</table>

**Privileges**

None
REPARENTED_ON_DROP

Lists re-parenting events of objects that were dropped from their original owner but still remain in Vertica. For example, a user may leave the organization and need to be removed from the database. When the database administrator drops the user from the database, that user's objects are re-parented to another user.

In some cases, a Vertica user's objects are reassigned based on the GlobalHeirUsername parameter. In this case, a user's objects are re-parented to the user indicated by this parameter.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPARENT_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time the re-parenting event occurred.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node or nodes on which the re-parenting occurred.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The identification number of the re-parenting event.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>The unique, system-generated user identification number.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user that caused the re-parenting event. For example, a dbadmin user may have dropped a user thus re-parenting that user's objects.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>The system-generated transaction identification number. Is NULL if a transaction id does not exist.</td>
</tr>
<tr>
<td>OLD_OWNER_NAME</td>
<td>VARCHAR</td>
<td>The the name of the dropped user who used to own the re-parented object.</td>
</tr>
<tr>
<td>OLD_OWNER_OID</td>
<td>INTEGER</td>
<td>The unique identification number of the user who used to own the re-parented object.</td>
</tr>
<tr>
<td>NEW_OWNER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user who now owns the re-parented objects.</td>

<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OBJ_NAME</td>
<td>VARCHAR</td>
<td>now owns the re-parented objects.</td>
</tr>
<tr>
<td>OBJ_OID</td>
<td>INTEGER</td>
<td>The unique identification number of the object being re-parented.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema in which the object resides.</td>
</tr>
<tr>
<td>SCHEMA_OID</td>
<td>INTEGER</td>
<td>The unique identification number of the schema in which the re-parented object resides.</td>
</tr>
</tbody>
</table>

**RESOURCE_ACQUISITIONS**

Retains information about resources (memory, open file handles, threads) acquired by each running request. Each request is uniquely identified by its transaction and statement IDs within a given session.

**Important:**
If a request cascades to one or more resource pools beyond the original pool, this table contains multiple records for the same request—one record for each resource pool. The following values are specific to each resource pool:

- Timestamp values: QUEUE_ENTRY_TIMESTAMP, ACQUISITION_TIMESTAMP, and RELEASE_TIMESTAMP
- DURATION_MS
- IS_EXECUTING

You can trace the history of cascade events by querying system table `RESOURCE_POOL_MOVE`.

<table>
<thead>

<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for each statement within a transaction. NULL indicates that no statement is currently being processed.</td>
</tr>
<tr>
<td>REQUEST_TYPE</td>
<td>VARCHAR</td>
<td>Type of request issued to a resource pool. End users always see this column set to Reserve, to indicate that the request is query-specific.</td>
</tr>
</tbody>
</table>
| POOL_ID / POOL_NAME      | INTEGER / VARCHAR | Each resource pool that participated in handling this request:  
  - POOL_ID: A unique numeric ID assigned by the Vertica catalog that uniquely identifies the resource pool.  
  - POOL_NAME: Name of the resource pool. |
| THREAD_COUNT             | INTEGER       | Number of threads in use by this request.                                                                                                    |
| OPEN_FILE_HANDLE_COUNT   | INTEGER       | Number of open file handles in use by this request.                                                                                         |
| MEMORY_INUSE_KB          | INTEGER       | Total amount of memory in kilobytes acquired by this query.  
  Column RESERVED_EXTRA_MEMORY_B in system table QUERY_PROFILES shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator.  
  If operators for a query acquire all memory specified by MEMORY_INUSE_KB, the plan must request more memory from the Vertica Resource Manager. |
| QUEUE_ENTRY_TIMESTAMP    | TIMESTAMPTZ   | Timestamp when the request was queued in this resource pool.                                                                                 |
| ACQUISITION_TIMESTAMP    | TIMESTAMPTZ   | Timestamp when the request was admitted to run.                                                                                               |
### Column Name

<table>
<thead>
<tr>
<th><strong>Column Name</strong></th>
<th><strong>Data Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>RELEASE_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica released this resource acquisition.</td>
</tr>
<tr>
<td>DURATION_MS</td>
<td>INTEGER</td>
<td>Duration in milliseconds of request execution. If the request cascaded across</td>
</tr>
<tr>
<td></td>
<td></td>
<td>multiple resource pools, DURATION_MS applies only to this resource pool.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Set to true if the resource pool is still executing this request. A value of</td>
</tr>
<tr>
<td></td>
<td></td>
<td>false can indicate one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The request was completed or denied.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The request cascaded to another resource pool.</td>
</tr>
</tbody>
</table>

### Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

### Queue Wait Time

You can calculate how long a resource pool queues a given request before it begins execution by subtracting QUEUE_ENTRY_TIMESTAMP from ACQUISITION_TIMESTAMP. For example:

```sql
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp, (acquisition_timestamp - queue_entry_timestamp) AS 'queue wait'
    FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

### See Also

**RESOURCE_POOL_STATUS**

Provides current state of built-in and user-defined resource pools on each node. Information includes:

- Current memory usage
- Resources requested and acquired by various requests
- Number of queries executing

For general information about resource pools, see Resource Pool Architecture.

<table>
<thead>
<tr>
<th>Column Name</th>

<td>BOOLEAN</td>
<td>Denotes whether a pool is one of the Built-In Pools.</td>
</tr>
<tr>
<td>MEMORY_SIZE_KB</td>
<td>INTEGER</td>
<td>Value of MEMORYSIZE setting of the pool in kilobytes.</td>
</tr>
</tbody>
</table>
| MEMORY_SIZE_ACTUAL_KB | INTEGER   | Current amount of memory, in kilobytes, allocated to the pool by the resource manager. The actual size can be less than specified in the DDL, if both the following conditions exist:  

- The pool has been recently altered in a running system.  
- The request to shuffle memory is pending. |
| MEMORY_INUSE_KB     | INTEGER    | Amount of memory, in kilobytes, acquired by requests running against this pool. |
| GENERAL_MEMORY_BORROWED_KB | INTEGER | Amount of memory, in kilobytes, borrowed from the GENERAL pool by requests running against this pool. The sum of MEMORY_INUSE_KB and GENERAL_MEMORY_BORROWED_KB should be less than MAX_MEMORY_SIZE_KB. |
| QUEUEING_THRESHOLD_KB | INTEGER | Calculated as MAX_MEMORY_SIZE_KB * 0.95. When the amount of memory used by all requests against this resource pool exceeds the QUEUEING_THRESHOLD_KB, new requests against the pool are queued until memory becomes available. |
| MAX_MEMORY_SIZE_KB  | INTEGER    | Value, in kilobytes, of the MAXMEMORYSIZE parameter as defined for the pool. After this threshold is reached, new requests against this pool are rejected or queued until memory becomes available. |

**Note:**

MAX_MEMORY_SIZE_KB might not reflect the set MAXMEMORYSIZE parameter value if the specified value cannot be reached. For example, if MAXMEMORYSIZE = 10G but less than 2G is available, MAX_MEMORY_SIZE_KB
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAX_QUERY_MEMORY_SIZE_KB</td>
<td>INTEGER</td>
<td>Value, in kilobytes, of the MAXQUERYMEMORYSIZE parameter as defined for the pool. The resource pool limits this amount of memory to all queries that execute in it.</td>
</tr>
<tr>
<td>RUNNING_QUERY_COUNT</td>
<td>INTEGER</td>
<td>Number of queries currently executing in this pool.</td>
</tr>
<tr>
<td>PLANNED_CONCURRENCY</td>
<td>INTEGER</td>
<td>Value of PLANNEDCONCURRENCY parameter as defined for the pool.</td>
</tr>
<tr>
<td>MAX_CONCURRENCY</td>

<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RUNTIME_PRIORITY_THRESHOLD</td>
<td>INTEGER</td>
<td>Value of RUNTIME_PRIORITY_THRESHOLD as defined for the pool.</td>
</tr>
<tr>
<td>SINGLE_INITIATOR</td>
<td>BOOLEAN</td>
<td>Value of SINGLEINITIATOR parameter, set for backward compatibility.</td>
</tr>
<tr>
<td>QUERY_BUDGET_KB</td>
<td>INTEGER</td>
<td>The current amount of memory that queries are tuned to use. The calculation that Vertica uses to determine this value is described in Query Budgeting.</td>
</tr>
</tbody>
</table>

**Note:**
The calculated value can change when one or more running queries needs more than the budgeted amount to run.

For a detailed example of query budget calculations, see [Do You Need to Put Your Query on a Budget?](https://community.vertica.com) in the Vertica User Community.

<table>
<thead>
<tr>
<th>CPU_AFFINITY_SET</th>
<th>VARCHAR</th>
<th>The set of CPUs on which queries associated with this pool are executed. Can be:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• A percentage of CPUs on the system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A zero-based list of CPUs (a four-CPU system c of CPUs 0, 1, 2, and 3).</td>
</tr>
</tbody>
</table>

| CPU_AFFINITY_MASK           | VARCHAR       | The bit mask of CPUs available for use in this pool, read from right to left. See Examples below. |

<table>
<thead>
<tr>
<th>CPU_AFFINITY_MODE</th>
<th>VARCHAR</th>
<th>The mode for the CPU affinity, one of the following:</th>
</tr>

RESOURCE_QUEUES

Provides information about requests pending for various resource pools.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node for which information is listed.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Transaction identifier for this request</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
POOL_NAME | VARCHAR | The name of the resource pool
MEMORY_REQUESTED_KB | INTEGER | Amount of memory in kilobytes requested by this request
PRIORITY | INTEGER | Value of PRIORITY parameter specified when defining the pool.
POSITION_IN_QUEUE | INTEGER | Position of this request within the pool’s queue
QUEUE_ENTRY_TIMESTAMP | TIMESTAMP | Timestamp when the request was queued

#### See Also

</tbody>
</table>

### SESSION_MARS_STORE

Shows Multiple Active Result Sets (MARS) storage information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier of the Vertica session. This identifier is unique within the cluster for the current session but can be reused in a subsequent session.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The username used to create the connection.</td>
</tr>
<tr>
<td>RESULTSET_ID</td>
<td>INTEGER</td>
<td>Identifier assigned to the result set.</td>
</tr>
<tr>
<td>ROW_COUNT</td>
<td>INTEGER</td>
<td>Number of rows requested by the query.</td>
</tr>
<tr>
<td>REMAINING_ROW_COUNT</td>
<td>INTEGER</td>
<td>Number of rows that still need to be returned.</td>
</tr>
<tr>
<td>BYTES_USED</td>
<td>INTEGER</td>
<td>The number of bytes requested.</td>
</tr>
</tbody>
</table>
SESSION_PARAMETERS

Provides information about user-defined parameters (UDPARAMETERS) set for the current session.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The unique identifier for the session.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema on which the session is running.</td>
</tr>
<tr>
<td>LIB_NAME</td>
<td>VARCHAR</td>
<td>The name of the user library running the UDx, if necessary.</td>
</tr>
<tr>
<td>LIB_OID</td>
<td>VARCHAR</td>
<td>The object ID of the library containing the function, if one is running.</td>
</tr>
<tr>
<td>PARAMETER_NAME</td>
<td>VARCHAR</td>
<td>The name of the session parameter.</td>
</tr>
<tr>
<td>CURRENT_VALUE</td>
<td>VARCHAR</td>
<td>The value of the session parameter.</td>
</tr>
</tbody>
</table>

SESSION_PROFILES

Provides basic session parameters and lock time out data. To obtain information about sessions, see Profiling Database Performance.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name used to log in to the database or NULL if the session is internal.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal.</td>
</tr>
<tr>
<td>LOGIN_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The date and time the user logged into the database or when the internal session was created. This field is useful for identifying sessions that have been left open for a period of time and could be idle.</td>
</tr>
<tr>
<td>LOGOUT_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The date and time the user logged out of the database or when the internal session was closed.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>EXECUTED_STATEMENT_SUCCESS_COUNT</td>
<td>INTEGER</td>
<td>The number of successfully run statements.</td>
</tr>
<tr>
<td>EXECUTED_STATEMENT_FAILURE_COUNT</td>
<td>INTEGER</td>
<td>The number of unsuccessfully run statements.</td>
</tr>
<tr>
<td>LOCK_GRANT_COUNT</td>
<td>INTEGER</td>
<td>The number of locks granted during the session.</td>
</tr>
<tr>
<td>DEADLOCK_COUNT</td>
<td>INTEGER</td>
<td>The number of deadlocks encountered during the session.</td>
</tr>
<tr>
<td>LOCK_TIMEOUT_COUNT</td>
<td>INTEGER</td>
<td>The number of times a lock timed out during the session.</td>
</tr>
<tr>
<td>LOCK_CANCELLATION_COUNT</td>
<td>INTEGER</td>
<td>The number of times a lock was canceled during the session.</td>
</tr>
<tr>
<td>LOCK_REJECTION_COUNT</td>
<td>INTEGER</td>
<td>The number of times a lock was rejected</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LOCK_ERROR_COUNT</td>
<td>INTEGER</td>
<td>The number of lock errors encountered during the session.</td>
</tr>
<tr>
<td>LOCK_ERROR_COUNT</td>
<td>INTEGER</td>
<td>The number of lock errors encountered during the session.</td>
</tr>
<tr>
<td>CLIENT_TYPE</td>
<td>VARCHAR</td>
<td>The type of client from which the connection was made. Possible client type values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ADO.NET Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ODBC Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• JDBC Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• vsql</td>
</tr>
<tr>
<td>CLIENT_VERSION</td>
<td>VARCHAR</td>
<td>Returns the client version.</td>
</tr>
<tr>
<td>CLIENT_OS</td>
<td>VARCHAR</td>
<td>Returns the client operating system.</td>
</tr>
<tr>
<td>CLIENT_OU_USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.</td>
</tr>
</tbody>
</table>

**See Also**

LOCKS

SECTIONS

Monitors external sessions. Use this table to perform the following tasks:

- Identify users who are running lengthy queries.
- Identify users who hold locks because of an idle but uncommitted transaction.
- Determine the details of the database security used for a particular session, either Secure Socket Layer (SSL) or client authentication.
- Identify client-specific information, such as client version.

**Note:**
During session initialization and termination, you might see sessions running
only on nodes other than the node on which you ran the virtual table query. This is a temporary situation that corrects itself when session initialization and termination complete.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name used to log in to the database or NULL if the session is internal.</td>
</tr>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal. Vertica accepts either IPv4 or IPv6 connections from a client machine. If the client machine contains mappings for both IPv4 and IPv6, the server randomly chooses one IP address family to make a connection. This can cause the CLIENT_HOSTNAME column to display either IPv4 or IPv6 values, based on which address family the server chooses.</td>
</tr>
<tr>
<td>CLIENT_PID</td>
<td>INTEGER</td>
<td>The process identifier of the client process that issued this connection. Remember that the client process could be on a different machine than the server.</td>
</tr>
<tr>
<td>LOGIN_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The date and time the user logged into the database or when the internal session was created. This field can help you identify sessions that have been left open for a period of time and could be idle.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The identifier required to close or interrupt a session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>IDLE_SESSION_TIMEOUT</td>
<td>VARCHAR</td>
<td>Specifies how long this session can remain idle before timing out, set by SET SESSION</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IDLESESSIONTIMEOUT</td>
<td></td>
<td>IDLESESSIONTIMEOUT.</td>
</tr>
<tr>
<td>GRACE_PERIOD</td>
<td>VARCHAR</td>
<td>Specifies how long a session socket remains blocked while awaiting client input or output for a given query, set by <code>SET SESSION GRACEPERIOD</code>. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated.</td>
</tr>
<tr>
<td>CLIENT_LABEL</td>
<td>VARCHAR</td>
<td>A user-specified label for the client connection that can be set when using ODBC. See Label in Data Source Name (DSN) Connection Properties in Connecting to Vertica. An MC output value means there are is a client connection to an MC-managed database for that USER_NAME.</td>
</tr>
<tr>
<td>TRANSACTION_START</td>
<td>DATE</td>
<td>The date/time the current transaction started or NULL if no transaction is running.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>A string containing the hexadecimal representation of the transaction ID, if any; otherwise, NULL.</td>
</tr>
<tr>
<td>TRANSACTION_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Description of the current transaction.</td>
</tr>
<tr>
<td>STATEMENT_START</td>
<td>TIMESTAMP</td>
<td>The timestamp the current statement started execution, or NULL if no statement is running.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the currently-executing statement.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A value of NULL indicates that no statement is currently being processed.</td>
</tr>
<tr>
<td>LAST_STATEMENT_DURATION_US</td>
<td>INTEGER</td>
<td>The duration of the last completed statement in microseconds.</td>
</tr>

- `CLOSE_SESSION`
- `CLOSE_ALL_SESSIONS`

**SPREAD_STATE**

Lists `spread` daemon settings for all nodes in the cluster.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Which node the settings are for.</td>
</tr>
<tr>
<td>TOKEN_TIMEOUT</td>
<td>INTEGER</td>
<td>The timeout period in milliseconds before <code>spread</code> considers a node to be down due to lack of response to a message.</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT * FROM V_MONITOR.SPREAD_STATE;

<table>
<thead>
<tr>
<th>node_name</th>
<th>token_timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0003</td>
<td>8000</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>8000</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>8000</td>
</tr>
</tbody>
</table>

(3 rows)
```

See Also

**STORAGE_BUNDLE_INFO_STATISTICS**

Indicates which projections have storage containers with invalid bundle metadata in the database catalog. If any ROS or DV container has invalid bundle metadata fields, Vertica increments the corresponding column (`ros_without_bundle_info_count` or `dv_ros_without_bundle_info_count`) by one.
To update the catalog with valid bundle metadata, call `UPDATE_STORAGE_CATALOG`, as an argument to Vertica meta-function `DO_TM_TASK`. For details, see [Writing Bundle Metadata to the Catalog](#).

- STORAGE_CONTAINERS
- STORAGE_USAGE

### STORAGE_TIERS

Provides information about all storage locations with the same label across all cluster nodes. This table lists data totals for all same-name labeled locations.

The system table shows what labeled locations exist on the cluster, as well as other cluster-wide data about the locations.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR</td>
<td>The label associated with a specific storage location.</td>
</tr>
</tbody>
</table>

The storage_tiers system table includes data totals for unlabeled locations, which are considered labeled with empty strings (' ').
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_COUNT</td>
<td>INTEGER</td>
<td>The total number of nodes that include a storage location named location_label.</td>
</tr>
</tbody>
</table>
| LOCATION_COUNT     | INTEGER   | The total number of storage locations named location_label. This value can differ from node_count if you create labeled locations with the same name at different paths on different nodes. For example:  

  - **v_vmart_node0001**: Create one labeled location, FAST  
  - **V_vmart_node0002**: Create two labeled locations, FAST, at different directory paths  

  In this case, node_count value = 2, while location_count value = 3. |
| ROS_CONTAINER_COUNT| INTEGER   | The total number of ROS containers stored across all cluster nodes for location_label.  |
| TOTAL_OCCUPIED_SIZE| INTEGER   | The total number of bytes that all ROS containers for location_label occupy across all cluster nodes. |

**Privileges**

None

STRATA

Contains internal details of how the Tuple Mover combines ROS containers in each projection, broken down by stratum and classifies the ROS containers by size and partition. The related STRATA_STRUCTURES table provides a summary of the strata values.

Mergeout in the Administrator's Guide describes how the Tuple Mover combines ROS containers.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>

<td>The total number of strata for this projection partition.</td>
</tr>
<tr>
<td>MERGING_STRATA_COUNT</td>
<td>INTEGER</td>
<td>In certain hardware configurations, a high strata could contain more ROS containers than the Tuple Mover can merge out; output from this column denotes the number of strata the Tuple Mover can merge out.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
NODE_NAME | VARCHAR | The node name for which information is listed.
STRATUM_CAPACITY | INTEGER | The maximum number of ROS containers that the strata can contained before it must merge them.
STRATUM_HEIGHT | FLOAT | The size ratio between the smallest and largest ROS container in a stratum.
ACTIVE_STRATA_COUNT | INTEGER | The total number of strata that have ROS containers in them.

#### Example

```
=> \pset expanded
Expanded display is on.

<td>VARCHAR</td>
<td>Type of service; can be one of:</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SERVICE_GROUP</td>
<td>VARCHAR</td>
<td>Group name, if there are multiple services of the same type.</td>
</tr>
<tr>
<td>SERVICE_NAME</td>
<td>VARCHAR</td>
<td>Name of the service.</td>
</tr>
<tr>
<td>SERVICE_INTERVAL_SEC</td>
<td>INTEGER</td>
<td>How often the service is executed (in seconds) during the history interval.</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>Denotes if the service is enabled.</td>
</tr>
<tr>
<td>LAST_RUN_START</td>
<td>TIMESTAMPTZ</td>
<td>Denotes when the service was started last time.</td>
</tr>
<tr>
<td>LAST_RUN_END</td>
<td>TIMESTAMPTZ</td>
<td>Denotes when the service was completed last time.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**SYSTEM_SESSIONS**

Provides information about system internal session history by system task.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>

**TABLE_RECOVERIES**

Provides detailed information about recovered and recovering tables during a recovery by table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is performing the recovery.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table being recovered.</td>
</tr>
<tr>
<td>TABLE_OID</td>
<td>INTEGER</td>
<td>The object ID of the table being recovered.</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>The status of the table. Tables can have the following status:</td>
</tr>
</tbody>
</table>
### Column Name

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PHASE</td>
<td>VARCHAR</td>
<td>The <strong>phase of the recovery</strong>.</td>
</tr>
<tr>
<td>THREAD_ID</td>
<td>VARCHAR</td>
<td>The ID of the thread that performed the recovery.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMPZ</td>
<td>The date and time that the table began recovery.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMPZ</td>
<td>The date and time that the table completed recovery.</td>
</tr>
<tr>
<td>RECOVER_PRIORITY</td>
<td>INTEGER</td>
<td>The <strong>recovery priority</strong> of the table being recovered.</td>
</tr>
<tr>
<td>RECOVER_ERROR</td>
<td>VARCHAR</td>
<td>Error that caused the recovery to fail.</td>
</tr>
<tr>
<td>IS_HISTORICAL</td>
<td>BOOLEAN</td>
<td>If ( f ), the record contains recovery information for the current process.</td>
</tr>
</tbody>
</table>

### Privileges

None

### Example

```sql
=> SELECT * FROM TABLE_RECOVERIES;
- [RECORD 1] ----------------------------------------------------------
```
TABLE_RECOVERY_STATUS

Provides node recovery information during a Recovery By Table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is performing the recovery.</td>
</tr>
<tr>
<td>NODE_RECOVERY_START_TIME</td>
<td>TIMESTAMPZ</td>
<td>The timestamp for when the node began recovering.</td>
</tr>
<tr>
<td>RECOVER_EPOCH</td>
<td>INTEGER</td>
<td>The epoch that the recovery operation is trying to recover to.</td>
</tr>
<tr>
<td>RECOVERING_TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table currently recovering.</td>
</tr>
<tr>
<td>TABLES_REMAIN</td>
<td>INTEGER</td>
<td>The total number of tables on the node.</td>
</tr>
<tr>
<td>IS_RUNNING</td>
<td>BOOLEAN</td>
<td>Indicates if the recovery process is still running.</td>
</tr>
</tbody>
</table>
Privileges

None

Example

```sql
=> SELECT * FROM TABLE_RECOVERY_STATUS;
- [ RECORD 1 ]---------------------------------
  node_name | v_vmart_node001
  node_recovery_start_time | 
  recover_epoch | 
  recovering_table_name | 
  tables_remain | 0
  is_running | f
- [ RECORD 2 ]---------------------------------
  node_name | v_vmart_node002
  node_recovery_start_time | 
  recover_epoch | 
  recovering_table_name | 
  tables_remain | 0
  is_running | f
- [ RECORD 3 ]---------------------------------
  node_name | v_vmart_node003
  node_recovery_start_time | 2017-12-13 08:47:28.282377-05
  recover_epoch | 23
  recovering_table_name | user_table
  tables_remain | 5
  is_running | y
```

TRANSACTIONS

Records the details of each transaction.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Beginning of history interval.</td>
</tr>
<tr>
<td>END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>End of history interval.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user for which transaction information is listed.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>Textual description of the transaction.</td>
</tr>
<tr>
<td>START_EPOCH</td>
<td>INTEGER</td>
<td>Number of the start epoch for the transaction.</td>
</tr>
<tr>
<td>END_EPOCH</td>
<td>INTEGER</td>
<td>Number of the end epoch for the transaction</td>
</tr>
<tr>
<td>NUMBER_OF_STATEMENTS</td>
<td>INTEGER</td>
<td>Number of query statements executed in this transaction.</td>
</tr>
<tr>
<td>ISOLATION</td>
<td>VARCHAR</td>
<td>Denotes the transaction mode as &quot;READ COMMITTED&quot; or &quot;SERIALIZABLE&quot;.</td>
</tr>
<tr>
<td>IS_READ_ONLY</td>
<td>BOOLEAN</td>
<td>Denotes &quot;READ ONLY&quot; transaction mode.</td>
</tr>
<tr>
<td>IS_COMMITTED</td>
<td>BOOLEAN</td>
<td>Determines if the transaction was committed. False means ROLLBACK.</td>
</tr>
<tr>
<td>IS_LOCAL</td>
<td>BOOLEAN</td>
<td>Denotes transaction is local (non-distributed).</td>
</tr>
<tr>
<td>IS_INITIATOR</td>
<td>BOOLEAN</td>
<td>Denotes if the transaction occurred on this node (t).</td>
</tr>
<tr>
<td>IS_DDL</td>
<td>BOOLEAN</td>
<td>Distinguishes between a DDL transaction (t) and non-DDL transaction (f).</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

Transactions

TRUNCATED_SCHEMA

Lists the original names of restored schemas that were truncated due to name lengths exceeding 128 characters.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESTORE_TIME</td>
<td>TIMESTAMPZ</td>
<td>The time that the table was restored.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for the restoring session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifier of the user for the restore event.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user for which Vertica lists restore information at the time it recorded the session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>ORIGINAL_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The original name of the schema prior to the restore.</td>
</tr>
<tr>
<td>NEW_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema after it was truncated.</td>
</tr>
</tbody>
</table>

Privileges

None

TUNING_RECOMMENDATIONS

Returns tuning recommendation results from the last call to ANALYZE_WORKLOAD. This information is useful for building filters on the Workload Analyzer result set.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>observation_count</td>
<td>INTEGER</td>
<td>Integer for the total number of events observed for this tuning recommendation. For example, if you see a return value of 1, Workload Analyzer is making its first tuning recommendation for the event in 'scope'.</td>
</tr>
<tr>
<td>first_observation_time</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the event first occurred. If this column returns a null value, the tuning recommendation is from the current status of the system instead of from any prior event.</td>
</tr>
<tr>
<td>last_observation_time</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the event last occurred. If this column returns a null value, the tuning recommendation is from the current status of the system instead of from any prior event.</td>
</tr>
<tr>
<td>tuning_parameter</td>
<td>VARCHAR</td>
<td>Objects on which you should perform a tuning action. For example, a return value of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• public.t informs the DBA to run Database Designer on table t in the public schema</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• bsmith notifies a DBA to set a password for user bsmith</td>
</tr>
<tr>
<td>tuning_description</td>
<td>VARCHAR</td>
<td>Textual description of the tuning recommendation to perform on the tuning_parameter object. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Run database designer on table schema.table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Create replicated projection for table schema.table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Consider incremental design on query</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Re-segment projection projection-name on high-cardinality column(s)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Drop the projection projection-name</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Alter a table's partition expression</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Reorganize data in partitioned table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Decrease the MoveOutInterval configuration parameter setting</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>tuning_command</td>
<td>VARCHAR</td>
<td>Command string if tuning action is a SQL command. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Update statistics on a particular schema's table.column:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>SELECT ANALYZE_STATISTICS('public.table.column');</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Resolve mismatched configuration parameter <code>LockTimeout</code>:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'LockTimeout';</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set the password for user bsmith:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>ALTER USER (bsmith) IDENTIFIED BY ('new_password');</code></td>
</tr>
<tr>
<td>tuning_cost</td>
<td>VARCHAR</td>
<td>Cost is based on the type of tuning recommendation and is one of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>LOW</strong>: minimal impact on resources from running the tuning command</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>MEDIUM</strong>: moderate impact on resources from running the tuning command</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>HIGH</strong>: maximum impact on resources from running the tuning command</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Depending on the size of your database or table, consider running high-cost operations after hours instead of during peak load times.</td>
</tr>
</tbody>
</table>

## UDFS_OPS_PER_HOUR

This table summarizes the S3 file system statistics for each minute.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node the file system is on.</td>
</tr>
<tr>
<td>FILESYSTEM</td>
<td>VARCHAR</td>
<td>Name of the file system, such as S3.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Start time for statistics gathering.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMP</td>
<td>Stop time for statistics gathering.</td>
</tr>
<tr>
<td>AVG_OPERATIONS_PER_SECOND</td>
<td>INTEGER</td>
<td>Average number of operations per second during the specified hour.</td>
</tr>
<tr>
<td>AVG_ERRORS_PER_SECOND</td>
<td>INTEGER</td>
<td>Average number of errors per second during the specified hour.</td>
</tr>
<tr>
<td>RETRIES</td>
<td>INTEGER</td>
<td>Number of retry events during the specified hour.</td>
</tr>
<tr>
<td>METADATA_READS</td>
<td>INTEGER</td>
<td>Number of requests to write metadata during the specified hour. For example, S3 POST and DELETE requests are metadata writes.</td>
</tr>
<tr>
<td>METADATA_WRITES</td>
<td>INTEGER</td>
<td>Number of requests to write metadata during the specified hour. For example, S3 POST and DELETE requests are metadata writes.</td>
</tr>
<tr>
<td>DATA_READS</td>
<td>INTEGER</td>
<td>Number of read operations, such as S3 GET requests to download files, during the specified hour.</td>
</tr>
<tr>
<td>DATA_WRITES</td>
<td>INTEGER</td>
<td>Number of write operations, such as S3 PUT requests to upload files, during the specified hour.</td>
</tr>
</tbody>
</table>
### Example

```sql
=> \x
Expanded display is on.
=> SELECT * FROM UDFS_OPS_PER_HOUR;
```

```
- [ RECORD 1 ]-----------------------------
 node_name | e1
 filesystem | S3
 start_time | 2018-04-06 04:00:00
 end_time | 2018-04-06 04:00:00
 avg_operations_per_second | 0
 avg_errors_per_second | 0
 retries | 0
 metadata_reads | 0
 metadata_writes | 0
 data_reads | 0
 data_writes | 0
 upstream_bytes | 0

UDFS_OPS_PER_HOUR

UDFS_STATISTICS

Records aggregate information about file-system operations. This table records information about the S3 file system, and records information about metadata (but not data) for the Libhdfs++ file system. This table does not record information for Webhdfs or the Linux file system.

An operation can be made up of many individual read, write, or retry requests. SUCCESSFUL_OPERATIONS and FAILED_OPERATIONS count operations; the other counters count individual requests. When an operation finishes, one of the OPERATIONS counters is incremented once, but several other counters could be incremented several times each.

The following query gets the total number of metadata RPCs for Libhdfs++ operations:

```sql
=> SELECT SUM(metadata_reads) FROM UDFS_STATISTICS WHERE filesystem = 'Libhdfs++';
```

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILESYSTEM</td>
<td>VARCHAR</td>
<td>Name of the file system, such as S3 or Libhdfs++</td>
</tr>
<tr>
<td>SUCCESSFUL_OPERATIONS</td>
<td>INTEGER</td>
<td>Number of successful file-system operations.</td>
</tr>
<tr>
<td>FAILED_OPERATIONS</td>
<td>INTEGER</td>
<td>Number of failed file-system operations.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RETRIES</td>
<td>INTEGER</td>
<td>Number of retry events.</td>
</tr>
<tr>
<td>METADATA_READS</td>
<td>INTEGER</td>
<td>Number of requests to read metadata. For example, S3 list bucket and HEAD requests are metadata reads.</td>
</tr>
<tr>
<td>METADATA_WRITES</td>
<td>INTEGER</td>
<td>Number of requests to write metadata. For example, S3 POST and DELETE requests are metadata writes.</td>
</tr>
<tr>
<td>DATA_READS</td>
<td>INTEGER</td>
<td>Number of read operations, such as S3 GET requests to download files.</td>
</tr>
<tr>
<td>DATA_WRITES</td>
<td>INTEGER</td>
<td>Number of write operations, such as S3 PUT requests to upload files.</td>
</tr>
<tr>
<td>DOWNSTREAM_BYTES</td>
<td>INTEGER</td>
<td>Number of bytes received.</td>

**Appendix: Compatibility with Other RDBMS**

This section describes compatibility of Vertica with other relational database management systems.

Information in this appendix is intended to simplify database migration to Vertica.

