>
<tr>
<td></td>
<td>DOQ recognizes leap year days.</td>
</tr>
<tr>
<td>DOW</td>
<td>Zero-based day of the week, where Sunday=0.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>EXTRACT's day of week numbering differs from the function <code>TO_CHAR</code>.</td>
</tr>
<tr>
<td>-----------</td>
<td>---------------------------------------------------------------</td>
</tr>
</tbody>
</table>

<p>| <strong>DOY</strong> | The day of the year (1–365/366) |
| <strong>EPOCH</strong> | Specifies to return one of the following: |
|          | - For DATE and TIMESTAMP values: the number of seconds before or since 1970-01-01 00:00:00-00 (if before, a negative number). |
|          | - For INTERVAL values, the total number of seconds in the interval. |
| <strong>HOUR</strong> | The hour field (0–23). |
| <strong>ISODOW</strong> | The ISO day of the week, an integer between 1 and 7 where Monday is 1. |
| <strong>ISOWEEK</strong> | The ISO week of the year, an integer between 1 and 53. |
| <strong>ISOYEAR</strong> | The ISO year. |
| <strong>MICROSECONDS</strong> | The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds. |
| <strong>MILLENNIUM</strong> | The millennium number, where the first millennium is 1 and each millenium starts on 01-01-001. For example, millennium 2 starts on 01-01-1001. |
| <strong>MILLISECONDS</strong> | The seconds field, including fractional parts, multiplied by 1000. This includes full seconds. |
| <strong>MINUTE</strong> | The minutes field (0 - 59). |
| <strong>MONTH</strong> | For TIMESTAMP values, the number of the month within the year (1 - 12); for interval values the number of months, modulo 12 (0 - 11). |
| <strong>QUARTER</strong> | The calendar quarter of the specified date as an integer, where the January-March quarter is 1, valid only for TIMESTAMP values. |
| <strong>SECOND</strong> | The seconds field, including fractional parts, 0–59, or 0-60 if the operating system implements leap seconds. |</p>
<table>
<thead>
<tr>
<th>TIME_ZONE</th>
<th>The time zone offset from UTC, in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIMEZONE_HOUR</td>
<td>The hour component of the time zone offset.</td>
</tr>
<tr>
<td>TIMEZONE_MINUTE</td>
<td>The minute component of the time zone offset.</td>
</tr>
<tr>
<td>WEEK</td>
<td>The number of the week of the calendar year that the day is in.</td>
</tr>
<tr>
<td>YEAR</td>
<td>The year field. There is no μ AD, so subtract BC years from AD years accordingly.</td>
</tr>
</tbody>
</table>

**Examples**

Extract the day of the week and day in quarter from the current TIMESTAMP:

```sql
=> SELECT CURRENT_TIMESTAMP AS NOW;

NOW
------------------------
2016-05-03 11:36:08.829004-04
(1 row)
=> SELECT EXTRACT (DAY FROM CURRENT_TIMESTAMP);
  date_part
----------
  3
(1 row)
=> SELECT EXTRACT (DOQ FROM CURRENT_TIMESTAMP);
  date_part
----------
  33
(1 row)
```

Extract the timezone hour from the current time:

```sql
=> SELECT CURRENT_TIMESTAMP;

?column?
----------
2016-05-03 11:36:08.829004-04
(1 row)
=> SELECT EXTRACT(TIMEZONE_HOUR FROM CURRENT_TIMESTAMP);
  date_part
----------
  -4
(1 row)
```

Extract the number of seconds since 01-01-1970 00:00:
Extract the number of seconds between 01-01-1970 00:00 and 5 days 3 hours before:

```sql
=> SELECT EXTRACT(EPOCH FROM '2001-02-16 20:38:40-08'::TIMESTAMPTZ);
   date_part
------------------------
  982384720.000000
(1 row)
```

Convert the results from the last example to a TIMESTAMP:

```sql
=> SELECT 'EPOCH'::TIMESTAMPTZ -442800 * '1 second'::INTERVAL;
   ?column?
------------------------
1969-12-26 16:00:00-05
(1 row)
```

**GETDATE**

Returns the current statement's start date and time as a TIMESTAMP value. This function is identical to `SYSDATE`.

GETDATE uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers. Internally, GETDATE converts `STATEMENT_TIMESTAMP` from TIMESTAMPTZ to TIMESTAMP.

**Behavior Type**

- Stable

**Syntax**

`GETDATE()`
**Example**

```sql
=> SELECT GETDATE();
   GETDATE
-------------------
2011-03-07 13:21:29.497742
(1 row)
```

**See Also**

Date/Time Expressions

**GETUTCDATE**

Returns the current statement's start date and time as a TIMESTAMP value.

GETUTCDATE uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers. Internally, GETUTCDATE converts STATEMENT_TIMESTAMP at TIME ZONE 'UTC'.

**Behavior Type**

Stable

**Syntax**

GETUTCDATE()
See Also

- Date/Time Expressions

HOUR

Returns the hour portion of the specified date as an integer, where 0 is 00:00 to 00:59.

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

```
HOUR( date )
```

Parameters

<table>
<thead>
<tr>
<th><strong>date</strong></th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- VARCHAR</td>
</tr>
<tr>
<td></td>
<td>- DATE</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMPTZ</td>
</tr>
<tr>
<td></td>
<td>- INTERVAL</td>
</tr>
</tbody>
</table>

Examples

```sql
=> SELECT HOUR (TIMESTAMP 'sep 22, 2011 12:34');
   HOUR
   ------
   12
   (1 row)
=> SELECT HOUR (INTERVAL '35 12:34');
   HOUR
```
ISFINITE

Tests for the special TIMESTAMP constant INFINITY and returns a value of type BOOLEAN.

Behavior Type

Immutable

Syntax

ISFINITE (timestamp )

Parameters

timestamp | Expression of type TIMESTAMP

Examples

SELECT ISFINITE(TIMESTAMP '2009-02-16 21:28:30');
ISFINITE
--------
t
(1 row)

SELECT ISFINITE(TIMESTAMP 'INFINITY');
ISFINITE
--------
f
(1 row)
**JULIAN_DAY**

Returns the integer value of the specified day according to the Julian calendar, where day 1 is the first day of the Julian period, January 1, 4713 BC (on the Gregorian calendar, November 24, 4714 BC).

**Behavior Type**

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the specified date is a TIMESTAMPTZ

**Syntax**

```
JULIAN_DAY ( date )
```

**Parameters**

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- VARCHAR</td>
</tr>
<tr>
<td></td>
<td>- DATE</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT JULIAN_DAY (DATE 'MARCH 15, 0044 BC');
JULIAN_DAY
----------
   1705428
(1 row)

=> SELECT JULIAN_DAY (DATE '2001-01-01');
JULIAN_DAY
----------
   2451911
(1 row)
```
LAST_DAY

Returns the last day of the month in the specified date.

Behavior Type

- **Immutable** if the specified is a TIMESTAMP or DATE
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

LAST_DAY ( date )

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DATE</td>
</tr>
<tr>
<td></td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

Examples

The following example returns the last day of February as 29 because 2016 is a leap year:

```sql
=> SELECT LAST_DAY('2016-02-28 23:30 PST') "Last Day";
  Last Day
------------
  2016-02-29
  (1 row)
```

The following example returns the last day of February in a non-leap year:

```sql
> SELECT LAST_DAY('2017/02/03') "Last";
  Last
--------------
  2017-02-28
  (1 row)
```
The following example returns the last day of March, after converting the string value to the specified DATE type:

```sql
=> SELECT LAST_DAY('2003/03/15') "Last";
Last
----------
2012-03-31
(1 row)
```

**LOCALTIME**

Returns a value of type TIME that represents the start of the current transaction. The return value does not change during the transaction. Thus, multiple calls to LOCALTIME within the same transaction return the same timestamp.

**Behavior Type**

*Stable*

**Syntax**

```
LOCALTIME [ ( precision ) ]
```

**Parameters**

| precision | Rounds the result to the specified number of fractional digits in the seconds field. |

**Example**

```sql
=> CREATE TABLE t1 (a int, b int);
CREATE TABLE

=> INSERT INTO t1 VALUES (1,2);
OUTPUT
-------
1
(1 row)

=> SELECT LOCALTIME time;
```
LOCALTIMESTAMP

Returns a value of type TIMESTAMP that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to LOCALTIMESTAMP within the same transaction return the same timestamp.

**Behavior Type**

*Stable*

**Syntax**

`LOCALTIMESTAMP [ ( precision ) ]`

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>precision</code></td>
<td>Rounds the result to the specified number of fractional digits in the seconds field.</td>
</tr>
</tbody>
</table>
Example

```sql
=> CREATE TABLE t1 (a int, b int);
CREATE TABLE

=> INSERT INTO t1 VALUES (1,2);
OUTPUT
-------
  1
(1 row)

=> SELECT CURRENT_TIMESTAMP(2) timestamp;
   timestamp
-------------------------
 2016-12-07 15:19:12.34-05
(1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT
-------
  1
(1 row)

=> SELECT CURRENT_TIMESTAMP(2) timestamp;
   timestamp
-------------------------
 2016-12-07 15:19:12.34-05
(1 row)

=> COMMIT;
COMMIT

=> SELECT CURRENT_TIMESTAMP(2) timestamp;
   timestamp
-------------------------
 2016-12-07 15:19:13.89-05
(1 row)
```

MICROSECOND

Returns the microsecond portion of the specified date as an integer.

Behavior Type

- **Immutable** if the specified date is a `TIMESTAMP`, `INTERVAL`, or `VARCHAR`
- **Stable** if the specified date is a `TIMESTAMP`
Syntax

MICROSECOND ( date )

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ</td>
</tr>
<tr>
<td></td>
<td>• INTERVAL</td>
</tr>
</tbody>
</table>

Example

```sql
=> SELECT MICROSECOND (TIMESTAMP 'Sep 22, 2011 12:34:01.123456');
MICROSECOND
----------
123456
(1 row)
```

MIDNIGHT_SECONDS

Within the specified date, returns the number of seconds between midnight and the date's time portion.

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

MIDNIGHT_SECONDS ( date )
Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- VARCHAR</td>
</tr>
<tr>
<td></td>
<td>- DATE</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

Examples

Get the number of seconds since midnight:

```sql
=> SELECT MIDNIGHT_SECONDS(CURRENT_TIMESTAMP);
MIDNIGHT_SECONDS
---------------------
36480
(1 row)
```

Get the number of seconds between midnight and noon on March 3 2016:

```sql
=> SELECT MIDNIGHT_SECONDS('3-3-2016 12:00'::TIMESTAMP);
MIDNIGHT_SECONDS
---------------------
43200
(1 row)
```

MINUTE

Returns the minute portion of the specified date as an integer.

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, VARCHAR or INTERVAL
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

```
MINUTE ( date )
```
Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR</td>
<td>DATE</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
</tr>
<tr>
<td>INTERVAL</td>
<td></td>
</tr>
</tbody>
</table>

Example

```
=> SELECT MINUTE('12:34:03.456789');
MINUTE
-------
 34
(1 row)
```

```
=> SELECT MINUTE (TIMESTAMP 'sep 22, 2011 12:34');
MINUTE
-------
 34
(1 row)
```

```
=> SELECT MINUTE (INTERVAL '35 12:34:03.456789');
MINUTE
-------
 34
(1 row)
```

MONTH

Returns the month portion of the specified date as an integer.

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, VARCHAR or INTERVAL
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

```
MONTH ( date )
```
Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• DATE</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ</td>
</tr>
<tr>
<td></td>
<td>• INTERVAL</td>
</tr>
</tbody>
</table>

Examples

In the following examples, Vertica returns the month portion of the specified string. For example, '6-9' represent September 6.

```sql
=> SELECT MONTH('6-9');
   MONTH
  -------
     9
   (1 row)
=> SELECT MONTH(TIMESTAMP 'sep 22, 2011 12:34');
   MONTH
  -------
     9
   (1 row)
=> SELECT MONTH(INTERVAL '2-35' year to month);
   MONTH
  -------
   11
   (1 row)
```

MONTHS_BETWEEN

Returns the number of months between two dates. MONTHS_BETWEEN can return an integer or a FLOAT:

- Integer: The day portions of date1 and date2 are the same, and neither date is the last day of the month. MONTHS_BETWEEN also returns an integer if both dates in date1 and date2 are the last days of their respective months. For example, MONTHS_BETWEEN calculates the difference between April 30 and March 31 as 1 month.
FLOAT: The day portions of date1 and date2 are different and one or both dates are not the last day of their respective months. For example, the difference between April 2 and March 1 is 1.03225806451613. To calculate month fractions, MONTHS_BETWEEN assumes all months contain 31 days.

MONTHS_BETWEEN disregards timestamp time portions.

**Behavior Type**

- **Immutable** if both date arguments are of data type TIMESTAMP or DATE
- **Stable** if either date is a TIMESTAMPTZ

**Syntax**

MONTHS_BETWEEN ( date1 , date2 );

**Parameters**

<table>
<thead>
<tr>
<th>date1</th>
<th>date2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the dates to evaluate where date1 and date2 evaluate to one of the following data types:</td>
<td></td>
</tr>
<tr>
<td>DATE</td>
<td></td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td></td>
</tr>
<tr>
<td>TIMESTAMPTZ</td>
<td></td>
</tr>
</tbody>
</table>

If date1 < date2, MONTHS_BETWEEN returns a negative value.

**Examples**

Return the number of months between April 7 2016 and January 7 2015:

```sql
=> SELECT MONTHS_BETWEEN ('04-07-16'::TIMESTAMP, '01-07-15'::TIMESTAMP);

-------------------
15
(1 row)
```

Return the number of months between March 31 2016 and February 28 2016 (MONTHS_BETWEEN assumes both months contain 31 days):

```sql
=> SELECT MONTHS_BETWEEN ('03-31-16'::TIMESTAMP, '02-28-16'::TIMESTAMP);

-------------------
14
(1 row)
```
Return the number of months between March 31 2016 and February 29 2016:

```sql
=> SELECT MONTHS_BETWEEN ('03-31-16':TIMESTAMP, '02-28-16':TIMESTAMP);
MONTHS_BETWEEN
---------------------
1.09677419354839
(1 row)
```

NEW_TIME

Converts a timestamp value from one time zone to another and returns a TIMESTAMP.

**Behavior Type**

*Immutable*

**Syntax**

```sql
NEW_TIME( 'timestamp', 'timezone1', 'timezone2')
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>The timestamp to convert, conforms to one of the following formats:</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP/TIMESTAMPZ</td>
</tr>
<tr>
<td></td>
<td>• DATE</td>
</tr>
<tr>
<td></td>
<td>• Character string that can be converted to a TIMESTAMP—for example, May 24, 2012 10:00.</td>
</tr>
<tr>
<td>timezone1</td>
<td>Specify the source and target timezones, one of the strings defined in /opt/vertica/share/timezonesets. For example:</td>
</tr>
<tr>
<td>timezone2</td>
<td>• GMT: Greenwich Mean Time</td>
</tr>
</tbody>
</table>
Examples

Convert the specified time from Eastern Standard Time (EST) to Pacific Standard Time (PST):

```sql
=> SELECT NEW_TIME('05-24-12 13:48:00', 'EST', 'PST');
       NEW_TIME
  ---------------
    2012-05-24 10:48:00
(1 row)
```

Convert 1:00 AM January 2012 from EST to PST:

```sql
=> SELECT NEW_TIME('01-01-12 01:00:00', 'EST', 'PST');
       NEW_TIME
  ---------------
    2011-12-31 22:00:00
(1 row)
```

Convert the current time EST to PST:

```sql
=> SELECT NOW();
       NOW
  ---------------
  2016-12-09 10:30:36.727307-05
(1 row)
=> SELECT NEW_TIME('NOW', 'EDT', 'CDT');
       NEW_TIME
  ---------------
  2016-12-09 09:30:36.727307
(1 row)
```

The following example returns the year 45 before the Common Era in Greenwich Mean Time and converts it to Newfoundland Standard Time:

```sql
=> SELECT NEW_TIME('April 1, 45 BC', 'GMT', 'NST')::DATE;
        NEW_TIME
  -------------
    0045-03-31 BC
(1 row)
```
NEXT_DAY

Returns the date of the first instance of a particular day of the week that follows the specified date.

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the specified date is a TIMESTAMPTZ

Syntax

NEXT_DAY( 'date', 'day-string' )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date to process, one of the following data types:</td>
</tr>
<tr>
<td></td>
<td>- VARCHAR</td>
</tr>
<tr>
<td></td>
<td>- DATE</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMPTZ</td>
</tr>
<tr>
<td>day-string</td>
<td>The day of the week to process, a CHAR or VARCHAR string or character constant. Supply the full English name such as Tuesday, or any conventional abbreviation, such as Tue or Tues. day-string is not case sensitive and trailing spaces are ignored.</td>
</tr>
</tbody>
</table>

Examples

Get the date of the first Monday that follows April 29 2016:

```sql
=> SELECT NEXT_DAY('4-29-2016'::TIMESTAMP,'Monday') "NEXT DAY" ;
  NEXT DAY
----------------
  2016-05-02
(1 row)
```

Get the first Tuesday that follows today:
SELECT NEXT_DAY(CURRENT_TIMESTAMP,'tues') "NEXT DAY";

2016-05-03 (1 row)

NOW [Date/Time]

Returns a value of type TIMESTAMP WITH TIME ZONE representing the start of the current transaction. NOW is equivalent to CURRENT_TIMESTAMP except that it does not accept a precision parameter.

The return value does not change during the transaction. Thus, multiple calls to CURRENT_TIMESTAMP within the same transaction return the same timestamp.

Behavior Type

Stable

Syntax

NOW()

Example

=> CREATE TABLE t1 (a int, b int);
CREATE TABLE
=> INSERT INTO t1 VALUES (1,2);
OUTPUT
-------
1
(1 row)

=> SELECT NOW();
   NOW
------------------------
2016-12-09 13:00:08.74685-05 (1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT
-------
1
(1 row)
OVERLAPS

Evaluates two time periods and returns true when they overlap, false otherwise.

Behavior Type

- **Stable** when TIMESTAMP and TIMESTAMPTZ are both used, or when TIMESTAMPTZ is used with INTERVAL
- **Immutable** otherwise

Syntax

\[
(\text{start, end}) \text{ OVERLAPS (start, end)}
\]

\[
(\text{start, interval}) \text{ OVERLAPS (start, interval)}
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{start}</td>
<td>DATE, TIME, or TIMESTAMPTZ/TIMESTAMPTZ value that specifies the beginning of a time period.</td>
</tr>
<tr>
<td>\textit{end}</td>
<td>DATE, TIME, or TIMESTAMPTZ/TIMESTAMPTZ value that specifies the end of a time period.</td>
</tr>
<tr>
<td>\textit{interval}</td>
<td>Value that specifies the length of the time period.</td>
</tr>
</tbody>
</table>
Examples

Evaluate whether date ranges Feb 16 - Dec 21, 2016 and Oct 10 2008 - Oct 3 2016 overlap:

```sql
=> SELECT (DATE '2016-02-16', DATE '2016-12-21') OVERLAPS (DATE '2008-10-30', DATE '2016-10-30');
  overlaps ---------
  t
(1 row)
```

Evaluate whether date ranges Feb 16 - Dec 21, 2016 and Jan 01 - Oct 30 2008 - Oct 3, 2016 overlap:

```sql
=> SELECT (DATE '2016-02-16', DATE '2016-12-21') OVERLAPS (DATE '2008-01-30', DATE '2008-10-30');
  overlaps ---------
  f
(1 row)
```

Evaluate whether date range Feb 02 2016 + 1 week overlaps with date range Oct 16 2016 - 8 months:

```sql
=> SELECT (DATE '2016-02-16', INTERVAL '1 week') OVERLAPS (DATE '2016-10-16', INTERVAL '-8 months');
  overlaps ---------
  t
(1 row)
```

QUARTER

Returns calendar quarter of the specified date as an integer, where the January-March quarter is 1.

Syntax

```sql
QUARTER ( date )
```

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR.
- **Stable** if the specified date is a TIMESTAMPTZ
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>The date to process, one of the following data types:</td>
</tr>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• DATE</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

Examples

```sql
=> SELECT QUARTER (TIMESTAMP 'sep 22, 2011 12:34');
QUARTER
---------
3
(1 row)
```

ROUND

Rounds the specified date or time. If you omit the precision argument, ROUND rounds to day (DD) precision.