**Data Type Mappings Between Vertica and Oracle**

Oracle uses proprietary data types for all main data types (for example, VARCHAR, INTEGER, FLOAT, DATE), if you plan to migrate your database from Oracle to Vertica, OpenText strongly recommends that you convert the schema—a simple and important exercise that can minimize errors and time lost spent fixing erroneous data issues.

The following table compares the behavior of Oracle data types to Vertica data types.
In Oracle, the NUMBER data type with no explicit precision stores each number \( N \) as an integer \( M \), together with a scale \( S \). The scale can range from -84 to 127, while the precision of \( M \) is limited to 38 digits. So \( N = M \times 10^S \).

When precision is specified, precision/scale applies to all entries in the column. If omitted, the scale defaults to 0.

For the common case where Oracle’s NUMBER with no explicit precision data type is used to store only integer values, INTEGER is the best suited and the fastest Vertica data type. However, INTEGER (the same as BIGINT) is limited to a little less than 19 digits, with a scale of 0; if the Oracle column contains integer values outside of the range \([-9223372036854775807, +9223372036854775807]\), use the Vertica data type NUMERIC\((p,0)\) where \( p \) is the maximum number of digits required to represent the values of \( N \).

Even though no explicit scale is specified for an Oracle NUMBER column, Oracle allows non-integer values, each with its own scale. If the data stored in the column is approximate, Vertica recommends using the Vertica data type FLOAT, which is standard IEEE floating point, like ORACLE BINARY_DOUBLE. If the data is exact with fractional places, for example dollar amounts, Vertica recommends NUMERIC\((p,s)\) where \( p \) is the precision (total number of digits) and \( s \) is the maximum scale (number of decimal places).

Vertica conforms to standard SQL, which requires that \( p \geq s \) and \( s \geq 0 \). Vertica's NUMERIC data type is most effective for \( p=18 \), and increasingly expensive for \( p=37, 58, 67, \) etc., where \( p \leq 1024 \).

Vertica recommends against using the data type NUMERIC\((38,s)\) as a default "failsafe" mapping to guarantee no loss of precision. NUMERIC\((18,s)\) is better, and INTEGER or FLOAT are better yet, if one of these data types will do the job.

</table>
Security and Authentication

Vertica provides tools and features that allow you to ensure your system is secure as well as to prevent unauthorized users from accessing sensitive information.

**Client Authentication** establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server.

**Client Authentication**

Implementing strong security programs provides Vertica users the assurance that access to sensitive information is closely guarded. Vertica uses several approaches to manage data access.

The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.
Encrypting Client-Server Communication

Vertica uses Transport Layer Security (TLS) to establish a secure connection between the client machine and the server. Configure SSL/TLS to:

- Authenticate the server so the client can confirm the server's identity. Vertica supports mutual authentication in which the server can also confirm the identity of the client. This authentication helps prevent "man-in-the-middle" attacks.
- Encrypt data sent between the client and database server to significantly reduce the likelihood that the data can be read if the connection between the client and server is compromised.
- Verify that data sent between the client and server has not been altered during transmission.

For details see TLS Protocol.

Authentication Management

Users with the DBADMIN can manage the following authentication tasks:

- Create authentication records using CREATE AUTHENTICATION.

**Important:**
Configure client authentication so that the DBADMIN user can always access the database locally. If a problem occurs with the authentication that blocks all users from logging in, the DBADMIN user needs access to correct the problem.

- Assign a specific authentication method to a user using GRANT (Authentication).
- Use ALTER AUTHENTICATION to:
  - Enable/disable authentication methods.
  - Define a default authentication method to be used if a user has not been assigned a specific authentication method.
- Define parameters required by LDAP, Ident, and Kerberos authentication methods.
- Revoke a user’s authentication record using REVOKE Authentication. This user now uses the default authentication.
• Delete an authentication record from the database using **DROP AUTHENTICATION**. Any users assigned the dropped record now use the default authentication method.

For details about managing authentication records, see:

- dbadmin Authentication Access
- Creating Authentication Records
- Enabling and Disabling Authentication Methods
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

See **Implementing Client Authentication**.

### User Authorization

Database users should have access to just the database resources they need to perform their required tasks. For example, some users need to query only specific sets of data. To prevent unauthorized access to additional data, you can limit their access to just the data that they need to run their queries. Other users should be able to read the data but not be able to modify or insert new data. Still other users might need more permissive access, including the right to create and modify schemas, tables, and views, or grant other users access to database resources.

For information on controlling data access, see the following:

- **Database Users** in Database Users and Privileges
- **Database Roles** to grant users access to a set of privileges.
- **Access Policies** to limit user's from viewing data from a specific table.

### Implementing Client Authentication

Vertica restricts which database users can connect through **client authentication**. The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.

When a user or client application connect to the Vertica database server, it supplies a unique user name and password to gain access.
Vertica offers several client authentication methods. You can configure Vertica to require just a user name for connections, you likely require more secure means of authentication, such as a password at a minimum.

**Note:**
Topics in this section describe authentication methods supported at the database server layer. For information on authentication between server and client, see [TLS Protocol](#).

## How Client Authentication Works

When connecting to a Vertica database, a user or client application must supply the name of a valid user account. In addition, the application usually includes a means of authentication, such as a password or security certificate.

There are two types of client authentication:

- **LOCAL**—Authenticating users or applications that are trying to connect from the same node that the database is running on.
- **HOST**—Authenticating users or applications that are trying to connect from a node that has a different IPv4 or IPv6 address than the database.

The DBADMIN user manages the client authentication information that the database uses to authenticate users.

Vertica takes the following steps to authenticate users:

1. When a user or application attempts to connect to a Vertica database, the system checks to see if the user is a DBADMIN user. If so, authentication occurs using the assigned authentication method, local trust or local hash authentication.

2. For non-DBADMIN users, the database checks to see if the user is associated with an authentication method through a GRANT statement. If so, the database allows the user to log in if they match the parameters required for that authentication method.

**Note:**
For detailed information on how authentication priorities work, see [Priorities for Client Authentication Methods](#).
The DBADMIN user can grant an authentication method to users or user roles. The DBADMIN user can also create a default authentication method that Vertica uses when no authentication has been associated with a user or role.

3. If the user has not been granted an authentication method, the database checks to see if the DBADMIN has established a default authentication method.

4. If the DBADMIN has specified a default authentication method, the database authenticates the user using that default method.

5. If you have not specified a default authentication method, the database checks to see if the DBADMIN user has defined any authentication methods. If not, no authentication information exists in the database. However, if a password exists, the DBADMIN user can log in.

6. If authentication information exists, Vertica rejects the user request to connect to the database. The DBADMIN has not granted an authentication method for that user nor has the DBADMIN defined a default authentication method for all users ('public').

7. If no authentication records exist in the database, Vertica uses implicit trust/implicit password to authenticate the user.

The following image illustrates the steps involved in client authentication:
IPv4 and IPv6 for Client Authentication

Vertica supports clients using either the IPv4 or the IPv6 protocol to connect to the database server. Internal communication between database servers must consistently use
one address family (IPv4 or IPv6). The client, however, can connect to the database from either type of IP address.

If the client will be connecting from either IPv4 or IPv6, you must create two authentication methods, one for each address. Any authentication method that uses HOST authentication requires an IP address.

For example, the first statement allows users to connect from any IPv4 address. The second statement allows users to connect from any IPv6 address:

```sql
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '::/0'; --IPv6
```

If you are using a literal IPv6 address in a URL, you must enclose the IPv6 address in square brackets as shown in the following examples:

```sql
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb:dbfa:0:65::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[:]:';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]:5678';
```

If you are working with a multi-node cluster, any IP/netmask settings in (HOST, HOST TLS, HOST NO TLS) must match all nodes in the cluster. This setup allows the database owner to authenticate with and administer every node in the cluster. For example, specifying 10.10.0.8/30 allows a CIDR address range of 10.10.0.8–10.10.0.11.

For detailed information about IPv6 addresses, see RFC 1924 and RFC 2732.

**Supported Client Authentication Methods**

Vertica supports the following types of authentication to prove a client’s identity.

- **Trust**—Authorizes any user that connects to the database using a valid user name, no password is required and authentication is not performed.
- **Reject**—Rejects the connection attempt when a user with an invalid user name attempts to connect to the database.
- **Kerberos (GSS)**—Authorizes connecting to the database using a MIT Kerberos implementation. The KDC must support Kerberos 5 using GSS-API. This API also provides compatibility with non-MIT Kerberos implementations, such as Java and Windows clients.
• Hash—Sends encrypted passwords hashed by the MD5 algorithm or the more secure SHA-512 method over the network. The server provides the client with salt.

• LDAP—Works like password authentication except the LDAP method authenticates the client against a Lightweight Directory Access Protocol or Active Directory server.
• Ident—Authenticates the client against the username in an Ident server.
• TLS authentication—Authenticates the client using digital certificates that contain a public key. Transport Layer Security (TLS) is the successor to Secure Sockets Layer (SSL) authentication.

Local and Host Authentication

You can define a client authentication method as:

• Local: Local connection to the database.
• Host: Remote connection to the database from different hosts, each with their own IPv4 or IPv6 address and host parameters. For more information see IPv4 and IPv6 for Client Authentication above.

Some authentication methods cannot be designated as local, as listed in this table:

<table>
<thead>
<tr>
<th>Authentication Method</th>
<th>Local?</th>
<th>Host?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kerberos (GSS)</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Ident</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>LDAP</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Hash</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Reject</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Trust</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Authentication for Chained Users and Roles

Vertica supports creating chained users and roles, where you can grant ROLE2 privileges to ROLE1. All users in ROLE1 use the same authentication assigned to ROLE2. For example:

```sql
=> CREATE USER user1;
=> CREATE ROLE role1;
=> CREATE ROLE role2;
=> CREATE AUTHENTICATION h1 method 'hash' local;
=> GRANT AUTHENTICATION h1 to role2;
=> GRANT role2 to role1;
=> GRANT role1 to user1;
```

The user and role chain in the example above can be illustrated as follows:

auth1 -> role2 -> role1 -> user1

In this example, since role2 privileges are granted to role1 you only need to grant authentication to role2 to also enable it for role1.

### dbadmin Authentication Access

The dbadmin user must have access to the database at all times, and its authentication record should:

- Use one of the following authentication methods:
  - TRUST with a LOCAL access method
  - HASH
- Have a high priority (e.g. 10,000) so it supersedes other authentication records like PUBLIC.

### LOCAL TRUST

The following example creates an authentication record `v_dbadmin_trust` with a high priority and grants it to the dbadmin user. The combination of the TRUST method and LOCAL access method allow the dbadmin to authenticate to the database without a password if the connection is local:
### HASH

The following example creates an authentication record `v_dbadmin_hash` and grants it to the dbadmin user. The HASH method indicates that the dbadmin's password is hashed with the database's **SECURITY ALGORITHM**. The HOST `0.0.0.0/0` access method indicates that the dbadmin can connect remotely from any IPv4 address:

```sql
cREATE AUTHENTICATION v_dbadmin_hash METHOD 'hash' HOST '0.0.0.0/0';
ALTER AUTHENTICATION v_dbadmin_hash PRIORITY 10000;
GRANT AUTHENTICATION v_dbadmin_hash TO dbadmin;
```

If you want to authenticate as the dbadmin from a local connection, but want to use the authentication record with the HOST access method, specify the `--host` option with the hostname or IP address of the database:

```
$ vsql database_name user --host hostname_or_ip;
```

### Creating Authentication Records

You can manage client authentication records using vsql commands. To use these statements, you must be connected to the database.

> **Important:**
> You cannot modify client authentication records using the Administration Tools. The Administration Tools interface allows you to modify the contents of the `vertica.conf` file. However, Vertica ignores any client authentication information stored in that file.

You create authentication records with `CREATE AUTHENTICATION`, which Vertica stores in the catalog and automatically enables.

### Examples

The following examples show how to create authentication records.
Create authentication method `localpwd` to authenticate users who are trying to log in from a local host using a password:

```sql
=> CREATE AUTHENTICATION localpwd METHOD 'hash' LOCAL;
```

Create authentication method `v_ldap` that uses LDAP over TLS to authenticate users logging in from the host with the IPv4 address 10.0.0.0/23:

```sql
=> CREATE AUTHENTICATION v_ldap METHOD 'ldap' HOST TLS '10.0.0.0/23';
```

Create authentication method `v_kerberos` to authenticate users who are trying to connect from any host in the networks 2001:0db8:0001:12xx:

```sql
=> CREATE AUTHENTICATION v_kerberos METHOD 'gss' HOST '2001:db8:1::1200/56';
```

Create authentication method `RejectNoSSL` that rejects users from any IP address that are trying to authenticate without TLS:

```sql
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '::/0'; --IPv6
```

- Enabling and Disabling Authentication Methods
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

Modifying Authentication Records

To modify existing authentication records, you must first be connected to your database. The following examples show how to make changes to your authentication records. For more information see `ALTER AUTHENTICATION`.

Rename an Authentication Method

Rename the `v_kerberos` authentication method to K5, and enable it. All users who have been associated with the `v_kerberos` authentication method are now associated with the
K5 method granted instead.

```sql
=> ALTER AUTHENTICATION v_kerberos RENAME TO K5 ENABLE;
```

## Specify a Priority for an Authentication Method

Specify a priority of 10 for K5 authentication:

```sql
=> ALTER AUTHENTICATION K5 PRIORITY 10;
```

For more information see Priorities for Client Authentication Methods.

## Change a Parameter

Set the `systemUsers` parameter for `ident1` authentication to `root`:

```sql
=> CREATE AUTHENTICATION ident1 METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION ident1 SET systemUsers='root';
```

Change the IP address and specify the parameters for an LDAP authentication method named `Ldap1`.

In this example, you specify the bind parameters for the LDAP server. Vertica connects to the LDAP server, which authenticates the Vertica client. If the authentication succeeds, Vertica authenticates any users who have been granted the `Ldap1` authentication method on the designated LDAP server:

```sql
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
  binddn_prefix='cn=', binddn_suffix=',dc=qa_domain,dc=com';
```

Change the IP address, and specify the parameters for an LDAP authentication method named `Ldap1`. Assume that Vertica does not have enough information to create the distinguished name (DN) for a user attempting to authenticate. Therefore, in this case, you must specify to use LDAP search and bind:

```sql
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';
```
ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177', basedn='dc=qa_domain,dc=com',binddn='cn=Manager,dc=qa_domain,dc=com',search_attribute='cn',bind_password='secret';

### Change the Associated Method

Change the `localpwd` authentication from trust to hash:

```sql
=> CREATE AUTHENTICATION localpwd METHOD 'trust' LOCAL;
=> ALTER AUTHENTICATION localpwd METHOD 'hash';
```

ALTER AUTHENTICATION validates the parameters you enter. If there are errors, it disables the authentication method that you are trying to modify.

### Using the Administration Tools

The advantages of using the Administration Tools are:

- You do not have to connect to the database
- The editor verifies that records are correctly formed
- The editor maintains records so they are available to you to edit later

**Note:**
You must restart the database to implement your changes.

For information about using the Administration Tools to create and edit authentication records, see [Creating Authentication Records](#).

### Using the Client Authentication Configuration Parameter

The advantage of using the ClientAuthentication configuration parameter is that the changes are implemented immediately across all nodes within the database cluster. You do not need to restart the database.
However, all the database nodes must be up and you must [connect to the database](#) before you set this parameter. Most importantly, this method does not verify that records are correctly formed and it does not maintain the records so you can modify them later.

New authentication records are appended to the list of existing authentication records. Because Vertica scans the list of records from top to bottom and uses the first record that matches the incoming connection, you might find your newly-added record does not have an effect if Vertica used an earlier record instead.

To configure client authentication through a connection parameter, use the ALTER DATABASE statement:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'connection type user name address method';
```

When you specify authentication records, make sure to adhere to the following guidelines:

- Fields that make up the record can be separated by white space or tabs
- Other than IP addresses and mask columns, field values cannot contain white space

**Examples**

The following example creates an authentication record for the trust method:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'hostnossl dbadmin 0.0.0.0/0 trust';
```

The following example creates an authentication record for the LDAP method:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'host all 10.0.0.0/8 ldap "ldap://summit.vertica.com;cn=,dc=vertica,dc=com"';
```

The following example specifies three authentication records. In a single command, separate each authentication record by a comma:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'hostnossl dbadmin 0.0.0.0/0 trust, hostnossl all 0.0.0.0/0 md5, local all trust';
```

**Deleting Authentication Records**

To delete client authentication record, use [DROP AUTHENTICATION](#). To use this approach, you have to be connected to your database.

To delete an authentication record for md5_auth use the following command:
To delete an authentication record for a method that has been granted to a user, use the CASCADE keyword:

```sql
=> DROP AUTHENTICATION md5_auth;
```

```sql
=> CREATE AUTHENTICATION localpwd METHOD 'password' LOCAL;
=> GRANT AUTHENTICATION localpwd TO jsmith;
=> DROP AUTHENTICATION localpwd CASCADE;
```

- Creating Authentication Records
- Granting and Revoking Authentication Methods

### Priorities for Client Authentication Methods

You can associate one or more authentication methods to a connection or user. For a user who has multiple authentication methods, specify the order in which Vertica should try them. To do so, assign a priority to each authentication method using `ALTER AUTHENTICATION`. All priority values should be a non-negative INTEGER.

Higher values indicate higher priorities. Vertica tries to authenticate a user with an authentication method in order of priority from highest to lowest. For example:

- A priority of 10 is higher than a priority of 5.
- A priority 0 is the lowest possible value.

**Important:**
Vertica does not support authentication chaining where you can configure multiple authentication modules to identify a specific user. For example, chaining to try a password authentication method after an LDAP authentication method failed is not supported.
Priority Order for Authentication Methods

When you associate multiple authentication methods with a connection, Vertica prioritizes them in the following order. For more information or to view the priority of your existing authentication methods, see CLIENT_AUTH:

1. Explicit priority set with ALTER AUTHENTICATION.
2. The priority of the authentication method itself. These are evaluated in the following order:
   1. Reject
   2. GSS, LDAP, Ident
   3. Hash
   4. Trust
3. The specificity of the netmask. Fewer zeros indicates greater specificity and therefore higher priority.

If there are two eligible methods with the same priority at one priority tier, Vertica evaluates the next priority tier to break the tie. For example: If GSS and Hash had the same explicit priority set with ALTER AUTHENTICATION, then Vertica would prioritize GSS, which, as a method, has an inherently higher authentication priority.

Authentication Attempts Using Multiple Methods

If there is only one authentication method associated with a user, Vertica uses that method to authenticate the login attempt.

If the administrator has associated multiple authentication methods with a given user or IP address, Vertica tries to authenticate as follows:

- If the highest priority authentication method is Ident and authentication fails, Vertica tries the next highest priority authentication method, regardless of what method it uses.

  If the next attempt does not use Ident authentication and fails, the authentication process ends. However, if the next attempt uses Ident and fails, Vertica continues to
the next highest priority method. This process continues until authentication is successful or a non-Ident authentication attempt fails.

- If the highest priority method is LDAP and authentication fails, Vertica searches for the next highest priority LDAP method. Authentication attempts continue until the authentication is successful, or there are no additional LDAP authentication methods that satisfy the connection criteria.

Note that if a user not found error occurs during LDAP authentication, the retry connection attempt initiates only if you set the `ldap_continue` parameter to yes.

- For all other authentication types, Vertica tries the highest priority authentication method associated with that user. If that authentication fails, the authentication process stops.

For example, suppose there are two client authentication methods associated with a user, as follows:

```
=> CREATE AUTHENTICATION auth_name1 METHOD 'hash' LOCAL;
=> GRANT AUTHENTICATION auth_name1 to user;
=> ALTER AUTHENTICATION auth_name1 PRIORITY 5;
=> CREATE AUTHENTICATION auth_name2 METHOD 'ident' LOCAL;
=> GRANT AUTHENTICATION auth_name2 to user;
=> ALTER AUTHENTICATION auth_name2 PRIORITY 10;
```

When user tries to connect to the database, Vertica first tries `auth_name2` to authenticate because it has a higher priority. If that fails, Vertica tries `auth_name1`. If that fails, authentication fails.

### Specifying Authentication Method Priority

To specify priorities for client authentication methods, use `ALTER AUTHENTICATION`. The priority value must be a non-negative INTEGER. Higher numbers indicate a higher priority. The default value, 0, is the lowest possible priority.

The syntax is:

```
ALTER AUTHENTICATION <name> ... PRIORITY <priority_value>;
```

If you do not specify a priority, or omit the `<priority_value>` when using `ALTER AUTHENTICATION`, Vertica sets the priority to 0.
DBADMIN and Authentication Priority

To allow the DBADMIN user to connect to the database at any time, Vertica recommends that you create an authentication method (LOCAL TRUST or LOCAL PASSWORD) with a very high priority, such as 10,000. Grant this method to the DBADMIN user, and set the priority using ALTER AUTHENTICATION.

With the high priority, this new authentication method supersedes any authentication methods you create for PUBLIC (which includes the DBADMIN user). Even if you make changes to PUBLIC authentication methods, the DBADMIN still has access.

Note:
For the DBADMIN user to be able to perform all Admintools functions, the DBADMIN must always be able to authenticate by LOCAL TRUST or LOCAL PASSWORD (the default for DBADMIN user). If you have changed DBADMIN user authentication from LOCAL TRUST or LOCAL PASSWORD, use the ALTER AUTHENTICATION statement to once again give the DBADMIN user LOCAL TRUST or LOCAL PASSWORD authentication.

Viewing Information About Client Authentication Records

For information about client authentication records that you have configured for your database, query the following system tables in the V_CATALOG schema:

- CLIENT_AUTH
- CLIENT_AUTH_PARAMS
- PASSWORD_AUDITOR
- USER_CLIENT_AUTH
To determine the details behind the client authentication used for a particular user session, query the following tables in the V_MONITOR schema:

- `SESSIONS`
- `USER_SESSIONS`

## Enabling and Disabling Authentication Methods

When you create an authentication method, Vertica stores it in the catalog and enables it automatically. To enable or disable an authentication method, use the `ALTER AUTHENTICATION` statement. To use this approach, you must be connected to your database.

If an authentication method has not been enabled, Vertica cannot use it to authenticate users and clients trying to connect to the database.

To enable an authentication method:

```
ALTER AUTHENTICATION v_kerberos ENABLE;
```

To disable this authentication method:

```
ALTER AUTHENTICATION v_kerberos DISABLE;
```

## See Also

- Creating Authentication Records
- Deleting Authentication Records
- Granting and Revoking Authentication Methods
- Modifying Authentication Records
Granting and Revoking Authentication Methods

Before Vertica can validate a user or client through an authentication method, you must first associate that authentication method with the user or role that requires it, with GRANT (Authentication). When that user or role no longer needs to connect to Vertica using that method, you can disassociate that authentication from that user with REVOKE AUTHENTICATION.

Grant Authentication Methods

You can grant an authentication method to a specific user or role. You can also specify the default authentication method by granting an authentication method to PUBLIC, as in the following examples.

- Associate v_ldap authentication with user jsmith:
  
  ```
  => GRANT AUTHENTICATION v_ldap TO jsmith;
  ```

- Associate v_gss authentication to the role DBprogrammer:
  
  ```
  => CREATE ROLE DBprogrammer;
  => GRANT AUTHENTICATION v_gss TO DBprogrammer;
  ```

- Associate client authentication method v_localpwd with role PUBLIC, which is assigned by default to all users:
  
  ```
  => GRANT AUTHENTICATION v_localpwd TO PUBLIC;
  ```

Revoke Authentication Methods

If you no longer want to authenticate a user or client with a given authentication method, use the REVOKE (Authentication) statement as in the following examples.

- Revoke v_ldap authentication from user jsmith:
  
  ```
  => REVOKE AUTHENTICATION v_ldap FROM jsmith;
  ```
• Revoke `v_gss` authentication from the role `DBprogrammer`:

```sql
=> REVOKE AUTHENTICATION v_gss FROM DBprogrammer;
```

• Revoke `localpwd` as the default client authentication method:

```sql
=> REVOKE AUTHENTICATION localpwd FROM PUBLIC;
```

## Hash Authentication

Vertica provides a hash authentication method that allows you to use the MD5 algorithm or the more secure algorithm, SHA-512, to store user passwords. SHA-512 is one of the industry-standard SHA-2 family of hash algorithms that address weaknesses in SHA-1 and MD5. For information on creating passwords to be hashed during authentication see [Passwords](#).

**Note:**
Vertica strongly recommends that you use SHA-512 for hash authentication because it is more secure than MD5.

Before you perform hash authentication, review the following topics:

- **Hash Authentication Parameters**—Describes the two hash authentication parameters that specify which hashing algorithm to use.
- **Upgrade Considerations for Hash Authentication**—Before you implement the SHA-512 algorithm for one or more users, you must be aware of several issues. For details, review this topic before proceeding.
- **How to Configure Hash Authentication**—After you decide to implement hash authentication in your database, follow the steps described in this topic.

## Hash Authentication Parameters

Two parameters control which algorithm hash authentication uses for hashing and storing user passwords:
• A user-level parameter, Security_Algorithm:

```sql
=> ALTER USER username SECURITY_ALGORITHM 'MD5' IDENTIFIED BY 'newpassword';
=> ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
```

• A system-level configuration parameter, SecurityAlgorithm:

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER SecurityAlgorithm = 'MD5';
=> ALTER DATABASE DEFAULT SET PARAMETER SecurityAlgorithm = 'SHA512';
```

Both parameters can have the following values:

- NONE
- MD5
- SHA512

**Note:**
If your current password is in the MD5 format you cannot rename a user with `ALTER USER`.

The user-level parameter usually has precedence over the system-level parameter. However, if the user-level parameter is NONE, Vertica hashes passwords with the algorithm assigned to the system-level parameter value. If both parameters are NONE, Vertica uses the MD5 algorithm.

These values, which are stored in system table `PASSWORD_AUDITOR`, affect the security algorithm that is actually used for hash authentication.

<table>
<thead>
<tr>
<th>Parameter value</th>
<th>Authentication algorithm</th>

<td>MD5</td>
</tr>
</tbody>
</table>
## How to Configure Hash Authentication

Follow these steps to configure hash authentication:

1. Create an authentication method that is based on hash encryption. When you create an authentication method, it is automatically enabled for use.

   The following example shows how to create an authentication method `v_hash` for users logging in from the IP address 10.0.0.0/0.

   ```
   => CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '10.0.0.0/0';
   ```

   If users are trying to connect from an IPv6 address, the statement might look like this example:

   ```
   => CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '2001:db8:ab::123/128';
   ```

2. Decide which password-hashing algorithm you want to use: MD5 or the more secure SHA-512.

3. Specify the security algorithm as follows:
   - At the system level, set the `SecurityAlgorithm` configuration parameter. This setting applies to all users, unless their user-level security is set to another value:
ALTER DATABASE DEFAULT SET SecurityAlgorithm = 'MD5';
ALTER DATABASE DEFAULT SET SecurityAlgorithm = 'SHA512';

If you want users to inherit the system-level security, set their passwords to expire immediately. Users must change their passwords before they log in again. Alternatively, you can ask users to change their passwords. Vertica hashes all new passwords using the system-level security algorithm.

- At the user level, use ALTER USER to set the Security_Algorithm user parameter. Changing this parameter at the user level overrides the system-level value:

  => ALTER USER username SECURITY_ALGORITHM 'MD5' IDENTIFIED BY 'newpassword';
  => ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';

4. Associate the v_hash authentication method with the desired users or user roles, using a GRANT statement:

  => GRANT AUTHENTICATION v_hash to user1, user2, ...;

For more information about how these parameters work, see Hash Authentication Parameters.

Upgrade Considerations for Hash Authentication

For Vertica releases before 7.1, MD5 is the only algorithm used for hashing passwords. In Vertica 7.1, you can use either the MD5 algorithm or the more secure SHA-512 algorithm. Before you upgrade, you must consider the following behaviors to avoid problems.

Upgrade the Client and Server

To implement the more secure SHA-512 algorithm for hashing passwords, you must upgrade BOTH the client and the server to Vertica 7.1 or higher. If you upgrade the server but not the client and specify that one or more users store their passwords using SHA-512, the client does not understand hashing with SHA-512. When it sends a message to the server, the server returns an error.
Change Existing Users to SHA-512 Hash Algorithm

When you upgrade from a pre-7.1 database, the user-level parameter Security_Algorithm, is set to 'NONE'. This allows all existing users to continue connecting to the Vertica server and their passwords are hashed using MD5.

If you want one or more users to use the SHA-512 algorithm, set the system-level parameter Security Algorithm to 'SHA512' and change the user passwords.

Use one of three methods to change the user password:

- Manually set the user’s user-level security algorithm to 'SHA512'. Then, change the user’s password, as in the following statement:

  ```sql
  => ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
  ```

- Set the user's password to expire immediately as in the following statement. After the password expires, the user responds by changing it.

  ```sql
  => ALTER USER username PASSWORD EXPIRE;
  ```

- Ask the user to change the password.

All new passwords inherit the system-level security algorithm, which is SHA-512.

Passwords

Assign a password to a user to allow that user to connect to the database using password authentication. When the user supplies the correct password a connection to the database occurs.

Vertica stores passwords in an encrypted format to prevent potential theft. However, the transmission of the password to Vertica is in plain text. Thus, it is possible for a "man-in-the-middle" attack to intercept the password.

Implementing Hash Authentication ensures secure login using passwords.
About Password Creation and Modification

You must be a superuser to create passwords for user accounts using the CREATE USER statement. A superuser can set any user account's password.

- To add a password, use the ALTER USER statement.
- To change a password, use ALTER USER or the vsq1 meta-command \password.

Users can also change their own passwords.

To make password authentication more effective, Vertica recommends that you enforce password policies that control how often users are forced to change passwords and the required content of a password. You set these policies using Profiles.

Default Password Authentication

When you have not specified any authentication methods, Vertica defaults to using password authentication for user accounts that have passwords.

If you create authentication methods, even for remote hosts, password authentication is disabled. In such cases, you must explicitly enable password authentication. The following commands create the local_pwd authentication method and make it the default for all users. When you create an authentication method, Vertica enables it automatically:

```sql
=> CREATE AUTHENTICATION local_pwd METHOD hash' LOCAL;
=> GRANT AUTHENTICATION local_pwd To Public;
```

Profiles

You can set password policies for users by assigning them profiles. You can create multiple profiles to manage the password policies for several categories of users. For example, you might create one profile for interactive users, requiring them to frequently change their passwords. You might create another profile for user accounts that are not required to change passwords.
Defining Profiles

You create profiles with `CREATE PROFILE` statement, and change existing profiles with `ALTER PROFILE`. Both statements let you set one or more profile parameters.

Each profile can specify one or more of the following policies:

- How often users must change their passwords.
- How many times users must change their passwords before they can reuse an old password.
- How many times a user can fail to log in before the account is locked.
- The required length and content of the password:
  - Maximum and minimum number of characters
  - Minimum number of capital letters, lowercase letters, digits, and symbols required in a password.

Assigning Profiles

After you define a profile, you can assign it to new and existing users with `CREATE USER` and `ALTER USER`, respectively.

Changes to profile policies for password content—for example, `PASSWORD_MAX_LENGTH` and `PASSWORD_MIN_SYMBOLS`—affect users only when they change their passwords. Vertica does not test existing passwords to verify that they comply with new password requirements. To enforce immediate compliance with new profile requirements, use `ALTER USER...PASSWORD_EXPIRE` to force immediate expiration of the user's current password. On the user's next login, Vertica prompts this user to supply a new password, which must comply with the new policy.

Default Profile

Each database contains a DEFAULT profile. Vertica assigns the default profile to users who are not explicitly assigned a profile. The default profile also sets parameters of non-default profiles in two cases:

- Profile parameters that are not explicitly set by `CREATE PROFILE`
- Parameters that `ALTER PROFILE` sets to DEFAULT
All parameters in the default profile are initially set to unlimited. You can use ALTER PROFILE to change these settings. For example, the following statement modifies the default profile parameter PASSWORD_MIN_SYMBOLS. The change requires passwords to contain at least one symbol, such as $, #, @. This change affects all profiles where PASSWORD_MIN_SYMBOLS is set to default:

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_MIN_SYMBOLS 1;
```

Profile Settings and Client Authentication

The following profile settings affect client authentication methods, such as LDAP or GSS:

- FAILED_LOGIN_ATTEMPTS
- PASSWORD_LOCK_TIME

All other profile settings are used only by Vertica to manage its passwords.

- PROFILES
- Creating a Database Name and Password

Password Guidelines

For passwords to be effective, they must be hard to guess. You need to protect passwords from:

- Dictionary-style, brute-force attacks
- Users who have knowledge of the password holder (family names, birth dates, etc.)