Behavior Type

- **Immutable** if the target date is a TIMESTAMPTZ or DATE
- **Stable** if the target date is a TIMESTAMPTZ

Syntax

```sql
ROUND( rounding-target[, 'precision'] )
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rounding-target</td>
<td>An expression that evaluates to one of the following data types:</td>
</tr>
<tr>
<td>precision</td>
<td>A string constant that specifies precision for the rounded value, one of the following:</td>
</tr>
<tr>
<td>-----------</td>
<td>----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DATE</td>
<td></td>
</tr>
<tr>
<td>TIMESTAMP/TIMESTAMPTZ</td>
<td></td>
</tr>
<tr>
<td>TIMESTAMPTZ</td>
<td></td>
</tr>
</tbody>
</table>

- **Century**: CC | SCC
- **Year**: SYYY | YYYY | YEAR | YYY | YY | Y
- **ISO Year**: IYYY | IYY | IY | I
- **Quarter**: Q
- **Month**: MONTH | MON | MM | RM
- **Same weekday as first day of year**: WW
- **Same weekday as first day of ISO year**: IW
- **Same weekday as first day of month**: W
- **Day** (default): DDD | DD | J
- **First weekday**: DAY | DY | D
- **Hour**: HH | HH12 | HH24
- **Minute**: MI
- **Second**: SS

**Note:**
Hour, minute, and second rounding is not supported by DATE expressions.

---

## Examples

### Round to the nearest hour:

```
=> SELECT ROUND(CURRENT_TIMESTAMP, 'HH');

ROUND
2016-04-28 15:00:00
(1 row)
```

### Round to the nearest month:

```
=> SELECT ROUND('9-22-2011 12:34:00'::TIMESTAMP, 'MM');

ROUND
2011-10-01 00:00:00
(1 row)
```
See Also

TIMESTAMP_ROUND

SECOND

Returns the seconds portion of the specified date as an integer.

Syntax

SECOND ( date )

Behavior Type

Immutable, except for TIMESTAMPTZ arguments where it is stable.

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ</td>
</tr>
<tr>
<td></td>
<td>• INTERVAL</td>
</tr>
</tbody>
</table>

Examples

=> SELECT SECOND ('23:34:03.456789');
SECOND
--------
   3
(1 row)
=> SELECT SECOND (TIMESTAMP 'sep 22, 2011 12:34');
SECOND
--------
   0
(1 row)
=> SELECT SECOND (INTERVAL '35 12:34:03.456789');
STATEMENT_TIMESTAMP

Similar to TRANSACTION_TIMESTAMP, returns a value of type TIMESTAMP WITH TIME ZONE that represents the start of the current statement.

The return value does not change during statement execution. Thus, different stages of statement execution always have the same timestamp.

Behavior Type

Stable

Syntax

STATEMENT_TIMESTAMP()

Example

```sql
=> SELECT foo, bar FROM (SELECT STATEMENT_TIMESTAMP() AS foo)foo, (SELECT STATEMENT_TIMESTAMP() as bar)bar;

<table>
<thead>
<tr>
<th>foo</th>
<th>bar</th>
</tr>
</thead>
</table>
```

See Also

- CLOCK_TIMESTAMP
- TRANSACTION_TIMESTAMP
SYSDATE

Returns the current statement's start date and time as a TIMESTAMP value. This function is identical to GETDATE.

SYSDATE uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers. Internally, GETDATE converts STATEMENT_TIMESTAMP from TIMESTAMPTZ to TIMESTAMP.

Behavior Type
Stable

Syntax

SYSDATE()

Note:
You can call this function with no parentheses.

Example

```sql
=> SELECT SYSDATE;
sysdate
--------------------
2016-12-12 06:11:10.699642 (1 row)
```

See Also
Date/Time Expressions

TIME_SLICE

Aggregates data by different fixed-time intervals and returns a rounded-up input TIMESTAMP value to a value that corresponds with the start or end of the time slice interval.
Given an input TIMESTAMP value such as 2000-10-28 00:00:01, the start time of a 3-second time slice interval is 2000-10-28 00:00:00, and the end time of the same time slice is 2000-10-28 00:00:03.

**Behavior Type**

Immutable

**Syntax**

```
TIME_SLICE( expression, slice-length [, 'time-unit' [, 'start-or-end'] ] )
```

**Parameters**

<table>
<thead>
<tr>
<th>expression</th>
<th>One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Column of type TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• String constant that can be parsed into a TIMESTAMP value.</td>
</tr>
<tr>
<td></td>
<td>For example: '2004-10-19 10:23:54'</td>
</tr>
<tr>
<td></td>
<td>Vertica evaluates expression on each row.</td>
</tr>
</tbody>
</table>

| slice-length     | A positive integer that specifies the slice length. |

<table>
<thead>
<tr>
<th>time-unit</th>
<th>Time unit of the slice, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• HOUR</td>
</tr>
<tr>
<td></td>
<td>• MINUTE</td>
</tr>
<tr>
<td></td>
<td>• SECOND (default)</td>
</tr>
<tr>
<td></td>
<td>• MILLISECOND</td>
</tr>
<tr>
<td></td>
<td>• MICROSECOND</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>start-or-end</th>
<th>Specifies whether the returned value corresponds to the start or end time with one of the following strings:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• START (default)</td>
</tr>
<tr>
<td></td>
<td>• END</td>
</tr>
</tbody>
</table>

**Note:**

This parameter can be included only if you also supply a non-
Null Argument Handling

TIME_SLICE handles null arguments as follows:

- TIME_SLICE returns an error when any one of slice-length, time-unit, or start-or-end parameters is null.
- If expression is null and slice-length, time-unit, or start-or-end contain legal values, TIME_SLICE returns a NULL value instead of an error.

Usage

The following command returns the (default) start time of a 3-second time slice:

```sql
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3);
  TIME_SLICE
----------------------
  2009-09-19 00:00:00
(1 row)
```

The following command returns the end time of a 3-second time slice:

```sql
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'SECOND', 'END');
  TIME_SLICE
----------------------
  2009-09-19 00:00:03
(1 row)
```

This command returns results in milliseconds, using a 3-second time slice:

```sql
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'ms');
  TIME_SLICE
----------------------
  2009-09-19 00:00:00.999
(1 row)
```

This command returns results in microseconds, using a 9-second time slice:

```sql
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'us');
  TIME_SLICE
----------------------
  2009-09-19 00:00:00.999999
(1 row)
```
The next example uses a 3-second interval with an input value of '00:00:01'. To focus specifically on seconds, the example omits date, though all values are implied as being part of the timestamp with a given input of '00:00:01':

- '00:00:00' is the start of the 3-second time slice
- '00:00:03' is the end of the 3-second time slice.
- '00:00:03' is also the start of the second 3-second time slice. In time slice boundaries, the end value of a time slice does not belong to that time slice; it starts the next one.

When the time slice interval is not a factor of 60 seconds, such as a given slice length of 9 in the following example, the slice does not always start or end on 00 seconds:

```sql
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 9);
TIME_SLICE
---------------------
2009-02-14 20:12:54
(1 row)
```

This is expected behavior, as the following properties are true for all time slices:

- Equal in length
- Consecutive (no gaps between them)
- Non-overlapping

To force the above example ('2009-02-14 20:13:01') to start at '2009-02-14 20:13:00', adjust the output timestamp values so that the remainder of 54 counts up to 60:

```sql
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 9) + '6 seconds'::INTERVAL AS time;
time
---------------------
2009-02-14 20:13:06
(1 row)
```
Alternatively, you could use a different slice length, which is divisible by 60, such as 5:

```sql
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 5);

2009-02-14 20:13:00
(1 row)
```

A TIMESTAMPTZ value is implicitly cast to TIMESTAMP. For example, the following two statements have the same effect.

```sql
=> SELECT TIME_SLICE('2009-09-23 11:12:01'::timestamptz, 3);

2009-09-23 11:12:00
(1 row)

=> SELECT TIME_SLICE('2009-09-23 11:12:01'::timestamptz::timestamp, 3);

2009-09-23 11:12:00
(1 row)
```

### Examples

You can use the SQL analytic functions `FIRST_VALUE` and `LAST_VALUE` to find the first/last price within each time slice group (set of rows belonging to the same time slice). This structure can be useful if you want to sample input data by choosing one row from each time slice group.

```sql
=> SELECT date_key, transaction_time, sales_dollar_amount, TIME_SLICE(DATE '2000-01-01' + date_key + transaction_time, 3),
   FIRST_VALUE(sales_dollar_amount)
OVER (PARTITION BY TIME_SLICE(DATE '2000-01-01' + date_key + transaction_time, 3)
   ORDER BY DATE '2000-01-01' + date_key + transaction_time) AS first_value
FROM store.store_sales_fact
LIMIT 20;
```

<table>
<thead>
<tr>
<th>date_key</th>
<th>transaction_time</th>
<th>sales_dollar_amount</th>
<th>time_slice</th>
<th>first_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>00:41:16</td>
<td>164</td>
<td>2000-01-02 00:41:15</td>
<td>164</td>
</tr>
<tr>
<td>1</td>
<td>00:41:33</td>
<td>310</td>
<td>2000-01-02 00:41:33</td>
<td>310</td>
</tr>
<tr>
<td>1</td>
<td>15:33:15</td>
<td>419</td>
<td>2000-01-02 15:33:15</td>
<td>419</td>
</tr>
<tr>
<td>1</td>
<td>15:33:44</td>
<td>193</td>
<td>2000-01-02 15:33:42</td>
<td>193</td>
</tr>
<tr>
<td>1</td>
<td>16:36:29</td>
<td>466</td>
<td>2000-01-02 16:36:27</td>
<td>466</td>
</tr>
</tbody>
</table>
TIME_SLICE rounds the transaction time to the 3-second slice length.

The following example uses the analytic (window) OVER clause to return the last trading price (the last row ordered by TickTime) in each 3-second time slice partition:

```sql
=> SELECT DISTINCT TIME_SLICE(TickTime, 3), LAST_VALUE(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING);
```

**Note:**
If you omit the windowing clause from an analytic clause, LAST_VALUE defaults to RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW. Results can seem non-intuitive, because instead of returning the value from the bottom of the current partition, the function returns the bottom of the *window*, which continues to change along with the current input row that is being processed. For more information, see Time Series Analytics and SQL Analytics in Analyzing Data.

In the next example, FIRST_VALUE is evaluated once for each input record and the data is sorted by ascending values. Use SELECT DISTINCT to remove the duplicates and return only one output record per TIME_SLICE:

```sql
=> SELECT DISTINCT TIME_SLICE(TickTime, 3), FIRST_VALUE(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ASC)
FROM tick_store;
```

```
<table>
<thead>
<tr>
<th>TIME_SLICE</th>
<th>?column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-09-21 00:00:06</td>
<td>20.00</td>
</tr>
<tr>
<td>2009-09-21 00:00:09</td>
<td>30.00</td>
</tr>
<tr>
<td>2009-09-21 00:00:00</td>
<td>10.00</td>
</tr>
</tbody>
</table>
```
The information output by the above query can also return MIN, MAX, and AVG of the trading prices within each time slice.

```sql
=> SELECT DISTINCT TIME_SLICE(TickTime, 3),FIRST_VALUE(Price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)
    ORDER BY TickTime ASC),
    MIN(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)),
    MAX(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)),
    AVG(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3))
FROM tick_store;
```

- TS_LAST_VALUE
- Using Time Zones With Vertica

**TIMEOFDAY**

Returns the wall-clock time as a text string. Function results advance during transactions.

**Behavior Type**

Volatile

**Syntax**

TIMEOFDAY()

**Example**

```sql
=> SELECT TIMEOFDAY();
TIMEOFDAY
-----------------------
Mon Dec 12 08:18:01.022710 2016 EST
(1 row)
```
TIMESTAMPADD

Adds the specified number of intervals to a TIMESTAMP or TIMESTAMPTZ value and returns a result of the same data type.

**Behavior Type**

- **Immutable** if the input date is a TIMESTAMP
- **Stable** if the input date is a TIMESTAMPTZ

**Syntax**

```
TIMESTAMPADD ( datepart, count, start-date );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>datepart</code></td>
<td>Specifies the type of time intervals that TIMESTAMPADD adds to the specified start date. If <code>datepart</code> is an expression, it must be enclosed in parentheses:</td>
</tr>
<tr>
<td><code>count</code></td>
<td>Integer or integer expression that specifies the number of <code>datepart</code> intervals to add to <code>start-date</code>.</td>
</tr>
<tr>
<td><code>start-date</code></td>
<td>TIMESTAMP or TIMESTAMPTZ value.</td>
</tr>
</tbody>
</table>
Examples

Add two months to the current date:

```sql
=> SELECT CURRENT_TIMESTAMP AS Today;
   Today
-----------------------------
   2016-05-02 06:56:57.923045-04
   (1 row)
=> SELECT TIMESTAMPADD(MONTH, 2, (CURRENT_TIMESTAMP)) AS TodayPlusTwoMonths;
   TodayPlusTwoMonths
-----------------------------
   2016-07-02 06:56:57.923045-04
   (1 row)
```

Add 14 days to the beginning of the current month:

```sql
=> SELECT TIMESTAMPADD(DD, 14, (SELECT TRUNC((CURRENT_TIMESTAMP), 'MM')));
   timestampadd
-----------------------------
   2016-05-15 00:00:00
   (1 row)
```

TIMESTAMPDIFF

Returns the time span between two TIMESTAMP or TIMESTAMPTZ values, in the intervals specified. TIMESTAMPDIFF excludes the start date in its calculation.

Behavior Type

- **Immutable** if start and end dates are TIMESTAMP
- **Stable** if start and end dates are TIMESTAMPTZ

Syntax

```
TIMESTAMPDIFF( datepart, start, end );
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datepart</td>
<td>Specifies the type of date or time intervals that TIMESTAMPDIFF returns. If datepart is an expression, it must be enclosed in parentheses: &lt;br&gt; [ \text{TIMESTAMPDIFF}((\text{expression}), \text{start}, \text{end}); ] &lt;br&gt; datepart must evaluate to one of the following string literals, either quoted or unquoted: &lt;br&gt; • year</td>
</tr>
</tbody>
</table>

| start, end | Specify the start and end dates, where start and end evaluate to one of the following data types: <br> • TIMESTAMP/TIMESTAMPTZ <br> • TIMESTAMPTZ <br> If end < start, TIMESTAMPDIFF returns a negative value. |

Date Part Intervals

TIMESTAMPDIFF uses the datepart argument to calculate the number of intervals between two dates, rather than the actual amount of time between them. For detailed information, see DATEDIFF.

Examples

=> SELECT TIMESTAMPDIFF (YEAR,'1-1-2006 12:34:00', '1-1-2008 12:34:00');
timestampdiff
--------------
See Also

DATEDIFF

TIMESTAMP_ROUND

Rounds the specified TIMESTAMP. If you omit the precision argument, TIMESTAMP_ROUND rounds to day (DD) precision.

Behavior Type

- **Immutable** if the target date is a TIMESTAMP
- **Stable** if the target date is a TIMESTAMPTZ

Syntax

```
TIMESTAMP_ROUND ( rounding-target[, 'precision'] )
```

Parameters

<table>
<thead>
<tr>
<th>rounding-target</th>
<th>An expression that evaluates to one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- TIMESTAMP/TIMESTAMPTZ</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>precision</th>
<th>A string constant that specifies precision for the rounded value, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- <strong>Century</strong>: CC</td>
</tr>
<tr>
<td></td>
<td>- <strong>Year</strong>: SYYY</td>
</tr>
<tr>
<td></td>
<td>- <strong>ISO Year</strong>: IYYY</td>
</tr>
<tr>
<td></td>
<td>- <strong>Quarter</strong>: Q</td>
</tr>
<tr>
<td></td>
<td>- <strong>Month</strong>: MONTH</td>
</tr>
<tr>
<td></td>
<td>- <strong>Same weekday as first day of year</strong>: WW</td>
</tr>
</tbody>
</table>
Examples

Round to the nearest hour:

```sql
=> SELECT TIMESTAMP_ROUND(CURRENT_TIMESTAMP, 'HH');
                 ROUND
---------------
2016-04-28 15:00:00
(1 row)
```

Round to the nearest month:

```sql
=> SELECT TIMESTAMP_ROUND('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
                 ROUND
---------------
2011-10-01 00:00:00
(1 row)
```

See Also

ROUND

TIMESTAMP_TRUNC

Truncates the specified TIMESTAMP. If you omit the precision argument, TIMESTAMP_TRUNC truncates to day (DD) precision.
Behavior Type

- **Immutable** if the target date is a TIMESTAMP
- **Stable** if the target date is a TIMESTAMPTZ

Syntax

`TIMESTAMP_TRUNC( trunc-target[, 'precision'] )`

Parameters

<table>
<thead>
<tr>
<th><strong>trunc-target</strong></th>
<th>An expression that evaluates to one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- TIMESTAMP/TIMESTAMPTZ</td>
</tr>
<tr>
<td></td>
<td>- TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>precision</strong></th>
<th>A string constant that specifies precision for the truncated value, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- <strong>Century</strong>: CC</td>
</tr>
<tr>
<td></td>
<td>- <strong>Year</strong>: SYYY</td>
</tr>
<tr>
<td></td>
<td>- <strong>ISO Year</strong>: IYYYY</td>
</tr>
<tr>
<td></td>
<td>- <strong>Quarter</strong>: Q</td>
</tr>
<tr>
<td></td>
<td>- <strong>Month</strong>: MONTH</td>
</tr>
<tr>
<td></td>
<td>- <strong>Same weekday as first day of year</strong>: WW</td>
</tr>
<tr>
<td></td>
<td>- <strong>Same weekday as first day of ISO year</strong>: IW</td>
</tr>
<tr>
<td></td>
<td>- <strong>Same weekday as first day of month</strong>: W</td>
</tr>
<tr>
<td></td>
<td>- <strong>Day</strong>: DDD</td>
</tr>
<tr>
<td></td>
<td>- <strong>First weekday</strong>: DAY</td>
</tr>
<tr>
<td></td>
<td>- <strong>Hour</strong>: HH</td>
</tr>
<tr>
<td></td>
<td>- <strong>Minute</strong>: MI</td>
</tr>
<tr>
<td></td>
<td>- <strong>Second</strong>: SS</td>
</tr>
</tbody>
</table>

**Note:**

Hour, minute, and second truncating is not supported by DATE expressions.

Examples

Truncate to the current hour:
Truncate to the month:

```sql
=> SELECT TIMESTAMP_TRUNC('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
TIMESTAMP_TRUNC
---------------------
2011-09-01 00:00:00
(1 row)
```

See Also

TRUNC

TRANSACTION_TIMESTAMP

Returns a value of type TIME WITH TIMEZONE that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to TRANSACTION_TIMESTAMP within the same transaction return the same timestamp.

TRANSACTION_TIMESTAMP is equivalent to CURRENT_TIMESTAMP, except it does not accept a precision parameter.

Behavior Type

Stable

Syntax

TRANSACTION_TIMESTAMP()
Example

```sql
=> SELECT foo, bar FROM (SELECT TRANSACTION_TIMESTAMP() AS foo)foo, (SELECT TRANSACTION_TIMESTAMP() as bar)bar;

<table>
<thead>
<tr>
<th>foo</th>
<th>bar</th>
</tr>
</thead>
<tbody>
<tr>
<td>2016-12-12 08:18:00.988528-05</td>
<td>2016-12-12 08:18:00.988528-05</td>
</tr>
</tbody>
</table>

(1 row)
```

See Also

- `CLOCK_TIMESTAMP`
- `STATEMENT_TIMESTAMP`

**TRUNC**

Truncates the specified date or time. If you omit the precision argument, TRUNC truncates to day (DD) precision.

**Behavior Type**

- **Immutable** if the target date is a `TIMESTAMP` or `DATE`
- **Stable** if the target date is a `TIMESTAMPTZ`

**Syntax**

```sql
TRUNC( trunc-target[, 'precision'] )
```

**Parameters**

<table>
<thead>
<tr>
<th><code>trunc-target</code></th>
<th>An expression that evaluates to one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <code>DATE</code></td>
</tr>
<tr>
<td></td>
<td>• <code>TIMESTAMP/TIMESTAMPTZ</code></td>
</tr>
<tr>
<td></td>
<td>• <code>TIMESTAMPTZ</code></td>
</tr>
</tbody>
</table>
A string constant that specifies precision for the truncated value, one of the following:

- **Century**: CC | SCC
- **Year**: SYYY | YYY | YEAR | YYY | YY | Y
- **ISO Year**: IYYY | IYY | IY | I
- **Quarter**: Q
- **Month**: MONTH | MON | MM | RM
- **Same weekday as first day of year**: WW
- **Same weekday as first day of ISO year**: IW
- **Same weekday as first day of month**: W
- **Day (default)**: DDD | DD | J
- **First weekday**: DAY | DY | D
- **Hour**: HH | HH12 | HH24
- **Minute**: MI
- **Second**: SS

**Note:**
Hour, minute, and second truncating is not supported by DATE expressions.

**Examples**

**Truncate to the current hour:**

```sql
=> SELECT TRUNC(CURRENT_TIMESTAMP, 'HH');

                          TRUNC
------------------------
2016-04-29 10:00:00
(1 row)
```

**Truncate to the month:**

```sql
=> SELECT TRUNC('9-22-2011 12:34:00'::TIMESTAMP, 'MM');

     TIMESTAMP_TRUNC
-----------------------
2011-09-01 00:00:00
(1 row)
```

**See Also**

`TIMESTAMP_TRUNC`
WEEK

Returns the week of the year for the specified date as an integer, where the first week begins on the first Sunday on or preceding January 1.

Syntax

WEEK ( date )

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the specified date is a TIMESTAMPTZ

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>VARCHAR, DATE, TIMESTAMP, TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

Examples

January 2 is on Saturday, so WEEK returns 1:

```
=> SELECT WEEK ('1-2-2016':::DATE);
   WEEK
  ------
     1
(1 row)
```

January 3 is the second Sunday in 2016, so WEEK returns 2:

```
=> SELECT WEEK ('1-3-2016':::DATE);
   WEEK
  ------
     2
(1 row)
```
WEEK_ISO

Returns the week of the year for the specified date as an integer, where the first week starts on Monday and contains January 4. This function conforms with the ISO 8061 standard.

Syntax

\[
\text{WEEK_ISO}(\text{date})
\]

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the specified date is a TIMESTAMPTZ

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
</table>
|      | - VARCHAR  
|      | - DATE  
|      | - TIMESTAMP  
|      | - TIMESTAMPTZ |

Examples

The first week of 2016 begins on Monday January 4:

\[
\Rightarrow \text{SELECT WEEK_ISO ('1-4-2016':DATE);}
\]

```
WEEK_ISO
--------
1
(1 row)
```

January 3 2016 returns week 53 of the previous year (2015):

\[
\Rightarrow \text{SELECT WEEK_ISO ('1-3-2016':DATE);}
\]

```
WEEK_ISO
--------
53
(1 row)
```
In 2015, January 4 is on Sunday, so the first week of 2015 begins on the preceding Monday (December 29 2014):

```sql
=> SELECT WEEK_ISO ('1-3-2016'::DATE);
 WEEK_ISO
 ------
 53
(1 row)
```

YEAR

Returns an integer that represents the year portion of the specified date.

**Syntax**

`YEAR( date )`

**Behavior Type**

- **Immutable** if the specified date is a `TIMESTAMP`, `DATE`, `VARCHAR`, or `INTERVAL`
- **Stable** if the specified date is a `TIMESTAMPTZ`

**Parameters**

<table>
<thead>
<tr>
<th><code>date</code></th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- VARCHAR</td>
</tr>
<tr>
<td></td>
<td>- <code>DATE</code></td>
</tr>
<tr>
<td></td>
<td>- <code>TIMESTAMP</code></td>
</tr>
<tr>
<td></td>
<td>- <code>TIMESTAMPTZ</code></td>
</tr>
<tr>
<td></td>
<td>- <code>INTERVAL</code></td>
</tr>
</tbody>
</table>
Examples