Use Profiles to enforce good password practices (password length and required content). Make sure database users know the password guidelines, and encourage them not to use personal information in their passwords.

For guidelines on creating strong passwords go to Microsoft Tips for Creating a Strong Password.
See Also

- Creating a Database Name and Password

**Password Expiration**

User profiles control how often users must change their passwords. Initially, the DEFAULT profile is set so that passwords never expire.

**Important:**
Password expiration has no effect on any of the user's current sessions.

**Set Password Expiration and Grace Period**

You can change the default value to set a password expiration. Alternatively, you can create additional profiles that set time limits for passwords and assign users to them.

When a password expires, the user must change the password on the next login. However, you can set a PASSWORD_GRACE_TIME in any individual user's profile, allowing that user to log in after the expiration. After the password expires, Vertica issues a warning about the password expiration but continues to recognize the password.

After the grace period ends, users must change their passwords to log in, unless they have changed them already in response to the warning.

**Expire a Password**

You can expire a user's password immediately using the ALTER USER statement's PASSWORD EXPIRE parameter. By expiring a password, you can:

- Force users to comply with a change to password policy.
- Set a new password when a user forgets the old password.
**Account Locking**

In a profile, you can set a password policy for how many consecutive failed login attempts a user account is allowed before locking. This locking mechanism helps prevent dictionary-style brute-force attempts to guess users' passwords.
Set Account Locking

Set this value using the FAILED_LOGIN_ATTEMPTS parameter using the CREATE PROFILE or ALTER PROFILE statement.

Vertica locks any user account that has more consecutive failed login attempts than the value to which you set FAILED_LOGIN_ATTEMPTS. The user cannot log in to a locked account, even by supplying the correct password.

Unlock a Locked Account

You can unlock accounts in one of two ways, depending on your privileges.

- **Manually**: If you are a superuser, you can manually unlock the account using the ALTER USER command.

  **Note:**
  
  A superuser account cannot be locked, because it is the only user that can unlock accounts. For this reason, choose a very secure password for a superuser account. See Password Guidelines for suggestions.

- **Password Lock Time Setting**: Specify the number of days until an account unlocks in the PASSWORD_LOCK_TIME parameter of the user's profile. Vertica automatically unlocks the account after the specified number of days has passed. If you set this parameter to UNLIMITED, the user’s account is never automatically unlocked, and a superuser must manually unlock it.

Ident Authentication

The Ident protocol, defined in RFC 1413, authenticates a database user with a system user name. To see if that system user can log in without specifying a password, you configure Vertica client authentication to query an Ident server. With this feature, the DBADMIN user can run automated scripts to execute tasks on the Vertica server.

**Caution:**

Ident responses can be easily spoofed by untrusted servers. Use Ident authentication only on local connections, where the Ident server is installed on the same computer as the Vertica database server.
Following the instructions in these topics to install, set up, and configure Ident authentication for your database:

- Installing and Setting Up an Ident Server
- Configuring Ident Authentication for Database Users

**Examples**

The following examples show several ways to configure Ident authentication.

Allow `system_user1` to connect to the database as Vertica `vuser1`:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
=> GRANT AUTHENTICATION v_ident to vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Allow `system_user1`, `system_user2`, and `system_user3` to connect to the database as `vuser1`. Use colons (:) to separate the user names:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
=> GRANT AUTHENTICATION v_ident TO vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Associate the authentication with Public using a GRANT AUTHENTICATION statement. The users, `system_user1`, `system_user2`, and `system_user3` can now connect to the database as any database user:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
=> GRANT AUTHENTICATION v_ident to Public;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Set the `system_users` parameter to `*` to allow any system user to connect to the database as `vuser1`:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='*';
=> GRANT AUTHENTICATION v_ident to vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Using a GRANT statement, associate the `v_ident` authentication with Public to allow `system_user1` to log into the database as any database user:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
```
GRANT AUTHENTICATION v_ident to Public;
=> ALTER AUTHENTICATION v_ident ENABLE;

Installing and Setting Up an Ident Server

To use Ident authentication, you must install one or more packages, depending on your operating system, and enable the Ident server on your Vertica server. oidentd is an Ident daemon that is compatible with Vertica and compliant with RFC 1413.

Note: You can find the source code and installation instructions for oidentd at the oidentd website.

To install and configure Ident authentication for use with your Vertica database, follow the appropriate steps for your operating system:

Red Hat 6.x/CentOS 6.x

Install oidentd on Red Hat 6.x or CentOS 6.x by running this command:

$ yum install oidentd

Depending on your configuration, you might receive the following error message:

No package oidentd available.

In this case, you must install the Red Hat/CentOS Extras Repository. Download and install the Extras Repository from the following location:

Red Hat 7.x/CentOS 7.x

Install an Ident server on Red Hat 7.x or CentOS 7.x by installing the authd and xinetd packages:

$ yum install authd
$ yum install xinetd
**Ubuntu/Debian**

Install oidentd on Ubuntu or Debian by running this command:

```
$ sudo apt-get install oidentd
```

**SUSE Linux Enterprise Server**

Install the pidentd and xinetd RPMs from the following locations:

**Post-Installation Steps for Red Hat 6.x/CentOS 6.x and Ubuntu/Debian**

After you install oidentd on your Red Hat 6.x/CentOS 6.x or Ubuntu/Debian system, continue with the following steps:

1. Verify that the Ident server accepts IPv6 connections to prevent authentication failure. To do so, you must enable this capability. In the script `/etc/init.d/oidentd`, change the line from:

   ```
   exec="/usr/sbin/oidentd"
   ```

   to

   ```
   exec="/usr/sbin/oidentd -a ::"
   ```

   Then, at the Linux prompt, start oidentd with `-a ::`.

2. Restart the server with the following command:

   ```
   $ /etc/init.d/oidentd restart
   ```
Post-Installation Steps for Red Hat 7.x/CentOS 7.x and SUSE Linux Enterprise Server

After you install the required packages on your Red Hat 7.x/CentOS 7.x or SUSE Linux Enterprise Server system, continue with the following steps:

1. Enable the auth service in the configuration file located at the following location: /etc/xinet.d/auth.
   
   Enter no for the disable option, as this sample configuration file shows.

   ```
   service auth {
       disable = no
       socket_type = stream
       wait = no
       user = ident
       cps = 4096 10
       instances = UNLIMITED
       server = /usr/sbin/in.authd
       server_args = -t60 --xerror --os
   }
   ```

2. Restart the xinetd service with the following command:

   ```
   $ service xinetd restart
   ```

Configuring Ident Authentication for Database Users

To configure Ident authentication, take the following steps:

1. Create an authentication method that uses Ident.

   The Ident server must be installed on the same computer as your database, so specify the keyword LOCAL. Vertica requires that the Ident server and database always be on the same computer as the database.

   ```
   => CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
   ```
2. Set the Ident authentication parameters, specifying the system users who should be allowed to connect to your database.

```sql
> ALTER AUTHENTICATION v_ident SET system_users='user1:user2:user3';
```

3. Associate the authentication method with the Vertica user. Use a GRANT statement that allows the system user user1 to log in using Ident authentication:

```sql
> GRANT AUTHENTICATION v_ident TO user1;
```

**Kerberos Authentication**

Kerberos authentication uses the following components to perform user authentication.

**Client Package**

The Kerberos 5 client package communicates with the KDC server. This package is not included as part of the Vertica Analytics Platform installation. Kerberos software is built into Microsoft Windows. If you are using another operating system, you must obtain and install the client package.

If you do not already have the Kerberos 5 client package on your system, download it from the [MIT Kerberos Distribution page](https://kerberos.mit.edu/distribution/). Install the package on each Vertica server and client used in Kerberos authentication, except the KDC itself.

Refer to the [Kerberos documentation](https://kerberos.mit.edu/) for installation instructions.

**Service Principals**

A service principal consists of a host name, a service name, and a realm to which a set of credentials gets assigned (service/hostname@REALM). These credentials connect to the service, which is a host that you connect to over your network and authenticate using the KDC.

See [Specify KDC Information and Configure Realms](#) to create the realm name. The host name must match the value supplied by the operating system. Typically this is the fully qualified host name. If the host name part of your principal does not match the value supplied by the operating system, Kerberos authentication fails.
Some systems use a hosts file (/etc/hosts or /etc/hostnames) to define host names. A hosts file can define more than one name for a host. The operating system supplies the first entry, so use that in your principal. For example, if your hosts file contains:

```
192.168.1.101 v_vmart_node0001.example.com v_vmart_node0001
```

then use `v_vmart_node0001.example.com` as the hostname value.

**Note:** Depending on your configuration it may be safer to use the fully qualified domain name rather than the hostname.

Configure the following as Kerberos principals:

- Each client (users or applications that connects to Vertica)
- The Vertica server

See the following topics for more information:

- [Configure Vertica for Kerberos Authentication](#)
- [Configure Clients for Kerberos Authentication](#)

## Keytab Files

Principals are stored in encrypted keytab files. The keytab file contains the credentials for the Vertica principal. The keytab allows the Vertica server to authenticate itself to the KDC. You need the keytab so that Vertica Analytic Database does not have to prompt for a password.

Create one service principal for each node in your cluster. You can then either create individual keytab files (one for each node containing only that node's principal) or create one keytab file containing all the principals.

- **Create one keytab file with all principals** to simplify setup: all nodes have the same file, making initial setup easier. If you add nodes later you either update (and redistribute) the global keytab file or make separate keytabs for the new nodes. If a principal is compromised it is compromised on all nodes where it is present in a keytab file.
- **Create separate keytab files on each node** to simplify maintenance. Initial setup is more involved as you must create a different file on each node, but no principals are shared across nodes. If you add nodes later you create keytabs on the new nodes. Each node's keytab contains only one principal, the one to use for that node.
Ticket-Granting Ticket

The Ticket-Granting Ticket (TGT) retrieves service tickets that authenticates users to servers in the domain. Future login requests use the cached HTTP Service Ticket for authentication, unless it has expired as set in the ticket_lifetime parameter in krb5.conf.

Multi-realm Support

Vertica provides multi-realm support for Kerberos authentication using the SET param=value parameter in ALTER AUTHENTICATION with REALM as the parameter:

```sql
=> ALTER AUTHENTICATION krb_auth_users set REALM='USERS.COM';
=> ALTER AUTHENTICATION krb_auth_realmad set REALM='REALM_AD.COM';
```

This allows you to assign a different realm so that users from another realm can authenticate to Vertica.

Multi-realm support applies to GSS authentication types only. You can have one realm per authentication method. If you have multiple authentication methods, each can have its own realm:

```
=> SELECT * FROM client_auth;
auth_oid | auth_name | is_auth_enabled | auth_host_type | auth_host_address | auth_method | auth_parameters | auth_priority
-------- | --------- | --------------- | -------------- | ----------------- | ----------- | --------------- | --------------
45035996  | krb001    | True            | HOST           | 0.0.0.0/0         | GSS         |                 |                
realm=USERS.COM | 0
45035997  | user_auth | True            | LOCAL          |                  | TRUST       |                 |                
| 1000
45035737  | krb002    | True            | HOST           | 0.0.0.0/0         | GSS         |                 |                
realm=REALM_AD.COM | 1
```

Configure Vertica for Kerberos Authentication

Kerberos provides a strong cryptographic authentication against the devices which lets the client & servers to communicate in a more secured manner. It addresses network security problems.
Your system must have one or more Kerberos Key Distribution Centers (KDC) installed and configured. The KDCs must be accessible from every node in your Vertica Analytic Database cluster.

The KDC must support Kerberos 5 using GSS-API. For details, see the [MIT Kerberos Distribution Page](https://kerberos.mit.edu/).

**In This Section**

**Create the Vertica Principals and Keytabs on Linux KDC**

Vertica uses service principals for system-level operations. These principals identify the Vertica service and are used as follows:

- Kerberized Vertica clients request access to this service when they authenticate to the database.
- System processes like the Tuple Mover use this identity when they authenticate to external services such as Hadoop.

Create principals and keys as follows:

1. Start the Kerberos 5 database administration utility (`kadmin` or `kadmin.local`) to create Vertica principals on a Linux KDC.
   - Use `kadmin` if you are accessing the KDC on a remote server. If you have access to the Kerberos administrator password, you can use `kadmin` on any machine where the Kerberos 5 client package is installed. When you start `kadmin`, the utility prompts you for the Kerberos administrator's password. You might need root privileges on the client to run `kadmin`.
   - Use `kadmin.local` if:
     - The KDC is on the machine that you are logging into.
     - You have root privileges on that server.
   `kadmin.local` does not require the administrators login credentials.

   For more information about the `kadmin` and `kadmin.local` commands, see the [kadmin documentation](https://kerberos.mit.edu/).

2. Create one service principal for Vertica on each node. The host name must match the value supplied by the operating system. The following example creates the service principal `vertica` for the node named `v_vmart_node001.example.com`:
Repeat the `ktadd` command once per principal. You can create separate keytabs for each principal user or add them all to a single keytab file (such as `krb5.keytab`). If you are using a single file, see the documentation for the `-glob` option in the MIT Kerberos documentation.

You must have a user principal for each Vertica Analytic Database user that uses Kerberos Authentication. For example:

```bash
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal vertica/v_vmart_node0001.example.com
```

3. Copy each keytab file to the `/etc` folder on the corresponding cluster node. Use the same path and file name on all nodes.

4. On each node, make the keytab file readable by the file owner who is running the database process (typically, the Linux dbadmin user). For example, you can change ownership of the files to dbadmin as follows:

```bash
$ sudo chown dbadmin *.keytab
```

**Important:**

In a production environment, you must control who can access the keytab file to prevent unauthorized users from delegating your server. For more information about delegation (also known as impersonation), see Technet.Microsoft.com.

After you create a keytab file, you can use the `klist` command to view keys stored in the file:

```bash
$ sudo /usr/kerberos/bin/klist -ke -t
Keytab name: FILE:/etc/krb5.keytab
KVNO  Timestamp       Principal
------- ---------------------------------------------------------------
        08/15/2017 7:35:41 vertica/v_vmart_node0001.example.com@EXAMPLE.COM (aes256-cts-hmac-sha1-96)
        08/15/2017 7:35:41 vertica/v_vmart_node0001.example.com@EXAMPLE.COM (aes128-cts-hmac-sha1-96)
```

5. On Vertica run the following to ensure the Kerberos parameters are set correctly:

```sql
=> select parameter_name, current_value from configuration_parameters where parameter_name like 'Ker%';
```

<table>
<thead>
<tr>
<th>parameter_name</th>
<th>current_value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Vertica Analytic Database (9.3.x)  Page 4358 of 6246
6. Ensure that all clients use the gss authentication method.

From Vertica:

```
=> CREATE USER bob;
CREATE USER

=> CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
CREATE AUTHENTICATION

=> ALTER AUTHENTICATION v_kerberos enable;
ALTER AUTHENTICATION

=> GRANT AUTHENTICATION v_kerberos to bob;
GRANT AUTHENTICATION
```

From the operating system command line:

```
$ kinit bob

$ vsql -U bob -k vertica -K v_vmart_node0001.example.com -h v_vmart_node0001 -c "select client_authentication_name, authentication_method from sessions;"

<table>
<thead>
<tr>
<th>client_authentication_name</th>
<th>authentication_method</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_kerberos</td>
<td>GSS-Kerberos</td>
</tr>
</tbody>
</table>
```

7. On Vertica, run `KERBEROS_CONFIG_CHECK` to verify the Kerberos configuration.

`KERBEROS_CONFIG_CHECK` verifies the following:

- The existence of the kinit and kb5.conf files.
- Whether the keytab file exists and is set
- The Kerberos configuration parameters set in the database:
  - KerberosServiceName
  - KerberosHostname
  - KerberosRealm
  - Vertica Principal
- That Kerberos can read the Vertica keys
- That Kerberos can get the tickets for the Vertica principal
- That Vertica can initialize the keys with kinit
Specify KDC Information and Configure Realms

Each client and Vertica Analytic Database server in the Kerberos realm must have a valid, identically configured Kerberos configuration (krb5.conf) file. Without this file, the client does not know how to reach the KDC.

If you use Microsoft Active Directory, you do not need to perform this step. Refer to the Kerberos documentation for your platform for more information about the Kerberos configuration file on Active Directory.

At a minimum, you must configure the following sections in the krb5.conf file.

- [libdefaults]—Settings used by the Kerberos 5 library
- [realms]—Realm-specific contact information and settings
- [domain_realm]—Maps server hostnames to Kerberos realms

See the Kerberos documentation for information about other sections in this configuration file.

You must update the /etc/krb5.conf file to reflect your site's Kerberos configuration. The simplest way to enforce consistency among all clients and servers in the Kerberos realm is to copy the /etc/krb5.conf file from the KDC. Then, place this file in the /etc directory on each Vertica cluster node.

Inform Vertica About the Kerberos Principal

Follow these steps to inform Vertica about the principal name and keytab location.

For information about the parameters that you are setting in this procedure, see Kerberos Configuration Parameters.

1. Log in to the database as an administrator (typically dbadmin).
2. Set the KerberosKeyTabFile configuration parameter to point to the location of the keytab file:

```
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosKeytabFile = '/etc/krb5.keytab';
```
The keytab file must be in the same location (/etc/krb5.keytab in this example) on all nodes.

3. Set the service name for the Vertica principal; for example, vertica:

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosServiceName = 'vertica';
```

4. Provide the realm portion of the principal, for example, EXAMPLE.COM:

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosRealm = 'EXAMPLE.COM'
```

**Configure the Authentication Method for All Clients**

To make sure that all clients use the gss authentication method, run the following statements:

```sql
=> CREATE AUTHENTICATION <method_name> METHOD 'gss' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION <method_name> TO Public;
```

For more information, see [Implementing Client Authentication](#).

**Creating the Principals and Keytab on Active Directory**

Active Directory stores information about members of the Windows domain, including users and hosts.

Vertica uses the Kerberos protocol to access this information in order to authenticate Windows users to the Vertica database. The Kerberos protocol uses principals to identify users and keytab files to store their cryptographic information. You need to install the keytab files into Vertica to enable the Vertica database to cryptographically authenticate windows users.

This procedure describes:

- Creating a Vertica service principal.
- Exporting the keytab files for these principals
- Installing the keytab files in the Vertica database. This allows Vertica to authenticate Windows users and grant them access to the Vertica database.

1. Create a Windows account (principal) for the Vertica service and one Vertica host for each node/host in the cluster. This procedure creates Windows accounts for host
verticanode01 and service vertica running on this node.

When you create these accounts, select the following:

- User cannot change password
- Password never expires

**Note:**
You can deselect **Password never expires**. However, if you change these user passwords, you must recreate the keytab files and reinstall them into Vertica. This includes repeating the entire procedure.

2. If you are using external tables on HDFS that are secured by Kerberos authentication, you **must** enable Delegation. To do so, access the Active Directory Users and Computers dialog, right-click the Windows account (principal) for the Vertica service, and select Delegation. Trust this user for delegation to any service.

3. Run the following command to create the keytab for the host verticanode01.dc.com node/host:

```
$ ktpass -out ./host.verticanode01.dc.com.keytab -princ host/verticanode01.dc.com@DC.COM -mapuser verticanode01 -mapop set -pass secret -ptype KRB5_NT_SRV_HST
```

4. Run the following command to create the keytab for the vertica service:

```
$ ktpass -out ./vertica.verticanode01.dc.com.keytab -princ vertica/verticanode01.dc.com@DC.COM -mapuser vertica -mapop set -pass secret -ptype KRB5_NT_PRINCIPAL
```

For more information about keytab files, see [Technet.Microsoft.com](https://technet.microsoft.com).

5. Run the following commands to verify that the service principal name is mapped correctly. You must run these commands for each node in your cluster:

```
$ setspn -L vertica
Registered ServicePrincipalNamefor CN=vertica,CN=Users,DC=dc,DC=com
vertica/verticanode01.dc.com

$ setspn -L verticanode01
Registered ServicePrincipalNamefor CN=verticanode01,CN=Users,DC=dc,DC=com
host/verticanode01.dc.com
```

7. Combine the keytab files into a single keytab:
This creates a single keytab file that contains the server principal for authentication.

8. Copy the new keytab file to the catalog directory. For example:

```
$ cp verticanode01.dc.com.keytab /home/dbadmin/VMart/v_vmart_nodennnnn_catalog
```

9. Test the keytab file’s ability to retrieve a ticket to ensure it works from the Vertica node:

```
$ kinit vertica/verticanode01.dc.com -k -t verticanode01.dc.com.keytab
$ klist
Ticket cache: KFILE:/tmp/krb_cache_1003
Default principal: vertica/verticanode01.dc.com@DC.COM
Valid starting Expires Service principal
04/08/2017 13:35:25 04/08/2017 23:35:25 krbtgt/DC.COM@DC.COM
renew until 04/15/2017 14:35:25
```

When the ticket expires or not automatically retrieved you need to manually run the kinit command. See Get the Kerberos Ticket and Authenticate Vertica.

10. Set the right permissions and ownership on the keytab files:

```
$ chmod 600 verticanode01.dc.com.keytab
$ chown dbadmin:verticadba verticanode01.dc.com.keytab
```

11. Set the following Kerberos Configuration Parameters using ALTER DATABASE to inform Vertica about the Kerberos principal:

```
KerberosKeytabFile=<CATALOGDIR>/verticanode01.dc.com.keytab
KerberosRealm=DC.COM
KerberosServiceName=vertica
KerberosTicketDuration = 0
KerberosHostname=verticanode01.dc.com
```

12. Restart the Vertica server.

13. Test your Kerberos setup as follows to ensure that all clients use the gss authentication method.

```
From Vertica:
```
CREATE USER windowsuser1;
CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
ALTER AUTHENTICATION v_kerberos enable;
GRANT AUTHENTICATION v_kerberos to windowsuser1;

From the operating system command line:

$ kinit windowsuser1
$ vsql -U windowsuser1 -k vertica -K verticanode01.dc.com -h verticanode01.dc.com -c "select client_authentication_name, authentication_method from sessions;"

v_kerberos | GSS-Kerberos
(1 row)

14. Run KERBEROS_CONFIG_CHECK to verify the Kerberos configuration. KERBEROS_CONFIG_CHECK verifies the following:

- The existence of the kinit and kb5.conf files.
- Whether the keytab file exists and is set
- The Kerberos configuration parameters set in the database:
  - KerberosServiceName
  - KerberosHostname
  - KerberosRealm
  - Vertica Principal
- That Kerberos can read the Vertica keys
- That Kerberos can get the tickets for the Vertica principal
- That Vertica can initialize the keys with kinit

Get the Kerberos Ticket and Authenticate Vertica

If your organization uses Kerberos as part of the login process, Kerberos tickets are automatically retrieved upon login. Otherwise, you need to run kinit to retrieve the Kerberos ticket.

The following example shows how to retrieve the ticket and authenticate Vertica Analytic Database with the KDC using the kinit command. EXAMPLE.COM is the realm name. You
must use the realm name with your username to retrieve a Kerberos ticket. See Specify KDC Information and Configure Realms.

```bash
$ kinit
Password for principal_user@EXAMPLE.COM: kpasswd
```

You are prompted for the password of the principal user name created when you created the principals and keytabs (see Create the Vertica Principals and Keytabs on Linux KDC).

The Kerberos ticket gets cached for a pre-determined length of time. See Ticket Management in the Kerberos documentation for more information on setting expiration parameters.

Upon expiration, you need to run the `kinit` command again to retrieve another Kerberos ticket.

---

**Configure Clients for Kerberos Authentication**

Each supported platform has a different security framework. Thus, the steps required to configure and authenticate against Kerberos differ among clients.

On the server side, you construct the Vertica Kerberos service name principal using this format:

```
Kerberos_Service_Name/Kerberos_Host_Name@Kerberos_Realms
```

For each client, the GSS libraries require the following format for the Vertica service principal:

```
Kerberos_Service_Name@Kerberos_Host_Name
```

You can omit the realm portion of the principal because GSS libraries use the realm name of the configured default (`Kerberos_Realms`) realm.

For information about client connection strings, see the following topics in Connecting to Vertica:

- ODBC DSN Parameters
- JDBC Connection Properties
- ADO.NET Connection Properties
- (vsql) Command-Line Options
Note:
A few scenarios exist in which the Vertica server principal name might not match the host name in the connection string. See Troubleshooting Kerberos Authentication for more information.

In This Section

- Configure ODBC and vsql Clients on Non-Windows Platforms
- Configure ODBC and vsql Clients on Windows and ADO.NET
- Configure JDBC Clients on all Platforms

Configure ODBC and vsql Clients on Non-Windows Platforms

To configure an ODBC or vsql client on Linux or MAC OSX, you must first install the Kerberos 5 client package. See Configuring Kerberos Authentication.

After you install the Kerberos 5 client package, you must provide clients with a valid Kerberos configuration file (krb5.conf). To communicate with the KDC, each client participating in Kerberos authentication must have a valid, identically configured krb5.conf file. The default location for the Kerberos configuration file is /etc/krb5.conf.

Tip:
To enforce consistency among clients, Vertica Analytic Database, and the KDC, copy the /etc/krb5.conf file from the KDC to the client's/etc directory.

The Kerberos configuration (krb5.conf) file contains Kerberos-specific information, including:

- How to reach the KDC
- Default realm name
- Domain
- Path to log files
- DNS lookup
- Encryption types to use
- Ticket lifetime

The default location for the Kerberos configuration file is /etc/krb5.conf.

When configured properly, the client can authenticate with Kerberos and retrieve a ticket through the kinit utility (see Acquire an ODBC Authentication Request and Connection below). Likewise, the server can then use ktutil to store its credentials in a keytab file.
Authenticating ODBC and vsq1 Clients Requests and Connections on Non-Windows Platforms

ODBC and vsq1 use the client's ticket established by kinit to perform Kerberos authentication. These clients rely on the security library's default mechanisms to find the ticket file and the Kerberos configuration file.

To authenticate against Kerberos, call the kinit utility to obtain a ticket from the Kerberos KDC server. The following two examples show how to send the ticket request using ODBC and vsq1 clients.

Acquire an ODBC Authentication Request and Connection

a. On an ODBC client, acquire a ticket for the kuser user by calling the kinit utility.

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

b. Connect to Vertica, and provide the principals in the connection string:

```c
char outStr[100];
SQLLEN len;
SQLDriverConnect(handle, NULL, "Database=VMart;User=kuser;
Server=myserver.example.com;Port=5433;KerberosHostname=vcluster.example.com",
SQL_NTS, outStr, &len);
```

Acquire a vsq1 Authentication Request Connection

If the vsq1 client is on the same machine you are connecting to, vsq1 connects through a UNIX domain socket. This connection bypasses Kerberos authentication. When you authenticate with Kerberos, especially if the client authentication method is configured as 'local', you must include the -h hostname option. See Command Line Options in Connecting to Vertica.
a. On the vsql client, call the kinit utility:

```bash
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

b. Connect to Vertica, and provide the host and user principals in the connection string:

```bash
$. /vsql -K vcluster.example.com -h myserver.example.com -U kuser
Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit
```

In the future, when you log in to vsql as kuser, vsql uses your cached ticket without prompting you for a password.

**Verify the Authentication Method**

You can verify the authentication method by querying the SESSIONS system table:

```sql
=> SELECT authentication_method FROM sessions;
    authentication_method
--------------------------
      GSS-Kerberos
(1 row)
```

**See Also**

- Data Source Name (DSN) Connection Properties in Connecting to Vertica
- (vsql) Command-Line Options in Connecting to Vertica

**Configure ADO.NET, ODBC, and vsql Clients on Windows**

The Vertica client drivers support the Windows SSPI library for Kerberos authentication. Windows Kerberos configuration is stored in the registry.

You can choose between two different setup scenarios for Kerberos authentication on ODBC and vsql clients on Windows and ADO.NET:
Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica

Kerberos authentication on Windows is commonly used with Active Directory, Microsoft's enterprise directory service/Kerberos implementation. Typically your organization's network or IT administrator performs the setup.

Windows clients have Kerberos authentication built into the authentication process. You do not need any additional software.

Your login credentials authenticate you to the Kerberos server (KDC) when you:

- Log in to Windows from a client machine
- Use a Windows instance that has been configured to use Kerberos through Active Directory

To use Kerberos authentication on Windows clients, log in as REALM\user.

**Important:**
When you use the ADO.NET driver to connect to Vertica, you can optionally specify `IntegratedSecurity=true` in the connection string. This informs the driver to authenticate the calling user against the user's Windows credentials. As a result, you do not need to include a user name or password in the connection string. Any `user=<username>` entry to the connection string is ignored.

Linux KDC with Windows Built-in Kerberos Client and Vertica

A simple, but less common scenario is to configure Windows to authenticate against a non-Windows KDC. In this implementation, you use the `ksetup` utility to point the Windows operating system native Kerberos capabilities at a non-Active Directory KDC. By logging in to Windows, you obtain a ticket-granting ticket, similar to the Active Directory implementation. However, in this case, Windows is internally communicating with a Linux KDC. See the Microsoft Windows Server [Ksetup page](#) for more information.
When a database/windows user logs into their Windows machine (or after performing a kinit on Windows) the Kerberos ticket MUST have ok_as_delegate and forwardable flag set to be able to access webhdfs based external tables as follows:

```bash
$ CMD \> klist
#2>   Client: release @ VERTQA.LOCAL
   Server: vertica/vqatest108.verticacorp.com @ VERTQA.LOCAL
   KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
   Ticket Flags 0x40a50000 forwardable renewable pre_authent ok_as_delegate name_canonicalize
   End Time: 9/27/2017 20:34:45 (local)
   Renew Time: 10/3/2017 15:04:45 (local)
   Session Key Type: RSADSI RC4-HMAC(NT)
   Cache Flags: 0
   Kdc Called: ADKDC01
```

**Note:**
The Ticket Flags setting above must contain ok_as_delegate and forwardable entries. For information on these parameters see [Kerberos documentation](https://kerberos.org/).  

### Configure Windows Clients for Kerberos Authentication

Depending on which implementation you want to configure, refer to one of the following pages on the Microsoft Server website:

- To set up Windows clients with the ksetup utility, refer to the [Ksetup page](https://docs.microsoft.com/en-us/windows-server/identity/ad-ds/active-directory-krb5/kerberos-ksetup).

### Authenticate and Connect Clients

The KDC can authenticate both an ADO.NET and a vsql client.

**Note:**
Use the fully-qualified domain name as the server in your connection string; for example, use host.example.com instead of just host. That way, if the server moves location, you do not have to change your connection string.
Verify an ADO.NET Authentication Request and Connection

This example shows how to use the IntegratedSecurity=true, setting to specify that the ADO.NET driver authenticate the calling user's Windows credentials:

```csharp
VerticaConnection conn = new VerticaConnection("Database=VMart;Server=host.example.com; Port=5433;IntegratedSecurity=true; KerberosServiceName=vertica;KerberosHostname=vcluster.example.com");
conn.open();
```

Verify a vsq1 Authentication Request and Connection

1. Log in to your Windows client, for example, as EXAMPLE\kuser.
2. Run the vsq1 client and supply the connection string to Vertica:

```
C:\Users\kuser\Desktop>vsq1.exe -h host.example.com -K vcluster -U kuser
Welcome to vsq1, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsq1 commands
\g or terminate with semicolon to execute query
\q to quit
```

Configure JDBC Clients on All Platforms

Kerberos authentication on JDBC clients uses Java Authentication and Authorization Service (JAAS) to acquire the initial Kerberos credentials. JAAS is an API framework that hides platform-specific authentication details and provides a consistent interface for other applications.
You specify the client login process through the JAAS Login Configuration File. This file contains options that specify the authentication method and other settings to use for Kerberos. A class called the LoginModule defines valid options in the configuration file.

The JDBC client principal is crafted as `jdbc-username@server-from-connection-string`.

**Implement the LoginModule**

Vertica recommends that you use the JAAS public class `com.sun.security.auth.module.Krb5LoginModul` provided in the Java Runtime Environment (JRE).

The `Krb5LoginModule` authenticates users using Kerberos protocols and is implemented differently on non-Windows and Windows platforms:

- **On non-Windows platforms**: The `Krb5LoginModule` defers to a native Kerberos client implementation. Thus, you can use the same `/etc/krb5.conf` setup as you use to configure ODBC and vsq1 clients on Linux and MAC OSX platforms.

- **On Windows platforms**: The `Krb5LoginModule` uses a custom Kerberos client implementation bundled with the Java Runtime Environment (JRE). Windows settings are stored in a `%WINDIR%\krb5.ini` file, which has similar syntax and conventions to the non-Windows `krb5.conf` file. You can copy a `krb5.conf` from a non-Windows client to `%WINDIR%\krb5.ini`.

You can find documentation for the LoginModules in the `com.sun.security.auth` package, and on the [Krb5LoginModule] web page.