```sql
=> SELECT YEAR(CURRENT_DATE::DATE);
 YEAR
-----
 2016
(1 row)
```

See Also

YEAR_iso

YEAR_iso

Returns an integer that represents the year portion of the specified date. The return value is based on the ISO 8061 standard.

The first week of the ISO year is the week that contains January 4.

Syntax

```sql
YEAR_ISO ( date )
```

Behavior Type

- **Immutable** if the specified date is a TIMESTAMP, DATE, or VARCHAR
- **Stable** if the specified date is a TIMESTAMPTZ

Parameters

<table>
<thead>
<tr>
<th>date</th>
<th>The date to process, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• VARCHAR</td>
</tr>
<tr>
<td></td>
<td>• DATE</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMPTZ</td>
</tr>
</tbody>
</table>
**Examples**

```
> SELECT YEAR_ISO(CURRENT_DATE::DATE);
YEAR_ISO
--------
    2016
(1 row)
```

**See Also**

YEAR

**Error-handling Functions**

Error-handling functions take a string and return the string when the query is executed.

**THROW_ERROR**

Returns a user-defined error message.

In a multi-node cluster, race conditions might cause the order of error messages to differ.

**Syntax**

```
THROW_ERROR ( message )
```

**Parameters**

<table>
<thead>
<tr>
<th>message</th>
<th>The VARCHAR string to return.</th>
</tr>
</thead>
</table>

**Examples**

Return an error message when a CASE statement is met:
CREATE TABLE pitcher_err (some_text varchar);
CREATE TABLE
COPY pitcher_err FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> big foo value
>> bigger foo other value
>> bar another foo value
>> 
=> SELECT (CASE WHEN true THEN THROW_ERROR('Failure!!!') ELSE some_text END) FROM pitcher_err;
ERROR 7137: USER GENERATED ERROR: Failure!!!

Return an error message when a CASE statement using REGEXP_LIKE is met:

=> SELECT (CASE WHEN REGEXP_LIKE(some_text, 'other') THEN THROW_ERROR('Failure at "' || some_text || '"') END) FROM pitcher_err;
ERROR 4566: USER GENERATED ERROR: Failure at "bar another foo value"
Formatting Functions

Formatting functions provide a powerful tool set for converting various data types (DATE/TIME, INTEGER, FLOATING POINT) to formatted strings and for converting from formatted strings to specific data types.

TO_BITSTRING

Returns a VARCHAR that represents the given VARBINARY value in bitstring format. This function is the inverse of BITSTRING_TO_BINARY.

Behavior Type

Immutable

Syntax

TO_BITSTRING ( expression )

Parameters

| expression | The VARCHAR string to process. |

Examples

```sql
=> SELECT TO_BITSTRING('ab'::BINARY(2));
  to_bitstring
-------------------
  0110000101100010
(1 row)

=> SELECT TO_BITSTRING(HEX_TO_BINARY('0x10'));
  to_bitstring
-------------------
  00010000
(1 row)
```
=> SELECT TO_BITSTRING(HEX_TO_BINARY('0xF0'));
to_bitstring
--------
11110000
(1 row)

See Also

BITCOUNT

TO_CHAR

Converts various date/time and numeric values into text strings.

Behavior Type

Stable

Syntax

TO_CHAR ( expression [, pattern ] )

Parameters

table

<table>
<thead>
<tr>
<th>expression</th>
<th>Specifies the value to convert, one of the following data types:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• DOUBLE PRECISION</td>
</tr>
<tr>
<td></td>
<td>• INTEGER</td>
</tr>
<tr>
<td></td>
<td>• INTERVAL</td>
</tr>
<tr>
<td></td>
<td>• TIME/TIMETZ</td>
</tr>
<tr>
<td></td>
<td>• TIMESTAMP/TIMESTAMPTZ</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>pattern</th>
<th>A CHAR or VARCHAR that specifies an output pattern string. See:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Template Patterns for Date/Time Formatting</td>
</tr>
<tr>
<td></td>
<td>• Template Patterns for Numeric Formatting</td>
</tr>
</tbody>
</table>
Notes

- **TO_CHAR( any )** casts any type, except BINARY/VARBINARY, to VARCHAR.

  The following example returns an error if you try to cast TO_CHAR to a binary data type:

  ```sql
  => SELECT TO_CHAR('abc'::VARBINARY);
  ERROR: cannot cast type varbinary to varchar
  ```

- **TO_CHAR** accepts TIME and TIMETZ data types as inputs if you explicitly cast TIME to TIMESTAMP and TIMETZ to TIMESTAMPTZ.

  ```sql
  => SELECT TO_CHAR(TIME '14:34:06.4','HH12:MI am');
  => SELECT TO_CHAR(TIMETZ '14:34:06.4+6','HH12:MI am');
  ```

  You can extract the timezone hour from TIMETZ:

  ```sql
  => SELECT EXTRACT(timezone_hour FROM TIMETZ '10:30+13:30');
  date_part
  ------------
     13
  (1 row)
  ```

- Ordinary text is allowed in to_char templates and is output literally. You can put a substring in double quotes to force it to be interpreted as literal text even if it contains pattern key words. For example, in "'Hello Year "YYYY', the YYYY is replaced by the year data, but the single Y in Year is not.

- **TO_CHAR**'s day-of-the-week numbering (see the 'D' template pattern) is different from that of the EXTRACT function.

- Given an INTERVAL type, **TO_CHAR** formats HH and HH12 as hours in a single day, while HH24 can output hours exceeding a single day, for example, >24.

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: ' \"YYYY Month\" '.

- **TO_CHAR** does not support the use of V combined with a decimal point. For example: 99.9V99 is not allowed.

- When rounding, the last digit of the rounded representation is selected to be even if the number is exactly half way between the two.
<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>

<td>'-4-85'</td>
</tr>
</tbody>
</table>
### See Also

- DATE_PART

### TO_DATE

Converts a string value to a DATE type.

### Behavior Type

**Stable**
Syntax

TO_DATE( expression, pattern )

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Specifies the string value to convert, either CHAR or VARCHAR.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern</td>
<td>A CHAR or VARCHAR that specifies an output pattern string. See:</td>
</tr>
<tr>
<td></td>
<td>• Template Patterns for Date/Time Formatting</td>
</tr>
<tr>
<td></td>
<td>• Template Patterns for Numeric Formatting</td>
</tr>
</tbody>
</table>

Input Value Considerations

TO_DATE requires a CHAR or VARCHAR expression. For other input types, use TO_CHAR to perform an explicit cast to a CHAR or VARCHAR before using this function.

Notes

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: ' \"YYYY Month\" '

- TO_TIMESTAMP, TO_TIMESTAMP_TZ, and TO_DATE skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:
  - TO_TIMESTAMP('2000 JUN', 'YYYY MON') is correct.
  - TO_TIMESTAMP('2000 JUN', 'FXYYYY MON') returns an error, because TO_TIMESTAMP expects one space only.

- The YYYY conversion from string to TIMESTAMP or DATE has a restriction if you use a year with more than four digits. You must use a non-digit character or template after YYYY, otherwise the year is always interpreted as four digits. For example, given the following arguments, TO_DATE interprets the five-digit year 20000 as a four-digit year:
=> SELECT TO_DATE('200001131','YYYYMMDD');
  TO_DATE
  2000-01-13
(1 row)

Instead, use a non-digit separator after the year. For example:

=> SELECT TO_DATE('2000-1131', 'YYYY-MMDD');
  TO_DATE
  2000-12-01
(1 row)

- In conversions from string to TIMESTAMP or DATE, the CC field is ignored if there is a YYY, YYYY or Y,YYY field. If CC is used with YY or Y, then the year is computed as (CC–1)*100+YY.

**Examples**

=> SELECT TO_DATE('13 Feb 2000', 'DD Mon YYYY');
  to_date
  2000-02-13
(1 row)

**See Also**

Date/Time Functions

**TO_HEX**

Returns a VARCHAR or VARBINARY representing the hexadecimal equivalent of a number. This function is the inverse of HEX_TO_BINARY.

**Behavior Type**

Immutable
**Syntax**

TO_HEX ( number )

**Parameters**

| number | An INTEGER or VARBINARY value to convert to hexadecimal. If you supply a VARBINARY argument, the function's return value is not preceded by 0x. |

**Examples**

```sql
=> SELECT TO_HEX(123456789);
   TO_HEX
----------
75bcd15
(1 row)
```

For VARBINARY inputs, the returned value is not preceded by 0x. For example:

```sql
=> SELECT TO_HEX('ab': :binary(2));
   TO_HEX
----------
6162
(1 row)
```

**TO_TIMESTAMP**

Converts a string value or a UNIX/POSIX epoch value to a TIMESTAMP type.

**Behavior Type**

Stable

**Syntax**

TO_TIMESTAMP ( { expression, pattern } | unix-epoch )
Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Specifies the string value to convert, of type CHAR or VARCHAR.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern</td>
<td>A CHAR or VARCHAR that specifies an output pattern string. See:</td>
</tr>
<tr>
<td></td>
<td>- Template Patterns for Date/Time Formatting</td>
</tr>
<tr>
<td></td>
<td>- Template Patterns for Numeric Formatting</td>
</tr>
<tr>
<td>unix-epoch</td>
<td>DOUBLE PRECISION value that specifies some number of seconds</td>
</tr>
<tr>
<td></td>
<td>elapsed since midnight UTC of January 1, 1970, excluding leap</td>
</tr>
<tr>
<td></td>
<td>seconds. INTEGER values are implicitly cast to DOUBLE PRECISION.</td>
</tr>
</tbody>
</table>

Notes

- Millisecond (MS) and microsecond (US) values in a conversion from string to TIMESTAMP are used as part of the seconds after the decimal point. For example TO_TIMESTAMP('12:3', 'SS:MS') is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format SS:MS, the input values 12:3, 12:30, and 12:300 specify the same number of milliseconds. To get three milliseconds, use 12:003, which the conversion counts as 12 + 0.003 = 12.003 seconds.

  Here is a more complex example: TO_TIMESTAMP('15:12:02.020.001230', 'HH:MI:SS.MS.US') is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: "\"YYYY Month\""

- TO_TIMESTAMP, TO_TIMESTAMP_TZ, and TO_DATE skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:
  - TO_TIMESTAMP('2000 JUN', 'YYYY MON') is correct.
  - TO_TIMESTAMP('2000 JUN', 'FXYYYY MON') returns an error, because TO_TIMESTAMP expects one space only.
- The YYYY conversion from string to TIMESTAMP or DATE has a restriction if you use a year with more than four digits. You must use a non-digit character or template after
YYYY, otherwise the year is always interpreted as four digits. For example, given the following arguments, TO_DATE interprets the five-digit year 20000 as a four-digit year:

```sql
=> SELECT TO_DATE('200001131', 'YYYYMMDD');
TO_DATE
--------
2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```sql
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
TO_DATE
-------
20000-12-01
(1 row)
```

- In conversions from string to TIMESTAMP or DATE, the CC field is ignored if there is a YYY, YYYY or Y,YYY field. If CC is used with YY or Y, then the year is computed as (CC–1)*100+YY.

**Examples**

```sql
=> SELECT TO_TIMESTAMP('13 Feb 2009', 'DD Mon YYYY');
TO_TIMESTAMP
-------------
1200-02-13 00:00:00
(1 row)
=> SELECT TO_TIMESTAMP(200120400);  
TO_TIMESTAMP
-------------
1976-05-05 01:00:00
(1 row)
```

**See Also**

Date/Time Functions

**TO_TIMESTAMP_TZ**

Converts a string value or a UNIX/POSIX epoch value to a TIMESTAMP WITH TIME ZONE type.
**Behavior Type**

Immutable if single argument form, Stable otherwise.

**Syntax**

```
TO_TIMESTAMP_TZ ( { expression, pattern } | unix-epoch )
```

**Parameters**

<table>
<thead>
<tr>
<th>expression</th>
<th>Specifies the string value to convert, of type CHAR or VARCHAR.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern</td>
<td>A CHAR or VARCHAR that specifies an output pattern string. See:</td>
</tr>
<tr>
<td></td>
<td>• Template Patterns for Date/Time Formatting</td>
</tr>
<tr>
<td></td>
<td>• Template Patterns for Numeric Formatting</td>
</tr>
<tr>
<td>unix-epoch</td>
<td>A DOUBLE PRECISION value that specifies some number of seconds</td>
</tr>
<tr>
<td></td>
<td>elapsed since midnight UTC of January 1, 1970, excluding leap</td>
</tr>
<tr>
<td></td>
<td>seconds. INTEGER values are implicitly cast to DOUBLE PRECISION.</td>
</tr>
</tbody>
</table>

**Notes**

- Millisecond (MS) and microsecond (US) values in a conversion from string to TIMESTAMP are used as part of the seconds after the decimal point. For example `TO_TIMESTAMP('12:3', 'SS:MS')` is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format SS:MS, the input values 12:3, 12:30, and 12:300 specify the same number of milliseconds. To get three milliseconds, use 12:003, which the conversion counts as 12 + 0.003 = 12.003 seconds.

  Here is a more complex example: `TO_TIMESTAMP('15:12:02.020.001230', 'HH:MI:SS.MS.US')` is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: `"\"YYYY Month\""`
• TO_TIMESTAMP, TO_TIMESTAMP_TZ, and TO_DATE skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:
  • TO_TIMESTAMP('2000 JUN', 'YYYY MON') is correct.
  • TO_TIMESTAMP('2000 JUN', 'FXYYYY MON') returns an error, because TO_TIMESTAMP expects one space only.
• The YYYY conversion from string to TIMESTAMP or DATE has a restriction if you use a year with more than four digits. You must use a non-digit character or template after YYYY, otherwise the year is always interpreted as four digits. For example, given the following arguments, TO_DATE interprets the five-digit year 20000 as a four-digit year:

```sql
=> SELECT TO_DATE('200001131', 'YYYYMMDD');
  TO_DATE
--------------
  2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```sql
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
  TO_DATE
--------------
  20000-12-01
(1 row)
```

• In conversions from string to TIMESTAMP or DATE, the CC field is ignored if there is a YYYY, YYYYY or Y,YYY field. If CC is used with YY or Y, then the year is computed as (CC−1)*100+YY.

**Examples**

```sql
=> SELECT TO_TIMESTAMP_TZ('13 Feb 2009', 'DD Mon YYYY');
  TO_TIMESTAMP_TZ
--------------
  2009-02-13 00:00:00-05
(1 row)
=> SELECT TO_TIMESTAMP_TZ('2001204000');
  TO_TIMESTAMP_TZ
--------------
  2001-05-01 00:00:00-04
(1 row)
```
See Also

Date/Time Functions

TO_NUMBER

Converts a string value to DOUBLE PRECISION.

Behavior Type

Stable

Syntax

TO_NUMBER ( expression, [ pattern ] )

Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>Specifies the string value to convert, either CHAR or VARCHAR.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern</td>
<td>A string value, either CHAR or VARCHAR, that specifies an output pattern string using one of the supported Template Patterns for Numeric Formatting. If you omit this parameter, TO_NUMBER returns a floating point.</td>
</tr>
</tbody>
</table>

Notes

To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: ' "YYYY Month\" '  

Note:
To convert a date string to a numeric value, use the appropriate date/time function, such as EXTRACT.
Examples

```sql
=> SELECT TO_NUMBER('MCML', 'rn');
TO_NUMBER
--------
1950
(1 row)
```

It the pattern parameter is omitted, the function returns a floating point. For example:

```sql
=> SELECT TO_NUMBER('-123.456e-01');
TO_NUMBER
--------
-12.3456
```
Template Patterns for Date/Time Formatting

In an output template string (for TO_CHAR), there are certain patterns that are recognized and replaced with appropriately-formatted data from the value to be formatted. Any text that is not a template pattern is copied verbatim. Similarly, in an input template string (for anything other than TO_CHAR), template patterns identify the parts of the input data string to be looked at and the values to be found there.

Note: Vertica uses the ISO 8601:2004 style for date/time fields in Vertica*.log files. For example, 2008-09-16 14:40:59.123 TM Moveout:0x2aaaac002180 [Txn] <INFO>

Certain modifiers can be applied to any template pattern to alter its behavior as described in Template Pattern Modifiers for Date/Time Formatting.

</tbody>
</table>

**Examples**

Use `TO_TIMESTAMP` to convert an expression using the pattern 'YYY MON':

```sql
=> SELECT TO_TIMESTAMP('2017 JUN', 'YYYY MON');
TO_TIMESTAMP
--------------------
2017-06-01 00:00:00
(1 row)
```

Use `TO_DATE` to convert an expression using the pattern 'YYY-MMDD':

```sql
```
`=> SELECT TO_DATE('2017-1231', 'YYYY-MMDD');
TO_DATE
------------
2017-12-31
(1 row)`

## Template Pattern Modifiers for Date/Time Formatting

Certain modifiers can be applied to any template pattern to alter its behavior. For example, `FMMonth` is the Month pattern with the FM modifier.

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AM</td>
<td>Time is before 12:00</td>
</tr>
<tr>
<td>AT</td>
<td>Ignored</td>
</tr>
<tr>
<td>JULIAN, JD, J</td>
<td>Next field is Julian Day</td>
</tr>
<tr>
<td>FM prefix</td>
<td>Fill mode (suppress padding blanks and zeros)</td>
</tr>
<tr>
<td></td>
<td>For example: FMMonth</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The FM modifier suppresses leading zeros and trailing blanks that would otherwise be added to make the output of a pattern fixed width.</td>
</tr>
<tr>
<td>FX prefix</td>
<td>Fixed format global option</td>
</tr>
<tr>
<td></td>
<td>For example: FX Month DD Day</td>
</tr>
<tr>
<td>ON</td>
<td>Ignored</td>
</tr>
<tr>
<td>PM</td>
<td>Time is on or after 12:00</td>
</tr>
<tr>
<td>T</td>
<td>Next field is time</td>
</tr>
<tr>
<td>TH suffix</td>
<td>Uppercase ordinal number suffix</td>
</tr>
<tr>
<td></td>
<td>For example: DDTH</td>
</tr>
<tr>
<td>th suffix</td>
<td>Lowercase ordinal number suffix</td>
</tr>
<tr>
<td></td>
<td>For example: DDth</td>
</tr>
<tr>
<td>TM prefix</td>
<td>Translation mode (print localized day and month names based on lc_messages). For example: TMMonth</td>
</tr>
</tbody>
</table>
Template Patterns for Numeric Formatting

<table>
<thead>

</tr>
<tr>
<td>V</td>
<td>Shift specified number of digits (see notes)</td>
</tr>
<tr>
<td>EEEE</td>
<td>Scientific notation (not implemented yet)</td>
</tr>
</tbody>
</table>

Usage

- A sign formatted using SG, PL, or MI is not anchored to the number; for example:
  - `TO_CHAR(-12, 'S9999')` produces '-12'
  - `TO_CHAR(-12, 'MI9999')` produces '-12'
9 results in a value with the same number of digits as there are 9s. If a digit is not available it outputs a space.

TH does not convert values less than zero and does not convert fractional numbers.

V effectively multiplies the input values by $10^n$, where $n$ is the number of digits following V. TO_CHAR does not support the use of V combined with a decimal point. For example: 99.9V99 is not allowed.

Geospatial Functions

The following topics describe the Vertica geospatial functions.

Function-Naming Conventions

The geospatial functions use the following naming conventions:

- The ST\_function\_name functions are compliant with the latest Open Geospatial Consortium standard OGC SFA-SQL version 1.2.1 (reference. number is OGC 06-104r4, date: 2010-08-04). Currently, some ST\_function\_name> functions may not support all data types. Each function page contains details about the supported data types.

  Note:

  Some functions, such as ST\_GeomFromText, are based on previous versions of the standard.

- The STV\_function\_name> functions are unique to Vertica and not compliant with OGC standards. Each function page explains its functionality in detail.

Verifying Spatial Objects Validity

Many spatial functions do not verify the validity of the parameters. If you pass an invalid spatial object to an ST\_ or STV\_ function, the function may return an error or produce incorrect results.

To avoid this issue, OpenText recommends that you first run ST\_IsValid on all spatial objects to verify their validity. If your object is not valid, run STV\_IsValidReason to get information about the location of the invalidity.
**Note:**

If you pass a valid polygon to STV_IsValidReason, it returns NULL.

### ST_AsText

Creates the Well-Known Text (WKT) representation of a spatial object. Use this function when you need to specify a spatial object in ASCII form.

### Behavior Type

**Immutable**

### Syntax

```
ST_AsText( g )
```

### Arguments

<table>
<thead>
<tr>
<th>g</th>
<th>Spatial object for which you want the WKT string, type GEOMETRY or GEOGRAPHY</th>
</tr>
</thead>
</table>

### Returns

LONG VARCHAR

### Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Example

The following example shows how to use `ST_AsText`.

Retrieve WKB and WKT representations:

```sql
=> CREATE TABLE locations (id INTEGER, name VARCHAR(100),
  geom1 GEOMETRY(800),
  geom2 GEOGRAPHY);
CREATE TABLE
=> COPY locations
  (id, geom1x FILLER LONG VARCHAR(800), geom1 AS ST_GeomFromText(geom1x), geom2x FILLER LONG VARCHAR(800),
   geom2 AS ST_GeographyFromText(geom2x))
FROM stdin;
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.