**Create the JAAS Login Configuration**

The `JAASConfigName` connection property identifies a specific configuration within a JAAS configuration that contains the `Krb5LoginModule` and its settings. The `JAASConfigName` setting lets multiple JDBC applications with different Kerberos settings coexist on a single host. The default configuration name is `verticajdbc`.

> **Important:**
> Carefully construct the JAAS login configuration file. If syntax is incorrect, authentication fails.
You can configure JAAS-related settings in the java.security master security properties file. This file resides in the lib/security directory of the JRE. For more information, see Appendix A in the Java™ Authentication and Authorization Service (JAAS) Reference Guide.

Create a JDBC Login Context

The following example shows how to create a login context for Kerberos authentication on a JDBC client. The client uses the default JAASConfigName of verticajdbc and specifies that:

- The ticket-granting ticket will be obtained from the ticket cache
- The user will not be prompted for a password if credentials cannot be obtained from the cache, keytab file, or through a shared state.

```java
verticajdbc {
   com.sun.security.auth.module.Krb5LoginModule
   required
   useTicketCache=true
   doNotPrompt=true;
};
```

JDBC Authentication Request and Connection

You can configure the Krb5LoginModule to use a cached ticket or keytab. The driver can also acquire a ticket or keytab automatically if the calling user provides a password.

In the preceding example, the login process uses a cached ticket and does not prompt for a password because both useTicketCache and doNotPrompt are set to true. If doNotPrompt=false and you provide a user name and password during the login process, the driver provides that information to the LoginModule. The driver then calls the kinit utility on your behalf.

1. On a JDBC client, call the kinit utility to acquire a ticket:

```bash
$ kinit kuser@EXAMPLE.COM
```

If you prefer to use a password instead of calling the kinit utility, see the next section.

2. Connect to Vertica:
Properties props = new Properties();
props.setProperty("user", "kuser");
props.setProperty("KerberosServiceName", "vertica");
props.setProperty("KerberosHostName", "vcluster.example.com");
props.setProperty("JAASConfigName", "verticajdbc");
Connection conn = DriverManager.getConnection
"jdbc:vertica://myserver.example.com:5433/VMart", props);

Have the Driver Acquire a Ticket

Sometimes, you may want to bypass calling the kinit utility yourself but still use encrypted, mutual authentication. In such cases, you can optionally pass the driver a clear text password to acquire the ticket from the KDC. The password is encrypted when sent across the network. For example, useTicketCache and doNotPrompt are both false in the following example. Thus, the calling user's credentials are not obtained through the ticket cache or keytab.

$ verticajdbc {
   com.sun.security.auth.module.Krb5LoginModule
   required
   useTicketCache=false
   doNotPrompt=false;
};

The preceding example demonstrates the flexibility of JAAS. The driver no longer looks for a cached ticket, and you do not have to call kinit. Instead, the driver takes the password and user name and calls kinit on your behalf.

- Java™ Authentication and Authorization Service (JAAS) Reference Guide (external website)

Troubleshooting Kerberos Authentication

These tips can help you avoid issues related to Kerberos authentication with Vertica Analytic Database and to troubleshoot any problems that occur.
**JDBC Client Authentication Fails**

If Kerberos authentication fails on a JDBC client, check the JAAS login configuration file for syntax issues. If syntax is incorrect, authentication fails.

**Working Domain Name Service (DNS) Not Configured**

Verify that the DNS entries and the system host file (/etc/hosts or /etc/hostnames) on the network are all properly configured for your environment. If you are using a fully qualified domain name, ensure that is properly configured as well. Refer to the Kerberos documentation for your platform for details.

**System Clocks Out of Sync**

**All Systems Except Red Hat 7/CentOS 7**

System clocks in your network must remain in sync for Kerberos authentication to work properly. To do so:

1. Install NTP on the Kerberos server (KDC).
2. Install NTP on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other.

Clock skew can be a problem on Linux virtual machines that need to sync with the Windows Time Service. Use the following stepsto keep time in sync:

1. Using any text editor, open /etc/ntp.conf.
2. Under the Undisciplined Local Clock section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

   ```
   # 0 */2 * * * /etc/init.d/ntpd restart
   ```
4. Alternatively, run the following command to force clock sync immediately:

   ```bash
   $ sudo /etc/init.d/ntpd restart
   ```

For more information, see Verify That NTP Is Running in Installing Vertica and the Network Time Protocol website.

**Red Hat 7/CentOS 7 Systems**

In Red Hat 7/CentOS 7, ntpd is deprecated in favor of chrony. To keep system clocks in your network in sync for Kerberos authentication to work properly, do the following:

1. Install chrony on the Kerberos server (KDC).
2. Install chrony on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other.

**Clock Skew on Linux Virtual Machines**

Clock skew can be problematic on Linux virtual machines that need to sync with the Windows Time Service. Try the following to keep time in sync:

1. Using any text editor, open `/etc/chrony.conf`.
2. Under the Undisciplined Local Clock section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

   ```bash
   # 0 */2 * * * systemctl start chronyd
   ```

4. Alternatively, run the following command to force clock sync immediately:

   ```bash
   $ sudo systemctl start chronyd
   ```

For more information, see the Red Hat chrony guide.

**Kerberos Ticket Is Valid, But Hadoop Access Fails**

Vertica uses Kerberos tickets to obtain Hadoop tokens. It then uses the Hadoop tokens to access the Hadoop data. Hadoop tokens expire after a period of time, so Vertica periodically refreshes them. However, if your Hadoop cluster is set to expire tokens...
frequently, it is possible that tokens might not be refreshed in time. If the token expires, you cannot access data.

Setting the HadoopFSTokenRefreshFrequency configuration parameter allows you to specify how often Vertica should refresh the token. Specify this value, in seconds, to be smaller than the expiration period set for Hadoop. For example:

```
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

### Encryption Algorithm Choices

Kerberos is based on symmetric encryption. Be sure that all Kerberos parties used in the Kerberos realm agree on the encryption algorithm to use. If they do not agree, authentication fails. You can review the exceptions in the `vertica.log`.

On a Windows client, be sure the encryption types match the types set on Active Directory. See [Configure Vertica for Kerberos Authentication](#).

Be aware that Kerberos is used only for securing the login process. After the login process completes, by default, information travels between client and server without encryption. If you want to encrypt traffic, use SSL. For details, see [Implementing SSL](#).

### Kerberos Passwords Not Recognized

If you change your Kerberos password, you must re-create all of your keytab files.

### Using the ODBC Data Source Configuration Utility

On Windows vsq1 clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica Analytic Database server.

### Authentication Failure in Backup, Restore, or Admin Tools

This problem can arise in configurations where each Vertica node uses its own Kerberos principal. (This configuration is recommended.) When using vbr or admintools you might see an error such as the following:
Backup/restore and the admin tools use the value of KerberosHostname, if it is set, in the Kerberos principal used to authenticate. The same value is used on all nodes. If you have defined one Kerberos principal per node, as recommended, this value does not match. To correct this, unset the KerberosHostname parameter:

```sql
=> ALTER DATABASE DEFAULT CLEAR KerberosHostname;
```

## Server's Principal Name Does Not Match Host Name

This problem can arise in configurations where a single Kerberos principal is used for all nodes. Vertica recommends against using a single Kerberos principal for all nodes. Instead, use one principal per node and do not set the KerberosHostname parameter.

In some cases during client connection, the Vertica server's principal name might not match the host name in the connection string. (See also *Using the ODBC Data Source Configuration Utility* in this topic.)

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica server.

On ODBC, JDBC, and ADO.NET clients, set the host name portion of the server's principal using the KerberosHostName connection string.

### Tip:

- On vsql clients, you set the host name portion of the server's principal name using the `-K KRB HOST` command-line option. The default value is specified by the `-h` switch, which is the host name of the machine on which the Vertica server is running. `-K` is equivalent to the drivers' KerberosHostName connection string value.

For details, see [Command Line Options](https://www.vertica.com/docs/9.3.x/vdm punisha Security and Authentication.html#vdm punisha Security and Authentication.html) in Connecting to Vertica.

## Principal/Host Mismatch Issues and Resolutions

The following issues can occur if the principal and host are mismatched.

**The KerberosHostname configuration parameter has been overridden**
For example, consider the following connection string:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser
```

Because the this connection string includes no explicit KerberosHostName parameter, the driver defaults to the host in the URL (v_vmart_node0001.example.com). If you overwrite the server-side KerberosHostName parameter as “abc”, the client generates an incorrect principal.

To resolve this issue, explicitly set the client’s KerberosHostName to the connection string, as in this example:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser&kerberoshostname=abc
```

**Connection load balancing is enabled...**

...but the node against which the client authenticates might not be the node in the connection string.

In this situation, consider changing all nodes to use the same KerberosHostName setting. When you use the default to the host that was originally specified in the connection string, load balancing cannot interfere with Kerberos authentication.

**A DNS name does not match the Kerberos host name**

For example, imagine a cluster of six servers, where you want hr-servers and finance-servers to connect to different nodes on the Vertica cluster. Kerberos authentication, however, occurs on a single (the same) KDC. In the following example, the Kerberos service host name of the servers is server.example.com.

Suppose you have the following list of example servers:

<table>
<thead>
<tr>
<th>Server</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>server1.example.com</td>
<td>192.16.10.11</td>
</tr>
<tr>
<td>server2.example.com</td>
<td>192.16.10.12</td>
</tr>
<tr>
<td>server3.example.com</td>
<td>192.16.10.13</td>
</tr>
<tr>
<td>server4.example.com</td>
<td>192.16.10.14</td>
</tr>
<tr>
<td>server5.example.com</td>
<td>192.16.10.15</td>
</tr>
<tr>
<td>server6.example.com</td>
<td>192.16.10.16</td>
</tr>
</tbody>
</table>

Now, assume you have the following DNS entries:

<table>
<thead>
<tr>
<th>DNS Name</th>
<th>IP Addresses</th>
</tr>
</thead>
<tbody>
<tr>
<td>finance-servers.example.com</td>
<td>192.168.10.11, 192.168.10.12, 192.168.10.13</td>
</tr>
<tr>
<td>hr-servers.example.com</td>
<td>192.168.10.14, 192.168.10.15, 192.168.10.16</td>
</tr>
</tbody>
</table>

When you connect to finance-servers.example.com, specify:

- Kerberos -h host name option as server.example.com
- -K host option for hr-servers.example.com

For example:
No DNS is set up on the client machine... 
...so you must connect by IP only

To resolve this issue, specify:

- Kerberos -h host name option for the IP address
- -K host option for server.example.com

For example:

```vsql -h 192.168.1.12 -K server.example.com```

There is a load balancer involved (Virtual IP)... 
...but there is no DNS name for the VIP

Specify:

- Kerberos -h host name option for the Virtual IP address
- -K host option for server.example.com

For example:

```vsql -h <virtual IP> -K server.example.com```

You connect to Vertica using an IP address... 
...but there is no host name to construct the Kerberos principal name.

Provide the instance or host name for the Vertica as described in Inform Vertica About the Kerberos Principal

The server-side KerberosHostName configuration parameter is set to a name other than the Vertica node's host name... 
...but the client cannot determine the host name based on the host name in the connection string alone.

Reset KerberosHostName to match the name of the Vertica node's host name. For more information, see the following topics:

- ODBC DSN Parameters
- JDBC Connection Properties
- ADO.NET Connection Properties
LDAP Authentication

Lightweight Directory Access Protocol (LDAP) is an authentication method that works like password authentication. The main difference is that the LDAP method authenticates clients trying to access your Vertica database against an LDAP or Active Directory server. Use LDAP authentication when your database needs to authenticate a user with an LDAP or Active Directory server.

LDAP Prerequisites and Definitions

Prerequisites

Before you configure LDAP authentication for your Vertica database you must have:

- IP address and host name for the LDAP server. Vertica supports IPv4 and IPv6 addresses.
- Your organization's Active Directory information.
- A service account for search and bind.
- Administrative access to your Vertica database.
- open-ldap-tools package installed on at least one node. This package includes ldapsearch.

Definitions

The following definitions are important to remember for LDAP authentication:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>IP address or host name of the LDAP server. Vertica supports IPv4 and IPv6 addresses. For more information, see IPv4 and IPv6 for Client Authentication.</td>
</tr>
<tr>
<td>Common name (CN)</td>
<td>Depending on your LDAP environment, this value can be either the username or the first and last name of the user.</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Domain component (DC)</td>
<td>Comma-separated list that contains your organization's domain component broken up into separate values, for example:</td>
</tr>
<tr>
<td></td>
<td>dc=vertica, dc=com</td>
</tr>
<tr>
<td>Distinguished name (DN)</td>
<td><em>domain.com</em>. A DN consists of two DC components, as in &quot;DC=example, DC=com&quot;.</td>
</tr>
<tr>
<td>Organizational unit (OU)</td>
<td>Unit in the organization with which the user is associated, for example, Vertica Users.</td>
</tr>
<tr>
<td>sAMAccountName</td>
<td>An Active Directory user account field. This value is usually the attribute to be searched when you use bind and search against the Microsoft Active Directory server.</td>
</tr>
<tr>
<td>UID</td>
<td>A commonly used LDAP account attribute used to store a username.</td>
</tr>
<tr>
<td>Bind</td>
<td>LDAP authentication method that allows basic binding using the DN.</td>
</tr>
<tr>
<td>Search and bind</td>
<td>LDAP authentication method that must log in to the LDAP server to search on the specified attribute.</td>
</tr>
<tr>
<td>Service account</td>
<td>An LDAP user account that can be used to log in to the LDAP server during bind and search. This account's password is usually shared.</td>
</tr>
<tr>
<td>Anonymous binding</td>
<td>Allows a client to connect and search the directory (search and bind) without needing to log in.</td>
</tr>
<tr>
<td>ldapsearch</td>
<td>A command-line utility to search the LDAP directory. It returns information that you use to configure LDAP search and bind.</td>
</tr>
<tr>
<td>basedn</td>
<td>Distinguished name where the directory search should begin.</td>
</tr>
<tr>
<td>binddn</td>
<td>Domain name to find in the directory search.</td>
</tr>
<tr>
<td>search_attribute</td>
<td>Text to search for to locate the user record. The default is UID.</td>
</tr>
</tbody>
</table>
LDAP Parameters

There are several parameters that you need to configure for LDAP authentication.

**General LDAP Parameters**

Use the following parameters to configure for either LDAP bind or LDAP bind and search:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
</table>
| host           | LDAP server URI in the following format:  
  `schema://host:optional_port`  
  *schema* is either `ldap` (for LDAP/Active Directory) or `ldaps` (for secure LDAP/Active Directory). |
| starttls       | Optional parameter that defines StartTLS behavior:  
  - *soft*—If the server does not support TLS, continue authenticating the user in plain text. This value is equivalent to the `-Z` option in `ldapsearch`.  
  - *hard*—If server does not support TLS, authentication should fail. This value is equivalent to the `-ZZ` in `ldapsearch`.  

Using `ldaps` is equivalent to `starttls='hard'`. However, if you use them together in the same connection string, authentication fails and the following error appears:  

FATAL 3846: LDAP authentication
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>failed</td>
<td>failed for user &quot;&lt;user_name&gt;&quot;</td>
</tr>
<tr>
<td>ldap_continue</td>
<td>When set to yes, this parameter allows a connection retry when a user not found error occurs during the previous connection attempt. For any other failure error, the system automatically retries the connection.</td>
</tr>
</tbody>
</table>

**LDAP Bind Parameters**

The following parameters create a bind name string, which specifies and uniquely identifies a user to the LDAP server. For details, see [Workflow for Configuring LDAP Bind](#).

To create a bind name string, you must set one (and only one) of the following:

- Both binddn_prefix and binddn_suffix (must be set together)
- domain_prefix
- email_suffix

For example, if you set binddn_prefix and binddn_suffix, you cannot also set email_suffix. Conversely, if you set email_suffix, you cannot set binddn_prefix and binddn_suffix.

If you do not set a bind parameter, Vertica performs bind and search operations instead of a bind operation.

The following examples use the authentication record v_ldap:

```sql
=> CREATE AUTHENTICATION v_ldap METHOD 'ldap' HOST '10.0.0.0/23';
```

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binddn_prefix</td>
<td>First half of the bind string. If you set this parameter, you must also set binddn_suffix. For example, to construct the bind name cn= exampleusername,cn=Users,dc=ExampleDomain,dc=com:</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>basedn</code></td>
<td>Base DN for search.</td>
</tr>
<tr>
<td><code>binddn</code></td>
<td>Bind DN. Domain name to find in the directory search.</td>
</tr>
</tbody>
</table>

**LDAP Search and Bind Parameters**

Use the following parameters when authenticating with LDAP search and bind. For more information see [Workflow for Configuring LDAP Search and Bind](#).
<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bind_password</td>
<td>Bind password. Required if you specify a binddn.</td>
</tr>
<tr>
<td>search_attribute</td>
<td>Optional attribute to search for on the LDAP server.</td>
</tr>
</tbody>
</table>

The following example shows how to set these three attributes. In this example, it sets

- binddn to `cn=Manager,dc=example,dc=com`
- bind_password to `secret`
- search_attribute to `cn`

```
=> ALTER AUTHENTICATION auth_method_name SET host='ldap://example13',
    basedn='dc=example,dc=com',binddn='cn=Manager,dc=example,dc=com',
    bind_password='secret',search_attribute='cn';
```

The binddn and bind_password parameters are optional. If you omit them, Vertica performs an anonymous search.

**Using LDAP Over TLS**

Vertica supports Transport Layer Security (TLS) for client authentication.

The terms SSL and TLS are often used interchangeably. TLS is the successor to SSL and offers greater security. The original SSL standard was renamed TLS at the time it became open source. The introduction of TLS began with version 1, which is essentially equal to SSL 3. You use openssl commands to create certificates and keys and TLS syntax to create an authentication method.

For more information see the [Information Security website](#).

You use ALTER AUTHENTICATION to specify LDAP and TLS parameters. If you specify a host URL that starts with `ldaps`, the Vertica server authenticates using TLS on the specified port or on the secure LDAPS port (636).

```
ldaps://abc.dc.com
```

If the LDAP server does not support SSL on that port, authentication fails.
If you specify a host URL that starts with `ldap` and set the LDAP `starttls` parameter, the Vertica server sends a StartTLS request. This request determines if the LDAP server supports TLS on the specified port or on the default LDAP port (389).

```sql
=> ALTER AUTHENTICATION Ldap1 SET host='ldaps://abc.dc.com',
    binddn_prefix='CN=', binddn_suffix='OU=Unit2,DC=dc,DC=com',
    basedn='dc=DC,dc=com',
    tls_cacert='/home/dc.com.ca.cer', tls_reqcert='never';
```

If the LDAP server does not support TLS on that port, the result depends on the value of the `starttls` parameter:

- `starttls = hard`: The Vertica server terminates the authentication process.
- `starttls = soft`: The Vertica server proceeds with the authentication but does not use TLS.

To configure LDAP over TLS, use the following configuration parameters:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TLS_REQCERT</td>
<td>hard—If the client does not provide a certificate, or provides an invalid certificate, it cannot connect. This is the default behavior. never—The client does not request or verify a certificate. allow—If the client does not provide a certificate or provides an invalid certificate, it can connect anyway. try—If the client does not provide a certificate, they can connect. If the client provides an invalid certificate, they cannot connect.</td>
</tr>
<tr>
<td>TLS_CADIR</td>
<td>Path to the folder with the CA certificates. For example:</td>
</tr>
<tr>
<td></td>
<td>ALTER AUTHENTICATION Ldap1 SET TLS_CADIR ='/scratch_b/qa/vertica/QA/VT_Scenario/V_SEC/';</td>
</tr>
<tr>
<td>TLS_CACERT</td>
<td>Path to the CA certificate. For example:</td>
</tr>
<tr>
<td></td>
<td>ALTER AUTHENTICATION Ldap1 SET TLS_CACERT ='/scratch_b/qa/vertica/QA/VT_Scenario/V_SEC/dc.com.ca.cer';</td>
</tr>
</tbody>
</table>

If you do not provide one or more of these parameters, the LDAP server checks to see if the LDAPNOINIT environment variable points to the `ldap.conf` file. If it does, the server uses the parameters specified in the `ldap.conf` file. If the LDAP server cannot find the `ldap.conf` file, authentication fails.

The following example shows how to specify the TLS parameters and the LDAP parameters when configuring LDAP over TLS:
Configuring Multiple LDAP Servers

If you need to configure multiple LDAP servers that have different URLs, create a separate authentication record for each server. Use the PRIORITY keyword to indicate which search the LDAP server performs first.

The following statements create two authentication methods, vldap1 and vldap2. They specify that the LDAP server first search the entire directory (basedn=dc=example,dc=com) for a DN with an OU attribute Sales. If the first search returns no results, or otherwise fails, the LDAP server next searches for a DN with the OU attribute Marketing:

```sql
=> CREATE AUTHENTICATION vldap1 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap1 SET
  host='ldap://ldap.example.com/search',
  basedn='dc=example,dc=com',
  search_attribute='Sales'
  PRIORITY 1;
=> GRANT AUTHENTICATION vldap1 to public;
=> CREATE AUTHENTICATION vldap2 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap2 SET
  host='ldap://ldap.example.com/search',
  basedn='dc=example,dc=com',
  search_attribute='Marketing'
  PRIORITY 0;
=> GRANT AUTHENTICATION vldap2 to public;
```

LDAP Bind Methods

There are two LDAP methods that you use to authenticate your Vertica database against an LDAP server.

- **Bind**—Use LDAP bind when Vertica connects to the LDAP server and binds using the CN and password. (These values are the username and password of the user logging into the database). Use the bind method when your LDAP account's CN field matches that of the username defined in your database. For more information see Workflow for Configuring LDAP Bind.
• Search and Bind — Use LDAP search and bind when your LDAP account's CN field is a user's full name or does not match the username defined in your database. For search and bind, the username is usually in another field such as UID or sAMAccountName in a standard Active Directory environment. Search and bind requires your organization's Active Directory information. This information allows Vertica to log into the LDAP server and search for the specified field. For more information see Workflow for Configuring LDAP Search and Bind.

If you are using search and bind, having a service account simplifies your server side configuration. In addition, you do not need to store your Active Directory password.

**LDAP Anonymous Binding**

*Anonymous binding* is an LDAP server function. Anonymous binding allows a client to connect and search the directory (bind and search) without logging in because binddn and bindpasswd are not needed.

You also do not need to log in when you configure LDAP authentication using Management Console.

**Workflow for Configuring LDAP Bind**

To configure your Vertica database to authenticate clients using LDAP bind, follow these steps:

1. Obtain a service account. For information see the [LDAP product documentation](#). You cannot use the service account in the connection parameters for LDAP bind.

2. Compare the user's LDAP account name to their Vertica username. For example, if John Smith's Active Directory (AD) sAMAccountName = jsmith, his Vertica username must also be jsmith.

However, the LDAP account does not have to match the database user name, as shown in the following example:

```sql
=> CREATE USER r1 IDENTIFIED BY 'password';
=> CREATE AUTHENTICATION ldap1 METHOD 'ldap' HOST '172.16.65.177';
=> ALTER AUTHENTICATION ldap1 SET HOST=
```
3. Run `ldapsearch` from a Vertica node against your LDAP or AD server. Verify the connection to the server and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication.

In the following example, `ldapsearch` returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username `jsmith`. This search succeeds only for LDAP servers that allow anonymous binding:

```bash
ldapsearch -x -h 10.10.10.10 -b "ou=Vertica Users,dc=CompanyCorp,dc=com" '(cn=jsmith*)' cn dn uid sAMAccountName
```

`ldapsearch` returns the following results. The relevant information for LDAP bind is in **bold**:

```
# extended LDIF
#
# LDAPv3
# base <ou=Vertica Users,dc=CompanyCorp,dc=com> with scope subtree
# filter: (cn=jsmith*)
# requesting: cn dn uid sAMAccountName
#
# jsmith, Users, CompanyCorp.com
dn: cn=jsmith,ou=Vertica Users,dc=CompanyCorp,dc=com
cn: jsmith
uid: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create a new authentication record based on the information from `ldapsearch`. In the `ldapsearch` entry, the CN is username `jsmith`, so you do not need to set it. Vertica automatically sets the CN to the username of the user who is trying to connect. Vertica uses that CN to bind against the LDAP server.

```sql
CREATE AUTHENTICATION v_ldap_bind METHOD 'ldap' HOST '0.0.0.0/0';
GRANT AUTHENTICATION v_ldap_bind TO public;
ALTER AUTHENTICATION v_ldap_bind SET
```
For more information see LDAP Parameters

**Workflow for Configuring LDAP Search and Bind**

To configure your Vertica database to authenticate clients using LDAP search and bind, follow these steps:

1. Obtain a service account. For information see the [LDAP product documentation](#).  
2. From a Vertica node, run `ldapsearch` against your LDAP or AD server. Verify the connection to the server, and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication.

   In the following example, `ldapsearch` returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username, John. This search succeeds only for LDAP servers that allow anonymous binding:

   ```bash
   $ ldapsearch -x -h 10.10.10.10 -b 'OU=Vertica Users,DC=CompanyCorp,DC=com' -s sub -D 'CompanyCorp\jsmith' -W '(cn=John*)' cn dn uid sAMAccountName
   
   3. Review the results that `ldapsearch` returns. The relevant information for search and bind is in bold:

```bash
# extended LDIF
#
# LDAPv3
# base <OU=Vertica Users,DC=CompanyCorp,DC=com> with scope subtree
# filter: (cn=John*)
# requesting: cn dn sAMAccountName
#
# John Smith, Vertica Users, CompanyCorp.com
dn: CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com
 cn: jsmith
 sAMAccountName: jsmith
# search result
search: 2
result: 0 Success
```
4. Create the client authentication record. The cn attribute contains the username you want—jsmith. Set your search attribute to the CN field so that the search finds the appropriate account.

```sql
=> CREATE AUTHENTICATION v_ldap_bind_search METHOD 'ldap' HOST '10.10.10.10';
=> GRANT AUTHENTICATION v_ldap_bind_search TO public;
=> ALTER AUTHENTICATION v_ldap_bind_search SET
    host='ldap://10.10.10.10',
    basedn='OU=Vertica,DC=CompanyCorp,DC=com',
    binddn='CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com',
    bind_password='password',
    search_attribute='CN';
```

For more information see [LDAP Parameters](#)

## Internode TLS

Internode TLS secures communication between nodes within a cluster. It is important to secure communications between nodes if you do not trust the network between the nodes.

Before setting up internode TLS, check the current status of your configuration with `SECURITY_CONFIG_CHECK`.

```sql
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

Communication between the server nodes uses two channels. To enable internode encryption, you must set the `EncryptSpreadComm` parameter, then the `DataSSLParams` parameter. Both are disabled by default.

1. **Control Channel Spread TLS**: Implemented using AES on top of spread
2. **Data Channel TLS**: Implemented using TCP

If you enable internode encryption, some of your queries may run slower than expected. The performance you experience depends on the data sent and the network's quality.

Admintools generates or retrieves the spread key to encrypt all traffic on the control channel and ships the spread key to all nodes. Vertica uses TLS to encrypt all traffic on the data channel. TLS credentials are shared between nodes over the encrypted control channel.

The following graphic illustrates the internode encryption process.
The control channel allows nodes to exchange plan information with one another, and to distribute calls among nodes. Enabling spread security secures this communication. See

See Also

- Control Channel Spread TLS
- Data Channel TLS
- Configuring TLS Server and Mutual Modes

Control Channel Spread TLS
Internode TLS for more information.

Internode TLS uses the following channels. Both must be enabled, and in the following order, before setting other parameters:

1. Control Channel to exchange plan information and distribute calls. It is implemented using Spread. For more information, visit spread.org.
2. Data Channel to exchange table data. It is implemented using TCP.

Enabling EncryptSpreadComm

EncryptSpreadComm can be set with one of two values:

- *vertica*. Vertica generates the spread encryption key for the cluster when the database starts up.
- *aws-kms|<key_name>*. Vertica fetches the user-specified key from the AWS Key Management Service when the database starts up, rather than generating one itself.

Setting the EncryptSpreadComm parameter is a prerequisite for enabling all other TLS-related parameters.

1. Set the EncryptSpreadComm parameter with ALTER DATABASE.

```
=> ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
```

2. Restart the database.
3. Verify your settings with SECURITY_CONFIG_CHECK.

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

Privileges

Superuser

Restrictions

After setting this parameter, you must restart your database.
Example

This enables the `EncryptSpreadComm` parameter and tells Vertica to generate a spread encryption key the next time the database starts up.

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
```

For more information on this and other security parameters, see Security Parameters.

- Internode TLS
- Data Channel TLS
- Configuring TLS Server and Mutual Modes

Data Channel TLS

Nodes use the data channel to exchange table data during operations such as queries.

Internode communication uses the following channels. Their associated components and parameters must be enabled, and in the following order, before enabling other components:

1. **Control Channel** to exchange plan information and distribute calls. It is implemented using Spread. For more information, visit spread.org.
2. Data Channel to exchange table data. It is implemented using TCP.

Setting DataSSLParams

1. Obtain the following. The `DataSSLParams` parameter takes these in a comma-separated list. To generate your own, see Generating TLS Certificates and Keys.
   - a TLS certificate
   - the corresponding TLS private key
   - the CA (Certificate Authority) certificate
2. Set the DataSSLParams parameter using `ALTER DATABASE`. To chain certificates, you should put in the first "section" of the statement (before the first comma). Here, the public CA verifies the non-root CA, and the non-root CA verifies the Cluster.

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER DataSSLParams = '-----BEGIN CERTIFICATE-----<certificate for Cluster>-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----<certificate for non-root CA>-----END CERTIFICATE-----,
-----BEGIN RSA PRIVATE KEY-----<private key for Cluster A>-----END RSA PRIVATE KEY-----,
-----BEGIN CERTIFICATE-----<certificate for public CA>-----END CERTIFICATE-----';
```

3. Restart the database.
4. Verify your settings with `SECURITY_CONFIG_CHECK`.

```sql
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

## Privileges

Superuser

## Restrictions

- Before setting this parameter, you must enable EncryptSpreadComm.
- After setting this parameter, you must restart your database.

## TLS Protocol

TLS (Transport Layer Security) is a cryptographic protocol used to secure communications between servers, their nodes, and clients.

Although TLS, SSL, and TLS/SSL are often used interchangeably, the Vertica documentation always uses TLS to reference the protocol. Some Vertica parameters and components use SSL, and in these cases the documentation uses SSL to reference them, but these too can be categorized under the TLS umbrella.
Enabling TLS is a multi-step process. First, check the status of your security configuration with `SECURITY_CONFIG_CHECK`. Then, you can configure TLS authentication records to reject non-TLS connections.

## TLS Overview

To secure communications and verify data integrity, you can configure Vertica and database clients to use TLS. The TLS protocol uses a key and certificate exchange system along with a trusted third party called a Certificate Authority (CA). Both the owner of a certificate and the other party that relies on the certificate must trust the CA to confirm the certificate holder's identity.

Vertica also supports the following authentication methods using the Transport Layer Security (TLS) v1.0, v1.1, and v1.2 protocol. Both methods encrypt and verify the integrity of the data in transit:

- **Server Mode** - In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.
- **Mutual Mode** - In mutual mode, the client and server must verify each other's identity before connecting.

In addition to the requirements detailed in this section, you must create [TLS authentication records](#) to reject non-TLS client connections.

## TLS Handshake Process

The following is a high-level/simplified overview of one possible "handshake" process for the client to verify the identity of the server in **Server Mode**. Additional actions taken in **Mutual Mode** for the server to identify the client are marked as such.

**Public and Private Key Pairs** - Key pairs are generated by clients and servers. The owner of a public key must be verified by a certificate authority. The key pairs are used to encrypt messages. For example, suppose Alice wants to send confidential data to Bob. Because she wants only Bob to read it, she encrypts the data with Bob's public key. Even if someone else gains access to the encrypted data, it remains protected. Because only Bob has access to his corresponding private key, he is the only person who can decrypt Alice's encrypted data back into its original form.
Certificates - Certificates contain a public key and identify the owner of the key. They are issued by the certificate authority (CA).

Certificate Authority (CA) - A certificate authority is a trusted party that verifies the identity of public key owners.

Client and Server Random - Client Random and Server Random are random strings that used to created a shared secret which encrypts communication if the handshake succeeds.

1. Before connecting, the server and client generate their own public and private key pairs. The CA then distributes identifying certificates to the server and client for their respective public keys.
2. The client sends its Client Random to the server and requests the server's certificate.
3. The server sends its certificate and its Server Random, encrypted with its private key, to the client. In Mutual Mode, the server also requests the client's certificate.
4. In Mutual Mode, the client sends its certificate.
5. The client uses the certificate to verify that the server owns its public key, then decrypts the Server Random with the server's public key to verify that the server owns its private key.
6. In Mutual Mode, the server uses the certificate to verify that the client owns its public key.
7. The server and client use the Client and Server Randoms to generate a new secret, called a session key, which encrypts future communication.

Configuring TLS Server and Mutual Modes

Before setting up TLS, check the status of your current configuration with SECURITY_CONFIG_CHECK.