> 1|POINT(2 3) |
> 2|LINESTRING(2 4,1 5) |
> 3|POLYGON((-70.96 43.27,-70.67 42.95,-66.90 44.74,-67.81 46.08,-67.81 47.20,-69.22 47.43,-71.09 45.25,-70.96 43.27)) |
> 
=> SELECT id, ST_AsText(geom1),ST_AsText(geom2) FROM locations ORDER BY id ASC;

<table>
<thead>
<tr>
<th>id</th>
<th>ST_AsText</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (2 3)</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>LINESTRING (2 4,1 5)</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>POLYGON((-70.96 43.27, -70.67 42.95, -66.9 44.74, -67.81 46.08, -67.81 47.2, -69.22 47.43, -71.09 45.25, -70.96 43.27))</td>
<td></td>
</tr>
</tbody>
</table>

(3 rows)

Calculate the length of a WKT using the Vertica SQL function `LENGTH`:

```sql
=> SELECT LENGTH(ST_AsText(ST_GeomFromText('POLYGON ((-1.2, 0.3, 1.2,
  0 1, -1 2)') )));

LENGTH
-------
37

(1 row)
```
See Also

- ST_AsBinary

ST_Area

Calculates the area of a spatial object.

The units are:

- GEOMETRY objects: spatial reference system identifier (SRID) units
- GEOGRAPHY objects: square meters

Behavior Type

Immutable

Syntax

ST_Area( $g$ )

Arguments

| $g$  | Spatial object for which you want to calculate the area, type GEOMETRY or GEOGRAPHY |

Returns

FLOAT

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
</table>

Point | Yes | Yes
---|---|---
Multipoint | Yes | Yes
Linestring | Yes | Yes
Multilinestring | Yes | Yes
Polygon | Yes | Yes
Multipolygon | Yes | Yes
GeometryCollection | Yes | No

**Examples**

The following examples show how to use `ST_Area`.

Calculate the area of a polygon:

```sql
=> SELECT ST_Area(ST_GeomFromText('POLYGON((0 0, 1 0, 1 1, 0 1, 0 0)))

ST_Area
--------
 1
(1 row)
```

Calculate the area of a multipolygon:

```sql
=> SELECT ST_Area(ST_GeomFromText('MultiPolygon(((0 0, 1 0, 1 1, 0 0)),
  ((2 2, 3 4, 6 3, 2 2)))'))

ST_Area
--------
 3
(1 row)
```

Suppose the polygon has a hole, as in the following figure.

![Polygon with a hole]
Calculate the area, excluding the area of the hole:

```sql
=> SELECT ST_Area(ST_GeomFromText('POLYGON((2 2,5 8, 2, 2),
(4 3, 5, 4 6, 3, 4))'));
ST_Area
--------
     8
(1 row)
```

Calculate the area of a geometry collection:

```sql
=> SELECT ST_Area(ST_GeomFromText('GEOMETRYCOLLECTION(POLYGON((20.5 20.45,
20.51 20.52, 20.69 20.32, 20.5 20.45)), POLYGON((10 20, 30 40, 25 50, 10 20)))));
ST_Area
--------
150.0073
(1 row)
```

Calculate the area of a geography object:

```sql
=> SELECT ST_Area(ST_GeographyFromText('POLYGON((20.5 20.45, 20.51 20.52,
20.69 20.32, 20.5 20.45))));
ST_Area
-------------
84627437.116037
(1 row)
```

**ST_AsBinary**

Creates the Well-Known Binary (WKB) representation of a spatial object. Use this function when you need to convert an object to binary form for porting spatial data to or from other applications.

**Behavior Type**

Immutable

**Syntax**

```sql
ST_AsBinary( g )
```
## Arguments

| g | Spatial object for which you want the WKB, type GEOMETRY or GEOGRAPHY |

## Returns

LONG VARBINARY

## Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

## Example

The following example shows how to use ST_AsBinary.

Retrieve WKB and WKT representations:

```sql
=> CREATE TABLE locations (id INTEGER, name VARCHAR(100), geom1 GEOMETRY(800), geom2 GEOGRAPHY);
CREATE TABLE
=> COPY locations
   (id, geom1x FILLER LONG VARCHAR(800), geom1 AS ST_GeomFromText(geom1x), geom2x FILLER LONG VARCHAR(800),
   geom2 AS ST_GeographyFromText(geom2x))
FROM stdin;
Enter data to be copied followed by a newline.
```
End with a backslash and a period on a line by itself.

1 | POINT(2 3) |
2 | LINESTRING(2 4,1 5) |
3 | POLYGON((-70.96 43.27,-70.67 42.95,-66.90 44.74,-67.81 46.08,-67.81 47.20,-69.22 47.43,-71.09 45.25,-70.96 43.27)) |

=> \.

> SELECT id, ST_AsText(geom1),ST_AsText(geom2) FROM locations ORDER BY id ASC;

<table>
<thead>
<tr>
<th>id</th>
<th>ST_AsText</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (2 3)</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>LINESTRING (2 4, 1 5)</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>POLYGON ((-70.96 43.27, -70.67 42.95, -66.90 44.74, -67.81 46.08, -67.81 47.20, -69.22 47.43, -71.09 45.25, -70.96 43.27))</td>
<td></td>
</tr>
</tbody>
</table>

> SELECT id, ST_AsBinary(geom1),ST_AsBinary(geom2) FROM locations ORDER BY id ASC;

(3 rows)

Calculate the length of a WKB using the Vertica SQL function LENGTH:

> SELECT LENGTH(ST_AsBinary(St_GeomFromText('POLYGON ((-1 2, 0 3, 1 2, 0 1, -1 2))')));

<table>
<thead>
<tr>
<th>LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>93</td>
</tr>
</tbody>
</table>

(1 row)

See Also

ST_AsText

ST_Boundary

Calculates the boundary of the specified GEOMETRY object. An object's boundary is the set of points that define the limit of the object.

For a linestring, the boundary is the start and end points. For a polygon, the boundary is a linestring that begins and ends at the same point.

Behavior Type

Immutable
**Syntax**

\[ \text{ST\textunderscore Boundary}(g) \]

**Arguments**

| \(g\) | Spatial object for which you want the boundary, type GEOMETRY |

**Returns**

GEOMETRY

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to use ST\textunderscore Boundary.

Returns a linestring that represents the boundary:

```sql
=> SELECT ST\textunderscore AsText(ST\textunderscore Boundary(ST\textunderscore GeomFromText('POLYGON((-1 -1,2 2, 0 1, -1 -1)))));
```

ST\textunderscore AsText
Returns a multilinestring that contains the boundaries of both polygons:

```sql
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((2 2,5 5,8 2,2 2),
(4 3,5 4,6 3,4 3)))));
```

```
MULTILINESTRING ((2 2, 5 5, 8 2, 2 2), (4 3, 5 4, 6 3, 4 3))
```

The boundary of a linestring is its start and end points:

```sql
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(1 1,2 3,4 4)')));
```

```
MULTIPOINT (1 1, 4 4)
```

A closed linestring has no boundary because it has no start and end points:

```sql
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(1 1,2 3,4 4,1 1)')));
```

```
MULTIPOINT EMPTY
```

## ST_Buffer

Creates a GEOMETRY object greater than or equal to a specified distance from the boundary of a spatial object. The distance is measured in Cartesian coordinate units. ST_Buffer does not accept a distance size greater than +1e15 or less than −1e15.

### Behavior Type

**Immutable**

### Syntax

```sql
ST_Buffer( g, d )
```
Arguments

<table>
<thead>
<tr>
<th>$g$</th>
<th>Spatial object for which you want to calculate the buffer, type GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>$d$</td>
<td>Distance from the object in Cartesian coordinate units, type FLOAT</td>
</tr>
</tbody>
</table>

Returns

GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Usage Tips

- If you specify a positive distance, ST_Buffer returns a polygon that represents the points within or equal to the distance outside the object. If you specify a negative distance, ST_Buffer returns a polygon that represents the points within or equal to the distance inside the object.
- For points, multipoints, linestrings, and multilinestrings, if you specify a negative distance, ST_Buffer returns an empty polygon.
- The Vertica Place version of ST_Buffer returns the buffer as a polygon, so the buffer object has corners at its vertices. It does not contain rounded corners.
Example

The following example shows how to use ST_Buffer.

Returns a GEOMETRY object:

```sql
=> SELECT ST_AsText(ST_Buffer(ST_GeomFromText('POLYGON((0 1,1 4,4 3,0 1))'),1));

ST_AsText
POLYGON ((-0.188847498856 -0.159920845081, 1.12155598386 0.649012935089, 0.290814745534 4.76344136152, -0.188847498856 -0.159920845081))
(1 row)
```

ST_Centroid

Calculates the geometric center—the centroid—of a spatial object. If points or linestrings or both are present in a geometry with polygons, only the polygons contribute to the calculation of the centroid. Similarly, if points are present with linestrings, the points do not contribute to the calculation of the centroid.

To calculate the centroid of a GEOGRAPHY object, see the examples for STV_Geometry and STV_Geography.

Behavior Type

Immutable

Syntax

```sql
ST_Centroid( g )
```

Arguments

| g            | Spatial object for which you want to calculate the centroid, type GEOMETRY |
Returns
GEOMETRY (POINT only)

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Centroid.

Calculate the centroid for a polygon:

```
=> SELECT ST_AsText(ST_Centroid(ST_GeomFromText('POLYGON((-1 -1,2,-1 2, -1 -1)))));
ST_AsText-------------------
POINT (-0 1)
(1 row)
```

Calculate the centroid for a multipolygon:

```
=> SELECT ST_AsText(ST_Centroid(ST_GeomFromText('MULTIPOLYGON(((1 0,2 1,2 0, 1 0)),((-1 -1,2,-1 2,-1 -1))'))));
ST_AsText------------------------
POINT (8.166666666667 8.93333333333)
(1 row)
```

This figure shows the centroid for the multipolygon.
ST_Contains

Determines if a spatial object is entirely inside another spatial object without existing only on its boundary. Both arguments must be the same spatial data type. Either specify two GEOMETRY objects or two GEOGRAPHY objects.

If an object such as a point or linestring only exists along a spatial object's boundary, then ST_Contains returns false. The interior of a linestring is all the points on the linestring except the start and end points.

ST_Contains($g1$, $g2$) is functionally equivalent to ST_Within($g2$, $g1$).

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior Type

Immutable

Syntax

```
ST_Contains( $g1$, $g2$ [USING PARAMETERS spheroid=(true | false)] )
```
Arguments

<table>
<thead>
<tr>
<th>$g_1$</th>
<th>Spatial object, type GEOMETRY or GEOGRAPHY</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g_2$</td>
<td>Spatial object, type GEOMETRY or GEOGRAPHY</td>
</tr>
</tbody>
</table>

Parameters

| spheroid = {true | false} | (Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. |
|--------------------------|--------------------------------------------------------------------------|
|                          | **Default**: False                                                        |

Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Compatible GEOGRAPHY pairs:
### Examples

The following examples show how to use ST_Contains.

The first polygon does not completely contain the second polygon:

```sql
=> SELECT ST_Contains(ST_GeomFromText('POLYGON((0 2,1,0 -1,0 2))'),
                      ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))'));
ST_Contains
------------
1
(1 row)
```

If a point is on a linestring, but not on an end point:

```sql
=> SELECT ST_Contains(ST_GeomFromText('LINESTRING(20 20,30 30)'),
                      ST_GeomFromText('POINT(25 25)'));
ST_Contains
------------
1
(1 row)
```
If a point is on the boundary of a polygon:

```sql
=> SELECT ST_Contains(ST_GeographyFromText('POLYGON((20 20,30 30,30 25,20 20))'),
   ST_GeographyFromText('POINT(20 20)'));
ST_Contains
-----------
f
(1 row)
```

Two spatially equivalent polygons:

```sql
=> SELECT ST_Contains(ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),
   ST_GeomFromText('POLYGON((0 3, -1 2, 0 1, 0 3))'));
ST_Contains
-----------
t
(1 row)
```
See Also
- `ST_Overlaps`
- `ST_Within`

**ST_ConvexHull**

Calculates the smallest convex GEOMETRY object that contains a GEOMETRY object.

**Behavior Type**

Immutable

**Syntax**

`ST_ConvexHull( g )`

**Arguments**

| g          | Spatial object for which you want the convex hull, type GEOMETRY |

**Returns**

GEOMETRY
Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_ConvexHull.

For a pair of points in a geometry collection:

```sql
=> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText('GEOMETRYCOLLECTION(
    POINT(1 1),POINT(0 0))')));

------------------------
LINESTRING (1 1, 0 0)
(1 row)
```

For a geometry collection:

```sql
=> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText('GEOMETRYCOLLECTION(
    LINESTRING(2.5 3,-2 1.5), POLYGON((0 1,1 3,1 -2,0 1)))')));

-------------------------------
POLYGON ((1 -2, -2 1.5, 1 3, 2.5 3, 1 -2))
(1 row)
```

The solid lines represent the original geometry collection and the dashed lines represent the convex hull.
**ST_Crosses**

Determines if one GEOMETRY object spatially crosses another GEOMETRY object. If two objects touch only at a border, ST_Crosses returns FALSE.

Two objects spatially cross when both of the following are true:

- The two objects have some, but not all, interior points in common.
- The dimension of the result of their intersection is less than the maximum dimension of the two objects.

**Behavior Type**

*Immutable*

**Syntax**

```
ST_Crosses( g1, g2 )
```

**Arguments**

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g1$</td>
<td>Spatial object, type GEOMETRY</td>
</tr>
<tr>
<td>$g2$</td>
<td>Spatial object, type GEOMETRY</td>
</tr>
</tbody>
</table>
Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Crosses.

```sql
=> SELECT ST_Crosses(ST_GeomFromText('LINESTRING(-1 3,1 4)'),
                        ST_GeomFromText('LINESTRING(-1 4,1 3)'));
          ST_Crosses
-----------
 t
(1 row)
```
SELECT ST_Crosses(ST_GeomFromText('LINESTRING(-1 1,1 2)'),'POLYGON((1 1,0 -1 -3 -1,2 1,1 1))');

SELECT ST_Crosses(ST_GeomFromText('POINT(-1 4)'),'LINESTRING(-1 4,1 3)');

ST_Difference

Calculates the part of a spatial object that does not intersect with another spatial object.

Behavior Type

Immutable

Syntax

ST_Difference( g1, g2 )
Arguments

<table>
<thead>
<tr>
<th>g1</th>
<th>Spatial object, type GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>g2</td>
<td>Spatial object, type GEOMETRY</td>
</tr>
</tbody>
</table>

Returns

GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Difference.

Two overlapping linestrings:

```sql
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('LINESTRING(0 0,0 2)'),
                                  ST_GeomFromText('LINESTRING(0 1,0 2)')));
ST_AsText
------------------
LINESTRING (0 0, 0 1)
(1 row)
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('LINESTRING(0 0,0 3)'),
                                  ST_GeomFromText('LINESTRING(0 0 2,0 4)')));
ST_AsText
------------------
LINESTRING (0 0, 0 1)
(1 row)
```
Two overlapping polygons:

```sql
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('POLYGON((0 1,0 3,2 3,2 1,0 1))'),
                                 ST_GeomFromText('POLYGON((0 0,0 2,2 2,0 0))')));
```

```sql
POLYGON ((0 1, 0 3, 2 3, 2 1, 0 1))
(1 row)
```

Two non-intersecting polygons:

```sql
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('POLYGON((1 1,1 3,3 3,3 1, 1 1))'),
                                 ST_GeomFromText('POLYGON((1 5,1 7,-1 7,-1 5,1 5))')));
```

```sql
POLYGON ((1 1, 1 3, 3 3, 3 1, 1 1))
(1 row)
```

**ST_Disjoint**

Determines if two GEOMETRY objects do not intersect or touch.
If ST_Disjoint returns TRUE for a pair of GEOMETRY objects, ST_Intersects returns FALSE for the same two objects.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

**Behavior Type**

*Immutable*

**Syntax**

```sql
ST_Disjoint( g1, g2 ) [USING PARAMETERS spheroid={true | false}] )
```

**Arguments**

<table>
<thead>
<tr>
<th>g1</th>
<th>Spatial object, type GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>g2</td>
<td>Spatial object, type GEOMETRY</td>
</tr>
</tbody>
</table>

**Parameters**

| spheroid = {true | false} | (Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. |
|---------------------------|---------------------------------------------------------------------------------|
|                           | **Default:** False                                                              |

**Returns**

BOOLEAN

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Geometry Type</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----</td>
<td>----</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Compatible GEOGRAPHY pairs:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point-Point</td>
<td>No</td>
</tr>
<tr>
<td>Linestring-Point</td>
<td>No</td>
</tr>
<tr>
<td>Polygon-Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon-Point</td>
<td>No</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to use ST_Disjoint.

Two non-intersecting or touching polygons:

```sql
=> SELECT ST_Disjoint (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
                      ST_GeomFromText('POLYGON((1 0, 1 1, 2 2, 1 0)'));
ST_Disjoint
----------
t
(1 row)
```

Two intersecting linestrings:

```sql
=> SELECT ST_Disjoint(ST_GeomFromText('LINESTRING(-1 2,0 3)'),
                      ST_GeomFromText('LINESTRING(0 2,-1 3)'));
ST_Disjoint
----------
f
(1 row)
```

Two polygons touching at a single point:

```sql
=> SELECT ST_Disjoint (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),
                      ST_GeomFromText('POLYGON((0 2, 1 1, 1 2, 0 2))'));
ST_Disjoint
         --
1 row
```

### See Also

- `ST_Intersects`

### ST_Distance

Calculates the shortest distance between two spatial objects. For GEOMETRY objects, the distance is measured in Cartesian coordinate units. For GEOGRAPHY objects, the distance is measured in meters.

Parameters $g1$ and $g2$ must be both GEOMETRY objects or both GEOGRAPHY objects.

### Behavior Type

**Immutable**

### Syntax

```sql
ST_Distance( $g1$, $g2$
             [USING PARAMETERS spheroid={ true | false } ]
)
```

### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g1$</td>
<td>Spatial object, type GEOMETRY or GEOGRAPHY</td>
</tr>
<tr>
<td>$g2$</td>
<td>Spatial object, type GEOMETRY or GEOGRAPHY</td>
</tr>
</tbody>
</table>

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spheroid</td>
<td>(Optional) BOOLEAN that specifies whether to use a perfect</td>
</tr>
</tbody>
</table>
false } sphere or WGS84.

**Default**: False

## Returns

FLOAT

## Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>

<tr>
<td>Multipolygon-Point</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

## Recommendations

Vertica recommends pruning invalid data before using ST_Distance. Invalid geography values could return non-guaranteed results.

## Examples

The following examples show how to use ST_Distance.

### Distance between two polygons:

```sql
=> SELECT ST_Distance(ST_GeomFromText('POLYGON((-1 -1,2,0 1,-1 -1))'),
                        ST_GeomFromText('POLYGON((5 2,7 4,5 5 5 2))'));

ST_Distance
------------
 3            
(1 row)
```

### Distance between a point and a linestring in meters:

```sql
=> SELECT ST_Distance(ST_GeographyFromText('POINT(31.75 31.25)'),
                       ST_GeographyFromText('LINESTRING(32 32,32 35,40.5 35,35 32 35,32 32)'));

ST_Distance
------------
86690.3950562969
(1 row)
```

## ST_Envelope

Calculates the minimum bounding rectangle that contains the specified GEOMETRY object.

## Behavior Type

**Immutable**
## Syntax

```
ST_Envelope( g )
```

## Arguments

| $g$ | Spatial object for which you want to find the minimum bounding rectangle, type GEOMETRY |

## Returns

GEOMETRY

## Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

## Example

The following example shows how to use ST_Envelope.

Returns the minimum bounding rectangle:
ST_Equals

Determines if two spatial objects are spatially equivalent. The coordinates of the two objects and their WKT/WKB representations must match exactly for ST_Equals to return TRUE.

The order of the points do not matter in determining spatial equivalence:

- LINestring(1 2, 4 3) equals LINestring(4 3, 1 2).
- POLYGON ((0 0, 1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0)) equals POLYGON((1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0, 1 1)).
- MULTILINESTRING((1 2, 4 3),(0 0, -1 -4)) equals MULTILINESTRING((0 0, -1 -4),(1 2, 4 3)).

Coordinates are stored as FLOAT types. Thus, rounding errors are expected when importing Well-Known Text (WKT) values because the limitations of floating-point number representation.

$g1$ and $g2$ must both be GEOMETRY objects or both be GEOGRAPHY objects. Also, $g1$ and $g2$ cannot both be of type GeometryCollection.
Behavior Type

Immutable

Syntax

```
ST_Equals( g1, g2 )
```

Arguments

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>g1</strong></td>
<td>Spatial object to compare to <strong>g2</strong>, type GEOMETRY or GEOGRAPHY</td>
</tr>
<tr>
<td><strong>g2</strong></td>
<td>Spatial object to compare to <strong>g1</strong>, type GEOMETRY or GEOGRAPHY</td>
</tr>
</tbody>
</table>

Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
Examples

The following examples show how to use ST_Equals.

Two linestrings:

```sql
=> SELECT ST_Equals (ST_GeomFromText('LINESTRING(-1 2, 0 3)'),
  ST_GeomFromText('LINESTRING(0 3, -1 2)'));
ST_Equals
----------
t
(1 row)
```

Two polygons:

```sql
=> SELECT ST_Equals (ST_GeographyFromText('POLYGON((43.22 42.21,40.3 39.88,
  42.1 50.03,43.22 42.21))'),ST_GeographyFromText('POLYGON((43.22 42.21,
  40.3 39.88,42.1 50.31,43.22 42.21))'));
ST_Equals
----------
f
(1 row)
```

ST_GeographyFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOGRAPHY object. Use this function to convert a WKT string into the format expected by the Vertica Place functions.

A GEOGRAPHY object is a spatial object with coordinates (longitude, latitude) defined on the surface of the earth. Coordinates are expressed in degrees (longitude, latitude) from reference planes dividing the earth.

The maximum size of a GEOGRAPHY object is 10 MB. If you pass a WKT to ST_GeographyFromText, the result is a spatial object whose size is greater than 10 MB, ST_GeographyFromText returns an error.

The Open Geospatial Consortium (OGC) defines the format of a WKT string in Section 7 in the Simple Feature Access Part 1 - Common Architecture specification.