```sql
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

For reference information on TLS, review the following:

- [OpenSSL Documentation](#)
- [OpenSSL Support](#)
- [OpenSSL FAQs](#)
- [OpenSSL Release](#)

Use the following files for TLS authentication. If you make changes to any of these files, you must restart the server:
- `root.crt` - contains the Certificate Authorities that are trusted for signing server certificates.
- `server.crt` - must reside in the server's catalog directory and contains the trusted server certificate. This file gets sent to the client where `root.crt` identifies the server.
- `server.key` - must reside in the server's catalog directory and proves the server certificate was sent by the certificate owner. It does not indicate the certificate owner is trustworthy.

You can also implement TLS with LDAP authentication. For more information see [Using LDAP Over TLS](#).

**Using wildcards**

You can enter wildcard characters as part of the server names in `root.crt`. For example, `server.crt` contains server names called `eng001.corptech.com`, `eng002.corptech.com`, and `eng003.corptech.com`. You can enter `*.corptech.com` in `root.crt` and it locates the required server.

The wildcard must be the first character of the hostname followed by a period, for example:

```
*.hostname.com
```

**Set Up TLS Server Mode Authentication**

In TLS Server mode, clients must verify the server's certificate. The client must be able to access the certificate authority file, and the SSLCertificate and SSLPrivateKey parameters must be set on the server.

In TLS Mutual mode, servers must also verify the client's certificate. The server must have a certificate authority file and the client must have a client certificate and a private key.

Follow these steps to set up server SSL authentication:

> **Important:**
> If you do not perform these steps, database operation may be compromised. If the client cannot authenticate the server, the database does not start.
1. Set the EnableSSL parameter to 1 to enable TLS authentication. By default, EnableSSL is set to 0 (disabled).

   => ALTER DATABASE database SET EnableSSL=1;

2. Copy the server certificate file (server.crt) and private key (server.key) to one of your server hosts in the cluster.

3. Distribute these files to all server hosts using the instruction in Copying Certificates and Keys to Configuration Files. The public key contained in the certificate and the corresponding private key allow the TLS/SSL connection to encrypt the data to protect data integrity.

4. If the VSQL_HOME environment variable is not set, copy the root.crt file to the .vsq1 directory of the login user's home directory (for example, ~/vsq1/root.crt).

5. If the VSQL_HOME environment variable is set, copy the root.crt file to the .vsq1 directory of the target directory (for example, $vsql_home/.vsq1/root.crt)

6. The root.crt file contains the Certificate Authority that issued the server certificate.

Set Up TLS Server for Mutual Mode Authentication

Use Mutual Mode to have both server and client mutually authenticate themselves with TLS keys. With TLS Mutual Mode the server requests a certificate from the client and the client requests a certificate from the server. Set up TLS Mutual Mode as follows:

1. Set the EnableSSL parameter to 1 to enable TLS authentication. By default, EnableSSL is set to 0 (disabled).

   => ALTER DATABASE database SET EnableSSL=1;

2. Copy the root.crt file to one server host in the cluster. This file is distributed to all server hosts when you distribute certificates and keys. See Copying Certificates and Keys to Configuration Files.

3. The root.crt file has the same name on the client and server though the file contents can differ. The contents are identical only if the client and server certificates were used by the same root certificate authority (CA).

4. Copy the client certificate file (client.crt) and private key (client.key) to each client. For vsql:

   - If the VSQL_HOME environment variable is set, copy the file to the .vsq1 directory of the target directory set up in the environment variable (e.g., $vsql_home/.vsq1/client.crt).
If the VSQL_HOME environment variable is not set, copy the two files to the .vsq1 directory of the login user's home directory. (e.g., ~/.vsq1/client.crt).

If you are using either ODBC or JDBC, you can place the files anywhere on your system. Then, provide the location in the connection string (ODBC/JDBC) or ODBCINI (ODBC only). See Configuring TLS for ODBC Clients and Configuring TLS for JDBC Clients.

**Important:**

If you're using ODBC, only the dbadmin should have read and write permissions for the private key file (client.key). Do not provide any additional permissions or extend them to any other users. To set these permissions, you can use this command:

```
$ chmod 600 client.key
```

### Generating TLS Certificates and Keys

This page includes examples and sample procedures to show how to create self-signed certificates and keys. The commands shown allow many other possible options not used in these examples. Create commands based on your specific environment.

For more detailed information on creating signed certificates, OpenSSL recommends the [OpenSSL Cookbook](https://www.openssl.org/docs/book/index.html). You can download this book for free.

#### Create a Certificate Authority Private Key and Public Certificate

Create a Certificate Authority (CA) private key and public certificate. For more information on using the following commands, see the [OpenSSL documentation](https://www.openssl.org/docs/man1.1.1/man1/openssl-genpkey.html).

**Important:**
The example below shows how to create a self-signed certificate. In a
production environment, you should always use certificates signed by a Certificate Authority.

**Note:**

Openssl.cnf is configuration file automatically created by OpenSSL that handles certificate generation requests. Its default location varies between distributions:

- RedHat, CentOS: /etc/pki/tls/openssl.cnf
- Debian: /etc/ssl/openssl.cnf

To specify a custom configuration file, use the following option when generating your certificates and keys:

```bash
-config filename
```

1. Generate CA files `serverca.crt` and `servercakey.pem`. This allows the signing of server and client keys:

   ```bash
   $ openssl genrsa -out servercakey.pem
   $ openssl req -new -x509 -key servercakey.pem -out serverca.crt
   ```

2. Create the server private key (`server.crt`) and public key (`server.key`):

   ```bash
   $ openssl genrsa -out server.key
   $ openssl req -new -key server.key -out server_reqout.txt
   $ openssl x509 -req -in server_reqout.txt -days 3650 -sha256 -CAcreateserial -CAserverca.crt -CAkey servercakey.pem -out server.crt
   ```

3. Create the client private key (`client.crt`) and public key (`client.key`):

   ```bash
   $ openssl genrsa -out client.key
   $ openssl req -new -key client.key -out client_reqout.txt
   $ openssl x509 -req -in client_reqout.txt -days 3650 -sha256 -CAcreateserial -CAserverca.crt -CAkey servercakey.pem -out client.crt
   ```

4. Set file permissions:

   ```bash
   $ chmod 700 server.crt server.key
   $ chmod 700 client.crt client.key
   ```

**Copying Certificates and Keys to Configuration Files**

Before using TLS, all hosts in the cluster must copy the contents of their certificates and keys to parameters in `vertica.conf`. These parameters determine the connection mode,
which then determines how hosts and clients verify each other before opening a secure connection.

Vertica offers two connection modes for TLS:

- **In Server Mode**, only the client must verify the host's certificate. Hosts must have `server.crt` and `server.key`.
- **In Mutual Mode**, the client and host must each verify the other's certificates. Hosts must have `server.crt`, `server.key`, and `root.crt`.

**Note:**
The database does not need to be running when you copy the contents of the certificates and key files to other hosts.

1. Enable TLS.
2. Generate TLS Certificates and Keys.
3. Log on to a host that contains the certificates and keys you want to copy.

**Note:**
To clear any of these parameters, run:

```
ALTER DATABASE dbname CLEAR parameter
```

4. Run the following commands for your desired configuration. The effects of these parameters only take effect for new connections.

- **To use Server Mode**, set the SSLCertificate and SSLPrivateKey parameters.

  ```
  => ALTER DATABASE DEFAULT SSLCertificate = 'content of server.crt';
  => ALTER DATABASE DEFAULT SSLPrivateKey = 'content of server.key';
  ```

- **To use Mutual Mode**, in addition to setting the above parameters for Server Mode, set the SSLCA parameter.

  ```
  => ALTER DATABASE DEFAULT SET SSLCA = 'content of root.crt';
  ```

To trust more than one CA:

```
ALTER DATABASE DEFAULT SET SSLCA = '-----BEGIN CERTIFICATE-----first CA-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----second CA-----END CERTIFICATE-----';
```

Generating Certificates and Keys for MC

A certificate signing request (CSR) is a block of encrypted text generated on the server on which the certificate is used. You send the CSR to a certificate authority (CA) to apply for a digital identity certificate. The CA uses the CSR to create your SSL certificate from information in your certificate; for example, organization name, common (domain) name, city, and country.

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the agents. Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the openssl package installed on your Linux environment first.

When you connect to MC through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

Create a Certificate and Submit it for Signing

For production, you must use certificates signed by a certificate authority. You can create and submit a certificate and when the certificate returns from the CA, import the certificate into MC.

Use the openssl command to generate a new CSR, entering the passphrase "password" when prompted:
When you press **Enter**, you are prompted to enter information to be incorporated into your certificate request. Some fields contain a default value, which you should change for security reasons. Other fields you can leave blank, such as password and optional company name. To leave the field blank, type `.'.

**Important:**
The keystore.key value for the `-key` option creates private key for the keystore. If you generate a new key and import it using the Management Console interface, the MC process does restart properly. You must restore the original keystore.jks file and **restart Management Console**.

This information is contained in the CSR and shows both the default and replacement values:

Country Name (2 letter code) [GB]: USState or Province Name (full name) [Berkshire]: Massachusetts
Locality Name (eg, city) [Newbury]: Cambridge
Organization Name (eg, company) [My Company Ltd]: Vertica
Organizational Unit Name (eg, section) []: Information Management
Common Name (eg, your name or your server's hostname) []: console.vertica.com
Email Address []: mcadmin@vertica.com

The **Common Name** field is the fully qualified domain name of your server. Your entry must exactly match what you type in your web browser, or you receive a name mismatch error.

**Self-Sign a Certificate for Testing**

To test your new SSL implementation, you can self-sign a CSR using either a temporary certificate or your own internal CA, if one is available.

**Note:**
A self-signed certificate generates a browser-based error notifying you that the signing certificate authority is unknown and not trusted. For testing purposes, accept the risks and continue.

The following command generates a temporary certificate, which expires after 365 days:

```bash
$ sudo openssl x509 -req -days 365 -in server.csr -signkey /opt/vconsole/config/keystore.key -out server.crt
Enter passphrase for /opt/vconsole/config/keystore.key:
Enter same passphrase again:
```
The previous example prompts you for a passphrase. This is required for Apache to start. To implement a passphrase you must put the SSLPassPhraseDialog directive in the appropriate Apache configuration file. For more information see your Apache documentation.

This example shows the command's output to the terminal window:

```plaintext
Signature ok
subject=/C=US/ST=Massachusetts/L=Cambridge/O=Vertica/OU=IT/CN=console.vertica.com/emailAddress=mcadmin@vertica.com
Getting Private key
```

You can now import the self-signed key, server.crt, into Management Console.

**See Also**

- Configuring TLS
- Key and Certificate Management Tool

**Importing a New Certificate to MC**

Use this procedure to import a new certificate into Management Console.

**Note:**

To generate a new certificate for Management Console, you must use the keystore.key file, which is located in /opt/vconsole/config on the server on which you installed MC. Any other generated key/certificate pair causes MC to restart incorrectly. You will then have to restore the original keystore.jks file and restart Management Console. See Generating Certifications and Keys for Management Console.

1. Connect to Management Console, and log in as an administrator.
2. On the Home page, click MC Settings.
3. In the button panel on the left, click SSL certificates.
4. To the right of "Upload a new SSL certificate," click Browse to import the new key.
5. Click Apply.
6. Restart Management Console.
Replacing the Agent Certificate

The Agent uses a preinstalled Certificate Authority (CA) certificate. You can replace it copying the your preferred certificate and its private key to the host.

To view your current agent certificate:

```
$ openssl s_client -prexit -connect database_IP:database_port
```

Generating a Certificate

If you don't already have one, you can generate a self-signed certificate. For more information, see Generating TLS Certificates and Keys

1. Generate the private key and certificate.

```
$ openssl req -new -newkey rsa:4096 -x509 -sha256 -days 365 -nodes -out agent.cert -keyout agent.key
```

You are about to be asked to enter information that will be incorporated into your certificate request.

What you are about to enter is what is called a Distinguished Name or a DN.

There are quite a few fields but you can leave some blank

For some fields there will be a default value,

If you enter '.', the field will be left blank.

```
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:IT
Common Name (e.g. server FQDN or YOUR name) []:*.*.mycompany.com
Email Address []:myaddress@mycompany.com
```

2. Make a copy of the certificate in PEM format.

```
$ openssl x509 -in agent.cert -out agent.pem -outform PEM
```

3. Review the certificate.

```
$ openssl x509 -in agent.pem -text
```
Replacing the Agent Certificate on a Host

The following procedure replaces the Agent's current private key and certificate on a single host. To replace this certificate and key across an entire cluster, repeat this procedure for all the hosts.

1. **Stop the Agent service on the host.**
   
   ```
   $ /etc/init.d/vertica_agent stop
   ```

2. **Backup and rename the existing agent certificate and key.**
   
   ```
   $ cd /opt/vertica/config/share
   $ mv agent.cert agent.cert.bck
   $ mv agent.key agent.key.bck
   $ mv agent.pem agent.pem.bck
   ```

3. **Transfer the new certificate and key to the host's /opt/vertica/config/share directory.**
   
   ```
   $ scp agent.* root@123.12.12.123:/opt/vertica/config/share
   ```

4. **Change the owner of the certificate and key to uidbadmin and the group to verticadba.**
   
   ```
   $ chown installed_Vertica_user:installed_Vertica_group agent.*
   ```

5. **Make the certificate and key files read-only.**
   
   ```
   $ chmod -R 400 agent.*
   ```

6. **Start the Agent service.**
   
   ```
   $ /etc/init.d/vertica_agent start
   starting agent
   Opening PID file "/opt/vertica/log/agent.pid".
   Overwriting /opt/vertica/log/agent_uidbadmin.log
   Overwriting /opt/vertica/log/agent_uidbadmin.err
   start OK for user: uidbadmin
   ```

7. **Verify that you can view information about your database with your API key.**
   
   ```
   $ curl -X GET https://10.20.80.145:5444/databases -H "VerticaApiKey:wCgXny3Wm+8OhEvGkAc1v7v9+VIlxgXblpr4rf" -k
   ```

8. **Verify that the Agent is using the new certificate.**
   
   ```
   $ openssl s_client -prexit -connect 10.20.80.145:5444
   ```
Configuring TLS

The procedures below describe configuring TLS directly on the Vertica database. To configure TLS on MC for MC connections, see Connecting Securely from MC to a Vertica Database.

Configure TLS for each server in the cluster.

1. Verify that you have performed at least the minimum steps required in Configuring TLS Server and Mutual Modes for server authentication and encryption and, optionally, for mutual authentication.
2. Verify that you have performed the steps in Copying Certificates and Keys to Configuration Files.
3. Set EnableSSL parameter to 1. By default, EnableSSL is set to 0 (disabled).

```
=> ALTER DATABASE database SET EnableSSL = 1;
```

4. If you are using either ODBC or JDBC, configure TLS for the appropriate client:
   - Configuring TLS for ODBC Clients
   - Configuring TLS for JDBC Clients

`vsq`l automatically tries to connect using TLS. If a connection fails on a server using Server Mode, vsq`l attempts to create an unencrypted followup connection. Vsq`l will not attempt an unencrypted followup connection in Mutual Mode.

Configure JDBC for TLS Mutual Mode

In addition to the procedure above, you need to perform the following to configure TLS in Mutual Mode:

1. Edit openssl_req_server.conf as follows:

```
[req]
prompt = no
distinguished_name = C=Store4Ever
req_extensions = v3_req

[CStore4Ever]
C = US
ST = Massachusetts
```
<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>O</td>
<td>Corp Server</td>
</tr>
<tr>
<td>CN</td>
<td>engXXX</td>
</tr>
<tr>
<td>emailAddress</td>
<td><a href="mailto:foo@bar.com">foo@bar.com</a></td>
</tr>
<tr>
<td>[v3_req]</td>
<td>basicConstraints: CA:FALSE</td>
</tr>
<tr>
<td></td>
<td>keyUsage: nonRepudiation, digitalSignature, keyEncipherment</td>
</tr>
<tr>
<td>subjectAltName</td>
<td>@alt_names</td>
</tr>
<tr>
<td>[alt_names]</td>
<td>DNS.1 = engXXX.corp.com</td>
</tr>
<tr>
<td></td>
<td>DNS.2 = engXXX</td>
</tr>
<tr>
<td></td>
<td>DNS.3 = *.corp.com</td>
</tr>
<tr>
<td></td>
<td>IP = 10.20.40.XX</td>
</tr>
</tbody>
</table>

2. Create the server private key (server.crt) and public key (server.key):

```bash
$ openssl genrsa -out server.key
$ openssl req -config openssl_req_server.conf -new -key server.key -out server_reqout.txt
```

3. Get your Certificate Signing Request (CSR) verified by your CA to receive a certificate. The exact steps depend on your CA. Check your CA’s documentation for more information.

**Note:**
If you are using mutual mode with JDBC, copy the root.crt file to a location on any one of the clients. After you copy the file to the client, root.crt is incorporated into the truststore. For more information, see [Generating TLS Certificates and Keys](#).

---

**Configuring TLS for ODBC Clients**

Configuring TLS for ODBC clients requires that you set the SSLMode connection property. If you want to configure optional TLS client authentication, you must also configure the Security Parameters SSLKeyFile and SSLCertFile connection properties.

How you configure the DSN depends on your operating system:

- **Linux and UNIX** — Enter the connection properties in the odbc.ini file. See [Creating an ODBC DSN for Linux](#).
- **Microsoft Windows** — Enter the connection properties in the Windows Registry. See [Creating an ODBC DSN for Windows Clients](#).

For Windows ODBC you can set connection string properties in the Client Settings tab on the ODBC DSN Configuration dialog. Connection string properties you can set are:
SSL CA file - the location of the root certificate file, for example root.crt.

SSL cert file - the location of the server certificate file, for example server.crt.

SSL key file - the location of the server key file, for example, server.key.

### Set SSLMode Connection Property

Set the SSLMode connection property to one of the following options for the DSN:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>verify_full</td>
<td>Encrypts data and connects to a user-specified trusted server.</td>
</tr>
<tr>
<td>verify_ca</td>
<td>Encrypts data and connects to a trusted server.</td>
</tr>
<tr>
<td>require</td>
<td>Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails.</td>
</tr>
<tr>
<td>prefer</td>
<td>(Default value) Indicates your preference that the server to use SSL. The first connection to the database tries to use SSL. If that connection fails, a second connection is attempted over a clear channel.</td>
</tr>
<tr>
<td>allow</td>
<td>Makes a connection to the server whether the server uses SSL or not. The first connection attempt to the database is made over a clear channel. If that connection fails, a second connection is attempted over SSL.</td>
</tr>
<tr>
<td>disable</td>
<td>Never connects to the server using SSL. This setting is typically used for troubleshooting.</td>
</tr>
</tbody>
</table>
Using verify_ca and verify_full

You can use the SSL Mode properties verify_ca and verify_full exclusively on client authentication. These properties require:

- The root.crt to allow the client to access the server's authentication certificate. If root.crt does not exist, and verify_can or verify_full are set, the connection fails upon SSL initialization.
- A server.crt, which contains the authentication certificate.
- A server.key, which contains the server's private key that prevents the server from accessing external systems.
- A server hostname that matches the hostname specified by the client, verify_full only.
- A certificate All nodes in the cluster must either share the same certificate or each certificate must contain all the hostnames or IP addresses in the Subject Alternative Name (SAN).

SSL Workflow

The following diagram shows an example workflow for SSL authentication. Your actual workflow may differ depending on what SSLMode Connection Properties you use.
In this workflow:
If the SSLMode Connection Property is set to none or allow, the client connects without authentication.

If the SSLMode Connection Property is set to verify_ca or verify_full, and root.crt does not exist, the SSL authentication fails. If root.crt exists, the authentication process proceeds.

During SSL authentication if the SSLMode Connection Property is set to verify_full, and the server hostname is not the same as the hostname specified by the client, authentication fails.

Enable SSL Mutual Mode Authentication

You can optionally configure SSL mutual mode by setting the following database Security Parameters:

- SSLKeyFile — Set this connection property to the file path and name of the client's private key. This key can reside anywhere on the client.
- SSLCertFile — Set this connection property to the file path and name of the client's public certificate. This file can reside anywhere on the client.

Configuring TLS for JDBC Clients

Configuring SSL Authentication for JDBC clients involves the following tasks:

- Set required properties
- Optionally run the SSL Debug Utility
- Configure TLS Mutual Mode (optional)

Set Required Properties

Set Properties When Location or the Keystore/Truststore Is Not the Default

If you are using a location or the keystore/truststore that is not the default, set the following system properties so that the JRE can find your keystore/truststore:

```
$ javax.net.ssl.keyStore
$ javax.net.ssl.trustStore
```
Set Properties When Keystore/Truststore Is Password Protected

If your keystore/truststore is password protected, set the following system properties so that the JRE has access to it:

```shell
$ javax.net.ssl.keyStorePassword
$ javax.net.ssl.trustStorePassword
```

Set the TLSmode Connection Property

You can set the TLSmode connection property to determine how certificates are handled. TLSmode is disabled by default.

TLSmode identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS connections before you can establish an encrypted connection to it. See TLS Protocol for details. Valid values are:

- **disable**: JDBC connects using plain text and implements no security measures.
- **require**: JDBC connects using TLS without verifying the CA certificate.
- **verify-ca**: JDBC connects using TLS and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated `ssl=true` property.
- **verify-full**: JDBC connects using TLS, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate.

If this property and the SSL property are set, this property takes precedence.

For example, to configure JDBC to connect to the server with TLS without verifying the CA certificate, you can set the TLSmode property to 'require' with the method `VerticaConnection.setProperty()`:

```java
Properties props = new Properties();
props.setProperty("TLSmode", "verify-full");
```

Run the SSL Debug Utility

After configuring TLS for JDBC, optionally run the following command to enable the debug utility for TLS:

```shell
$ -Djavax.net.debug=ssl
```
You can use several debug specifiers (options) with the debug utility. The specifiers help narrow the scope of the debugging information that is returned. For example, you could specify one of the options that prints handshake messages or session activity.

For information on the debug utility and its options, see Debugging Utilities in the Oracle document, JSSE Reference Guide.

For information on interpreting debug information, refer to the Oracle document, Debugging SSL/TLS Connections.

**Importing and Exporting Data with TLS**

Vertica uses TLS to secure connections and communications between clients and servers. When you import or export data between Vertica clusters, one of the clusters functions as a client, which means you can use TLS to protect that connection, too.

The ImportExportTLSMode parameter controls the strictness of TLS when importing or exporting data.

By default, ImportExportTLSMode is set to PREFER. With this setting, Vertica attempts to use TLS and falls back to plaintext; you can change this to always require encryption and, further, to validate the certificate on each connection. For more information about TLS during import and export operations, see Configuring Connection Security Between Clusters in the Administrator's Guide.

**TLS Authentication**

This section contains information about the tls authentication method, which is one of several authentication methods used to manage client connections.

Before creating a tls authentication method, you must configure your server to use TLS (TLS is disabled by default). The supported modes are:

- **Server Mode** - In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.
- **Mutual Mode** - In mutual mode, the client and server must verify each other's identity before connecting. Client authentication is optional because Vertica can
authenticate the client at the application protocol level with the client's username and password.

You can use the tls authentication method with either Server Mode or Mutual Mode. However, to use client self-authentication, your server must use Mutual Mode.

Before you create a tls authentication method, perform the pre-requisite tasks necessary for your specific environment (for example, certificate creation). Refer to TLS Protocol and all subsections applicable to your environment.

To create a tls authentication method, see Creating Authentication Records.

Implementing Client Self-Authentication

To use a client self-authentication method, your server must be in SSL Mutual Mode.

To create an authentication method for client self-authentication, use the CREATE AUTHENTICATION statement. Specify the auth_type 'tls' and with HOST TLS.

Important:
You use the 'tls' auth_type only when you want to create an authentication method for client self-authentication. You must use the 'tls' auth_type with the HOST TLS syntax.

Create an Authentication Method with Client Self-Authentication Method

This section provides sample chronological steps for setting up a client for self-authentication, creating an authentication method, and associating the method with a user through a grant statement.

1. Follow all applicable procedures for implementing SSL and distributing certificates and keys. Refer to TLS Protocol as it applies to your environment.

   When you create a client key, make sure to include a Common Name (CN) that is the database user name you want to use with the target database.

   $ Common Name <server hostname> []:<database username>
2. Create the authentication method. Authentication methods are automatically enabled when you create them.

```sql
=> CREATE AUTHENTICATION myssltest METHOD 'tls' HOST TLS '10.0.0.0/23;
```

3. Associate the method with the user through a grant statement.

```sql
=> GRANT AUTHENTICATION myssltest TO mydatabaseusername;
```

Your client can now log on and be recognized.

For information on creating authentication methods, refer to the SQL Reference Manual topic, `CREATE AUTHENTICATION`.

### Specify TLS for Client Connections

You can require clients to use TLS when connecting to Vertica. To do so, create a client authentication method for them that uses the HOST TLS syntax with the `CREATE AUTHENTICATION` statement.

Specific clients might connect through a network connection known to be insecure. In such cases, you can choose to limit specific users to connecting through TLS. You can also require all clients to use TLS.

Create authentication method `RejectNoSSL` that rejects users from any IP address that are trying to authenticate without TLS:

```sql
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '::/0'; --IPv6
```

See [Creating Authentication Records](#) for more information about creating client authentication methods.

### LDAP Link Service

LDAP Link enables synchronization between the LDAP and Vertica servers. This eliminates the need for you to manage two sets of users and groups or roles, one on the LDAP server and another on the Vertica server. With LDAP synchronization, the Vertica server becomes a replication database for the LDAP server.
Automatic Synchronization

With LDAP Link the Vertica server closely integrates with an existing directory service such as MS Active Directory or OpenLDAP. The Vertica server automatically synchronizes:

- LDAP users to Vertica users
- LDAP groups to Vertica roles

You manage all user and group properties in the LDAP server. If you are the Vertica database administrator, you need only to set up permissions for Vertica Analytic Database access on the users and groups.

Configure LDAP Link with LDAP Link connection parameters that reside in the catalog. See Set LDAP Link Parameters for more information.

Configure LDAP Link with Dry Runs

The LDAP Link dry run metafunctions allow you to configure the service in discrete stages before making any changes to your database. These stages are:

1. **LDAP Link Bind**: the connection between the LDAP server and the Vertica database
2. **LDAP Link Search**: Searching the LDAP server for users and groups
3. **LDAP Link Sync**: Mapping LDAP users and groups to their equivalents in Vertica

Query the system table `LDAP_LINK_DRYRUN_EVENTS` to view the results of each dry run.

For more information on dry runs and configuring LDAP Link, see Configuring LDAP Link with Dry Runs.

Enable LDAP Link

Enable LDAP Link as shown:

```sql
=> ALTER DATABASE `dbname` SET PARAMETER LDAPLinkURL='ldap://example.dc.com',
   LDAPLinkSearchBase='dc=DC,dc=com', LDAPLinkBindDN='CN=jsmith,OU=QA,DC=dc,DC=com,
   LDAPLinkBindPswd='password',LDAPLinkFilterUser='(objectClass=inetOrgPerson)',
   LDAPLinkFilterGroups='(objectClass=group)', LDAPLinkOn=1;
=> SELECT ldap_link_sync_start();
```
LDAP Link Workflow

After you enable LDAP Link, synchronization occurs according to this workflow:

1. The System Administrator creates users and user groups on the LDAP server.
2. The System Administrator sets up LDAP Link service parameters as required and enables the service.
3. Using the LDAP Link service, Vertica Analytic Database replicates the users and user groups from the Application LDAP to the Vertica database, creating Vertica users and roles.
4. The LDAP server uses Kerberos (KDC) to authenticate the user logging in to Vertica.
   - The LDAP user can log into Vertica if assigned the appropriate authentication type.
   - After login, you can grant users privileges using GRANT statements or as part of a Group.

See LDAP Link Parameters.
Note:
After synchronization the Vertica Analytic Database user does not have an associated authentication method. To allow the user to login, you must assign an authentication method to the user. See Implementing Client Authentication.

## Configuring LDAP Link with Dry Runs

Vertica supports several meta-functions that let you tweak LDAP Link settings before syncing with Vertica. Each meta-function takes [LDAP Link parameters](https://www.vertica.com/documentation/security-and-authentication-guide/current/0605-ldaplink.html) as arguments and tests a separate part of LDAP Link:

- **LDAP_LINK_DRYRUN_CONNECT** connects to the LDAP server.
- **LDAP_LINK_DRYRUN_SEARCH** searches for LDAP users and groups.
- **LDAP_LINK_DRYRUN_SYNC** maps and synchronizes LDAP users and groups to their equivalents in Vertica, creating and orphaning them accordingly.

These meta-functions are meant to be used and tested in succession, and their arguments are cumulative. That is, the parameters you use to configure **LDAP_LINK_DRYRUN_CONNECT** are used for **LDAP_LINK_DRYRUN_SEARCH**, and the arguments for those functions are used for **LDAP_LINK_DRYRUN_SYNC**.

Be sure to query the **LDAP_LINK_DRYRUN_EVENTS** system table to verify the results of each dry run before moving to the next meta-function.

## Configuring LDAP Link Bind

Before configuring LDAP users and importing them to Vertica, you must first connect or "bind," with the LDAP server. Connections are managed with several parameters. For more information on each parameter, related functions, options, and default values, see [LDAP Link Parameters](https://www.vertica.com/documentation/security-and-authentication-guide/current/0605-ldaplink.html).

**LDAP_LINK_DRYRUN_CONNECT** requires a Distinguished Name (DN), a password to authenticate with the LDAP server, and the URL to the LDAP server. If you want to encrypt the connection, you can use the optional TLS parameters.

By providing an empty string for the **LDAPLinkBindPswd** argument, you can also perform an anonymous bind if your LDAP server allows unauthenticated binds.
Dry Run Bind Example

This tests the connection to an LDAP server at ldap://glw2k8-64.dc.com with the DN CN=amir,OU=QA,DC=dc,DC=com with the optional TLS parameters. This begins the connection with StartTLS but does not require a valid certificate from the client, and specifies certificate ~/ca.crt.

To check the results of the bind, query the system table LDAP_LINK_DRYRUN_EVENTS.

Configuring LDAP Link Search

After a successful connection between Vertica and the LDAP server, you should configure and test your user and group search space for correctness and efficiency.

To search for users and groups on the LDAP server to import to your database, pass both the connection and search parameters to the LDAP_LINK_DRYRUN_SEARCH meta-function. The LDAP server responds with a list of users and groups that would be imported into Vertica with the given parameters.

By providing an empty string for the LDAPLinkBindPswd argument, you can also perform an anonymous search if your LDAP server's Access Control List (ACL) is configured to allow unauthenticated searches. The settings for allowing anonymous binds are different from the ACL settings for allowing anonymous searches.
Dry Run Search Example

This searches for users and groups in the LDAP server. In this case, the LDAPLinkSearchBase parameter specifies the dc.com domain and a sub scope, which replicates the entire subtree under the DN.

To further filter results, the function checks for users and groups with the person and group objectClass attributes. It then searches the group attribute cn, identifying members of that group with the member attribute, and then identifying those individual users with the attribute uid.

```sql
=> SELECT LDAP_LINK_DRYRUN_SEARCH
('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPwd','LDAPLinkSearchBase',
 'LDAPLinkScope', 'LDAPLinkFilterUser', 'LDAPLinkFilterGroup', 'LDAPLinkUserName', 'LDAPLinkGroupName',
 'LDAPLinkGroupMembers', 'LDAPLinkSearchTimeout', 'LDAPLinkStartTLS', 'LDAPLinkTLSEnforce',
 ['LDAPLinkTLSCACert'], ['LDAPLinkTLSClientAuth'])
```

Dry Run Search Completed. Query v_monitor.ldap_link_dryrun_events for results.

To check the results of the search, query the system table LDAP_LINK_DRYRUN_EVENTS.

```sql
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```

<table>
<thead>
<tr>
<th>event_timestamp</th>
<th>event_type</th>
<th>entry_name</th>
<th>ldapurihash</th>
<th>link_scope</th>
<th>search_base</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-01-03 21:03:26.411753+05:30</td>
<td>BIND_STARTED</td>
<td>------------</td>
<td>0</td>
<td>sub</td>
<td></td>
</tr>
<tr>
<td>2020-01-03 21:03:26.422188+05:30</td>
<td>BIND_FINISHED</td>
<td>------------</td>
<td>0</td>
<td>sub</td>
<td></td>
</tr>
<tr>
<td>2020-01-03 21:03:26.422223+05:30</td>
<td>SYNC_STARTED</td>
<td>------------</td>
<td>0</td>
<td>sub</td>
<td></td>
</tr>
<tr>
<td>2020-01-03 21:03:26.422229+05:30</td>
<td>SEARCH_STARTED</td>
<td>*******</td>
<td>0</td>
<td>sub</td>
<td></td>
</tr>
<tr>
<td>2020-01-03 21:03:32.043107+05:30</td>
<td>LDAP_GROUP_FOUND</td>
<td>Account Operators</td>
<td>0</td>

<tr>
<td>2020-01-03 21:03:32.043124+05:30</td>
<td>LDAP_GROUP_FOUND</td>
<td>Administrators</td>
<td>0</td>
<td>sub</td>
<td></td>
</tr>
<tr>
<td>2020-01-03 21:03:32.043182+05:30</td>
<td>LDAP_USER_FOUND</td>
<td>user1</td>
<td>0</td>
<td>sub</td>
<td></td>
</tr>
<tr>
<td>2020-01-03 21:03:32.043186+05:30</td>
<td>LDAP_USER_FOUND</td>
<td>user2</td>
<td>0</td>
<td>sub</td>
<td></td>
</tr>
<tr>
<td>2020-01-03 21:03:32.043195+05:30</td>
<td>SEARCH_FINISHED</td>
<td>*******</td>
<td>0</td>
<td>sub</td>
<td></td>
</tr>
</tbody>
</table>
```
Configuring LDAP Link Sync

After configuring the search space, you'll have a list of users and groups. LDAP sync maps the LDAP users and groups to their equivalents in Vertica. The LDAPLinkUserName maps to the Vertica usernames and the LDAPLinkGroupName maps to Vertica roles.

```sql
=> SELECT LDAP_LINK_DRYRUN_SYNC
('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd','LDAPLinkSearchBase',
 'LDAPLinkScope','LDAPLinkFilterUser','LDAPLinkFilterGroup','LDAPLinkUserName',
 'LDAPLinkGroupName','LDAPLinkSearchTimeout','LDAPLinkStartTLS','LDAPLinkTLSReqCert',
 ['LDAPLinkTLSACert'],['LDAPLinkTLSACDir']);
```

**Dry Run Sync Example**

To dry run map the users and groups returned from LDAP_LINK_DRYRUN_SEARCH, pass the same parameters as arguments to LDAP_LINK_DRYRUN_SYNC.

```sql
=> SELECT LDAP_LINK_DRYRUN_SYNC('ldap://glw2k8-
64.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
'(objectClass=person)','(objectClass=group)','uid','cn','member',10,1,'allow','~/ca.cert');
```

Dry Run Connect and Sync Completed. Query v_monitor.ldap_link_dryrun_events for results.

To check the results of the sync, query the system table LDAP_LINK_DRYRUN_EVENTS.

```sql
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```

<table>
<thead>
<tr>

Using LDAP Link

When you implement LDAP Link the following are directly affected and help you manage and monitor the LDAP Link - Vertica Analytic Database synchronization:

- User and Group management
- LDAP Link User Flag
- Blocked Commands
- Client Authentication types

User and Group Management

Users and groups created on the LDAP server have a specific relationship with those users and roles replicated to the Vertica server:

- The user-group relationship on the LDAP server is maintained when those users and groups (roles) are synchronized with Vertica Analytic Database.

- If a user or group name exists on the Vertica database and a user or group with the same names is synchronized from the LDAP Server using LDAP Link, the users or groups become conflicted. Vertica can not support multiple users with the same name. For a resolution of this conflict, see User Conflicts.

LDAP Link uses the entries in the dn: section of the LDAP configuration file as the unique user identifier when synchronizing a user to the Vertica Analytic Database:

dn: cn=user1,ou=dev,dc=example,dc=com
cn: user1
The `uid` parameter in the LDAP configuration file indicates the LDAP user name.

Upon synchronization, the `dn:` entry gets mapped to the `uid:` to identify the Vertica Analytic Database user.

If you change a setting in the `dn:` and do not change the `uid:` LDAP Link interprets the user as a new user when re-synchronizing with the Vertica Analytic Database. In this case, the existing Vertica Analytic Database user with that `uid:` gets deleted from Vertica and a new Vertica Analytic Database user is created.

If you change the `uid:` and not the `dn:` on LDAP, the `uid` on the Vertica Analytic Database gets updated to the new `uid`. Since you did not change the `dn:` LDAP Link does not interpret the user as a new user.

**LDAP Link User Flag**

As a `dbadmin` user, you can access the `vs_users` table to monitor user behavior on the Vertica Analytic Database. The `users` table contains an `ldap_dn` field that identifies whether or not the Vertica Analytic Database user is also an LDAP Link user. This example shows the `ldap_dn` field set to `dn` indicating the Vertica Analytic Database user is also an LDAP Link user:

```sql
=> SELECT * FROM vs_users;
- [ RECORD 1 ]-------------------------------------------------------------------------------------------------------------------
user_id | 45035996273704962
user_name | dbadmin
is_super_user | t
profile_name | default
is_locked | f
lock_time |
resource_pool | general
memory_cap_kb | unlimited
temp_space_cap_kb | unlimited
run_time_cap | unlimited
max_connections | unlimited
connection_limit_mode | database
idle_session_timeout | unlimited
all_roles | dbduser*, dbadmin*, pseudosuperuser*
default_roles | dbduser*, dbadmin*, pseudosuperuser*
search_path |
ldap_dn | dn
ldap_uri_hash | 0
is_orphaned_from_ldap | f
```
Blocked Commands

Be aware that the following SQL statements are blocked for Vertica Analytic Database users with ldapdn set to dn in the vs_users table:

- DROP USER and DROP ROLE
- ALTER ROLE RENAME
- ALTER USER name IDENTIFIED BY 'password' [REPLACE 'old_password']
- ALTER USER name PASSWORD EXPIRE
- ALTER USER name PROFILE
- ALTER USER name SECURITY_ALGORITHM...
- ALTER USER name DEFAULT ROLE role-name
- GRANT (Role)

Client Authentication Types

LDAP user and groups cannot log into Vertica if client authentication is not assigned to the user or group. You can use the following valid authentication types for LDAP users and groups:

- GSS
- Ident
- LDAP
- Reject
- Trust

LDAP Link Parameters

Use LDAP Link parameters to determine:

- LDAP Link operations, such as enabling or disabling LDAP Link and how often to perform replication
- Authentication parameters, including SSL authentication parameters
- Users and groups that inherit unowned objects
- How to resolve conflicts
Set LDAP Link Parameters

This example shows how you can set:

- The URL of the LDAP server (LDAPLinkURL) and
- The base DN from where to start replication (LDAPLinkSearchBase)

You also see how to set the LDAP Link Bind authentication parameters (LDAPLinkBindDN and LDAPLinkBindPswd) and enables LDAP Link (LDAPLinkOn).

```sql
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkURL='ldap://10.60.55.128',
    LDAPLinkSearchBase='dc=corp,dc=com',LDAPLinkBindDN='dc=corp,dc=com',LDAPLinkBindPswd='password';
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkOn = '1';
```

General and Connection Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLinkOn</td>
<td>Enables or disables LDAP Link. Valid Values: 0—LDAP Link disabled, 1—LDAP Link enabled</td>
</tr>
<tr>
<td>LDAPLinkURL</td>
<td>The LDAP server URL. Example: SET PARAMETER LDAPLinkURL='ldap://glw2k8-64.dc.com';</td>
</tr>
<tr>
<td>LDAPLinkInterval</td>
<td>The time interval, in seconds, by which the LDAP Server and Vertica server synchronize. Default Value: 86400 (one day).</td>
</tr>
<tr>
<td>LDAPLinkFirstInterval</td>
<td>The first interval, in seconds, for LDAP/Vertica synchronization after the clerk node joins the cluster. Default Value: 120</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LDAPLinkRetryInterval</td>
<td>The time, in seconds, the system waits to retry a failed synchronization.</td>
</tr>
<tr>
<td><strong>Default Value:</strong> 10</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkRetryNumber</td>
<td>The number of retry attempts if synchronization failed.</td>
</tr>
<tr>
<td><strong>Default Value:</strong> 10.</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkSearchBase</td>
<td>The base dn from where to start replication.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>SET PARAMETER</td>
</tr>
<tr>
<td></td>
<td>LDAPLinkSearchBase='ou=vertica,dc=mycompany,dc=com';</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>Vertica recommends using a separate OU for database users.</td>
</tr>
<tr>
<td>LDAPLinkSearchTimeout</td>
<td>The timeout length, in seconds, for the LDAP search operation during an LDAP Link Service run.</td>
</tr>
<tr>
<td><strong>Default Value:</strong> 10</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkScope</td>
<td>Indicates what dn level to replicate.</td>
</tr>
<tr>
<td></td>
<td><strong>Valid Values:</strong></td>
</tr>
<tr>
<td></td>
<td>* sub—Replicate entire subtree under baseDN</td>
</tr>
<tr>
<td></td>
<td>* one—Replicate to one level under baseDN</td>
</tr>
<tr>
<td></td>
<td>* base —Replicate only the baseDN level</td>
</tr>
<tr>
<td></td>
<td>If you decrease the scope (for example, sub to one), some users may not be recognized during the next synchronization.</td>
</tr>
<tr>
<td><strong>Default Value:</strong> sub</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkFilterUser</td>
<td>Determines how to filter users to be replicated.</td>
</tr>
<tr>
<td><strong>Default Value:</strong> &quot;(objectClass=inetOrgPerson)&quot;</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkFilterGroup</td>
<td>Determines how to filter groups to be replicated.</td>
</tr>
<tr>
<td><strong>Default Value:</strong> &quot;(objectClass=groupofnames)&quot;</td>
<td></td>
</tr>
</tbody>
</table>
### Authentication Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLinkBindDN</td>
<td>The LDAP Bind DN used for authentication.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td>```sql</td>
</tr>
<tr>
<td></td>
<td>&gt; SET PARAMETER LDAPLinkBindDN='CN=amir,OU=QA,DC=dc,DC=com';</td>
</tr>
<tr>
<td>LDAPLinkBindPswd</td>
<td>The valid password for the LDAP Bind DN to access the server. Only accessible by the dbadmin user.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td>```sql</td>
</tr>
<tr>
<td></td>
<td>&gt; SET PARAMETER LDAPLinkBindPswd='password';</td>
</tr>
</tbody>
</table>

### TLS Authentication Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLinkStartTLS</td>
<td>[Optional] Specifies whether or not to use the StartTLS operation during bind. You can only use this parameter if the LDAP server's URL is &quot;ldap://...&quot; (not &quot;ldaps://...&quot;)</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Valid Values:</strong></td>
<td></td>
</tr>
<tr>
<td>0 - Do not use starttls</td>
<td></td>
</tr>
<tr>
<td>1 - Use starttls</td>
<td></td>
</tr>
<tr>
<td><strong>Default Value:</strong> 0</td>
<td></td>
</tr>
</tbody>
</table>

**LDAPLinkTLSReqCert**

[Optional] Specifies how Vertica behaves when verifying the LDAP server's certificate when using TLS. The connection between Vertica and the LDAP server will only succeed if conditions for the specified value are met.

Valid Values:

- **hard**: LDAP server must provide a valid certificate.
- **allow**: LDAP server does not have to provide a certificate.
- **try**: LDAP server must either provide a valid certificate or not provide one at all.
- **never**: No requirements (Vertica does not request the LDAP server's certificate).

For details, see Using LDAP Over TLS.

**Default Value:** allow

**LDAPLinkTLSCACert**

[Optional] The path to a CA certificate.

**LDAPLinkTLS CADir**

[Optional] The path to the directory containing CA certificates.

### Miscellaneous Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>LDAPLinkConflictPolicy</strong></td>
<td>Determines how to resolve a user conflict.</td>
</tr>
<tr>
<td>Valid Values:</td>
<td></td>
</tr>
<tr>
<td>IGNORE—Ignores the incoming LDAP user and</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Parameter</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>MERGE</td>
<td>Maintains the existing Vertica user.</td>
</tr>
<tr>
<td></td>
<td>MERGE—Converts the existing user to an LDAP user.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> MERGE</td>
</tr>
<tr>
<td>LDAPLinkStopIfZeroUsers</td>
<td>Enables or disables the shutdown of LDAPLink synchronization if no users are found in LDAP.</td>
</tr>
<tr>
<td></td>
<td><strong>Valid values:</strong></td>
</tr>
<tr>
<td></td>
<td>0 - Disables the LDAPLink synchronization shutdown if no users are found. This may lead to inadvertent dropping of Vertica users.</td>
</tr>
<tr>
<td></td>
<td>1 - Enables the LDAPLink synchronization shutdown if no users are found. This prevents inadvertent dropping of Vertica users.</td>
</tr>
<tr>
<td>LDAPLinkDryRun</td>
<td>[Optional] Tests the connection to the LDAP server and logs the response without doing a synchronization. Also tests if parameters are correctly set.</td>
</tr>
<tr>
<td></td>
<td>Note that this parameter is not the preferred dry run method. Instead, the LDAP_Link_Dryrun family of metafunctions provides more granular control over configurations and is the preferred way to perform LDAP Link dry runs.</td>
</tr>
<tr>
<td></td>
<td><strong>Valid Values:</strong></td>
</tr>
<tr>
<td></td>
<td>0 - Disables LDAPLinkDryRun</td>
</tr>
<tr>
<td></td>
<td>1 - Enables LDAPLinkDryRun</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> 0</td>
</tr>
<tr>
<td>LDAPLinkConfigFile</td>
<td>[Optional] If this parameter is set with the path to a .LDIF file, the LDAP Link service will use the file as the source tree instead of connecting to the LDAP server.</td>
</tr>
</tbody>
</table>

See Managing Configuration Parameters: VSQL for information on setting LDAP Link parameters.
Note:
When you change any Connection or Authentication parameter, LDAP Link reconnects and re-initializes the synchronization.

Troubleshooting LDAP Link Issues

Various issues can arise with LDAP Link Service, including:

- Disconnected (Orphaned) Users and Roles
- Lost Objects
- User Conflicts

Disconnected (Orphaned) Users and Roles

Vertica Analytic Database users and roles synchronized through LDAP Link can become disconnected, or orphaned, if an issue arises with the LDAP Link service. For example, users and roles become orphaned when you change the connection to the LDAP server as the following scenario describes:

1. Create an LDAP connection as follows:

```
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkURL='ldap://ebuser',
   LDAPLinkSearchBase='dc=example,dc=com', LDAPLinkBindDN='mega',
   LDAPLinkBindPswd='$megapassword$';
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkOn = '1';
```

2. Run an LDAP Link session to synchronize LDAP and Vertica users.
3. Change one or more connection parameters from Step 1. You can change the connection only if you change one of the LDAPLinkURL or LDAPLinkSearchBase parameters.

4. Run another LDAP Link session. The system attempts to re-synchronize LDAP and Vertica users. Since the connection has changed, the existing Vertica users cannot be synchronized with the LDAP users from the new connection. These Vertica users become orphaned.

As a dbadmin user, you can identify orphaned users by checking the field is_orphaned_from_ldap in the users system table:
A field value of `t` indicates that the user is an orphaned user. Orphaned Vertica users cannot connect to the LDAP server and cannot login to Vertica using LDAP authentication (however, other authentication methods assigned to the user work). In this case, you can delete the orphaned Vertica user and run the LDAP Link service to resynchronize users.

## Re-parented Objects

When you delete users or groups from linked LDAP, the LDAP Link service removes the same users and roles from Vertica Analytic Database. However, the service does not delete objects owned by the deleted user. Use the `GlobalHeirUsername` parameter to assign the objects to a new owner (re-parent).

Example:

```sql
=> ALTER DATABASE example_db SET PARAMETER GlobalHeirUsername=user1;
```

This creates a new user named `user1`, if it does not exist. The `GlobalHeirUsername` user serves as the new parent for all the objects owned by deleted users.

By default, this parameter is set to `<auto>` which re-parents the objects to the dbadmin user.

If you leave `GlobalHeirUsername` empty, the objects are not re-parented to another user.

For more information see `GlobalHeirUsername` in Security Parameters.

## User Conflicts

Vertica Analytic Database users and roles synchronized using LDAP Link can become conflicted. Such conflicts can occur, for example, when you create a new user or group on the LDAP server and another user or role with the same name exists on the Vertica Analytic Database.

As a dbadmin user, use one of the following parameters to resolve user conflicts:

- `LDAPLinkConflictPolicy`
- `LDAPLinkStopIfZeroUsers`
**LDAPLinkConflictPolicy**

Use LDAPLinkConflictPolicy to resolve any user conflicts:

- **LDAPLinkConflictPolicy=IGNORE** - Ignores the incoming LDAP users and maintains the existing Vertica user
- **LDAPLinkConflictPolicy=MERGE** - Merges the incoming LDAP user with the Vertica user and converts the database user to an LDAP user retaining the database user's objects

Example:

```sql
=> ALTER DATABASE example_db SET PARAMETER LDAPLinkConflictPolicy='MERGE';
```

The default is MERGE. If you change LDAPLinkConflictPolicy, the change takes affect on the next synchronization.

**LDAPLinkStopIfZeroUsers**

Use LDAPLinkStopIfZeroUsers to prevent an accidental dropping of Vertica users if the LDAP Link synchronization does not find any LDAP users.

- **LDAPLinkStopIfZeroUsers=0** - Does not stop the LDAP Link synchronization if no users are found in LDAP. This drops all Vertica users during synchronization.
- **LDAPLinkStopIfZeroUsers=1** - Stops the LDAP Link synchronization if no users are found in LDAP and displays an error. This prevents the dropping of Vertica users due to some issue.

**Monitoring LDAP Link**

Use the ldap_link_events table to monitor events that occurred during an LDAP Link synchronization:

```sql
=> SELECT transaction_id, event_type, entry_name, entry_oid FROM ldap_link_events;
```

<table>
<thead>
<tr>
<th>transaction_id</th>
<th>event_type</th>
<th>entry_name</th>
<th>entry_oid</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996273705317</td>
<td>SYNC_STARTED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>45066962732553589</td>
<td>SYNC_FINISHED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>45066988112255317</td>
<td>PROCESSING_STARTED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>2341123456789765</td>
<td>USER_CREATED</td>
<td>tuser</td>
<td>234548899</td>
</tr>
</tbody>
</table>

(4 rows)
Connector Framework Service

The Connector Framework Service (CFS) allows secure indexing of documents from IDOL to the Vertica Analytic Database. Access control lists determine which users have permissions to access documents. Documents transferred from IDOL are stored in a flex table (Using Flex Tables).

Important:
Vertica 9.1.1 does not support the IdolLib function library. If you have the IdolLib function library installed and are upgrading to Vertica 9.1.1, you see an error and you cannot access the IdolLib function library.

To determine if the IdolLib library is installed, run the following script:

```
$ /opt/vertica/packages/idol/ddl/isinstalled.sql
```

To uninstall the IdolLib library, run the following script:

```
$ /opt/vertica/packages/idol/ddl/uninstall.sql
```

CFS Components

Use the following CFS components to implement the service on the Vertica:

- IDOL document metadata
- CFS Configuration file

For detailed information, see Implementing CFS.

IDOL Document Metadata

Vertica Analytic Database stores IDOL document metadata in a flex table. Set the name of the flex table with the TableName parameter in the CFS configuration file (see Implementing CFS). The metadata includes the following:

- AUTONOMYMETADATA (Mandatory): An alphanumeric designation for the ACL designated for the document.
- DREFIELD: Assigns permission levels to users and groups for accessing IDOL
documents.

## CFS Configuration File

You must index IDOL metadata in Vertica Analytic Database to be available for queries. See Implementing CFS.

## Implementing CFS

After Vertica ingests documents from IDOL into flex tables, you can implement CFS to secure those documents. Implementing the security requires that the Vertica database administrator modify the CFS configuration file.

## Modify the CFS Configuration File

The database administrator must modify the following in the CFS configuration file to have CFS automatically index the metadata:

1. In the [Indexing] section, set the IndexerSections parameter to vertica:

   ```
   [Indexing]
   IndexerSections=vertica
   IndexBatchSize=1
   IndexTimeInterval=30
   ```

2. Create a new section with the same name you entered in the IndexerSections parameter and enter the following parameters and keywords:

   ```
   [vertica]
   IndexerType=Library

   ConnectionString=Driver=Vertica;Server=123.456.478.900;Database=myDb;UID=dbadmin;PWD=password
   TableName=myFlexTable
   LibraryDirectory= ./shared_library_indexers
   LibraryName=VerticaIndexer
   ```
The VerticaIndexer (LibraryName above) is part of CFS. To use this tool, you must install and configure the Vertica ODBC drivers on the same machine as CFS. CFS sends JSON-formatted data to the Flex table using ODBC.

For more information, see Installing ODBC Drivers on Linux.

Query the IDOL Data

To query the IDOL data in a flex table, run a simple SELECT query. In this example, idol_table is the name of the flex table:

```sql
=> SELECT * FROM idol_table;
```

Federal Information Processing Standard

When running on a FIPS-compliant operating system that Vertica supports, Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module. This meets the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries.

The standard specifies the security requirements that a cryptographic module needs in a system protecting sensitive information. For details on the standard see the Computer Security Resource Center.

Note:
Vertica itself is not FIPS compliant but it is compatible with running on a FIPS-enabled system using FIPS resources.

For a list of FIPS prerequisites, see FIPS 140-2 Supported Platforms.
OpenSSL Behavior

**Important:**
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or [upgrade to 10.1.1](#) or above.

If you install or upgrade from Vertica 9.2.x to Vertica 9.3. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 9.3.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: [uninstall the Vertica RPM](#) on every node in the cluster and then [reinstall](#) Vertica 9.2.x.

Dynamic OpenSSL linking is a requirement for a FIPS implementation on the client and server. The Vertica 9.2 server uses the OpenSSL that resides on the host system (as indicated in [FIPS 140-2 Supported Platforms](#)). OpenSSL dynamically links with LDAP and Kerberos.

For more information see [Locate OpenSSL Libraries](#).

Libraries on CentOS Systems

On a FIPS-compliant CentOS system, Vertica 9.2 runs only with the OpenSSL libraries listed in [FIPS 140-2 Supported Platforms](#). Other versions of these libraries do not run on a FIPS system. This incompatibility occurs because the FIPS security policy checksums the library to which an application is linked and verifies that the library the application executes with the same checksum.

Library Versioning on Non-FIPS Systems

Be aware that on some non-FIPS systems, versioning anomalies can occur when you install a new version of OpenSSL. Sometimes, the default OpenSSL build procedure produces libraries with versions named 1.0.0. For Vertica to recognize that a library has a higher version number, you must provide the library name with a higher version number. For example, when installing OpenSSL version 1.0.1t, name the libraries libcrypto.so.1.0.1t or libssl.1.0.1t (symbolic links with these names are sufficient).
FIPS-Enabled Databases: Limitations

Manually creating a new database on a FIPS-enabled Vertica Analytic Database requires a different approach than for a non-FIPS machine. Be aware of the following limitations:

- You cannot create a FIPS-enabled database on a non-FIPS machine.
- You cannot create a non-FIPS database on a FIPS-enabled machine.
- Copying data generated with the MD5 hashing algorithm from a non-FIPS machine to a FIPS-enabled machine results in data corruption.
- Due to limitations in the FIPS cryptographic module, Vertica does not recommend enabling internode encryption in FIPS environments. If you use FIPS and internode encryption, you may experience occasional query failure due to socket closure in workloads that send a high volume of data across the network.

Implementing FIPS 140-2

**Important:**
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 9.3. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 9.3.x-xxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstall Vertica 9.2.x.

Implementing FIPS 140-2 on your Vertica Analytic Database requires configuration on the server and client. The Vertica 9.2.x server uses FIPS-approved algorithms; however Vertica clients may be running on non-FIPS-approved systems. Therefore, you must implement FIPS 140-2 compliance from end to end.

For more information on implementing FIPS, see:

- Implement FIPS on the Server
- Implement FIPS on the Client
Implement FIPS on the Server

To implement FIPS on the Vertica server, you must:

- Generate a secure SSL certificate to establish a secure connection to the client.
- If necessary, set the LD_LIBRARY_PATH environment variable to locate the OpenSSL libraries.

**Require FIPS Parameter**

Upon startup Vertica sets the RequireFIPS configuration parameter on the server to reflect the FIPS state of the system: 1 if FIPS is enabled and 0 if FIPS is disabled.

The value of RequireFIPS matches the value of crypto.fips_enabled file.

Depending on the FIPS state, the following behaviors can occur:

- If the file `/proc/sys/crypto/fips_enabled` exists and contains a 1 (FIPS-enabled), Vertica sets RequireFIPS to 1.
- If the file `/proc/sys/crypto/fips_enabled` does not exist, or exists and contains a 0 (non-FIPS), Vertica automatically sets RequireFIPS to 0.
- If the FIPS state of a node, as determined from the existence of `/proc/sys/crypto/fips_enabled`, differs from the state received from the cluster initiator, the node fails. This behavior prevents the creation of clusters of mixed FIPS and non-FIPS systems.

**Important:**

If you attempt to restore a FIPS-enabled node to a non-FIPS cluster, the restore process fails.

**Locate OpenSSL Libraries**

Vertica must find and load the libcrypto.so.10 and libssl.so.10 libraries from one of the supported OpenSSL versions. To do so, it searches the system directory where the libraries reside. If the SSL libraries are not found, Vertica uses its own OpenSSL libraries that reside under `/opt/vertica/lib`.
Note:
If you do not use admintools to start Vertica, or have conflicting libraries in your system, you must manually set LD_LIBRARY_PATH and /opt/vertica/lib must appear first in the list. When admintools starts or reboots Vertica, the path is set automatically.

Secure Client-Server Connection

Vertica uses TLS 1.2 to support the server-client connection for a FIPS-enabled system. This specification includes using a server certificate issued by a Certificate Authority.

Note:
Using TLS 1.2 prevents you from using the MD5 algorithm for hashing passwords. Vertica accepts only AuthenticatedClearTextPasswords hashed by SHA-512. Users with MD5 passwords must migrate to SHA-512 passwords. For more information, see Upgrade Considerations for Hash Authentication.

For instructions on generating a self-signed certificate see Generating TLS Certificates and Keys.

After generating a certificate, you need to distribute it to all hosts on the cluster. See Copying Certificates and Keys to Configuration Files. This distribution stores the certificate in the SSLCertificate parameter and the private key in the SSLPrivateKey parameter. For more information see Security Parameters.

Implement FIPS on the Client

Vertica provides a FIPS-compliant client driver, which you can install on a FIPS-enabled system. The 64-bit client includes vsql and ODBC drivers.

For information about installing the FIPS client, and installation, refer to the following

- Installing the FIPS Client Driver for ODBC and vsql
- Installing the FIPS Client Driver for JDBC
FIPS 140-2 Compliance Statement

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 9.3. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 9.3.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstall Vertica 9.2.x.

Contents

1. Summary
2. Overview
   a. About Vertica
   b. About FIPS 140-2
3. Vertica and FIPS 140-2

1. Summary

Vertica 9.2.x complies with Federal Information Processing Standard 140-2 (FIPS 140-2), which defines the technical requirements to be used by Federal Agencies when these organizations specify cryptographic-based security systems for protection of sensitive or valuable data. The compliance of Vertica with FIPS 140-2 is ensured by: 1) Integrating validated and NIST-certified third party cryptographic module(s), and using the module(s) as the only provider(s) of cryptographic services; 2) Using FIPS-approved cryptographic functions; 3) Using FIPS-approved and NIST-validated technologies applicable for Vertica design, implementation and operation.
2. Overview

a. About Vertica

- Vertica is a high performance relational database management system used for advanced analytics applications. Its performance and scale is achieved through a columnar storage and execution architecture that offers a massively parallel processing solution. Aggressive encoding and compression allows Vertica analytics to perform by reducing CPU, memory and disk I/O Processing times.
- For more details about Vertica and its usage, see Vertica Concepts.

b. About FIPS 140-2

FIPS (Federal Information Processing Standard) 140-2, *Security requirements for cryptographic modules*, is the Federal standard for proper cryptography for computer systems purchased by the government.

The benefits of using FIPS 140-2 validated crypto module is that the crypto algorithms are deemed appropriate and that they perform the encrypt/decrypt/hash functions correctly. The standard specifies the security requirements for cryptographic modules utilized within a security system that protects sensitive or valuable data. The requirements can be found in the following documents:

- [SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES](#)
- [Annex A: Approved Security Functions for FIPS PUB 140-2, Security Requirements for Cryptographic Modules](#)

3. Vertica and FIPS 140-2

**FIPS 140-2 validated third party module**

Vertica 9.2.x conforms with FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by the Operating System, which in our initial release is [Red Hat Enterprise Linux 6.6 OpenSSL Module](#).
Vertica can be configured to operate in FIPS-compliant mode ensuring its functions and procedures like SSL/TLS connections, which require cryptography (secure hash, encryption, digital signatures, etc.) makes use of the crypto services provided by RedHat Enterprise Linux 6.6 OpenSSL Module v3.0 which is validated for FIPS 140-2. If you are not running on a FIPS-compliant operating system that Vertica supports, you will not be able to run Vertica on FIPS mode. The assurance that Vertica is using the right FIPS 140-2 encryption modules is managed at the operating system level by RedHat’s implementation.

Vertica checks the OS level flag setting /proc/sys/crypto/fips_enabled to kick off Vertica’s FIPS mode installation. Further details about how to install and configure Vertica and its components to conform to FIPS 140-2 standard appear in the installation and security guides:

- Installing Vertica with the Installation Script
- Federal Information Processing Standard

**Modes of Operation**

Vertica Server operates in one of two modes determined by the OS configuration.

- FIPS-compliant mode – supports FIPS 140-2 compliant cryptographic functions. In this mode, all cryptographic functions, default algorithms and key lengths are bound to those allowed by FIPS 140-2.
- Standard mode – non-FIPS 140-2 compliant mode which utilizes all existing Vertica cryptography functions.

**TLS/SSL3.x**

All the Vertica client/server communications can be secured with FIPS-compliant Transport Layer Security TLS1.2/SSL3.1 or higher. It is relying on FIPS 140-2 approved hash algorithms and ciphers.

- TLS handshake, key negotiation and authentication provides data integrity and uses secure hash and FIPS 140-2 approved cryptography and digital signature.
- TLS encryption of data in transit provides confidentiality and making use of FIPS 140-2 approved cryptography.

**Secure Hash**

Per FIPS 140-2 standards, Vertica, in the FIPS 140-2 compliant mode, can be configured to use only the SHA-512 algorithm.
FIPS 140-2 Architecture

Vertica is a relational database system that is comprised of a client component and a server component. On the Client Side, we offer a suite of drivers for host clients to access the Vertica Server Side component. Both client and server Vertica components conform to FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by RedHat Enterprise Linux 6.6 OpenSSL Module.

Supported Platforms

See FIPS 140-2 Supported Platforms for information about FIPS-compliant operating systems and client drivers that Vertica supports.

Design Assurance

Vertica uses the security provider Red Hat Enterprise Linux 6.6 OpenSSL Module v3.0. This is the only supported security provider for FIPS 140-2.

Once you have configured Vertica to be compliant with FIPS 140-2, you cannot revert back to the standard configuration unless you disable FIPS 140-2 at the operating system level. Please reference the following documentation section for considerations:

- Implement FIPS on the Server
- Implement FIPS on the Client

Database Auditing

Database auditing often involves observing a database to be aware of the actions the database users are taking. Auditing can help with security, for example, to ensure that a user does not change information to which they should not have access. Audit categories make it easier to track changes within the database. You can see system tables that will bring together logged queries, tables, and changes to configuration parameters.
For example, the authentication audit category tracks queries, system tables, and configuration parameters related to security and authentication, such as:

- DROP AUTHENTICATION statement
- GRANT/REVOKE authentication statements
- LDAP Link related configuration parameters

You can also use the authentication audit category for weekly security reports to better understand attempts to gain access to data or to view unauthorized changes.

There are three system tables that can be used to track changes for queries, parameters, and tables as follows:

- LOG_PARAMS
- LOG_QUERIES
- LOG_TABLES

There is also a system table for tracking changes to privileges for users:

- AUDIT_MANAGING_USERS_PRIVILEGES

**System Table Restriction and Access**

Two functions let you restrict and open access to system tables for a given session:

- **RESTRICT_SYSTEM_TABLES_ACCESS** restricts access to non-superuser-only tables that are not accessible during lockdown.
- **RELEASE_SYSTEM_TABLES_ACCESS** allows access to non-superuser-only tables that are not accessible during lockdown.
You can extend Vertica to perform new operations or handle new types of data. There are several types of extensions:

- **External procedures** let you execute external scripts or programs that are installed on a host in your database cluster.
- **User-defined SQL functions** let you store frequently-used SQL expressions. They can help you simplify and standardize your SQL scripts.
- **User-defined extensions (UDxs)** let you develop your own analytic or data-loading tools using the C++, Python, Java, and R programming languages. They are useful when the type of data processing you want to perform is difficult or slow using SQL.

The following sections explain how to use extensions that have already been written:

- External Procedures
- User-Defined SQL Functions
- User-Defined Extensions

**Developing User-Defined Extensions (UDxs)** explains how to write new UDxs, including the following types:

- User-Defined Aggregate Functions
- Analytic Functions (UDAnFs)
- Scalar Functions (UDSFs)
- Transform Functions (UDTFs)
- User-Defined Load (UDL)
External Procedures

The external procedure feature lets you call a script or executable program on a host in your database cluster from within Vertica. You can pass literal values to this external procedure as arguments. The external procedure cannot communicate back to Vertica.

This chapter explains how to create, install, and use external procedures.
Implementing External Procedures

To implement an external procedure:

   
   See Requirements for External Procedures.

2. Enable the set-user-ID (SUID), user execute, and group execute attributes for the file. The file must either be readable by the dbadmin or the file owner's password must be given with the Administration Tools install_procedure command.

3. Install the external procedure executable file.
4. Create the external procedure in Vertica.

Once a procedure is created in Vertica, you can execute or drop it, but you cannot alter it.

Requirements for External Procedures

External procedures have requirements regarding their attributes, where you store them, and how you handle their output. You should also be cognizant of their resource usage.

Procedure File Attributes

The procedure file cannot be owned by root. It must have the set-user-ID (SUID), user execute, and group execute attributes set. If it is not readable by the Linux database administrator user, then the owner's password will have to be specified when installing the procedure.

Handling Procedure Output

Vertica does not provide a facility for handling procedure output. Therefore, you must make your own arrangements for handling procedure output, which should include writing error, logging, and program information directly to files that you manage.
Handling Resource Usage

The Vertica resource manager is unaware of resources used by external procedures. Additionally, Vertica is intended to be the only major process running on your system. If your external procedure is resource intensive, it could affect the performance and stability of Vertica. Consider the types of external procedures you create and when you run them. For example, you might run a resource-intensive procedure during off hours.

Sample Procedure File

```
#!/bin/bash
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

Installing External Procedure Executable Files

To install an external procedure, use the Administration Tools through either menu or the command line.