Behavior Type

Immutable
Syntax

ST_GeographyFromText( wkt [ USING PARAMETERS ignore_errors='y'|'n' ] )

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wkt</td>
<td>Well-Known Text (WKT) string of a GEOGRAPHY object, type LONG VARCHAR</td>
</tr>
<tr>
<td>ignore_errors</td>
<td>(Optional) ST_GeographyFromText returns the following, based on the parameters supplied:</td>
</tr>
<tr>
<td></td>
<td>• NULL—If wkt is invalid and ignore_errors='y'.</td>
</tr>
<tr>
<td></td>
<td>• Error—If wkt is invalid and ignore_errors='n' or is unspecified.</td>
</tr>
</tbody>
</table>

Returns

GEOGRAPHY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
Example

The following example shows how to use ST_GeographyFromText.

Convert WKT into a GEOGRAPHY object:

```sql
=> CREATE TABLE wkt_ex (g GEOGRAPHY);
CREATE TABLE
=> INSERT INTO wkt_ex VALUES(ST_GeographyFromText('POLYGON((1 2,3,2,3,1,2)));
OUTPUT
-------
 1
(1 row)
```

ST_GeographyFromWKB

Converts a Well-Known Binary (WKB) value into its corresponding GEOGRAPHY object. Use this function to convert a WKB into the format expected by Vertica Place functions.

A GEOGRAPHY object is a spatial object defined on the surface of the earth. Coordinates are expressed in degrees (longitude, latitude) from reference planes dividing the earth. All calculations are in meters.

The maximum size of a GEOGRAPHY object is 10 MB. If you pass a WKB to ST_GeographyFromWKB that results in a spatial object whose size is greater than 10 MB, ST_GeographyFromWKB returns an error.

The Open Geospatial Consortium (OGC) defines the format of a WKB representation in Section 8 in the Simple Feature Access Part 1 - Common Architecture specification.

Behavior Type

Immutable

Syntax

```sql
ST_GeographyFromWKB( wkb [ USING PARAMETERS ignore_errors={'y' | 'n'} ] )
```
Arguments

<table>
<thead>
<tr>
<th>wkb</th>
<th>Well-Known Binary (WKB) value of a GEOGRAPHY object, type LONG VARBINARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>ignore_errors</td>
<td>(Optional) ST_GeographyFromWKB returns the following, based on the parameters supplied:</td>
</tr>
<tr>
<td></td>
<td>• NULL—If wkb is invalid and ignore_errors='y'.</td>
</tr>
<tr>
<td></td>
<td>• Error—If wkb is invalid and ignore_errors='n' or is unspecified.</td>
</tr>
</tbody>
</table>

Returns

GEOGRAPHY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Example

The following example shows how to use ST_GeographyFromWKB.

Convert WKB into a GEOGRAPHY object:
CREATE TABLE wkb_ex (g GEOGRAPHY);
CREATE TABLE => INSERT INTO wkb_ex VALUES(ST_GeographyFromWKB(X'01030000000100000000 ... ');
OUTPUT
--------
 1
(1 row)

**ST_GeoHash**

Returns a GeoHash in the shape of the specified geometry.

**Behavior Type**

*Immutable*

**Syntax**

```
ST_GeoHash( SpatialObject [ USING PARAMETERS numchars=n ] )
```

**Arguments**

<table>
<thead>
<tr>
<th>Spatial object</th>
<th>A GEOMETRY or GEOGRAPHY spatial object. Inputs must be in polar coordinates (-180 &lt;= x &lt;= 180 and -90 &lt;= y &lt;= 90) for all points inside the given geometry.</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>Specifies the length, in characters, of the returned GeoHash.</td>
</tr>
</tbody>
</table>

**Returns**

GEOHASH

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Geometry Type</td>
<td>Point</td>
<td>Multipoint</td>
<td>Linestring</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------</td>
<td>------------</td>
<td>------------</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to use `ST_PointFromGeoHash`.

Generate a full precision GeoHash for the specified geometry:

```sql
=> SELECT ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'));
ST_GeoHash
------------------------
kpf0rkn3zmcswks75010
(1 row)
```

Generate a GeoHash based on the first five characters of the specified geometry:

```sql
=> select ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)') USING PARAMETERS numchars=5);
ST_GeoHash
----------
kpf0r
(1 row)
```

**ST_GeometryN**

Returns the $n$\textsuperscript{th} geometry within a geometry object.

If $n$ is out of range of the index, then NULL is returned.

**Behavior Type**

*Immutable*
**Syntax**

\[ \text{ST\_GeometryN}( \ g \ , \ n \ ) \]

**Arguments**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>( g )</td>
<td>Spatial object of type GEOMETRY.</td>
</tr>
<tr>
<td>( n )</td>
<td>The geometry's index number, 1-based.</td>
</tr>
</tbody>
</table>

**Returns**

GEOMETRY

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to use \( \text{ST\_GeometryN} \).

Return the second geometry in a multipolygon:
CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));

COPY multipolygon_geom (gid, gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6),((0 0, 0 5, 1 0, 0 0),((0 2, 2 5, 4 5, 0 2)))

CREATE TABLE series_numbers (numbs int);

COPY series_numbers FROM STDIN;

1 | 2 | 3 | 4 | 5 | 

SELECT numbs, ST_AsText(ST_GeometryN(geom, numbs))
FROM multipolygon_geom, series_numbers
WHERE ST_AsText(ST_GeometryN(geom, numbs)) IS NOT NULL
ORDER BY numbs ASC;

1 | POLYGON ((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
2 | POLYGON ((0 0, 0 5, 1 0, 0 0))
3 | POLYGON ((0 2, 2 5, 4 5, 0 2))

(3 rows)

Return all the geometries within a multipolygon:

See Also

ST_NumGeometries

ST_GeometryType

Determines the class of a spatial object.
**Behavior Type**

*Immutable*

**Syntax**

\[\text{ST\_GeometryType}( \ g \ )\]

**Arguments**

<table>
<thead>
<tr>
<th>(g)</th>
<th>Spatial object for which you want the class, type GEOMETRY or GEOGRAPHY</th>
</tr>
</thead>
</table>

**Returns**

VARCHAR

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

**Example**

The following example shows how to use ST\_GeometryType.
Returns spatial class:

```sql
=> SELECT ST_GeometryType(ST_GeomFromText('GEOMETRYCOLLECTION(LINESTRING(1 1, 2 2), POLYGON((1 3, 4 5, 2 2, 1 3)))));
```

ST_GeometryType
------------------
ST_GeometryCollection
(1 row)

**ST_GeomFromGeoHash**

Returns a polygon in the shape of the specified GeoHash.

**Behavior Type**

Immutable

**Syntax**

```
ST_GeomFromGeoHash(GeoHash)
```

**Arguments**

<table>
<thead>
<tr>
<th>GeoHash</th>
<th>A valid GeoHash string of arbitrary length.</th>
</tr>
</thead>
</table>

**Returns**

GEOGRAPHY

**Examples**

The following examples show how to use ST_GeomFromGeoHash.

Converts a GeoHash string to a Geography object and back to a GeoHash

```sql
=> SELECT ST_Geohash(ST_GeomFromGeoHash('vert1c9'));
```

ST_Geohash
-----------
vert1c9
Returns a polygon of the specified GeoHash and uses `ST_AsText` to convert the polygon, rectangle map tile, into Well-Known Text:

```sql
=> SELECT ST_AsText(ST_GeomFromGeoHash('drt3jj9n4dpcbcdef'));
ST_AsText
-----------------------------
POLYGON ((-71.1459699298 42.3945346513, -71.1459699297 42.3945346513, -71.1459699298 42.3945346513, -71.1459699298 42.3945346513))
(1 row)
```

Returns multiple polygons and their areas for the specified GeoHashes. The polygon for the high level GeoHash (1234) has a significant area, while the low level GeoHash (1234567890bcdefhjkmn) has an area of zero.

```sql
=> SELECT ST_Area(short) short_area, ST_AsText(short) short_WKT, ST_Area(long) long_area, ST_AsText(long) long_WKT from (SELECT ST_GeomFromGeoHash('1234') short, ST_GeomFromGeoHash('1234567890bcdefhjkmn') long) as foo;
-| RECORD 1 ---------------------------------------------------------------
-| short_area | 24609762.8991076 |
-| short_WKT | POLYGON ((-122.34375 -88.2421875, -121.9921875 -88.2421875, -121.9921875 -88.06640625, -122.34375 -88.06640625, -122.34375 -88.2421875)) |
-| long_area | 0 |
-| long_WKT | POLYGON ((-122.196077187 -88.2297377551, -122.196077187 -88.2297377551, -122.196077187 -88.2297377551)) |
```

## ST_GeomFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOMETRY object. Use this function to convert a WKT string into the format expected by the Vertica Place functions.

A GEOMETRY object is a spatial object defined by the coordinates of a plane. Coordinates are expressed as points on a Cartesian plane \((x, y)\). SRID values of 0 to \(2^{32}-1\) are valid. SRID values outside of this range will generate an error.

The maximum size of a GEOMETRY object is 10 MB. If you pass a WKT to `ST_GeomFromText` and the result is a spatial object whose size is greater than 10 MB, `ST_GeomFromText` returns an error.

Behavior Type

Immutable

Syntax

ST_GeomFromText( wkt [, srid] [ USING PARAMETERS ignore_errors=\'y\'|\'n\' ] )

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wkt</td>
<td>Well-Known Text (WKT) string of a GEOMETRY object, type LONG VARCHAR.</td>
</tr>
<tr>
<td>srid</td>
<td>(Optional when not performing operations) Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER. The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.</td>
</tr>
</tbody>
</table>
| ignore_errors | (Optional) ST_GeomFromText returns the following, based on parameters supplied:  
- NULL—If wkt is invalid and ignore_errors=\'y\'.  
- Error—If wkt is invalid and ignore_errors=\'n\' or is unspecified. |

Returns

GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Example

The following example shows how to use ST_GeomFromText.

Convert WKT into a GEOMETRY object:

```sql
=> SELECT ST_Area(ST_GeomFromText('POLYGON((1 1,2 3,3 5,0 5,1 -2,0 1,1 1))'));

ST_Area
--------
   6
(1 row)
```

### ST_GeomFromWKB

Converts the Well-Known Binary (WKB) value to its corresponding GEOMETRY object. Use this function to convert a WKB into the format expected by many of the Vertica Place functions.

A GEOMETRY object is a spatial object with coordinates \((x,y)\) defined in the Cartesian plane.

The maximum size of a GEOMETRY object is 10 MB. If you pass a WKB to ST_GeomFromWKB and the result is a spatial object whose size is greater than 10 MB, ST_GeomFromWKB returns an error.

### Behavior Type

**Immutable**
Syntax

ST_GeomFromWKB( wkb[, srid] [ USING PARAMETERS ignore_errors={'y'|'n'} ])  

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wkb</td>
<td>Well-Known Binary (WKB) value of a GEOMETRY object, type LONGVARBINARY</td>
</tr>
<tr>
<td>srid</td>
<td>(Optional) Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER. The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.</td>
</tr>
</tbody>
</table>
| ignore_errors | (Optional) ST_GeomFromWKB returns the following, based on the parameters supplied:  
  - NULL—If wkb is invalid and ignore_errors='y'.  
  - Error—If wkb is invalid and ignore_errors='n' or is unspecified. |

Returns

GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Example

The following example shows how to use ST_GeomFromWKB.

Convert GEOMETRY into WKT:

```sql
=> CREATE TABLE t(g GEOMETRY);
CREATE TABLE
=> INSERT INTO t VALUES( 
  ST_GeomFromWKB(X'0103000000100000004000000000000000000000000000000000000000000000000000f
  03f000000000000000000f64ae1c7022db544000000000000000000f03f00000000000000000000000000000000f
)
OUTPUT
-----------
  1
(1 row)
=> SELECT ST_AsText(g) from t;
ST_AsText
-----------
POLYGON ((0 0, 1 0, 1e+23 1, 0 0))
(1 row)
```

ST_Intersection

Calculates the set of points shared by two GEOMETRY objects.

Behavior Type

Immutable

Syntax

`ST_Intersection( g1, g2 )`

Arguments

| g1         | Spatial object, type GEOMETRY |
Spatial object, type GEOMETRY

Returns
GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Intersection.

Two polygons intersect at a single point:
Two polygons:

```sql
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('POLYGON((0 2,1 0 -1, 0 2)'), ST_GeomFromText('POLYGON((-1 2,0 0,-2 0,-1 2)'))));
ST_AsText---------------------
POINT(0 0)
(1 row)
```

Two non-intersecting linestrings:

```sql
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('POLYGON((1 2,1 5,4 5, 4 2,1 2)'), ST_GeomFromText('POLYGON((3 1,3 3,5 3,5 1,3 1))')));
ST_AsText---------------------
POLYGON ((4 3, 4 2, 3 2, 3 3, 4 3))
(1 row)
```
ST_Intersection

Determines if two GEOMETRY or GEOGRAPHY objects intersect or touch at a single point. If ST_Disjoint returns TRUE, ST_Intersects returns FALSE for the same GEOMETRY or GEOGRAPHY objects.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior Type

Immutable

Syntax

ST_Intersects( g1, g2
            [USING PARAMETERS bbox={true | false}, spheroid={true | false}] )
Arguments

<table>
<thead>
<tr>
<th>$g_1$</th>
<th>Spatial object, type GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g_2$</td>
<td>Spatial object, type GEOMETRY</td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bbox</td>
<td>Boolean. Intersects the bounding box of $g_1$ and $g_2$.</td>
</tr>
<tr>
<td>spheroid</td>
<td>(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.</td>
</tr>
</tbody>
</table>

Default: False

Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Compatible GEOGRAPHY pairs:
### Examples

The following examples show how to use `ST_Intersects`.

**Two polygons do not intersect or touch:**

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
                        ST_GeomFromText('POLYGON((1 0,1 1,2,1 0))'));
ST_Intersects
----------
  f
(1 row)
```

**Two polygons touch at a single point:**
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
                   ST_GeomFromText('POLYGON((1 0,1 1,1 0))'));
                  
ST_Intersects

-------------
t
(1 row)

Two polygons intersect:

=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),
                   ST_GeomFromText('POLYGON((0 2, -1 3, -2 0, 0 2))'));
                  
ST_Intersects

-------------
t
(1 row)
See Also

ST_Disjoint

ST_IsEmpty

Determines if a spatial object represents the empty set. An empty object has no dimension.

Behavior Type

Immutable

Syntax

`ST_IsEmpty( g )`

Arguments

| g | Spatial object, type GEOMETRY or GEOGRAPHY |

Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Example

The following example shows how to use `ST_IsEmpty`.

An empty polygon:

```sql
=> SELECT ST_IsEmpty(ST_GeomFromText('GeometryCollection EMPTY'));
ST_IsEmpty
---------
t (1 row)
```

### ST_IsSimple

Determines if a spatial object does not intersect itself or touch its own boundary at any point.

### Behavior Type

**Immutable**

### Syntax

```
ST_IsSimple( g )
```

### Arguments

| g  | Spatial object, type GEOMETRY or GEOGRAPHY |
Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_IsSimple.

Polygon does not intersect itself:
SELECT ST_IsSimple(ST_GeomFromText('POLYGON((-1 2, 0 3, 1 2, -2, -1 2))'));
ST_IsSimple
-------------
t
(1 row)

Linestring intersects itself:

=> SELECT ST_IsSimple(ST_GeometryFromText('LINESTRING(10 10, 25 25, 34.5, 10 30, 10 20, 10)'));
ST_IsSimple
-------------
f
(1 row)

Linestring touches its interior at one or more locations:

=> SELECT ST_IsSimple(ST_GeometryFromText('LINESTRING(0 0, 1 1, 2 2, 0 0)'));
ST_IsSimple
-------------
f
**ST_IsValid**

Determines if a spatial object is well formed or valid. If the object is valid, ST_IsValid returns TRUE; otherwise, it returns FALSE. Use STV_IsValidReason to identify the location of the invalidity.

Spatial validity applies only to polygons and multipolygons. A polygon or multipolygon is valid if all of the following are true:

- The polygon is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- The boundary does not touch or cross itself.
- Any polygons in the interior do not touch the boundary of the exterior polygon except at a vertex.

If you are not sure if a polygon is valid, run ST_IsValid first. If you pass an invalid spatial object to a Vertica Place function, the function fails or returns incorrect results.

**Behavior Type**

*Immutable*

**Syntax**

```
ST_IsValid( g )
```

**Arguments**

| g | Geospatial object to test for validity, value of type GEOMETRY or GEOGRAPHY (WGS84). |
Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_IsValid.

Valid polygon:
```sql
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1, 1 3, 3 3, 3 1, 1 1))'));
ST_IsValid
---------
t
(1 row)

Invalid polygon:

```

```sql
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 3, 3 2, 1 3, 0 1, 0 1 3))'));
ST_IsValid
---------
f
(1 row)

Invalid polygon:

```

```sql
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((0 0, 2 2, 0 2, 0 0))'));
ST_IsValid
---------
f
(1 row)

Invalid multipolygon:
```
Valid polygon with hole:

Invalid polygon with hole:
```sql
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,3,6 -1,0.5 -1,1 1),
(1 1,4.5 1,2 0,1 1)))
ST_IsValid
-----------
f
(1 row)
```

### ST_Length

Calculates the length of a spatial object. For GEOMETRY objects, the length is measured in Cartesian coordinate units. For GEOGRAPHY objects, the length is measured in meters.

Calculates the length as follows:

- The length of a point or multipoint object is 0.
- The length of a linestring is the sum of the lengths of each line segment. The length of a line segment is the distance from the start point to the end point.
- The length of a polygon is the sum of the lengths of the exterior boundary and any interior boundaries.
- The length of a multilinestring, multipolygon, or geometrycollection is the sum of the lengths of all the objects it contains.

**Note:**
ST_Length does not calculate the length of WKTs or WKBs. To calculate the lengths of those objects, use the Vertica LENGTH SQL function with ST_AsBinary or ST_AsText.

### Behavior Type

**Immutable**
Syntax

ST_Length( g )

Arguments

| g  | Spatial object for which you want to calculate the length, type GEOMETRY or GEOGRAPHY |

Returns

FLOAT

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Length.

Returns length in Cartesian coordinate units:
ST_Length

Returns length in meters:

```sql
=> SELECT ST_Length(ST_GeomFromText('LINESTRING(-1 -1,2,4 5,6 7)'));
  ST_Length
--------------------------
  10.6766190873295
(1 row)
```

```sql
=> SELECT ST_Length(ST_GeographyFromText('LINESTRING(-56.12 38.26,-57.51 39.78,
  -56.37 45.24)'));
  ST_Length
--------------------------
  821580.025733461
(1 row)
```

**ST_NumGeometries**

Returns the number of geometries contained within a spatial object. Single GEOMETRY or GEOGRAPHY objects return 1 and empty objects return NULL.

**Behavior Type**

Immutable

**Syntax**

```sql
ST_NumGeometries( g )
```

**Arguments**

<table>
<thead>
<tr>
<th>g</th>
<th>Spatial object of type GEOMETRY or GEOGRAPHY</th>
</tr>
</thead>
</table>

**Returns**

INTEGER
### Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

### Examples

The following example shows how to use ST_NumGeometries.

Return the number of geometries:

```sql
=> SELECT ST_NumGeometries(ST_GeomFromText('MULTILINESTRING ((1 5, 2 4, 5 3, 6 6), (3 5, 3 7))'));
ST_NumGeometries
--------------------
 2
```

(1 row)

### See Also

- [ST_GeometryN](#)

### ST_NumPoints

Calculates the number of vertices of a spatial object, empty objects return NULL.

The first and last vertex of polygons and multipolygons are counted separately.
Behavior Type

Immutable

Syntax

ST_NumPoints( g )

Arguments

| g  | Spatial object for which you want to count the vertices, type GEOMETRY or GEOGRAPHY |

Returns

INTEGER

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
Examples

The following examples show how to use ST_NumPoints.

Returns the number of vertices in a linestring:

```sql
=> SELECT ST_NumPoints(ST_GeomFromText('LINESTRING(1.33 1.56,2.31 3.4,2.78 5.82,
3.76 3.9,4.11 3.27,5.85 4.34,6.9 4.231,7.61 5.77)'));
ST_NumPoints
----------
     8
(1 row)
```

Use ST_Boundary and ST_NumPoints to return the number of vertices of a polygon:

```sql
=> SELECT ST_NumPoints(ST_Boundary(ST_GeomFromText('POLYGON((1 2,1 4,
2 5,3 6,4 6,5 4,3 3,1 2))')));
ST_NumPoints
----------
     9
(1 row)
```

ST_Overlaps

Determines if a GEOMETRY object shares space with another GEOMETRY object, but is not completely contained within that object. They must overlap at their interiors. If two objects touch at a single point or intersect only along a boundary, they do not overlap. Both parameters must have the same dimension; otherwise, ST_Overlaps returns FALSE.

Behavior Type

Immutable

Syntax

ST_Overlaps ( g1, g2 )
Arguments

<table>
<thead>
<tr>
<th></th>
<th>Spatial object, type GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>( g^1 )</td>
<td></td>
</tr>
<tr>
<td>( g^2 )</td>
<td></td>
</tr>
</tbody>
</table>

Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Overlaps.

Polygon_1 overlaps but does not completely contain Polygon_2:
Two objects with different dimensions:

```sql
=> SELECT ST_Overlaps(ST_GeomFromText('POLYGON((0 0, 0 1, 1 1, 0 0))'),
    ST_GeomFromText('POLYGON((0.5 0.5, 0.7 0.5, 0.7 0.7, 0.5 0.7, 0.5 0.5))'));

ST_Overlaps
-----------
t
1 row
```

```sql
=> SELECT ST_Overlaps(ST_GeomFromText('LINESTRING(2 2,4 4)'),
    ST_GeomFromText('POINT(3 3)'));

ST_Overlaps
-----------
f
1 row
```
Returns

GEOGRAPHY POINT

Examples

The following examples show how to use ST_PointFromGeoHash.

Returns the geography point of a high-level GeoHash and uses ST_AsText to convert that point into Well-Known Text:

```sql
=> SELECT ST_AsText(ST_PointFromGeoHash('dr'));
ST_AsText
------------------------
POINT (-73.125 42.1875)  
(1 row)
```

Returns the geography point of a detailed GeoHash and uses ST_AsText to convert that point into Well-Known Text:

```sql
=> SELECT ST_AsText(ST_PointFromGeoHash('1234567890bcdefhjkmn'));
ST_AsText
------------------------
POINT (-122.196077187 -88.2297377551)  
(1 row)
```

ST_PointN

Finds the \( n \)th point of a spatial object. If you pass a negative number, zero, or a number larger than the total number of points on the linestring, ST_PointN returns NULL.

The vertex order is based on the Well-Known Text (WKT) representation of the spatial object.

Behavior Type

Immutable
**Syntax**

ST_PoinN( g, n )

**Arguments**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>g</td>
<td>Spatial object to search, type GEOMETRY or GEOGRAPHY</td>
</tr>
<tr>
<td>n</td>
<td>Point in the spatial object to be returned. The index is one-based, type INTEGER</td>
</tr>
</tbody>
</table>

**Returns**

GEOMETRY or GEOGRAPHY

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to use ST_PoinN.

Returns the fifth point:

```sql
=> SELECT ST_AsText(ST_PointN(ST_GeomFromText('POLYGON(( 2 6, 2 9, 6 9, 7 7, 4 6, 2 6))'), 5));

ST_AsText
----------
POINT (4 6)
(1 row)
```

Returns the second point:

```sql
=> SELECT ST_AsText(ST_PointN(ST_GeographyFromText('LINESTRING(23.41 24.93,34.2 32.98,40.7 41.19)'), 2));

ST_AsText
----------
POINT (34.2 32.98)
(1 row)
```

**ST_Relate**

Determines if a given GEOMETRY object is spatially related to another GEOMETRY object, based on the specified DE-9IM pattern matrix string.

The DE-9IM standard identifies how two objects are spatially related to each other.

**Behavior Type**

*Immutable*

**Syntax**

`ST_Relate( g1, g2, matrix )`

**Arguments**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>g1</code></td>
<td>Spatial object, type GEOMETRY</td>
</tr>
<tr>
<td><code>g2</code></td>
<td>Spatial object, type GEOMETRY</td>
</tr>
<tr>
<td><code>matrix</code></td>
<td>DE-9IM pattern matrix string, type CHAR(9). This string represents a 3 x 3 matrix of restrictions on the dimensions of the respective intersections of the interior, boundary, and exterior of the two geometries. Must contain exactly 9 of the following characters:</td>
</tr>
</tbody>
</table>
Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Relate.

The DE-9IM pattern for "equals" is 'T**F**F2':

```sql
=> SELECT ST_Relate(ST_GeomFromText('LINESTRING(0 1, 2)'),
                   ST_GeomFromText('LINESTRING(2, 0 1)'), 'T**F**F2');

<table>
<thead>
<tr>
<th>t</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>

(1 row)

The DE-9IM pattern for "overlaps" is 'T*T***T**':

```sql
```
=> SELECT ST_Relate(ST_GeomFromText('POLYGON((-1 -1,0 1,2,-1 -1))'),
    ST_GeomFromText('POLYGON((0 1,1 -1,1 0 1))'), 'T*T***T**');

(1 row)

**ST_SRID**

Identifies the spatial reference system identifier (SRID) stored with a spatial object.

The SRID of a GEOMETRY object can only be determined when passing an SRID to either \(\text{ST}_\text{GeomFromText} \) or \(\text{ST}_\text{GeomFromWKB} \). \(\text{ST}_\text{SRID} \) returns this stored value. SRID values of 0 to \(2^{32}-1 \) are valid.

**Behavior Type**

**Immutable**

**Syntax**

\[
\text{ST}_{\text{SRID}}( \text{g} )
\]

**Arguments**

<table>
<thead>
<tr>
<th>g</th>
<th>Spatial object for which you want the SRID, type GEOMETRY or GEOGRAPHY</th>
</tr>
</thead>
</table>

**Returns**

\(\text{INTEGER}\)

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
</table>
### Examples

The following examples show how to use ST_SRID.

The default SRID of a GEOMETRY object is 0:

```sql
=> SELECT ST_SRID(ST_GeomFromText('POLYGON((-1 -1, 2, 0 1, -1 -1))'));

ST_SRID
--------
 0
(1 row)
```

The default SRID of a GEOGRAPHY object is 4326:

```sql
=> SELECT ST_SRID(ST_GeographyFromText('POLYGON((22 35, 24 35, 26 32, 22 35))'));

ST_SRID
--------
4326
(1 row)
```

### ST_SymDifference

Calculates all the points in two GEOMETRY objects except for the points they have in common, but including the boundaries of both objects.

This result is called the symmetric difference and is represented mathematically as: Closure \((g1 - g2) \cup \text{Closure} (g2 - g1)\)
Behavior Type

Immutable

Syntax

ST_SymDifference( $g1$, $g2$ )

Arguments

<table>
<thead>
<tr>
<th>$g1$</th>
<th>Spatial object, type GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g2$</td>
<td>Spatial object, type GEOMETRY</td>
</tr>
</tbody>
</table>

Returns

GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Examples

The following examples show how to use ST_SymDifference.

Returns the two linestrings:

```sql
=> SELECT ST_AsText(ST_SymDifference(ST_GeomFromText('LINESTRING(30 40, 30 55)'), ST_GeomFromText('LINESTRING(30 32.5,30 47.5)')))
   ST_AsText
-------------------
MULTILINESTRING ((30 47.5, 30 55),(30 32.5,30 40))
(1 row)
```

Returns four squares:

```sql
=> SELECT ST_AsText(ST_SymDifference(ST_GeomFromText('POLYGON((2 1,2 4,3 4, 3 1,2 1))'), ST_GeomFromText('POLYGON((1 2,1 3,4 3,4 2,1 2))')));
```
ST_Touches

Determines if two GEOMETRY objects touch at a single point or along a boundary, but do not have interiors that intersect.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior Type

Immutable

Syntax

```
ST_Touches( g1, g2 )
[USING PARAMETERS spheroid={true | false} ]
```

Arguments

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>g1</td>
<td>Spatial object, value of type GEOMETRY</td>
</tr>
<tr>
<td>g2</td>
<td>Spatial object, value of type GEOMETRY</td>
</tr>
</tbody>
</table>

Parameters

| spheroid = {true | false} | (Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. |
|---------------------------|------------------------------------------------------------------|
|                           | **Default:** False                                                 |
Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Compatible GEOGRAPHY pairs:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point-Point</td>
<td>No</td>
</tr>
<tr>
<td>Linestring-Point</td>
<td>No</td>
</tr>
<tr>
<td>Polygon-Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon-Point</td>
<td>No</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Touches.

Two polygons touch at a single point:

```sql
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
                      ST_GeomFromText('POLYGON((1 3,0 3,1 2,1 3))'));
```
Two polygons touch only along part of the boundary:

```sql
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
                  ST_GeomFromText('POLYGON((1 2,0 3,0 1,1 2))'));
ST_Touches
-----------
t
(1 row)
```

Two polygons do not touch at any point:

```sql
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
                  ST_GeomFromText('POLYGON((0 2,-1 3,-2 0,0 2))'));
ST_Touches
-----------
f
(1 row)
```

**ST_Transform**

Returns a new GEOMETRY with its coordinates converted to the spatial reference system identifier (SRID) used by the `sr_id` argument.

This function supports the following transformations:

- EPSG 4326 (WGS84) to EPSG 3857 (Web Mercator)
- EPSG 3857 (Web Mercator) to EPSG 4326 (WGS84)

For EPSG 4326 (WGS84), unless the coordinates fall within the following ranges, conversion results in failure:

- Longitude limits: -572 to +572
- Latitude limits: -89.9999999 to +89.9999999

**Behavior Type**

*Immutable*
Syntax

```
ST_Transform( g1, srid )
```

**Arguments**

<table>
<thead>
<tr>
<th>arg</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>g1</td>
<td>Spatial object of type GEOMETRY.</td>
</tr>
<tr>
<td>srid</td>
<td>Spatial reference system identifier (SRID) to which you want to convert your spatial object, of type INTEGER.</td>
</tr>
</tbody>
</table>

**Returns**

GEOMETRY

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Examples**

The following example shows how you can transform data from Web Mercator (3857) to WGS84 (4326):
The following example shows how you can transform linestring data in a table from WGS84 (4326) to Web Mercator (3857):

```sql
SELECT ST_AsText(ST_Transform(STV_GeometryPoint(7910240.56433, 5215074.23966, 3857), 4326));
```

```
POINT (71.0589 42.3601)
```

The following example shows how you can transform point data in a table from WGS84 (4326) to Web Mercator (3857):

```sql
SELECT ST_AsText(ST_Transform(STV_GeometryPoint(x, y, srid), 3857)) FROM transform_example;
```

```
POINT (4715504.76195 11422441.5961)
POINT (13627665.2712 4547675.35434)
POINT (10528441.5919 4735962.8206)
```

**ST_Union**

Calculates the union of all points in two spatial objects.

This result is represented mathematically by: $g1 \cup g2$
Behavior Type

Immutable

Syntax

```
ST_Union( g1, g2 )
```

Arguments

<table>
<thead>
<tr>
<th>g1</th>
<th>Spatial object, type GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>g2</td>
<td>Spatial object, type GEOMETRY</td>
</tr>
</tbody>
</table>

Returns

GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Example

The following example shows how to use ST_Union.

Returns a polygon that represents all the points contained in these two polygons:

```
=> SELECT ST_AsText(ST_Union(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,-1 1,0 2)'),
   ST_GeomFromText('POLYGON((-1 2, 0 0, -2 0, -1 2)'))));
```

```
POLYGON ((0 2, 1 1, 0 -1, -0.5 0, -2 0, -1 2, -0.666666666667 1.33333333333, 0 2))
```

(1 row)

ST_Within

If spatial object g1 is completely inside of spatial object g2, then ST_Within returns true. Both parameters must be the same spatial data type. Either specify two GEOMETRY objects or two GEOGRAPHY objects.

If an object such as a point or linestring only exists along a polygon's boundary, then ST_Within returns false. The interior of a linestring is all the points along the linestring except the start and end points.

ST_Within(g1,g2) is functionally equivalent to ST_Contains(g2,g1).

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.
Behavior Type

Immutable

Syntax

\[
\text{ST\_Within}(\ g1, \ g2) \quad \text{[USING PARAMETERS spheroid={true | false} ]}
\]

Arguments

<table>
<thead>
<tr>
<th>$g1$</th>
<th>Spatial object, type GEOMETRY or GEOGRAPHY</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g2$</td>
<td>Spatial object, type GEOMETRY or GEOGRAPHY</td>
</tr>
</tbody>
</table>

Parameters

| spheroid = {true | false} | (Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. |
|---------------------------|---------------------------------------------------------------------|
|                           | Default: False                                                      |

Returns

BOOLEAN

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>
### Examples

The following examples show how to use `ST_Within`.

The first polygon is completely contained within the second polygon:

```sql
=> SELECT ST_Within(ST_GeomFromText('POLYGON((0 2,1 0 -1 0 2))'),
          ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))'));
ST_Within
----------
t
(1 row)
```

The point is on a vertex of the polygon, but not in its interior:

```sql
=> SELECT ST_Within (ST_GeographyFromText('POINT(30 25)'),
          ST_GeographyFromText('POLYGON((25 25,35,32.2 35,30 25,25 25))'));
ST_Within
----------
f
(1 row)
```

Two polygons are spatially equivalent:

```sql
=> SELECT ST_Within (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),
          ST_GeomFromText('POLYGON((0 3, -1 2, 0 1, 0 3))'));
ST_Within
----------
t
(1 row)
```
See Also

- ST_Contains
- ST_Overlaps

ST_X

Determines the x-coordinate for a GEOMETRY point or the longitude value for a GEOGRAPHY point.

Behavior Type

Immutable

Syntax

ST_X( g )

Arguments

| g     | Point of type GEOMETRY or GEOGRAPHY |

Returns

FLOAT

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
</table>
### Examples

The following examples show how to use ST_X.

**Returns the x-coordinate:**

```sql
=> SELECT ST_X(ST_GeomFromText('POINT(3.4 1.25)'));
   ST_X
  ------
   3.4
(1 row)
```

**Returns the longitude value:**

```sql
=> SELECT ST_X(ST_GeographyFromText('POINT(25.34 45.67)'));
   ST_X
  ------
   25.34
(1 row)
```

### ST_XMax

Returns the maximum x-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes maximum coordinates by calculating the maximum longitude of the great circle arc from (MAX(longitude), ST_YMin(GEOGRAPHY)) to (MAX(longitude), ST_YMax(GEOGRAPHY)). In this case, MAX(longitude) is the maximum longitude value of the geography object.
If either latitude or longitude is out of range, ST_XMax returns the maximum plain value of the geography object.

**Behavior Type**

*Immutable*

**Syntax**

```sql
ST_XMax( g )
```

**Arguments**

<table>
<thead>
<tr>
<th>g</th>
<th>Spatial object for which you want to find the maximum x-coordinate, type GEOMETRY or GEOGRAPHY.</th>
</tr>
</thead>
</table>

**Returns**

*FLOAT*

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>
Examples

The following examples show how to use ST_XMax.

Returns the maximum x-coordinate within a rectangle:

```sql
=> SELECT ST_XMax(ST_GeomFromText('POLYGON((0 1,0 2,1 2,1 0 1))'));
ST_XMax
--------
1
(1 row)
```

Returns the maximum longitude value within a rectangle:

```sql
=> SELECT ST_XMax(ST_GeographyFromText('POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))'));
ST_XMax
--------
-71
(1 row)
```

**ST_XMin**

Returns the minimum x-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes minimum coordinates by calculating the minimum longitude of the great circle arc from (MIN(longitude), ST_YMin(GEOGRAPHY)) to (MIN(longitude), ST_YMax(GEOGRAPHY)). In this case, MIN(latitude) represents the minimum longitude value of the geography object.

If either latitude or longitude is out of range, ST_XMin returns the minimum plain value of the geography object.

**Behavior Type**

*Immutable*

**Syntax**

```
ST_XMin( g )
```
Arguments

| g     | Spatial object for which you want to find the minimum x-coordinate, type GEOMETRY or GEOGRAPHY. |

Returns

FLOAT

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_XMin.

Returns the minimum x-coordinate within a rectangle:

```sql
=> SELECT ST_XMin(ST_GeomFromText('POLYGON((0 0 2, 1 2, 1 0, 0 0 1)))');
ST_XMin
---------
0
(1 row)
```

Returns the minimum longitude value within a rectangle:
=> SELECT ST_XMin(ST_GeographyFromText('POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))'));
ST_XMin
----------
-71.5
(1 row)

ST_YMax

Returns the maximum y-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes maximum coordinates by calculating the maximum latitude of the great circle arc from (ST_XMin(GEOGRAPHY), MAX(latitude)) to (ST_XMax(GEOGRAPHY), MAX(latitude)). In this case, MAX(latitude) is the maximum latitude value of the geography object.

If either latitude or longitude is out of range, ST_YMax returns the maximum plain value of the geography object.

**Behavior Type**

**Immutable**

**Syntax**

ST_YMax( g )

**Arguments**

| g | Spatial object for which you want to find the maximum y-coordinate, type GEOMETRY or GEOGRAPHY. |

**Returns**

FLOAT
**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to use ST_YMax.

**Returns the maximum y-coordinate within a rectangle:**

```
=> SELECT ST_YMax(ST_GeomFromText('POLYGON((0 1,0 4,1 1,0 1))'));
ST_YMax
--------
 4
(1 row)
```

**Returns the maximum latitude value within a rectangle:**

```
=> SELECT ST_YMax(ST_GeographyFromText('POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))'));
ST_YMax
----------
 42.3802715689979
(1 row)
```

**ST_YMin**

Returns the minimum y-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.
For GEOGRAPHY types, Vertica Place computes minimum coordinates by calculating the minimum latitude of the great circle arc from \((ST_\text{XMin}(\text{GEOGRAPHY}), \text{MIN(latitude)})\) to \((ST_\text{XMax}(\text{GEOGRAPHY}), \text{MIN(latitude)})\). In this case, \(\text{MIN(latitude)}\) represents the minimum latitude value of the geography object.

If either latitude or longitude is out of range, \(\text{ST_YMin}\) returns the minimum plain value of the geography object.

**Behavior Type**

*Immutable*

**Syntax**

\[ \text{ST_YMin}(\ g\ ) \]

**Arguments**

- \(g\) Spatial object for which you want to find the minimum \(y\)-coordinate, type GEOMETRY or GEOGRAPHY.

**Returns**

FLOAT

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Multipolygon | Yes | Yes
---|---|---
GeometryCollection | Yes | No

## Examples

The following examples show how to use ST_YMin.

Returns the minimum \( y \)-coordinate within a rectangle:

```sql
=> SELECT ST_YMin(ST_GeomFromText('POLYGON((0 1,0 4,1 4,1 1,0 1))'));
ST_YMin
---------
1
(1 row)
```

Returns the minimum latitude value within a rectangle:

```sql
=> SELECT ST_YMin(ST_GeometryFromText('POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))'));
ST_YMin
---------
42.35
(1 row)
```

### ST_Y

Determines the \( y \)-coordinate for a GEOMETRY point or the latitude value for a GEOGRAPHY point.

## Behavior Type

**Immutable**

## Syntax

\[ \text{ST}_Y( \ g \ ) \]

## Arguments

| \( g \) | Point of type GEOMETRY or GEOGRAPHY |
Returns

FLOAT

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Examples

The following examples show how to use ST_Y.

Returns the y-coordinate:

```sql
=> SELECT ST_Y(ST_GeomFromText('POINT(3 5.25)'));
  ST_Y
  -------
  5.25
(1 row)
```

Returns the latitude value:

```sql
=> SELECT ST_Y(ST_GeographyFromText('POINT(35.44 51.04)'));
  ST_Y
  -------
  51.04
(1 row)
```
**STV_AsGeoJSON**

Returns the geometry or geography argument as a Geometry Javascript Object Notation (GeoJSON) object.

**Behavior Type**

**Immutable**

**Syntax**

```sql
STV_AsGeoJSON( g, [USING PARAMETERS maxdecimals=[dec_value]])
```

**Arguments**

<table>
<thead>
<tr>
<th>g</th>
<th>Spatial object of type GEOMETRY or GEOGRAPHY</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxdecimals = dec_value</td>
<td>(Optional) Integer value. Determines the maximum number of digits to output after the decimal of floating point coordinates. Valid values: Between 0 and 15. Default value: 6</td>
</tr>
</tbody>
</table>

**Returns**

LONG VARCHAR

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Examples

The following examples show how you can use STV_AsGeoJSON.

Convert a geometry polygon to GeoJSON:

```sql
=> SELECT STV_AsGeoJSON(ST_GeomFromText('POLYGON((3 2, 4 3, 5 1, 3 2), (3.5 2, 4 2.5, 4.5 1.5, 3.5 2))'));

STV_AsGeoJSON
-------------------------------------------
{"type":"Polygon","coordinates":
[[[3,2],[4,3],[5,1],[3,2]],
[[3.5,2],[4,2.5],[4.5,1.5],[3.5,2]]]
(1 row)
```

Convert a geography point to GeoJSON:

```sql
=> SELECT STV_AsGeoJSON(ST_GeographyFromText('POINT(42.36011 71.05899)') USING PARAMETERS maxdecimals=4);

STV_AsGeoJSON
-------------------------------------------
{"type":"Point","coordinates":[42.3601,71.059]}
(1 row)
```

STV_Create_Index

Creates a spatial index on a set of polygons to speed up spatial intersection with a set of points.

A spatial index is created from an input polygon set, which can be the result of a query. Spatial indexes are created in a global name space. Vertica uses a distributed plan whenever the input table or projection is segmented across nodes of the cluster.

The OVER() clause must be empty.

Important:
You cannot access spatial indexes on newly added nodes without
rebalancing your cluster. For more information, see REBALANCE_CLUSTER.

### Behavior Type

**Immutable**

**Note:**
Indexes are not connected to any specific table. Subsequent DML commands on the underlying table or tables of the input data source do not modify the index.

### Syntax

```
STV_Create_Index ( gid, g
   USING PARAMETERS index='index_name'
   [, overwrite={ true | false } ]
   [, max_mem_mb=maxmem_value]
   [, skip_nonindexable_polygons={true | false} ]
)
```

### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>gid</code></td>
<td>Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.</td>
</tr>
<tr>
<td><code>g</code></td>
<td>Name of a geometry or geography (WGS84) column or expression that contains polygons and multipolygons. Only polygon and multipolygon can be indexed. Other shape types are excluded from the index.</td>
</tr>
</tbody>
</table>

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>index='index_name'</code></td>
<td>Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.</td>
</tr>
<tr>
<td>`overwrite=[ true</td>
<td>false ]`</td>
</tr>
</tbody>
</table>
max_mem_mb = maxmem_value

A positive integer that assigns a limit to the amount of memory in megabytes that STV_Create_Index can allocate during index construction. On a multi-node database this is the memory limit per node. The default value is 256. Do not assign a value higher than the amount of memory in the GENERAL resource pool. For more information about this pool, see Querying Resource Pool Data.

Setting a value for max_mem_mb that is at or near the maximum memory available on the node can negatively affect your system's performance. For example, it could cause other queries to time out waiting for memory resources during index construction.

skip_nonindexable_polygons = [ true | false ]

(Optional) BOOLEAN

In rare cases, intricate polygons (for instance, with too high resolution or anomalous spikes) cannot be indexed. These polygons are considered non-indexable. When set to False, non-indexable polygons cause the index creation to fail. When set to True, index creation can succeed by excluding non-indexable polygons from the index.

To review the polygons that were not able to be indexed, use STV_Describe_Index with the parameter list_polygon.

Default: False

---

**Returns**

<table>
<thead>
<tr>
<th>polygons</th>
<th>Number of polygons indexed.</th>
</tr>
</thead>
</table>
**SRID**

| Spatial reference system identifier. |

**min_x, min_y, max_x, max_y**

Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. \((min_x, min_y)\) are the south-west coordinates, and \((max_x, max_y)\) are the north-east coordinates.

**info**

Lists the number of excluded spatial objects as well as their type that were excluded from the index.