Using the Admin Tools Menus

1. Run the Administration Tools.

   `$ /opt/vertica/bin/adminTools`

2. On the AdminTools Main Menu, click Configuration Menu, and then click OK.

3. On the Configuration Menu, click Install External Procedure and then click OK.

4. Select the database on which you want to install the external procedure.

5. Either select the file to install or manually type the complete file path, and then click OK.

6. If you are not the superuser, you are prompted to enter your password and click OK.

   The Administration Tools automatically create the `<database_catalog_path>/procedures` directory on each node in the database and installs the
external procedure in these directories for you.

7. Click OK in the dialog that indicates that the installation was successful.

**Command Line**

If you use the command line, be sure to specify the full path to the procedure file and the password of the Linux user who owns the procedure file;

For example:

```
$ admintools -t install_procedure -d vmartdb -f /scratch/hELLOWorld.sh -p ownerpassword
Installing external procedure...
External procedure installed
```

Once you have installed an external procedure, you need to make Vertica aware of it. To do so, use the CREATE PROCEDURE statement, but review Creating External Procedures first.

**Creating External Procedures**

After you install an external procedure, you must make Vertica aware of it with CREATE PROCEDURE.

Only superusers can create an external procedure, and by default, only they have execute privileges. However, superusers can grant users and roles EXECUTE privilege on the stored procedure.

After you create a procedure, its metadata is stored in system table USER_PROCEDURES. Users can see only those procedures that they have been granted the privilege to execute.

**Example**

The following example creates a procedure named helloplanet for external procedure file helloplanet.sh. This file accepts one VARCHAR argument. The sample code is provided in Requirements for External Procedures.

```
=> CREATE PROCEDURE helloplanet(arg1 VARCHAR) AS 'helloplanet.sh' LANGUAGE 'external'
    USER 'dbadmin';
```
The next example creates a procedure named `proctest` for the script `copy_vertica_database.sh`. This script copies a database from one cluster to another; it is included in the server RPM located in directory `/opt/vertica/scripts`.

```
=> CREATE PROCEDURE proctest(ghosts VARCHAR, thosts VARCHAR, dbdir VARCHAR)
    AS 'copy_vertica_database.sh' LANGUAGE 'external' USER 'dbadmin';
```

**Overloading External Procedures**

You can create multiple external procedures with the same name if they have different signatures—that is, accept a different set of arguments. For example, you can overload the `helloplanet` external procedure to also accept an integer value:

```
=> CREATE PROCEDURE helloplanet(arg1 INT) AS 'helloplanet.sh' LANGUAGE 'external'
    USER 'dbadmin';
```

After executing this statement, the database catalog stores two external procedures named `helloplanet`—one that accepts a `VARCHAR` argument and one that accepts an integer. When you call the external procedure, Vertica evaluates the arguments in the procedure call to determine which procedure to call.

**See Also**

- CREATE PROCEDURE
- GRANT (Procedure)

**Executing External Procedures**

Once you define a procedure through the `CREATE PROCEDURE` statement, you can use it as a meta command through a simple `SELECT` statement. Vertica does not support using procedures in more complex statements or in expressions.

The following example runs a procedure named `helloplanet`:

```
=> SELECT helloplanet('earthlings');
helloplanet
---------
 0
(1 row)
```
The following example runs a procedure named proctest. This procedure references the copy_vertica_database.sh script that copies a database from one cluster to another. It is installed by the server RPM in the /opt/vertica/scripts directory.

```sql
=> SELECT proctest(     
    '-s qa01',      
    '-t rbench1',  
    '-D /scratch_b/qa/PROC_TEST' );
```

**Note:**
External procedures have no direct access to database data. If available, use ODBC or JDBC for this purpose.

Procedures are executed on the initiating node. Vertica runs the procedure by forking and executing the program. Each procedure argument is passed to the executable file as a string. The parent fork process waits until the child process ends.

To stop execution, cancel the process by sending a cancel command (for example, CTRL+C) through the client. If the procedure program exits with an error, an error message with the exit status is returned.

**Permissions**

To execute an external procedure, the user needs:

- EXECUTE privilege on procedure
- USAGE privilege on schema that contains the procedure

**Dropping External Procedures**

Only a superuser can drop an external procedure. To drop the definition for an external procedure from Vertica, use the DROP PROCEDURE statement. Only the reference to the procedure is removed. The external file remains in the <database>/procedures directory on each node in the database.

**Note:**
The definition Vertica uses for a procedure cannot be altered; it can only be dropped.
Example

=> DROP PROCEDURE helloplanet(arg1 varchar);

- DROP PROCEDURE

User-Defined SQL Functions

User-defined SQL functions let you define and store commonly-used SQL expressions as a function. User-defined SQL functions are useful for executing complex queries and combining Vertica built-in functions. You simply call the function name you assigned in your query.

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in a table partition clause or the projection segmentation clause.

For syntax and parameters for the commands and system table discussed in this section, see the following topics in the SQL Reference Manual:

- CREATE FUNCTION
- ALTER FUNCTION (Scalar)
- DROP FUNCTION
- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)
- V_CATALOG.USER_FUNCTIONS

Creating User-Defined SQL Functions

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.
To create a SQL function, the user must have CREATE privileges on the schema. To use a SQL function, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function.

This following statement creates a SQL function called myzeroifnull that accepts an INTEGER argument and returns an INTEGER result.

```sql
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
       RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
   END;
```

You can use the new SQL function (myzeroifnull) anywhere you use an ordinary SQL expression. For example, create a simple table:

```sql
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
   a
   ---
   1
   0
   (3 rows)
```

Use the myzeroifnull function in a SELECT statement, where the function calls col1 from table tabwnulls:

```sql
=> SELECT myzeroifnull(col1) FROM tabwnulls;
   myzeroifnull
----------
     1
     0
     0
   (3 rows)
```

Use the myzeroifnull function in the GROUP BY clause:

```sql
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
   count
    ----
      2
      1
   (2 rows)
```

If you want to change a user-defined SQL function's body, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```sql
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
```

RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
END;

To see how this information is stored in the Vertica catalog, see Viewing Information About SQL Functions.

See Also

- CREATE FUNCTION (SQL)
- USER_FUNCTIONS

Altering and Dropping User-Defined SQL Functions

Vertica allows multiple functions to share the same name with different argument types. Therefore, if you try to alter or drop a SQL function without specifying the argument data type, the system returns an error message to prevent you from dropping the wrong function:

```
=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull
```

Note:
Only a superuser or owner can alter or drop a SQL Function.

Altering a User-Defined SQL Function

The ALTER FUNCTION (Scalar) command lets you assign a new name to a user-defined function, as well as move it to a different schema.

In the previous topic, you created a SQL function called myzeroifnull. The following command renames the myzeroifnull function to zerowhennull:

```
=> ALTER FUNCTION myzeroifnull(x INT) RENAME TO zerowhennull;
ALTER FUNCTION
```

This next command moves the renamed function into a new schema called macros:
Dropping a SQL Function

The `DROP FUNCTION` command drops a SQL function from the Vertica catalog.

Like with `ALTER FUNCTION`, you must specify the argument data type or the system returns the following error message:

```sql
=> DROP FUNCTION zerowhennull();
ROLLBACK:   Function with specified name and parameters does not exist: zerowhennull
```

Specify the argument type:

```sql
=> DROP FUNCTION macros.zerowhennull(x INT);
DROP FUNCTION
```

Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL Functions), Vertica returns an error when those objects are used, not when the function is dropped.

**Tip:**
To view a list of all user-defined SQL functions on which you have EXECUTE privileges, (which also returns their argument types), query the `V__CATALOG.USER_FUNCTIONS` system table.

See Also

- `ALTER FUNCTION` (Scalar)
- `DROP FUNCTION`

Managing Access to SQL Functions

Before a user can execute a user-defined SQL function, he or she must have USAGE privileges on the schema and EXECUTE privileges on the defined function. Only the superuser or owner can grant/revoke EXECUTE usage on a function.

To grant EXECUTE privileges to user Fred on the `myzeroifnull` function:
To grant EXECUTE privileges on the function myzeroifnull to user Fred:

```sql
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Fred;
```

To revoke EXECUTE privileges from user Fred on the myzeroifnull function:

```sql
=> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Fred;
```

### See Also

- [GRANT (User Defined Extension)](verticaansi.html#GRANT(User Defined Extension))
- [REVOKE (User Defined Extension)](verticaansi.html#REVOKE(User Defined Extension))

### Viewing Information About User-Defined SQL Functions

You can access information about user-defined SQL functions on which you have EXECUTE privileges. This information is available in system table `USER_FUNCTIONS` and from the vsql meta-command \df.

To view all user-defined SQL functions on which you have EXECUTE privileges, query `USER_FUNCTIONS`:

```sql
=> SELECT * FROM USER_FUNCTIONS;
- [ RECORD 1 ]-----------------------------------------------
    schema_name | public
    function_name | myzeroifnull
    function_return_type | Integer
    function_argument_type | x Integer
    function_definition | RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END
    volatility | immutable
    is_strict | f
```

If you want to change the body of a user-defined SQL function, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```sql
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
    AS BEGIN
        RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
    END;
```

Now when you query `USER_FUNCTIONS`, you can see the changes in the `function_definition` column:
=> SELECT * FROM USER_FUNCTIONS;

| schema_name | public |
| function_name | myzeroifnull |
| function_return_type | Integer |
| function_argument_type | x Integer |
| function_definition | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END |
| volatility | immutable |
| is_strict | f |

If you use CREATE OR REPLACE syntax to change only the argument name or argument type (or both), the system maintains both versions of the function. For example, the following command tells the function to accept and return a numeric data type instead of an integer for the myzeroifnull function:

=> CREATE OR REPLACE FUNCTION myzeroifnull(z NUMERIC) RETURN NUMERIC
   AS BEGIN
       RETURN (CASE WHEN (z IS NULL) THEN 0 ELSE z END);
   END;

Now query the USER_FUNCTIONS table, and you can see the second instance of myzeroifnull in Record 2, as well as the changes in the function_return_type, function_argument_type, and function_definition columns.

Note: Record 1 still holds the original definition for the myzeroifnull function:

=> SELECT * FROM USER_FUNCTIONS;

| schema_name | public |
| function_name | myzeroifnull |
| function_return_type | Integer |
| function_argument_type | x Integer |
| function_definition | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END |
| volatility | immutable |
| is_strict | f |

| schema_name | public |
| function_name | myzeroifnull |
| function_return_type | Numeric |
| function_argument_type | z Numeric |
| function_definition | RETURN (CASE WHEN (z IS NULL) THEN (0) ELSE z END)::numeric |
| volatility | immutable |
| is_strict | f |

Because Vertica allows functions to share the same name with different argument types, you must specify the argument type when you alter or drop a function. If you do not, the system returns an error message:

=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull
Migrating Built-In SQL Functions

If you have built-in SQL functions from another RDBMS that do not map to a Vertica-supported function, you can migrate them into your Vertica database by using a user-defined SQL function.

The example scripts below show how to create user-defined functions for the following DB2 built-in functions:

- **UCASE()**
- **LCASE()**
- **LOCATE()**
- **POSSTR()**

**UCASE()**

This script creates a user-defined SQL function for the `UCASE()` function:

```sql
=> CREATE OR REPLACE FUNCTION UCASE (x VARCHAR)
  RETURN VARCHAR
  AS BEGIN
  RETURN UPPER(x);
  END;
```

**LCASE()**

This script creates a user-defined SQL function for the `LCASE()` function:

```sql
=> CREATE OR REPLACE FUNCTION LCASE (x VARCHAR)
  RETURN VARCHAR
  AS BEGIN
  RETURN LOWER(x);
  END;
```

**LOCATE()**

This script creates a user-defined SQL function for the `LOCATE()` function:

```sql
=> CREATE OR REPLACE FUNCTION LOCATE (x VARCHAR)
  RETURN VARCHAR
  AS BEGIN
  RETURN LOWER(x);
  END;
```

### User-Defined Extensions

A user-defined extension (UDx) is a component that expands Vertica functionality—for example, new types of data analysis and the ability to parse and load new types of data.

This section provides an overview of how to install and use a UDx. If you are using a UDx developed by a third party, consult its documentation for detailed installation and usage instructions.

### Loading UDxs

User-defined extensions (UDxs) are contained in libraries. A library can contain multiple UDxs. To add UDxs to Vertica you must:

1. Load the library (once per library).
2. Declare each UDx (once per UDx).

If you are using UDxs written in Java, you must also set up a Java runtime environment. See [Installing Java on Vertica Hosts](#).
Loading Libraries

To deploy a library to your Vertica database:

1. Copy the UDx shared library file (.so), Python file, or JAR that contains your function to a node on your Vertica cluster. You do not need to copy it to every node.
2. Connect to the node where you copied the library (for example, using `vsql`).
3. Add your library to the database catalog using the `CREATE LIBRARY` statement.

```sql
=> CREATE LIBRARY libname AS '/path_to_lib/filename'
   LANGUAGE 'Language';
```

`libname` is the name you want to use to reference the library. `path_to_lib/filename` is the fully-qualified path to the library or JAR file you copied to the host. `language` is the implementation language.

For example, if you created a JAR file named `TokenizeStringLib.jar` and copied it to the dbadmin account's home directory, you would use this command to load the library:

```sql
=> CREATE LIBRARY tokenizelib AS '/home/dbadmin/TokenizeStringLib.jar'
   LANGUAGE 'Java';
```

You can load any number of libraries into Vertica.

Declaring Individual UDxs

Once the library is loaded, define individual UDxs using SQL statements such as `CREATE FUNCTION` and `CREATE SOURCE`. These statements assign SQL function names to the extension classes in the library. They add the UDx to the database catalog and remain available after a database restart.

The statement you use depends on the type of UDx you are declaring, as shown in the following table.

<table>
<thead>
<tr>
<th>UDx Type</th>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregate Function (UDAF)</td>
<td><code>CREATE AGGREGATE FUNCTION</code></td>
</tr>
<tr>
<td>Analytic Function (UDAnF)</td>
<td><code>CREATE ANALYTIC FUNCTION</code></td>
</tr>
<tr>
<td>UDx Type</td>
<td>SQL Statement</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>Scalar Function (UDFS)</td>
<td>CREATE FUNCTION (Scalar)</td>
</tr>
<tr>
<td>Transform Function (UDTF)</td>
<td>CREATE TRANSFORM FUNCTION</td>
</tr>
<tr>
<td>Load (UDL): Source</td>
<td>CREATE SOURCE</td>
</tr>
<tr>
<td>Load (UDL): Filter</td>
<td>CREATE FILTER</td>
</tr>
<tr>
<td>Load (UDL): Parser</td>
<td>CREATE PARSER</td>
</tr>
</tbody>
</table>

After you add the UDx to the database, you can use your extension within SQL statements. The database superuser can grant access privileges to the UDx for users. See GRANT (User Defined Extension) in the SQL Reference Manual for details.

When you call a UDx, Vertica creates an instance of the UDx class on each node in the cluster and provides it with the data it needs to process.

**Installing Java on Vertica Hosts**

If you are using UDxs written in Java, follow the instructions in this section.

You must install a Java Virtual Machine (JVM) on every host in your cluster in order for Vertica to be able to execute your Java UDxs.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.

**Installing a Java Runtime**

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or OpenJDK. You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution’s documentation for information about installing and configuring OpenJDK.
To install the Oracle Java runtime, see the [Java Standard Edition (SE) Download Page](#). You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the `java` command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

**Note:**
Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

### Setting the JavaBinaryForUDx Configuration Parameter

The `JavaBinaryForUDx` configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a database superuser:
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';

See ALTER DATABASE for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the CONFIGURATION_PARAMETERS system table:

=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
- [ RECORD 1 ]----------------------------------------------------------------------
  node_name | ALL
  parameter_name | JavaBinaryForUDx
  current_value | /usr/bin/java
  default_value | |
  change_under_support_guidance | f
  change_requires_restart | f
  description | Path to the java binary for executing UDx written in Java

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

**Note:**
Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

**UDx Restrictions**

You cannot use any UDx on inputs containing complex types (see External Types). For example, you cannot transform or aggregate a ROW column.

Some UDx types have special considerations or restrictions.

**Aggregate Functions**

You cannot use the DISTINCT clause in queries with more than one aggregate function.

**Analytic Functions**

UDAnFs do not support framing windows using ROWS.
As with Vertica's built-in analytic functions, UDAnFs cannot be used with Pattern Matching Functions.

**Scalar Functions**

If the result of applying a UDSF is an invalid record, COPY aborts the load even if CopyFaultTolerantExpressions is set to true.

**Transform Functions**

A query that includes a UDTF cannot:

- Include statements other than the SELECT statement that calls this UDTF and a PARTITION BY expression
- Call an analytic function
- Call another UDTF
- Include one of the following clauses:
  - TIMESERIES
  - Pattern matching
  - Gap filling and interpolation

**Load Functions**

Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDx's to untrusted users.

You cannot ALTER UDL functions.

**Fenced Mode**

User-defined extensions (UDxs) written in the C++ programming language have the option of running in unfenced mode, which means running directly within the Vertica process. Since they run within Vertica, unfenced UDxs have little overhead, and can perform almost as fast as Vertica's own built-in functions. However, since they run within Vertica directly,
any bugs in their code (memory leaks, for example) can destabilize the main Vertica process that can bring one or more database nodes down.

You can instead opt to run most C++ UDxs in fenced mode, which runs the UDxs code outside of the main Vertica process in a separate zygote process. UDx code that crashes while running in fenced mode does not impact the core Vertica process. There is a small performance impact when running UDx code in fenced mode. On average, using fenced mode adds about 10% more time to execution compared to unfenced mode.

Fenced mode is currently available for all C++ UDxs with the exception of user-defined aggregates. All UDxs developed in the Python, R, and Java programming languages must run in fenced mode, since the Python, R, and Java runtimes cannot be directly run within the Vertica process.

Using fenced mode does not affect the development of your UDx. Fenced mode is enabled by default for UDx's that support fenced mode. The CREATE FUNCTION command can optionally be issued with the NOT FENCED modifier to disable fenced mode for the function. Also, you can enable or disable fenced mode on any fenced mode-supported C++ UDx by using the ALTER FUNCTION command.

### About the Zygote Process

The Vertica zygote process starts when Vertica starts. Each node has a single zygote process. Side processes are created "on demand". The zygote listens for requests and spawns a UDx side session that runs the UDx in fenced mode when a UDx is called by the user.

### About Fenced Mode Logging:

UDx code that runs in fenced mode is logged in the `UDxZygote.log` and is stored in the `UDxLogs` directory in the catalog directory of Vertica. Log entries for the side process are denoted by the UDx language (for example, C++), node, and zygote process ID, and the UDxSideProcess ID.

For example, for the following processes...

```sql
=> SELECT * FROM UDX_FENCED PROCESSES;
node_name | process_type | session_id | pid | port | status
----------|--------------|------------|-----|------|-------
v_vmart_node0001 | UDXZygoteProcess |         | 27468 | 51900 | UP
v_vmart_node0001 | UDXSideProcess  | localhost.localdoma-27465:0x800b | 5677 | 44123 | UP
```
... the corresponding log file displays:

```
2016-05-16 11:24:43.990 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 UDx side process started
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Finished setting up signal handlers.
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 My port: 44123
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 My address: 0.0.0.0
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Vertica port: 51900
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Vertica address: 127.0.0.1
11:25:19.749 [C++-localhost.localdoma-27465:0x800b-5677] 0x41837940 Setting memory resource limit to -1
11:30:11.523 [C++-localhost.localdoma-27465:0x800b-5677] 0x41837940 Exiting UDx side process
```

The last line indicates that the side process was killed. In this case it was killed when the user session (vsql) closed.

**About Fenced Mode Configuration Parameters**

Fenced mode supports three [configuration parameters]:

- **FencedUDxMemoryLimitMB** - The maximum memory size, in MB, to use for Fenced Mode processes. The default is -1 (no limit). The side process is killed if this limit is exceeded.
- **ForceUDxFencedMode** - When set to 1, force all UDx's that support fenced mode to run in fenced mode even if their definition specified NOT FENCED. The default is 0 (disabled).
- **UDxFencedBlockTimeout** - The maximum time, in seconds, that the Vertica server waits for a UDx to return before aborting with ERROR 3399. The default is 60.

Updating UDx Libraries

There are two cases where you need to update libraries that you have already deployed:

- When you have upgraded Vertica to a new version that contains changes to the SDK API. For your libraries to work with the new server version, you need to recompile them with new version of the SDK. See UDx Library Compatibility with New Server Versions for more information.
- When you have made changes to your UDxs and you want to deploy these changes. Before updating your UDx library, you need to determine if you have changed the signature of any of the functions contained in the library. If you have, you need to drop the functions from the Vertica catalog before you update the library.

UDx Library Compatibility with New Server Versions

The Vertica SDK defines an application programming interface (API) that UDxs use to interact with the database. When developers compile their UDx code, it is linked to the SDK code to form a library. This library is only compatible with Vertica servers that support the version of the SDK API used to compile the code. The library and servers that share the same API version are compatible on a binary level (referred to as "binary compatible").

The Vertica server returns an error message if you attempt to load a library that is not binary compatible with it. Similarly, if you upgrade your Vertica server to a version that supports a new SDK API, any existing UDx that relies on newly-incompatible libraries returns an error messages when you call it:

```
ERROR 2858: Could not find function definition
HINT: This usually happens due to missing or corrupt libraries, libraries built with the wrong SDK version, or due to a concurrent session dropping the library or function. Try recreating the library and function
```

To resolve this issue, you must install UDx libraries that have been recompiled with correct version of the SDK.

New versions of the Vertica server do not always change the SDK API version. The SDK API version changes whenever OpenText changes the components that make up the SDK. If the SDK API does not change in a new version of the server, then the old libraries remain compatible with the new server.
The SDK API almost always changes in Vertica releases (major, minor, service pack) as OpenText expands the SDK's features. Vertica will never change the API in a hotfix patch.

These policies mean that you must update UDx libraries when you upgrade between major versions. For example, if you upgrade from version 9.2 to 9.3, you must update your UDx libraries.

**Note:**
Since the R language is interpreted, a UDx written in R is not linked to the Vertica SDK. There is no binary compatibility that has to be maintained from one version to another. Therefore, changes to the Vertica SDK between Vertica versions do not make your R-based UDx libraries incompatible with a new server version. An R-based UDx only becomes incompatible if the APIs uses in the SDK actually change. For example, if the number of arguments to an API call changes, the UDx written in R has to be changed to use the new number of arguments.

**Pre-Upgrade Steps**

Before upgrading your Vertica server, consider whether you have any UDx libraries that may be incompatible with the new version. Consult the release notes of the new server version to determine whether the SDK API has changed between the version of Vertica server you currently have installed and the new version. As mentioned previously, only upgrades from a previous major version or from the initial release of a major version to a service pack release can cause your currently-loaded UDx libraries to become incompatible with the server.

Any UDx libraries that are incompatible with the new version of the Vertica server must be recompiled. If you got the UDx library from a third party (such as through the Vertica Marketplace), you need to see if a new version has been released. If so, download the UDx library and deploy it after you have upgraded the server (see Deploying A New Version of Your UDx Library).

If you developed the UDx yourself (or if whoever developed it supplied the UDx's source code) you must:

1. Recompile your UDx library using the new version of the Vertica SDK. See Compiling Your C++ Library or Compiling and Packaging a Java Library for more information.
2. Deploy the new version of your library. See Deploying A New Version of Your UDx Library.
Determining If a UDx Signature Has Changed

You need to be careful when making changes to UDx libraries that contain functions you have already deployed in your Vertica database. When you deploy a new version of your UDx library, Vertica does not ensure that the signatures of the functions that are defined in the library match the signature of the function that is already defined in the Vertica catalog. If you have changed the signature of a UDx in the library then update the library in the Vertica database, calls to the altered UDx will produce errors.

Making any of the following changes to a UDx alters its signature:

- Changing the number of arguments accepted or the data type of any argument accepted by your function (not including polymorphic functions).
- Changing the number or data types of any return values or output columns.
- Changing the name of the factory class that Vertica uses to create an instance of your function code.
- Changing the null handling or volatility behavior of your function.
- Removed the function's factory class from the library completely.

The following changes do not alter the signature of your function, and do not require you to drop the function before updating the library:

- Changing the number or type of arguments handled by a polymorphic function. Vertica does not process the arguments the user passes to a polymorphic function.
- Changing the name, data type, or number of parameters accepted by your function. The parameters your function accepts are not determined by the function signature. Instead, Vertica passes all of the parameters the user included in the function call, and your function processes them at runtime. See UDx Parameters for more information about parameters.
- Changing any of the internal processing performed by your function.
- Adding new UDxs to the library.

After you drop any functions whose signatures have changed, you load the new library file, then re-create your altered functions. If you have not made any changes to the signature of your UDxs, you can just update the library file in your Vertica database without having to drop or alter your function definitions. As long as the UDx definitions in the Vertica catalog match the signatures of the functions in your library, function calls will work transparently after you have updated the library. See Deploying A New Version of Your UDx Library.
Deploying A New Version of Your UDx Library

You need to deploy a new version of your UDx library if:

- You have made changes to the library that you now want to roll out to your Vertica database.
- You have upgraded your Vertica to a new version whose SDK is incompatible with the previous version.

The process of deploying a new version of your library is similar to deploying it initially.

1. If you are deploying a UDx library developed in C++ or Java, you must compile it with the current version of the Vertica SDK.
2. Copy your UDx's library file (a .so file for libraries developed in C++, a .py file for libraries developed in Python, or a .jar file for libraries developed in Java) or R source file to a host in your Vertica database.
3. Connect to the host using vsql.
4. If you have changed the signature of any of the UDxs in the shared library, you must drop them using DROP statements such as DROP FUNCTION or DROP SOURCE. If you are unsure whether any of the signatures of your functions have changed, see Determining If a UDx Signature Has Changed.

**Note:**
If all of the UDx signatures in your library have changed, you may find it more convenient to drop the library using the DROP LIBRARY statement with the CASCADE option to drop the library and all of the functions and loaders that reference it. Dropping the library can save you the time it would take to drop each UDx individually. You can then reload the library and recreate all of the extensions using the same process you used to deploy the library in the first place. See CREATE LIBRARY in the SQL Reference Manual.

5. Use the ALTER LIBRARY statement to update the UDx library definition with the file you copied in step 1. For example, if you want to update the library named ScalarFunctions with a file named ScalarFunctions-2.0.so in the dbadmin user's home directory, you could use the command:

```sql
=> ALTER LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions-2.0.so';
```
Once you have updated the UDx library definition to use the new version of your shared library, the UDxs that are defined using classes in your UDx library begin using the new shared library file without any further changes.

6. If you had to drop any functions in step 4, recreate them using the new signature defined by the factory classes in your library. See CREATE FUNCTION Statements in the SQL Reference Manual.
Listing the UDxs Contained in a Library

Once a library has been loaded using the **CREATE LIBRARY** statement, you can find the UDxs and UDLs it contains by querying the **USER_LIBRARY_MANIFEST** system table:

```sql
=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions.so';
CREATE LIBRARY
=> \
Expanded display is on.
=> SELECT * FROM USER_LIBRARY_MANIFEST WHERE lib_name = 'ScalarFunctions';
- [ RECORD 1 ] -----------------------
schema_name | public
lib_name     | ScalarFunctions
lib_oid      | 45035996273792402
obj_name     | RemoveSpaceFactory
obj_type     | Scalar Function
arg_types    | Varchar
return_type  | Varchar
- [ RECORD 2 ] -----------------------
schema_name | public
lib_name     | ScalarFunctions
lib_oid      | 45035996273792402
obj_name     | Div2intsInfo
obj_type     | Scalar Function
arg_types    | Integer, Integer
return_type  | Integer
- [ RECORD 3 ] -----------------------
schema_name | public
lib_name     | ScalarFunctions
lib_oid      | 45035996273792402
obj_name     | Add2intsInfo
obj_type     | Scalar Function
arg_types    | Integer, Integer
return_type  | Integer
```

The **obj_name** column lists the factory classes contained in the library. These are the names you use to define UDxs and UDLs in the database catalog using statements such as **CREATE FUNCTION** and **CREATE SOURCE**.

Using Wildcards In Your UDx

Vertica supports wildcard * characters in the place of column names in user-defined functions.

You can use wildcards when:
• Your query contains a table in the FROM clause
• You are using a Vertica-supported development language
• Your UDx is running in fenced or unfenced mode

**Supported SQL Statements**

The following SQL statements can accept wildcards:

- DELETE
- INSERT
- SELECT
- UPDATE

**Unsupported Configurations**

The following situations do not support wildcards:

- You cannot pass a wildcard in the OVER clause of a query
- You cannot use a wildcard with a DROP statement
- You cannot use wildcards with any other arguments

**Examples**

These examples show wildcards and user-defined functions in a range of data manipulation operations.

**DELETE statements:**

```
=> DELETE FROM tablename WHERE udf(tablename.*) = 5;
```

**INSERT statements:**

```
=> INSERT INTO table1 SELECT udf(*) FROM table2;
```

**SELECT statements:**
SELECT udf(*) FROM tablename;
SELECT udf(tablename.*) FROM tablename;
SELECT udf(f.*) FROM table f;
SELECT udf(*) FROM table1,table2;
SELECT udf1( udf2(*) ) FROM table1,table2;
SELECT udf( db.schema.table.*) FROM tablename;
SELECT udf(sub.*) FROM (select col1, col2 FROM table) sub;
SELECT x FROM tablename WHERE udf(*) = y;
WITH sub as (SELECT * FROM tablename) select x, udf(*) FROM sub;
SELECT udf(*) using parameters x=1) FROM tablename;
SELECT udf(table1.*, table2.col2) FROM table1,table2;

UPDATE statements:

UPDATE tablename set col1 = 4 FROM tablename WHERE udf(*) = 3;
Developing User-Defined Extensions (UDxs)

User-defined extensions (UDxs) are functions contained in external shared libraries that are developed in C++, Python, Java, or R using the Vertica SDK. The external libraries are defined in the Vertica catalog using the CREATE LIBRARY statement. They are best suited for analytic operations that are difficult to perform in SQL, or need to be performed frequently enough that their speed is a major concern.

The primary strengths of UDxs are:

- They can be used anywhere an internal function can be used.
- They take full advantage of Vertica’s distributed computing features. The extensions usually execute in parallel on each node in the cluster.
- Vertica handles the distribution of the UDx library to the individual nodes. You only need to copy the library to the initiator node.
- All of the complicated aspects of developing a distributed piece of analytic code are handled for you by Vertica. Your main programming task is to read in data, process it, and then write it out using the Vertica SDK APIs.