---

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multipoint</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

---

**Privileges**

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

---

**Recommendations**

- Segment large polygon tables across multiple nodes. Table segmentation causes index creation to run in parallel, leveraging the Massively Parallel Processing (MPP) architecture in Vertica. This significantly reduces execution time on large tables.
Vertica recommends that you segment the table from which you are building the index when the total number of polygons is large.

- **STV_Create_Index** can consume large amounts of processing time and memory.

Vertica recommends that when indexing new data for the first time, you monitor memory usage to be sure it stays within safe limits. Memory usage depends on number of polygons, number of vertices, and the amount of overlap among polygons.

- **STV_Create_Index** tries to allocate memory before it starts creating the index. If it cannot allocate enough memory, the function fails. If not enough memory is available, try the following:
  
  - Create the index at a time of less load on the system.
  - Avoid concurrent index creation.
  - Try segmenting the input table across the nodes of the cluster.

- Ensure that all of the polygons you plan to index are valid polygons. **STV_Create_Index** and **STV_Refresh_Index** do not check polygon validity when building an index.

For more information, see [Ensuring Polygon Validity Before Creating or Refreshing an Index](https://docs.vertica.com/9.3-x/Vertica_Suite/Vertica_Documentation/SQL_Reference_Manual.html#Ensuring-Polygon-Validity-Before-Creating-or-Refreshing-an-Index).

## Limitations

- Any indexes created prior to 9.3.x need to re-created.
- Index creation fails if there are WGS84 polygons with vertices on the International Date Line (IDL) or the North and South Poles.

- The backslash or tab characters are not allowed in index names.
- Indexes cannot have names greater than 110 characters.
- The following geometries are excluded from the index:
  - Non-polygons
  - Geometries with NULL identifiers
  - NULL (multi) polygon
  - EMPTY (multi) polygon
  - Invalid (multi) polygon

- The following geographies are excluded from the index:
  - Polygons with holes
  - Polygons crossing the International Date Line
  - Polygons covering the north or south pole
  - Antipodal polygons
Usage Tips

- To cancel an STV_Create_Index run, use Ctrl + C.
- If there are no valid polygons in the geom column, STV_Create_Index reports an error in vertica.log and stops index creation.
- If index creation uses a large amount of memory, consider segmenting your data to utilize parallel index creation.

Examples

The following examples show how to use STV_Create_Index. Create an index with a single literal argument:

```
=> SELECT STV_Create_Index((1 0 15.2 3.9 15.2 3.9 0 0))
  USING PARAMETERS index='my_polygon' OVER();
```

```
+---------------------+-----+----+----+----+----+
| polygons | SRID | min_x | min_y | max_x | max_y | info |
|----------+------+--------+--------+--------+--------+------|
|         1 | 0    | 0      | 0      | 3.9    | 15.2   |      |
+---------------------+-----+----+----+----+----+
(1 row)
```

Create an index from a table:

```
=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|POLYGON((10 20,15 60,20 45,46 15,10 20))
>> 4|POLYGON((5 20,9 30,20 45,36 35,5 20))
>> 5|POLYGON((12 23,9 30,20 45,36 35,37 67,45 80,50 20,12 23))
>> 
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
  max_mem_mb=256) OVER() FROM pols;
```

```
+---------------------+-----+----+----+----+----+
| polygons | SRID | min_x | min_y | max_x | max_y | info |
|----------+------+--------+--------+--------+--------+------|
|         5 | 0    | -38    | 13     | 50    | 80    |      |
+---------------------+-----+----+----+----+----+
(1 row)
```

Create an index in parallel from a partitioned table:

```
=> CREATE TABLE pols (p INT, gid INT, geom GEOMETRY(1000)) SEGMENTED BY HASH(p) ALL NODES;
CREATE TABLE
=> COPY pols (p, gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
```
\[
\text{POLYGON((-31 74,8 70,8 50,-36 53,-31 74))}
\]
\[
\text{POLYGON((-38 50,4 13,11 45,0 65,-38 50))}
\]
\[
\text{POLYGON((-12 42,-12 42,27 48,14 26,-12 42))}
\]

\[
\Rightarrow \text{SELECT STV\_Create\_Index(gid, geom USING PARAMETERS index='my\_polygons', overwrite=true, max\_mem\_mb=256) OVER() FROM pols;}
\]

```
+------------+---+-----+-----+-----+-----+-----+
| polygons   | SRID | min_x | min_y | max_x | max_y | info |
|------------+------+-------+-------+-------+-------+-----+
| 3          | 0    | -38   | 13    | 27    | 74    |      |
(1 row)
```

**STV\_Describe\_Index**

Retrieves information about an index that contains a set of polygons. If you do not pass any parameters, STV\_Describe\_Index returns all of the defined indexes.

The OVER() clause must be empty.

**Behavior Type**

**Immutable**

**Syntax**

```
STV\_Describe\_Index ( [ USING PARAMETERS [index='index\_name']
                      [, list\_polygons=\{true | false \} ] ] ) OVER ()
```

**Arguments**

```
index = 'index\_name' Name of the index, type VARCHAR. Index names cannot exceed 110
```
characters. The slash, backslash, and tab characters are not allowed in index names.

| list_polygon | (Optional) BOOLEAN that specifies whether to list the polygons in the index. The index argument must be used with this argument. |

## Returns

<table>
<thead>
<tr>
<th>polygons</th>
<th>Number of polygons indexed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRID</td>
<td>Spatial reference system identifier.</td>
</tr>
<tr>
<td>min_x, min_y, max_x, max_y</td>
<td>Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. (min_x, min_y) are the south-west coordinates, and (max_x, max_y) are the north-east coordinates.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the spatial index(es).</td>
</tr>
<tr>
<td>gid</td>
<td>Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.</td>
</tr>
<tr>
<td>state</td>
<td>The spatial object's state in the index. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>• INDEXED - The spatial object was successfully indexed.</td>
</tr>
<tr>
<td></td>
<td>• SELF_INTERSECT - (WGS84 Only) The spatial object was not indexed because one of its edges intersects with another of its edges.</td>
</tr>
<tr>
<td></td>
<td>• EDGE_CROSS_IDL - (WGS84 Only) The spatial object was not indexed because one of its edges crosses the International Date Line.</td>
</tr>
<tr>
<td></td>
<td>• EDGE_HALF_CIRCLE - (WGS84 Only) The spatial object was not indexed because it contains two adjacent vertices that are antipodal.</td>
</tr>
<tr>
<td></td>
<td>• NON_INDEXABLE - The spatial object was not able to be indexed.</td>
</tr>
<tr>
<td>geography</td>
<td>The Well-Known Binary (WKB) representation of the spatial object.</td>
</tr>
<tr>
<td>geometry</td>
<td>The Well-Known Binary (WKB) representation of the spatial object.</td>
</tr>
</tbody>
</table>
Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

Some functionality will require the index to be rebuilt if the index was created with 9.3.x or earlier.

Examples

The following examples show how to use STV_Describe_Index.

Retrieve information about the index:

```sql
=> SELECT STV_Describe_Index (USING PARAMETERS index='my_polygons') OVER ();
  type  | polygons | SRID | min_x | min_y | max_x | max_y
------------------------------------------------------------------------
 GEOMETRY | 4 | 0 | -1 | -1 | 12 | 12
(1 row)
```

Return the names of all the defined indexes:

```sql
=> SELECT STV_Describe_Index() OVER ();
  name
----------------------
 MA_counties_index
 my_polygons
 NY_counties_index
 US_States_Index
(4 rows)
```

Return the polygons included in an index:

```sql
=> SELECT STV_Describe_Index(USING PARAMETERS index='my_polygons', list_polygons=TRUE) OVER ();
  gid  |  state    | geometry
--------------------
 12   | INDEXED   | \260\000\000\000\000\000\000\ ... 
 14   | INDEXED   | \200\000\000\000\000\000\000\ ... 
 10   | NON_INDEXABLE | \274\000\000\000\000\000\000\ ... 
 11   | INDEXED   | \260\000\000\000\000\000\000\ ... 
(4 rows)
```
See Also

- STV_Intersect Scalar Function
- STV_Intersect Transform Function
- STV_Drop_Index
- STV_Rename_Index

STV_Drop_Index

Deletes a spatial index. If STV_Drop_Index cannot find the specified spatial index, it returns an error.

The OVER clause must be empty.

Behavior Type

Immutable

Syntax

STV_Drop_Index( USING PARAMETERS index = 'index_name' ) OVER ()

Arguments

| index = 'index_name' | Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names. |

Example

The following example shows how to use STV_Drop_Index.

Drop an index:
=> SELECT STV_Drop_Index(USING PARAMETERS index = 'my_polygons') OVER ();
     drop_index
              --------
     Index dropped
 (1 row)

- STV_Describe_Index
- STV_Rename_Index
- STV_Intersect Scalar Function
- STV_Intersect Transform Function

STV_DWithin

Determines if the shortest distance from the boundary of one spatial object to the boundary of another object is within a specified distance.

Parameters $g1$ and $g2$ must be both GEOMETRY objects or both GEOGRAPHY objects.

Behavior Type

Immutable

Syntax

\[
\text{STV_DWithin}(g1, g2, d)
\]

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g1$</td>
<td>Spatial object of type GEOMETRY or GEOGRAPHY</td>
</tr>
<tr>
<td>$g2$</td>
<td>Spatial object of type GEOMETRY or GEOGRAPHY</td>
</tr>
<tr>
<td>$d$</td>
<td>Value of type FLOAT indicating a distance. For GEOMETRY objects, the distance is measured in Cartesian coordinate units. For GEOGRAPHY objects, the distance is measured in the same units as the geographic coordinates.</td>
</tr>
</tbody>
</table>
measured in meters.

**Returns**

BOOLEAN

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Compatible GEOGRAPHY pairs:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point-Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Point-Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Point-Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Point-Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Point-Multipolygon</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to use STV_DWithin.

Two geometries are one Cartesian coordinate unit from each other at their closest points:
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1 2 0 1,-1 -1))'),
    ST_GeomFromText('POLYGON((4 3,2 3,4 5,4 3))'),1);
STV_DWithin
----------
t
(1 row)

If you reduce the distance to 0.99 units:

=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1 2 0 1,-1 -1))'),
    ST_GeomFromText('POLYGON((4 3,2 3,4 5,4 3))'),0.99);
STV_DWithin
----------
f
(1 row)

The first polygon touches the second polygon:

=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1 2 0 1,-1 -1))'),
    ST_GeomFromText('POLYGON((1 1,2 3,4 5,1 1))'),0.00001);
STV_DWithin
----------
t
(1 row)

The first polygon is not within 1000 meters from the second polygon:

=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((45.2 40,50.65 51.29,
    55.67 47.6,50 47.6,45.2 40))'),ST_GeomFromText('POLYGON((25 25,25 30,
    30 30,25 25,25 25))'),1000);
STV_DWithin
----------
t
(1 row)

**STV_Export2Shapefile**

Exports GEOGRAPHY or GEOMETRY data from a database table or a subquery to a shapefile. Writes the output to the directory specified using `STV_SetExportShapefileDirectory`.

**Behavior Type**

Immutable
## Syntax

```plaintext
STV_Export2Shapefile( columns
    USING PARAMETERS shapefile = 'name_of_shapefile'
    [, overwrite = { TRUE | FALSE }] 
    [, shape = '{ Point | Polygon | Linestring | Multipoint | Multipolygon | Multilinestring }' ] )

OVER()
```

## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>shapefile = 'name_of_shapefile'</code></td>
<td>Prefix of the component names of the shapefile, type VARCHAR. Must end with the file extension .shp. Limited to 128 octets in length. For example, city-data.shp. If you want to save the shapefile to a sub-directory you can do so by concatenating the sub-directory to <code>name_of_shapefile</code>. For example, visualizations/city-data.shp. You can also export a shapefile to a mounted S3 directory where you have read and write permissions. Use the syntax '&lt;bucketname&gt;/path/file name'.</td>
</tr>
<tr>
<td>`overwrite = { TRUE</td>
<td>FALSE }`</td>
</tr>
</tbody>
</table>
Arguments

| columns | The columns to export to the shapefile. A value of asterisk (*) is the equivalent to listing all columns of the FROM clause. |

Returns

Three files in the shapefile export directory with the extensions .shp, .shx, and .dbf.

Limitations

- If a multipolygon, multilinestring, or multipoint contains only one element, then it is written as a polygon, line, or point, respectively.
- Column names longer than 10 characters are truncated.
Empty POINTS cannot be exported.

All rows with NULL geometry or geography data are skipped.

Unsupported or invalid dates are replaced with NULLs.

Numeric values may lose precision when they are exported. This loss occurs because the target field in the .dbf file is a 64-bit FLOAT column, which can only represent about 15 significant digits.

Shapefiles cannot exceed 4GB in size. If your shapefile is too large, try splitting the data and exporting to multiple shapefiles.

Examples

The following example shows how you can use STV_Export2Shapefile to export all columns from the table geo_data to a shapefile named city-data.shp:

```sql
=> SELECT STV_Export2Shapefile(*
     USING PARAMETERS shapefile = 'visualizations/city-data.shp',
     overwrite = true, shape = 'Point')
OVER()
FROM geo_data
WHERE REVENUE > 25000;
```

<table>
<thead>
<tr>
<th>Rows Exported</th>
<th>File Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>6442892</td>
<td>v_geo-db_node0001: /home/geo/temp/visualizations/city-data.shp</td>
</tr>
</tbody>
</table>

STV_Extent

Returns a bounding box containing all of the input data.

Use STV_Extent inside of a nested query for best results. The OVER clause must be empty.

**Important:**

STV_Extent does not return a valid polygon when the input is a single point.

Behavior Type

Immutable
Syntax

STV_Extent( g )

Arguments

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>g</td>
<td>Spatial object, type GEOMETRY.</td>
</tr>
</tbody>
</table>

Returns

GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Examples

The following examples show how you can use STV_Extent.

Return the bounding box of a linestring, and verify that it is a valid polygon:

=> SELECT ST_AsText(geom) AS bounding_box, ST_IsValid(geom)
   FROM (SELECT STV_Extent(ST_GeomFromText('LineString(0 0, 1 1)')) OVER() AS geom AS g;
         bounding_box | ST_IsValid
Return the bounding box of spatial objects in a table:

```sql
=> CREATE TABLE misc_geo_shapes (id IDENTITY, geom GEOMETRY);
CREATE TABLE
=> COPY misc_geo_shapes (gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
=> POINT(-71.03 42.37)
=> LINESTRING(-71.058849 42.367501, -71.062240 42.371276, -71.067938 42.371246)
=> POLYGON((-71.066030 42.380617, -71.055827 42.376734, -71.060811 42.376011, -71.066030 42.380617))
=> \
=> SELECT ST_AsText(geom_col) AS bounding_box
    FROM (SELECT ST_V_Extent(geom) OVER() AS geom_col FROM misc_geo_shapes) AS g;

bouncing_box

POLYGON ((-71.067938 42.367501, -71.03 42.367501, -71.03 42.380617, -71.03 42.380617, -71.03 42.380617, -71.067938 42.367501))
(1 row)
```

**STV_ForceLHR**

Alters the order of the vertices of a spatial object to follow the left-hand-rule.

**Behavior Type**

*Immutable*

**Syntax**

```
STV_ForceLHR( g, [USING PARAMETERS skip_nonreorientable_polygons={true | false} ])
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>g</code></td>
<td>Spatial object, type GEOGRAPHY.</td>
</tr>
<tr>
<td><code>skip_nonreorientable_polygons</code> = { true</td>
<td>false }</td>
</tr>
<tr>
<td></td>
<td>When set to False, non-orientable polygons</td>
</tr>
</tbody>
</table>
generate an error. For example, if you use STV_ForceLHR or STV_Reverse with skip_nonorientable_polygons set to False, a geography polygon containing a hole generates an error. When set to True, the result returned is the polygon, as passed to the API, without alteration.

This argument can help you when you are creating an index from a table containing polygons that cannot be re-oriented.

Vertica Place considers these polygons non-orientable:

- Polygons with a hole
- Multipolygons
- Multipolygons with a hole

**Default value:** False

## Returns

**GEOGRAPHY**

### Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>No</td>

</table>
Examples

The following example shows how you can use STV_ForceLHR.

Re-orient a geography polygon to left-hand orientation:

```sql
=> SELECT ST_AsText(STV_ForceLHR(ST_GeographyFromText('Polygon((1 1, 3 1, 2 2, 1 1))')));

ST_AsText
POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

Reverse the orientation of a geography polygon by forcing left-hand orientation:

```sql
=> SELECT ST_AsText(STV_ForceLHR(ST_GeographyFromText('Polygon((1 1, 2 2, 3 1, 1 1))')));

ST_AsText
POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

See Also

STV_Reverse

STV_Geography

Casts a GEOMETRY object into a GEOGRAPHY object. The SRID value does not affect the results of Vertica Place queries.

When STV_Geography converts a GEOMETRY object to a GEOGRAPHY object, it sets its SRID to 4326.

Behavior Type

Immutable

Syntax

```
STV_Geography( geom )
```
# Arguments

| geom | Spatial object that you want to cast into a GEOGRAPHY object, type GEOMETRY |

# Returns

GEOGRAPHY

# Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
</tr>
</tbody>
</table>

# Example

The following example shows how to use STV_Geography.

To calculate the centroid of the GEOGRAPHY object, convert it to a GEOMETRY object, then convert it back to a GEOGRAPHY object:

```sql
=> CREATE TABLE geogs(g GEOGRAPHY);
CREATE TABLE
=> COPY geogs(gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimeter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
=> MULTIPOLY(-108.619726 45.000284,-107.866813 45.00107,-106.363711 44.994223,-70.847746 41.205814)
=> 
=> SELECT ST_AsText(STV_Geography(ST_Centroid(STV_Geometry(g)))) FROM geogs;
ST_AsText
```
STV_GeographyPoint

Returns a GEOGRAPHY point based on the input values.

This is the optimal way to convert raw coordinates to GEOGRAPHY points.

**Behavior Type**

*Immutable*

**Syntax**

\[
\text{STV\_GeographyPoint}(x, y)
\]

**Arguments**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>(x)</td>
<td>(x)-coordinate or longitude, FLOAT.</td>
</tr>
<tr>
<td>(y)</td>
<td>(y)-coordinate or latitude, FLOAT.</td>
</tr>
</tbody>
</table>

**Returns**

GEOGRAPHY

**Examples**

The following examples show how to use STV_GeographyPoint.

Return a GEOGRAPHY point:

```
=> SELECT ST_AsText(STV_GeographyPoint(-114.101588, 47.909677));
ST_AsText
---
POINT (-114.181588 47.909677)
```
Return GEOGRAPHY points using two columns:

```
=> CREATE TABLE geog_data (id IDENTITY, x FLOAT, y FLOAT);
CREATE TABLE
=> COPY geog_data FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> -114.181588|47.909677
>> -111.532377|46.430753
>> 
=> SELECT id, ST_AsText(STV_GeographyPoint(x, y)) FROM geog_data;
<table>
<thead>
<tr>
<th>id</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (-114.181588 47.909677)</td>
</tr>
<tr>
<td>2</td>
<td>POINT (-111.532377 46.430753)</td>
</tr>
</tbody>
</table>
(2 rows)
```

Create GEOGRAPHY points by manipulating data source columns during load:

```
=> CREATE TABLE geog_data_load (id IDENTITY, geog GEOGRAPHY);
CREATE TABLE
=> COPY geog_data_load (lon FILLER FLOAT,
                          lat FILLER FLOAT,
                          geog AS STV_GeographyPoint(lon, lat))
                           FROM 'test_coords.csv' DELIMITER ',';
Rows Loaded
--------
2
(1 row)
=> SELECT id, ST_AsText(geog) FROM geog_data_load;
<table>
<thead>
<tr>
<th>id</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (-75.101654451 43.363830536)</td>
</tr>
<tr>
<td>2</td>
<td>POINT (-75.106444487 43.367093798)</td>
</tr>
</tbody>
</table>
(2 rows)
```

STV_GeometryPoint

STV_Geometry

Casts a GEOGRAPHY object into a GEOMETRY object.

The SRID value does not affect the results of Vertica Place queries.
Behavior Type

Immutable

Syntax

STV_Geometry( geog )

Arguments

| geog       | Spatial object that you want to cast into a GEOMETRY object, type GEOGRAPHY |

Returns

GEOMETRY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>

<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Example

The following example shows how to use STV_Geometry.
Convert the GEOGRAPHY values to GEOMETRY values, then convert the result back to a GEOGRAPHY type:

```sql
=> CREATE TABLE geogs(g GEOGRAPHY);
CREATE TABLE
=> COPY geogs(gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> MULTIPOINT(-108.619726 45.000284, -107.866813 45.00107, -106.363711 44.994223, -70.847746 41.205814)
>> 
=> SELECT ST_AsText(STV_Geometry(ST_Centroid(STV_Geometry(g)))) FROM geogs;
ST_AsText
------------------------
POINT (-98.424499 44.05034775)
```

**STV_GeometryPoint**

Returns a GEOMETRY point, based on the input values.

This approach is the most-optimal way to convert raw coordinates to GEOMETRY points.

**Behavior Type**

Immutable

**Syntax**

```
STV_GeometryPoint( x, y [, srid] )
```

**Arguments**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>x-coordinate or longitude, FLOAT.</td>
</tr>
<tr>
<td>y</td>
<td>y-coordinate or latitude, FLOAT.</td>
</tr>
<tr>
<td>srid</td>
<td>(Optional) Spatial Reference Identifier (SRID) assigned to the point, INTEGER.</td>
</tr>
</tbody>
</table>

**Returns**

GEOMETRY
Examples

The following examples show how to use STV_GeometryPoint.

Return a GEOMETRY point with an SRID:

```sql
=> SELECT ST_AsText(STV_GeometryPoint(71.148562, 42.989374, 4326));
ST_AsText
-------------------
POINT (-71.148562 42.989374) (1 row)
```

Return GEOMETRY points using two columns:

```sql
=> CREATE TABLE geom_data (id INT PRIMARY KEY, x FLOAT, y FLOAT, SRID INT);
CREATE TABLE
=> COPY geom_data FROM stdin;
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
> 42.363883053600848|71.10165445099966|4326
> 42.36709379800085|71.10644448699964|4326
> .
=> SELECT id, ST_AsText(STV_GeometryPoint(x, y, SRID)) FROM geom_data;
```

Create GEOMETRY points by manipulating data source columns during load:

```sql
=> CREATE TABLE geom_data_load (id INT PRIMARY KEY, geom GEOMETRY);
CREATE TABLE
=> COPY geom_data_load (lon, lat) FROM 'test_coords.csv' DELIMITER ',';
```

See Also

STV_GeographyPoint
STV_GetExportShapefileDirectory

Returns the path of the export directory.

Behavior Type

Immutable

Syntax

STV_GetExportShapefileDirectory( )

Returns

The path of the shapefile export directory.

Examples

The following example shows how you can use STV_GetExportShapefileDirectory to query the path of the shapefile export directory:

```
=> SELECT STV_GetExportShapefileDirectory();
STV_GetExportShapefileDirectory
----------------------------------------
Shapefile export directory: [/home/user/temp]
(1 row)
```

STV_Intersect Scalar Function

Spatially intersects a point or points with a set of polygons. The STV_Intersect scalar function returns the identifier associated with an intersecting polygon.

Behavior Type

Immutable
**Syntax**

```
STV_Intersect( { g | x, y } 
                       USING PARAMETERS index= 'index_name')
```

**Arguments**

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>g</td>
<td>A geometry or geography (WGS84) column that contains points. The g column can contain only point geometries or geographies. If the column contains a different geometry or geography type, STV_Intersect terminates with an error.</td>
</tr>
<tr>
<td>x</td>
<td>x-coordinate or longitude, FLOAT.</td>
</tr>
<tr>
<td>y</td>
<td>y-coordinate or latitude, FLOAT.</td>
</tr>
</tbody>
</table>

**Parameters**

```
index = 'index_name' Name of the spatial index, of type VARCHAR.
```

**Returns**

The identifier of a matching polygon. If the point does not intersect any of the index's polygons, then the STV_Intersect scalar function returns NULL.

**Examples**

The following examples show how you can use STV_Intersect scalar.

Using two floats, return the gid of a matching polygon or NULL:

```sql
=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
=> 1|POLYGON((31 74,8 76,8 50,36 53,31 74))
=> 
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true, 
                           max_mem_mb=256) OVER() FROM pols;
    type | polygons | SRID | min_x | min_y | max_x | max_y | info
```
Using a GEOMETRY column, return the gid of a matching polygon or NULL:

```sql
=> CREATE TABLE polygons (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY polygons (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|POLYGON((-18 42,-10 65,27 48,14 26,-18 42))
>> 
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true,
    max_mem_mb=256) OVER() FROM polygons;
    type | polygons | SRID | min_x | min_y | max_x | max_y | info
-------------------------------------------------------------
GEOMETRY | 3 | 0 | -38 | 13 | 27 | 74 |
(1 row)
=> CREATE TABLE points (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY points (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
>> 100|POINT(-1 52)
>> 101|POINT(-20 0)
>> 102|POINT(-8 25)
>> 103|POINT(0 0)
>> 104|POINT(1 5)
>> 105|POINT(20 45)
>> 106|POINT(-20 5)
>> 107|POINT(-20 1)
>> 
=> SELECT gid AS pt_gid, STV_Intersect(geom USING PARAMETERS index='my_polygons') AS pol_gid
    FROM points ORDER BY pt_gid;
pt_gid | pol_gid
----------
100 | 1
101 | 1
102 | 2
103 | 9
104 | 3
105 | 3
106 | 107 | 9
(8 rows)
```

- STV_Intersect: Scalar Function vs. Transform Function
- STV_Intersect Transform Function
- STV_Create_Index

STV_Intersect Transform Function

Spatially intersects points and polygons. The STV_Intersect transform function returns a tuple with matching point/polygon pairs. For every point, Vertica returns either one or many matching polygons.

You can improve performance when you parallelize the computation of the STV_Intersect transform function over multiple nodes. To parallelize the computation, use an OVER (PARTITION BEST) clause.

Behavior Type

Immutable

Syntax

```
STV_Intersect ( { gid | i }, { g | x, y } 
    USING PARAMETERS index='index_name') 
OVER() AS (pt_gid, pol_gid)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gid</td>
<td>An integer column or integer that uniquely identifies the spatial object(s) of g or x and y.</td>
</tr>
<tr>
<td>g</td>
<td>A geometry or geography (WGS84) column that contains points. The g column can contain only point geometries or geographies. If the column contains a different geometry or geography type, STV_Intersect terminates with an error.</td>
</tr>
<tr>
<td>x</td>
<td>x-coordinate or longitude, FLOAT.</td>
</tr>
<tr>
<td>(y)</td>
<td>(y)-coordinate or latitude, FLOAT.</td>
</tr>
</tbody>
</table>

**Parameters**

\(index = \text{'index\_name'}\) | Name of the spatial index, of type VARCHAR.

**Returns**

| \(pt\_gid\) | Unique identifier of the point geometry or geography, of type INTEGER. |
| \(pol\_gid\) | Unique identifier of the polygon geometry or geography, of type INTEGER. |

**Examples**

The following examples show how you can use STV_\_Intersect transform.

Using two floats, return the matching point-polygon pairs.

```sql
=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
=> 1|POLYGON((31 74,8 70,8 50,36 53,31 74))
=> 
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my\_polygons\_1', overwrite=true, max_mem_mb=256) OVER() FROM pols;
   type | polygons | SRID | min\_x | min\_y | max\_x | max\_y | info
--------------------------------------------
GEOMETRY | 1 | 0 | 8 | 50 | 36 | 74 | (1 row)

=> SELECT STV_\_Intersect(56, 12.5683, 55.6761 USING PARAMETERS index = 'my\_polygons\_1') OVER();
   pt\_gid | pol\_gid
-----------------------
   56 | 1
(1 row)
```

Using a GEOMETRY column, return the matching point-polygon pairs.

```sql
=> CREATE TABLE polygons (gid int, geom GEOMETRY(700));
CREATE TABLE
=> COPY polygons (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin;
Enter data to be copied followed by a newline.
```
End with a backslash and a period on a line by itself.

```
>> 10|POLYGON((5 5, 5 10, 10 10, 10 5, 5 5))
>> 11|POLYGON((0 0, 0 2, 2 2, 2 0, 0 0))
>> 12|POLYGON((1 1, 1 3, 3 3, 3 1, 1 1))
>> 14|POLYGON((-1 -1, -1 12, 12 12, 12 -1, -1 -1))
>> \
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true, max_mem_mb=256)
    OVER() FROM polygons;
<table>
<thead>
<tr>
<th>type</th>
<th>polygons</th>
<th>SRID</th>
<th>min_x</th>
<th>min_y</th>
<th>max_x</th>
<th>max_y</th>
<th>info</th>
</tr>
</thead>
<tbody>
<tr>
<td>GEOMETRY</td>
<td>4</td>
<td>0</td>
<td>-1</td>
<td>-1</td>
<td>12</td>
<td>12</td>
<td></td>
</tr>
</tbody>
</table>
(1 row)
```

```
=> CREATE TABLE points (gid INT, geom GEOMETRY);
CREATE TABLE
=> COPY points (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> 1|POINT(9 9)
>> 2|POINT(0 1)
>> 3|POINT(2.5 2.5)
>> 4|POINT(0 0)
>> 5|POINT(1 5)
>> 6|POINT(1.5 1.5)
>> \
=> SELECT STV_Intersect(gid, geom USING PARAMETERS index='my_polygons') OVER (PARTITION BEST)
    AS (point_id, polygon_gid)
    FROM points;
```

```
<table>
<thead>
<tr>
<th>point_id</th>
<th>polygon_gid</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>14</td>
</tr>
<tr>
<td>1</td>
<td>14</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>4</td>
<td>14</td>
</tr>
<tr>
<td>4</td>
<td>11</td>
</tr>
<tr>
<td>6</td>
<td>12</td>
</tr>
<tr>
<td>6</td>
<td>14</td>
</tr>
<tr>
<td>6</td>
<td>11</td>
</tr>
<tr>
<td>2</td>
<td>14</td>
</tr>
<tr>
<td>2</td>
<td>11</td>
</tr>
<tr>
<td>3</td>
<td>12</td>
</tr>
<tr>
<td>3</td>
<td>14</td>
</tr>
</tbody>
</table>
(12 rows)
```

You can improve query performance by using the STV_Intersect transform function in a WHERE clause. Performance improves because this syntax eliminates all points that do not intersect polygons in the index.

Return the count of points that intersect with the polygon, where gid = 14:

```
=> SELECT COUNT(pt_id) FROM
  (SELECT STV_Intersect(gid, geom USING PARAMETERS index='my_polygons')
    OVER (PARTITION BEST) AS (pt_id, pol_id) FROM points)
  AS T WHERE pol_id = 14;
COUNT
-------
6
```
See Also

- Best Practices for Spatial Joins
- STV_Intersect: Scalar Function vs. Transform Function
- STV_Create_Index

STV_IsValidReason

Determines if a spatial object is well formed or valid. If the object is not valid, STV_IsValidReason returns a string that explains where the invalidity occurs.

A polygon or multipolygon is valid if all of the following are true:

- The polygon is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- The boundary does not touch or cross itself.
- Any polygons in the interior that do not have more than one point touching the boundary of the exterior polygon.

If you pass an invalid object to a Vertica Place function, the function fails or returns incorrect results. To determine if a polygon is valid, first run ST_IsValid. ST_IsValid returns TRUE if the polygon is valid, FALSE otherwise.

Important:

STV_IsValidReason supports only polygon and multipolygon GEOMETRY data types.

Behavior Type

Immutable

Syntax

STV_IsValidReason( g )
Arguments
g
Geospatial object to test for validity, value of type GEOMETRY or GEOGRAPHY (WGS84).

Returns
LONG VARCHAR

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Example

The following example shows how to use STV_IsValidReason.

Returns a string describing where the polygon is invalid:

```sql
=> SELECT STV_IsValidReason(ST_GeomFromText('POLYGON((1 3,3 2,1 1, 3 0,1 0,1 3)))');
   STV_IsValidReason
---------------------------------------------
  Ring Self-intersection at or near POINT (1 1)
(1 row)
```
See Also

ST_IsValid

STV_LineStringPoint

Retrieves the vertices of a linestring or multilinestring. The values returned are points of either GEOMETRY or GEOGRAPHY type depending on the input object’s type. GEOMETRY points inherit the SRID of the input object.

STV_LineStringPoint is an analytic function. For more information, see Analytic Functions.

Behavior Type

Immutable

Syntax

STV_LineStringPoint( g )
OVER([PARTITION NODES]) AS

Arguments

| g   | Linestring or multilinestring, value of type GEOMETRY or GEOGRAPHY |

Returns

GEOMETRY or GEOGRAPHY

Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
</table>
Examples

The following examples show how to use STV_LineStringPoint.

Returns the vertices of the geometry linestring and their SRID:

```sql
=> SELECT ST_AsText(Point), ST_SRID(Point)
FROM (SELECT STV_LineStringPoint(
       ST_GeomFromText('MULTILINESTRING((1 2, 2 3, 3 1, 4 2),
       (10 20, 20 30, 30 10, 40 20))', 4269)) OVER () AS Point) AS foo;
```

<table>
<thead>
<tr>
<th>ST_AsText</th>
<th>ST_SRID</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT (1 2)</td>
<td>4269</td>
</tr>
<tr>
<td>POINT (2 3)</td>
<td>4269</td>
</tr>
<tr>
<td>POINT (3 1)</td>
<td>4269</td>
</tr>
<tr>
<td>POINT (4 2)</td>
<td>4269</td>
</tr>
<tr>
<td>POINT (10 20)</td>
<td>4269</td>
</tr>
<tr>
<td>POINT (20 30)</td>
<td>4269</td>
</tr>
<tr>
<td>POINT (30 10)</td>
<td>4269</td>
</tr>
<tr>
<td>POINT (40 20)</td>
<td>4269</td>
</tr>
</tbody>
</table>

(8 rows)

Returns the vertices of the geography linestring:

```sql
=> SELECT ST_AsText(g)
FROM (SELECT STV_LineStringPoint(
       ST_GeographyFromText('MULTILINESTRING ((42.1 71.0, 41.4 70.0, 41.3 72.9),
       (42.99 71.46, 44.47 73.21))', 4269)) OVER () AS g) AS line_geom_points;
```

<table>
<thead>
<tr>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT (42.1 71.0)</td>
</tr>
<tr>
<td>POINT (41.4 70.0)</td>
</tr>
<tr>
<td>POINT (41.3 72.9)</td>
</tr>
<tr>
<td>POINT (42.99 71.46)</td>
</tr>
<tr>
<td>POINT (44.47 73.21)</td>
</tr>
</tbody>
</table>

(5 rows)
See Also

STV_PolygonPoint

STV_MemSize

Returns the length of the spatial object in bytes as an INTEGER.

Use this function to determine the optimal column width for your spatial data.

Behavior Type

Immutable

Syntax

STV_MemSize( g )

Arguments

| g  | Spatial object, value of type GEOMETRY or GEOGRAPHY |

Returns

INTEGER

Examples

The following example shows how you can optimize your table by sizing the GEOMETRY or GEOGRAPHY column to the maximum value returned by STV_MemSize:

```sql
=> CREATE TABLE mem_size_table (id int, geom geometry(800));
CREATE TABLE
=> COPY mem_size_table (id, gx filler LONG VARCHAR, geom as ST_GeomFromText(gx)) FROM STDIN DELIMITER '|
Enter data to be copied followed by a newline.
```
STV_NN

Calculates the distance of spatial objects from a reference object and returns (object, distance) pairs in ascending order by distance from the reference object.

Parameters $g1$ and $g2$ must be both GEOMETRY objects or both GEOGRAPHY objects.

STV_NN is an analytic function. For more information, see Analytic Functions.

Behavior Type

Immutable

Syntax

$$STV_{\text{NN}}(g, \text{ref}_{\text{obj}}, k) \text{ OVER() }$$

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$g$</td>
<td>Spatial object, value of type GEOMETRY or GEOGRAPHY</td>
</tr>
<tr>
<td>ref_obj</td>
<td>Reference object, type GEOMETRY or GEOGRAPHY</td>
</tr>
<tr>
<td>$k$</td>
<td>Number of rows to return, type INTEGER</td>
</tr>
</tbody>
</table>
**Returns**

(Object, distance) pairs, in ascending order by distance. If a parameter is EMPTY or NULL, then 0 rows are returned.

**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipoint</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Linestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

**Example**

The following example shows how to use STV_NN.

Create a table and insert nine GEOGRAPHY points:

```sql
=> CREATE TABLE points (g geography);
CREATE TABLE
=> COPY points (gx filler LONG VARCHAR, g AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
> POINT (21.5 18.4)
> POINT (21.5 19.2)
> POINT (21.5 20.7)
> POINT (22.5 16.4)
> POINT (22.5 17.15)
> POINT (22.5 18.33)
> POINT (23.5 13.68)
> POINT (23.5 15.9)
> POINT (23.5 18.4)
> 
```
Calculate the distances (in meters) of objects in table `points` from the GEOGRAPHY point (23.5, 20).

Returns the five objects that are closest to that point:

```sql
=> SELECT ST_AsText(nn), dist FROM (SELECT STV_PolygonPoint(g), ST_GeographyFromText('POINT(23.5 20)'), 5) OVER() AS (nn, dist) FROM points) AS example;
```

<table>
<thead>
<tr>
<th>ST_AsText</th>
<th>dist</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(23.5 18.4)</td>
<td>177912.12757541</td>
</tr>
<tr>
<td>POINT(22.5 18.33)</td>
<td>213339.210738322</td>
</tr>
<tr>
<td>POINT(21.5 20.7)</td>
<td>222561.43679943</td>
</tr>
<tr>
<td>POINT(21.5 19.2)</td>
<td>227604.371833335</td>
</tr>
<tr>
<td>POINT(21.5 18.4)</td>
<td>275239.416790128</td>
</tr>
</tbody>
</table>

(5 rows)

**STV_PolygonPoint**

Retrieves the vertices of a polygon as individual points. The values returned are points of either GEOMETRY or GEOGRAPHY type depending on the input object's type. GEOMETRY points inherit the SRID of the input object.

STV_PolygonPoint is an analytic function. For more information, see [Analytic Functions](https://www.vertica.com/docs/9.3.x/VRP/g8716079593.html).

**Behavior Type**

Immutable

**Syntax**

```sql
STV_PolygonPoint( g )
OVER( [PARTITION NODES] ) AS
```

**Arguments**

- `g` | Polygon, value of type GEOMETRY or GEOGRAPHY

**Returns**

GEOMETRY or GEOGRAPHY
**Supported Data Types**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multipoint</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Examples**

The following examples show how to use STV_PolygonPoint.

Returns the vertices of the geometry polygon:

```sql
=> SELECT ST_AsText(g) FROM (SELECT STV_PolygonPoint(ST_GeomFromText('POLYGON((1 2, 2 3, 3 1, 1 2))'))
    OVER (PARTITION NODES) AS g) AS poly_points;
ST_AsText
-------------
POINT (1 2)
POINT (2 3)
POINT (3 1)
POINT (1 2)
(4 rows)
```

Returns the vertices of the geography polygon:

```sql
=> SELECT ST_AsText(g) FROM (SELECT STV_PolygonPoint(ST_GeographyFromText('POLYGON((25.5 28.76, 28.83 29.13, 27.2 30.99, 25.5 28.76))'))
    OVER (PARTITION NODES) AS g) AS poly_points;
ST_AsText
-------------
POINT (25.5 28.76)
POINT (28.83 29.13)
POINT (27.2 30.99)
POINT (25.5 28.76)
```
See Also

STV_LineStringPoint

STV_Reverse

Reverses the order of the vertices of a spatial object.

Behavior Type

Immutable

Syntax

STV_Reverse( g, [USING PARAMETERS skip_nonreorientable_polygons={true | false} ])

Arguments

<table>
<thead>
<tr>
<th>g</th>
<th>Spatial object, type GEOGRAPHY.</th>
</tr>
</thead>
<tbody>
<tr>
<td>skip_nonreorientable_polygons = { true</td>
<td>false }</td>
</tr>
</tbody>
</table>

When set to False, non-orientable polygons generate an error. For example, if you use STV_ForceLHR or STV_Reverse with skip_nonorientable_polygons set to False, a geography polygon containing a hole generates an error. When set to True, the result returned is the polygon, as passed to the API, without alteration.

This argument can help you when you are creating an index from a table containing polygons that cannot be re-oriented.
Vertica Place considers these polygons non-orientable:

- Polygons with a hole
- Multipolygons
- Multipolygons with a hole

Default value: False

## Returns

GEOGRAPHY

## Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>GEOMETRY</th>
<th>GEOGRAPHY (Perfect Sphere)</th>
<th>GEOGRAPHY (WGS84)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multipoint</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Linestring</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Multilinestring</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Polygon</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Multipolygon</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GeometryCollection</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

## Examples

The following examples show how you can use STV_Reverse.

Reverse vertices of a geography polygon:

```sql
=> SELECT ST_AsText(STV_Reverse(ST_GeographyFromText('Polygon((1 1, 3 1, 2 2, 1 1))')));
ST_AsText
-----------------------------------
POLYGON (((1 1, 2 2, 3 1, 1 1))
```
Force the polygon to reverse orientation:

```sql
=> SELECT ST_AsText(ST_Reverse(ST_GeographyFromText('Polygon((1 1, 2 2, 3 1, 1 1))')));

POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

STV_ForceLHR

STV_Rename_Index

Renames a spatial index. If the index format is out of date, you cannot rename the index.

A spatial index is created from an input polygon set, which can be the result of a query. Spatial indexes are created in a global name space. Vertica uses a distributed plan whenever the input table or projection is segmented across nodes of the cluster.

The OVER() clause must be empty.

Behavior Type

Immutable

Syntax

```
STV_Rename_Index( USING PARAMETERS
    source = 'old_index_name',
    dest = 'new_index_name',
    overwrite = [ 'true' | 'false' ]
) OVER ()
```

Arguments

| source = 'old_index_name' | Current name of the spatial index, type VARCHAR. |
dest = 'new_index_name'  
New name of the spatial index, type VARCHAR.

overwrite = [ 'true' | 'false' ]  
(Optional) BOOLEAN value that specifies whether to overwrite the index, if an index exists. This parameter cannot be NULL.

Default: False

Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

- Index names cannot exceed 110 characters.
- The backslash or tab characters are not allowed in index names.

Example

The following example shows how to use STV_Rename_Index.

Rename an index:

```sql
=> SELECT STV_Rename_Index (  
    USING PARAMETERS  
    source = 'my_polygons',  
    dest = 'US_states',  
    overwrite = 'false'  
)  
OVER ();
rename_index
-------------------
Index renamed
(1 Row)
```

STV_Reload_Index

Appends newly added or updated polygons and removes deleted polygons from an existing spatial index.

The OVER() clause must be empty.
Behavior Type

Mutable

Syntax

```
STV_Refresh_Index( gid, g
    USING PARAMETERS index='index_name'
    [, skip_nonindexable_polygons={ true | false } ]
)
OVER()
[ AS (type, polygons, srid, min_x, min_y, max_x, max_y, info,
          indexed, appended, updated, deleted) ]
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>gid</code></td>
<td>Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.</td>
</tr>
<tr>
<td><code>g</code></td>
<td>Name of a geometry or geography (WGS84) column or expression that contains polygons and multipolygons. Only polygon and multipolygon can be indexed. Other shape types are excluded from the index.</td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>index = 'index_name'</td>
<td>Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.</td>
</tr>
<tr>
<td>skip_nonindexable_polygons = { true</td>
<td>false }</td>
</tr>
</tbody>
</table>
To review the polygons that were not able to be indexed, use STV_Describe_Index with the parameter list_polygon.

Default: False

## Returns

<table>
<thead>
<tr>