There are a few things to keep in mind about developing UDxs:

- UDxs can be developed in the programming languages C++, Python, Java, and R. (Not all UDx types support all languages.)
- UDxs written in Java always run in Fenced Mode, because the Java Virtual Machine that executes Java programs cannot run directly within the Vertica process.
- UDxs written in Python and R always run in Fenced Mode.
- UDxs developed in C++ have the option of running in unfenced mode, which means they load and run directly in the Vertica database process. This option provides the lowest overhead and highest speed. However, any bugs in the UDx's code can cause database instability. You must thoroughly test any UDxs you intend to run in unfenced mode before deploying them in a live environment. Consider whether the performance boost of running a C++ UDx unfenced is worth the potential database instability that a buggy UDx can cause.
- Because a UDx runs on the Vertica cluster, it can take processor time and memory away from the database processes. A UDx that consumes large amounts of computing resources can negatively impact database performance.
Structure

Each UDx type consists of two classes. The main class does the primary work (a transformation, an aggregation, and so on). The class usually has at least three methods: one to set up, one to tear down (release reserved resources), and one to do the actual work. Sometimes additional methods are defined.

The main processing method receives an instance of the ServerInterface class as an argument. This object is used by the underlying Vertica SDK code to make calls back into the Vertica process, for example to allocate memory. You can use this class to write to the server log during UDx execution.

The second class is a singleton factory. It defines one method that produces instances of the first class, and might define other methods to manage parameters.

When implementing a UDx you must subclass both classes.

Conventions

The C++, Python, and Java APIs are nearly identical. Where possible, this documentation describes these interfaces without respect to language. Documentation specific to C++, Python, or Java is covered in language-specific sections.

Because some documentation is language-independent, it is not always possible to use ideal, language-based terminology. This documentation uses the term "method" to refer to a Java method or a C++ member function.

Loading UDxs
Setting Up a Development Environment

Before you start developing your UDx, you need to configure your development environment. You can choose to develop your UDx on a node in a development Vertica database (not in a production environment) or on another machine.

To test, you need access to a (non-production) Vertica database. You can install a single-node Vertica database on your development machine for easier development.

You should develop your UDx code on the same Linux platform that you use on your Vertica database cluster. This will ensure that your UDx library is compatible with the Vertica version deployed on your cluster.

The following sections describe language-specific requirements.

C++ Requirements

At a minimum, you need to install the following on your development machine:

- `g++` and its associated tool chain such as ld. *(Note: some Linux distributions package g++ separately from gcc.)*
- A copy of the Vertica SDK. See Setting Up the C++ SDK for details.

**Note:**

The Vertica binaries are compiled using the default version of g++ installed on the supported Linux platforms. Vertica requires a minimum of gcc version 4.8.4 and a maximum version of 7.3. The default versions of g++ on Amazon Linux 2.0 and Ubuntu 16.04 are not compatible.

You must compile with the flag `-std=c++11`. The Vertica SDK uses features of C++ 11.

While not required, the following additional software packages can ease development:

- make, or some other build-management tool.
- gdb, or some other debugger.
- Valgrind, or similar tools that detect memory leaks.

If you want to use any third-party libraries (for example, statistical analysis libraries), you need to install them on your development machine. If you do not statically link these
libraries into your UDx library, you also have to install them on every node in the cluster. See Compiling Your C++ Library for details.

**CentOS-Based Operating Systems**

Installations on the following CentOS-based operating systems require the devtoolset-7 package:

- CentOS
- Red Hat Enterprise Linux
- Oracle Enterprise Linux

Consult the documentation for your operating system for the specific installation command.

**Debian-Based Operating Systems**

Installations on the following Debian-based operating systems require the GCC-7 package:

- Debian
- Ubuntu
- SUSE
- OpenSUSE
- Amazon Linux (The GCC package is pre-installed on Amazon Linux)

Consult the documentation for your operating system for the specific installation command.

**Java Requirements**

At a minimum, you need to install the following on your development machine:

- The Java Development Kit (JDK) version that matches the Java version you have installed on your database hosts (see Installing Java on Vertica Hosts).
- A copy of the Vertica SDK. See Setting Up the Java SDK for details.

While not required, make or some other build-management tool can ease development.
Python Requirements

Vertica does not require any additional files or packages. You can develop your Python UDx on any system with a text editor.

Important:
Your UDx must be able to run with the version of Python bundled with Vertica. You can find this with /opt/vertica/sbin/python3 --version. You cannot change the version used by the Vertica Python interpreter.

When Vertica calls your UDx, it starts a side process that manages the interaction between the server and the Python interpreter.

R Requirements

Vertica requires a version of the libgfortran4 library later than 7.1 to create R extensions. Libgfortran is included by default with the required devtool and GCC packages.

Downloading and Running UDx Example Code

You can download all of the examples shown in this documentation, and many more, from the Vertica GitHub repository. This repository includes examples of all types of UDxs.

You can download the examples in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the repository. Using a terminal window, run the following command:

  $ git clone https://github.com/vertica/UDx-Examples.git

The repository includes a makefile that you can use to compile the C++ and Java examples. It also includes .sql files that load and use the examples. See the README file for instructions on compiling and running the examples. To compile the examples you will need g++ or a JDK and make. See Setting Up a Development Environment for related information.
Running the examples not only helps you understand how a UDx works, but also helps you ensure your development environment is properly set up to compile UDx libraries.

- User-Defined Aggregate Functions
- Analytic Functions (UDAnFs)
- Scalar Functions (UDSFs)
- Transform Functions (UDTFs)
- User-Defined Load (UDL)

### Types of UDxs

Vertica supports five types of user-defined extensions:

- **User-defined scalar functions** (UDSFs) take in a single row of data and return a single value. These functions can be used anywhere a native function can be used, except `CREATE TABLE BY PARTITION` and `SEGMENTED BY` expressions. UDSFs can be developed in C++, Python, Java, and R.

- **User-defined aggregate functions** (UDAF) allow you to create custom Aggregate Functions specific to your needs. They read one column of data, and return one output column. UDAFs can be developed in C++.

- **User-defined analytic functions** (UDAnF) are similar to UDSFs, in that they read a row of data and return a single row. However, the function can read input rows independently of outputting rows, so that the output values can be calculated over several input rows. UDAnFs can be developed in C++ and Java.

- **User-defined transform functions** (UDTFs) operate on table partitions (as specified by the query's `OVER ( )` clause) and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, with its own ordering and segmentation expressions. They can only be used in the SELECT list of a query. UDTFs can be developed in C++, Python, Java, and R.

To optimize query performance, you can use live aggregate projections to pre-aggregate the data that a UDTF returns. For more information, see [Pre-Aggregating UDTF Results](#).
• **User-defined load** allows you to create custom sources, filters, and parsers to load data. These extensions can be used in COPY statements. UDLs can be developed in C++, Java and Python.

While each UDx type has a unique base class, developing them is similar in many ways. Different UDx types can also share the same library.
Handling Different Numbers and Types of Arguments

Usually, your UDxs accept a set number of arguments that are a specific data type (called its signature). You can create UDxs that handle multiple signatures, or even accept all arguments supplied to them by the user, using either of these techniques:

- Overloading your UDx by assigning the same SQL function name to multiple factory classes, each of which defines a unique function signature. When a user uses the function name in a query, Vertica tries to match the signature of the function call to the signatures declared by the factory's getPrototype method. This is the best technique to use if your UDx needs to accept a few different signatures (for example, accepting two required and one optional argument).
- Creating a polymorphic UDx by using the special "Any" argument type that tells Vertica to send all arguments that the user supplies to your function. Your UDx decides whether it can handle the arguments or not.

Overloading Your UDx

You may want your UDx to accept several different signatures (sets of arguments). For example, you might want your UDx to accept:

- One or more optional arguments.
- One or more arguments that can be one of several data types.
- Completely distinct signatures (either all INTEGER or all VARCHAR, for example).

You can create a function with this behavior by creating several factory classes, each of which accepts a different signature (the number and data types of arguments). You can then associate a single SQL function name with all of them. You can use the same SQL function name to refer to multiple factory classes as long as the signature defined by each factory is unique. When a user calls your UDx, Vertica matches the number and types of arguments supplied by the user to the arguments accepted by each of your function's factory classes. If one matches, Vertica uses it to instantiate a function class to process the data.

Multiple factory classes can instantiate the same function class, so you can re-use one function class that is able to process multiple sets of arguments and then create factory
classes for each of the function signatures. You can also create multiple function classes if you want.

See the C++ Example: Overloading Your UDx and Java Example: Overloading Your UDx examples.

**C++ Example: Overloading Your UDx**

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The Add2or3ints class is prepared to handle two or three arguments. The processBlock() function checks the number of arguments that have been passed to it, and adds all two or three of them together. It also exits with an error message if it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user’s function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else’s) factory class inaccurately reports a set of arguments your function class cannot handle.

```cpp
#include "Vertica.h"
using namespace Vertica;
using namespace std;

// a ScalarFunction that accepts two or three integers and adds them together.
class Add2or3ints : public Vertica::ScalarFunction
{
    public:
        virtual void processBlock(Vertica::ServerInterface &srvInterface,
                                   Vertica::BlockReader &arg_reader,
                                   Vertica::BlockWriter &res_writer)
        {
            const size_t numCols = arg_reader.getNumCols();

            // Ensure that only two or three parameters are passed in
            if (numCols < 2 || numCols > 3) {
                vt_report_error(0, "Function only accept 2 or 3 arguments, "
                                "but %zu provided", arg_reader.getNumCols());
            }

            // Add two integers together
            do {
                const vint a = arg_reader.getIntRef(0);
                const vint b = arg_reader.getIntRef(1);
                vint c = 0;

                // Check for third argument, add it in if it exists.
                if (numCols == 3) {
                    c = arg_reader.getIntRef(2);
                    res_writer.setInt(a+b+c);
                    res_writer.next();
                }
            } while (arg_reader.next());
        }

    // This factory accepts function calls with two integer arguments.
};
```
The example has two `ScalarFunctionFactory` classes, one for each signature that the function accepts (two integers and three integers). There is nothing unusual about these factory classes, except that their implementation of `ScalarFunctionFactory::createScalarFunction()` both create `Add2or3Ints` objects.

The final step is to bind the same SQL function name to both factory classes. You can assign multiple factories to the same SQL function, as long as the signatures defined by each factory's `getPrototype()` implementation are different.

```sql
=> CREATE LIBRARY add2or3IntsLib AS '/home/dbadmin/Add2or3Ints.so';
CREATE LIBRARY
=> CREATE FUNCTION add2or3ints as NAME 'Add2intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> CREATE FUNCTION add2or3ints as NAME 'Add3intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> SELECT add2or3ints(1,2);
add2or3ints
-------
3
(1 row)
=> SELECT add2or3ints(1,2,4);
```
add2or3Ints
------------
7
(1 row)
=> SELECT add2or3Ints(1,2,3,4); -- Will generate an error
ERROR 3467: Function add2or3Ints(int, int, int, int) does not exist, or
permission is denied for add2or3Ints(int, int, int, int)
HINT: No function matches the given name and argument types. You may
need to add explicit type casts

The error message in response to the final call to the add2or3Ints function was generated by Vertica, since it could not find a factory class associated with add2or3Ints that accepted four integer arguments. To expand add2or3Ints further, you could create another factory class that accepted this signature, and either change the Add2or3ints ScalarFunction class or create a totally different class to handle adding more integers together. However, adding more classes to accept each variation in the arguments quickly becomes overwhelming. In that case, you should consider creating a polymorphic UDx.

Java Example: Overloading Your UDx

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The Add2or3ints class is prepared to handle two or three arguments. It checks the number of arguments that have been passed to it, and adds all two or three of them together. The `processBlock()` method checks whether it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class reports that your function class accepts a set of arguments that it actually does not.

```java
// You need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;

// Import the entire Vertica SDK
import com.vertica.sdk.*;

// This ScalarFunction accepts two or three integer arguments. It tests
// the number of input columns to determine whether to read two or three
// arguments as input.
public class Add2or3ints extends ScalarFunction
{
    @Override
    public void processBlock(ServerInterface srvInterface,
                              BlockReader argReader,
                              BlockWriter resWriter)
        throws UdfException, DestroyInvocation
    {
        // See how many arguments were passed in
```
int numCols = argReader.getNumCols();

// Return an error if less than two or more than 3 arguments
// were given. This error only occurs if a Factory class that
// accepts the wrong number of arguments instantiates this
// class.
if (numCols < 2 || numCols > 3) {
    throw new UdfException(0,
        "Must supply 2 or 3 integer arguments");
}

// Process all of the rows of input.
do {
    // Get the first two integer arguments from the BlockReader
    long a = argReader.getLong(0);
    long b = argReader.getLong(1);

    // Assume no third argument.
    long c = 0;

    // Get third argument value if it exists
    if (numCols == 3) {
        c = argReader.getLong(2);
    }

    // Process the arguments and come up with a result. For this
    // example, just add the three arguments together.
    long result = a+b+c;

    // Write the integer output value.
    resWriter.setLong(result);

    // Advance the output BlockWriter to the next row.
    resWriter.next();

    // Continue processing input rows until there are no more.
    while (argReader.next());
} while (argReader.next());

The main difference between the Add2ints class and the Add2or3ints class is the inclusion of a section that gets the number of arguments by calling BlockReader.getNumCols(). This class also tests the number of columns it received from Vertica to ensure it is in the range it is prepared to handle. This test will only fail if you create a ScalarFunctionFactory whose getPrototype() method defines a signature that accepts less than two or more than three arguments. This is not really necessary in this simple example, but for a more complicated class it is a good idea to test the number of columns and data types that Vertica passed your function class.

Within the do loop, Add2or3ints uses a default value of zero if Vertica sent it two input columns. Otherwise, it retrieves the third value and adds that to the other two. Your own class needs to use default values for missing input columns or alter its processing in some other way to handle the variable columns.
You must define your function class in its own source file, rather than as an inner class of one of your factory classes since Java does not allow the instantiation of an inner class from outside its containing class. You factory class has to be available for instantiation by multiple factory classes.

Once you have created a function class or classes, you create a factory class for each signature you want your function class to handle. These factory classes can call individual function classes, or they can all call the same class that is prepared to accept multiple sets of arguments.

The following example's createScalarFunction() method instantiates a member of the Add2or3ints class.

```java
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
        ColumnTypes argTypes,
        ColumnTypes returnType)
    {
        // Accept two integers as input
        argTypes.addInt();
        argTypes.addInt();
        // writes one integer as output
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiate the class that can handle either 2 or 3 integers.
        return new Add2or3ints();
    }
}
```

The following ScalarFunctionFactory subclass accepts three integers as input. It, too, instantiates a member of the Add2or3ints class to process the function call:

```java
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add3intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
        ColumnTypes argTypes,
        ColumnTypes returnType)
    {
```

Vertica Analytic Database (9.3.x)
// Accepts three integers as input
argTypes.addInt();
argTypes.addInt();
argTypes.addInt();
// Returns a single integer
returnType.addInt();

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface)
{
    // Instantiates the Add2or3ints ScalarFunction class, which is able to
    // handle either 2 or 3 integers as arguments.
    return new Add2or3ints();
}

The factory classes and the function class or classes they call must be packaged into the
same JAR file (see Compiling and Packaging a Java Library for details). If a host in the
database cluster has the JDK installed on it, you could use the following commands to
compile and package the example:

$ cd pathToJavaProject
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
> com/mycompany/multiparamexample/*.java
$ jar -cvf Add2or3intslib.jar com/vertica/sdk/BuildInfo.class \
> com/mycompany/multiparamexample/*.class
  added manifest
  adding: com/vertica/sdk/BuildInfo.class (in = 1202) (out = 689) (deflated 42%)
  adding: com/mycompany/multiparamexample/Add2intsFactory.class (in = 677) (out = 366) (deflated 45%)
  adding: com/mycompany/multiparamexample/Add2or3ints.class (in = 919) (out = 601) (deflated 34%)
  adding: com/mycompany/multiparamexample/Add3intsFactory.class (in = 685) (out = 369) (deflated 46%)

Once you have packaged your overloaded UDx, you deploy it the same way as you do a
regular UDx, except you use multiple CREATE FUNCTION statements to define the function,
once for each factory class.

=> CREATE LIBRARY add2or3intslib as '/home/dbadmin/Add2or3intslib.jar'
  -> language 'Java';
  CREATE LIBRARY
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
  'com.mycompany.multiparamexample.Add2intsFactory' LIBRARY add2or3intslib;
  CREATE FUNCTION
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
  'com.mycompany.multiparamexample.Add3intsFactory' LIBRARY add2or3intslib;
  CREATE FUNCTION

You call the overloaded function the same way you call any other function.

=> SELECT add2or3ints(2,3);
add2or3ints
----------
5
(1 row)
=> SELECT add2or3ints(2,3,4);
The last error was generated by Vertica, not the UDx code. It returns an error if it cannot find a factory class whose signature matches the function call's signature.

Creating an overloaded UDx is useful if you want your function to accept a limited set of potential arguments. If you want to create a more flexible function, you can create a polymorphic function.

**Creating a Polymorphic UDx**

Polymorphic UDx's accept any number and type of argument that the user supplies. Vertica does not check the number or types of argument that the user passes to the UDx—it just passes the UDx all of the arguments supplied by the user. It is up to your polymorphic UDx's main processing function (for example, `processBlock()` in user-defined scalar functions) to examine the number and types of arguments it received and determine if it can handle them.

**Note:**
UDxs have a maximum 1600 arguments.

Polymorphic UDx's are more flexible than using multiple factory classes for your function (see Overloading Your UDx), because your function can determine at run time if it can process the arguments rather than accepting specific sets of arguments. However, your polymorphic function needs to perform more work to determine whether it can process the arguments that it has been given.

Your polymorphic UDx declares that it accepts any number of arguments in its factory's `getPrototype()` function by calling the `addAny()` function on the `ColumnType` object that defines its arguments. This "any parameter" argument type is the only one that your function can declare. You cannot define required arguments and then call `addAny()` to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.
Polymorphic UDxs and Schema Search Paths

If a user does not supply a schema name as part of a UDx call, Vertica searches each schema in the schema search path for a function whose name and signature match the function call. See Setting Search Paths in the Administrator's Guide for more information about schema search paths.

Since polymorphic UDxs do not have a specific signature associated with them, Vertica initially skips them when searching for a function to handle the function call. If none of the schemas in the search path contain a UDx whose name and signature match the function call, Vertica searches the schema search path again for a polymorphic UDx whose name matches the function name in the function call.

This behavior gives precedence to UDxs whose signature exactly matches the function call. It allows you to create a "catch all" polymorphic UDx that Vertica calls only when none of the non-polymorphic UDxs with the same name have matching signatures.

This behavior may cause confusion if your users expect the first polymorphic function in the schema search path to handle a function call. To avoid confusion, you should:

- Avoid using the same name for different UDxs. You should always uniquely name UDxs unless you intend to create an overloaded UDx with multiple signatures.
- When you cannot avoid having UDxs with the same name in different schemas, always supply the schema name as part of the function call. Using the schema name prevents ambiguity and ensures that Vertica uses the correct UDx to process your function calls.

C++ Example: Polymorphic UDx

The following example shows an implementation of a ScalarFunction that adds together two or more integers.

```cpp
#include "Vertica.h"
using namespace Vertica;
using namespace std;
// Adds two or more integers together.
class AddManyInts : public Vertica::ScalarFunction
{
public:
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                               Vertica::BlockReader &arg_reader,
```
```cpp
Vertica::BlockWriter &res_writer)
{
    // Always catch exceptions to prevent causing the side process or
    // Vertica itself from crashing.
    try {
        // Find the number of arguments sent.
        size_t numCols = arg_reader.getNumCols();

        // Make sure at least 2 arguments were supplied
        if (numCols < 2)
            vt_report_error(0, "Function expects at least 2 integer parameters");

        // Make sure all types are ints
        const SizedColumnTypes &inTypes = arg_reader.getTypeMetaData();
        for (int param=0; param < (int)numCols; param++)
        {
            const VerticaType &t = inTypes.getColumnType(param);
            if (!t.isInt())
            {
                string typeDesc = t.getPrettyPrintStr();
                // Report that the user supplied a non-integer value.
                vt_report_error(0, "Function expects all arguments to be "
                               "INTEGER. Argument %d was %s", param+1,
                               typeDesc.c_str());
            }
        }
        do {
            // total up the arguments and write out the total.
            vint total = 0;
            int x;
            // Loop over all params, adding them up.
            for (x=0; x<(int)numCols; x++)
            {
                total += arg_reader.getIntRef(x);
            }
            res_writer.setInt(total);
            res_writer.next();
        } while (arg_reader.next());
        catch(exception& e) {
            // Standard exception. Quit.
            vt_report_error(0, "Exception while processing partition: [%s]",
                            e.what());
        }
    }
};
```

// Defines the AddMany function.
class AddManyIntsFactory : public Vertica::ScalarFunctionFactory
{
    // Return the function object to process the data.
    virtual Vertica::ScalarFunction *createScalarFunction(
        Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, AddManyInts); }
    // Define the number and types of arguments that this function accepts
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addAny(); // Must be only argument type.
        returnType.addInt();
    }
};
Most of the work in the example is done by the `ScalarFunction.processBlock()` function. It performs two checks on the arguments that have been passed in through the `BlockReader` object:

- Ensures there are at least two arguments
- Checks the data type of all arguments to ensure they are all integers

Once the checks are performed, the example processes the block of data by looping over the arguments and adding them together.

You assign a SQL name to your polymorphic UDX using the same statement you use to assign one to a non-polymorphic UDX. The following demonstration shows how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY addManyIntsLib AS '/home/dbadmin/AddManyInts.so';
CREATE LIBRARY
=> CREATE FUNCTION addManyInts AS 'AddManyIntsFactory' LIBRARY addManyIntsLib FENCED;
CREATE FUNCTION
=> SELECT addManyInts(1,2);
addManyInts
--------
 3
(1 row)
=> SELECT addManyInts(1,2,3,40,50,60,70,80,900);
addManyInts
--------
1206
(1 row)
=> SELECT addManyInts(1);  -- Too few parameters
ERROR 3412: Failure in UDX RPC call InvokeProcessBlock(): Error calling processBlock() in User-Defined Object [addManyInts] at [AddManyInts.cpp:51], error code: 0, message: Exception while processing partition: [Function expects at least 2 integer parameters]
=> SELECT addManyInts(1,2.232343);  -- Wrong data type
ERROR 3412: Failure in UDX RPC call InvokeProcessBlock(): Error calling processBlock() in User-Defined Object [addManyInts] at [AddManyInts.cpp:51], error code: 0, message: Exception while processing partition: [Function expects all arguments to be INTEGER. Argument 2 was Numeric(7,6)]
```

Notice that the errors returned by last two calls to the function were generated by the `processBlock()` function. It is up to your UDX to ensure that the user supplies the correct number and types of arguments to your function and exit with an error if it cannot process them.
Java Example: Polymorphic UDx

The following example shows an implementation of a ScalarFunctionFactory class with an inner ScalarFunction class that adds together two or more integers.

```java
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// Factory class to create polymorphic UDSF that adds all of the integer
// arguments it receives and returns a sum.
public class AddManyIntsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface,
        ColumnTypes argTypes,
        ColumnTypes returnType)
    {
        // Accepts any number and type or arguments. The ScalarFunction
        // class handles parsing the arguments.
        argTypes.addAny();
        // writes one integer as output
        returnType.addInt();
    }
    // This polymorphic ScalarFunction adds all of the integer arguments passed
    // to it. Returns an error if there are less than two arguments, or if one
    // argument is not an integer.
    public class AddManyInts extends ScalarFunction {
        @Override
        public void processBlock(ServerInterface srvInterface,
            BlockReader argReader,
            BlockWriter resWriter)
            throws UdfException, DestroyInvocation
        {
            // See how many arguments were passed in
            int numCols = argReader.getNumCols();

            // Return an error if less than two arguments were given.
            if (numCols < 2) {
                throw new UdfException(0,
                    "Must supply at least 2 integer arguments");
            }

            // Make sure all input columns are integer.
            SizedColumnTypes inTypes = argReader.getTypeMetaData();
            for (int param = 0; param < numCols; param++) {
                VerticaType paramType = inTypes.getColumnType(param);
                if (!paramType.isInt()) {
                    throw new UdfException(0,
                        "Error: Argument " + (param+1) + 
                        " was not an integer. All arguments must be integer.");
                }
            }
        }
    }
}
```
// Process all of the rows of input.
    do {
        long total = 0; // Hold the running total of arguments

        // Get all of the arguments and add them up
        for (int x = 0; x < numCols; x++) {
            total += argReader.getLong(x);
        }

        // Write the integer output value.
        resWriter.setLong(total);

        // Advance the output BlockWriter to the next row.
        resWriter.next();

        // Continue processing input rows until there are no more.
    } while (argReader.next());

@override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
{
    // Instantiate the polymorphic UDF class.
    return new AddManyInts();
}

The ScalarFunctionFactory.getPrototype() method calls the addAny() method to declare that the UDSF is polymorphic.

Most of the work in the example is done by the ScalarFunction.processBlock() method. It performs two checks on the arguments that have been passed in through the BlockReader object:

- There are at least two arguments.
- The data type of all arguments are integers.

It is up to your polymorphic UDx to determine that all of the input passed to it is valid.

Once the processBlock() method validates its arguments, it loops over them, adding them together.

You assign a SQL name to your polymorphic UDx using the same statement you use to assign one to a non-polymorphic UDx. The following demonstration shows how you load and call the polymorphic function from the example.

```sql
=> CREATE LIBRARY addmanyintslib AS '/home/dbadmin/AddManyIntsLib.jar'
    -> LANGUAGE 'Java';
CREATE LIBRARY
=> CREATE FUNCTION addmanyints AS LANGUAGE 'Java' NAME
    -> 'com.mycompany.multiparamexample.AddManyIntsFactory' LIBRARY addmanyintslib;
CREATE FUNCTION
R Example: Polymorphic UDx

The following example shows an implementation of a Transform Function (UDTF) that performs kmeans clustering on one or more input columns.

```r
kmeansPoly <- function(v.data.frame, v.param.list) {
# Computes clusters using the kmeans algorithm.
#
# Input: A dataframe and a list of parameters.
# Output: A dataframe with one column that tells the cluster to which each data
# point belongs.
# Args:
# v.data.frame: The data from Vertica cast as an R data frame.
# v.param.list: List of function parameters.
# Returns:
# The cluster associated with each data point.
# Ensure k is not null.
if(!is.null(v.param.list[['k']])) {
    number_of_clusters <- as.numeric(v.param.list[['k']])
} else {
    stop("K cannot be NULL! Please use a valid value."")
}
# Run the kmeans algorithm.
kmeans_clusters <- kmeans(v.data.frame, number_of_clusters)
final.output <- data.frame(kmeans_clusters$cluster)
return(final.output)
```
kmeansFactoryPoly <- function() {
  # This function tells Vertica the name of the R function, 
  # and the polymorphic parameters.
  list(name=kmeansPoly, udxtype=c("transform"), intype=c("any"), 
       outtype=c("int"), parametertypecallback=kmeansParameters)
}

kmeansParameters <- function() {
  # Callback function for the parameter types.
  function.parameters <- data.frame(datatype=rep(NA, 1), length=rep(NA,1), 
                                   scale=rep(NA,1), name=rep(NA,1))
  function.parameters[1,1] = "int"
  function.parameters[1,4] = "k"
  return(function.parameters)
}

The polymorphic R function declares it accepts any number of arguments in its factory function by specifying "any" as the argument to the intype parameter and optionally the outtype parameter. If you define "any" argument for intype or outtype, then it is the only type that your function can declare for the respective parameter. You cannot define required arguments and then call "any" to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

The outtypecallback method is used to indicate the argument types and sizes it has been called with, and is expected to indicate the types and sizes that the function returns. The outtypecallback method can also be used to check for unsupported types and/or number of arguments. For example, the function may require only integers, with no more than 10 of them.

You assign a SQL name to your polymorphic U Dx using the same statement you use to assign one to a non-polymorphic U Dx. The following statements show how you load and call the polymorphic function from the example.

```sql
=> CREATE LIBRARY rlib2 AS '/home/dbadmin/R_UDx/poly_kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION kmeansPoly AS LANGUAGE 'R' name 'kmeansFactoryPoly' LIBRARY rlib2;
CREATE FUNCTION
=> SELECT spec, kmeansPoly(sl,sw,pl,pw USING PARAMETERS k = 3) 
OVER(PARTITION BY spec) AS Clusters 
FROM iris; 
spec | Clusters 
-------------------+----------------- 
Iris-setosa | 1 
Iris-setosa | 1 
Iris-setosa | 1 
Iris-setosa | 1 
. 
. 
. 
```
**UDx Parameters**

Parameters let you define arguments for your UDxs that remain constant across all of the rows processed by the SQL statement that calls your UDx. Typically, your UDxs accept arguments that come from columns in a SQL statement. For example, in the following SQL statement, the arguments a and b to the `add2ints` UDSF change value for each row processed by the SELECT statement:

```sql
=> SELECT a, b, add2ints(a,b) AS 'sum' FROM example;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>11</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>15</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>19</td>
</tr>
</tbody>
</table>

(5 rows)

Parameters remain constant for all the rows your UDx processes. You can also make parameters optional so that if the user does not supply it, your UDx uses a default value. For example, the following example demonstrates calling a UDSF named `add2intsWithConstant` that has a single parameter value named constant whose value is added to each the arguments supplied in each row of input:

```sql
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS constant=42)
     AS 'a+b+42' FROM example;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a+b+42</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>45</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>49</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>53</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>57</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>61</td>
</tr>
</tbody>
</table>

(5 rows)

**Note:**
When calling a UDx with parameters, there is no comma between the last argument and the USING PARAMETERS clause.

The topics in this section explain how to develop UDxs that accept parameters.
Defining the Parameters Your UDx Accepts

You define the parameters that your UDx accepts in its factory class (ScalarFunctionFactory, AggregateFunctionFactory, and so on) by implementing getParameterType(). This method is similar to getReturnType(): you call data-type-specific methods on a SizedColumnTypes object that is passed in as a parameter. Each function call sets the name, data type, and width or precision (if the data type requires it) of the parameter.

Setting Parameter Properties (C++ Only)

When you add parameters to the getParameterType() function using the C++ API, you can also set properties for each parameter. For example, you can define a parameter as being required by the UDx. Doing so lets the Vertica server know that every UDx invocation must provide the specified parameter, or the query fails.

By passing an object to the SizedColumnTypes::Properties class, you can define the following four parameter properties:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>visible</td>
<td>BOOLEAN</td>
<td>If set to TRUE, the parameter appears in the USER_FUNCTION_PARAMETERS table. You may want to set this to FALSE to declare a parameter for internal use only.</td>
</tr>
<tr>
<td>required</td>
<td>BOOLEAN</td>
<td>If set to TRUE:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The parameter is required when invoking the UDx.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Invoking the UDx without supplying the parameter results in an error, and the UDx does not run.</td>
</tr>
<tr>
<td>canBeNull</td>
<td>BOOLEAN</td>
<td>If set to TRUE, the parameter can have a NULL value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If set to FALSE, make sure that the supplied parameter does not contain a NULL value when invoking the UDx. Otherwise, an error results, and the UDx does not run.</td>
</tr>
<tr>
<td>comment</td>
<td>VARCHAR(128)</td>
<td>A comment to describe the parameter.</td>
</tr>
</tbody>
</table>
### Setting Parameter Properties (R Only)

When using parameters in your R UDx, you must specify a field in the factory function called `parametertypecallback`. This field points to the callback function that defines the parameters expected by the function. The callback function defines a four-column data frame with the following properties:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datatype</td>
<td>VARCHAR(128)</td>
<td>The data type of the parameter.</td>
</tr>
<tr>
<td>length</td>
<td>INTEGER</td>
<td>The dimension of the parameter.</td>
</tr>
<tr>
<td>scale</td>
<td>INTEGER</td>
<td>The proportional dimensions of the parameter.</td>
</tr>
<tr>
<td>name</td>
<td>VARCHAR(128)</td>
<td>The name of the parameter.</td>
</tr>
</tbody>
</table>

If any of the columns are left blank (or the `parametertypecallback` function is omitted), then Vertica uses default values.

For more information, see [parametertypecallback Function](#).

### Getting Parameter Values in UDxs

Your UDx uses the parameter values it declared in its factory class (see [Defining the Parameters Your UDx Accepts](#)) in its function class's processing method (for example, `processBlock()` or `processPartition()`). It gets its parameter values from a `ParamReader` object, which is available from the `ServerInterface` object that is passed to your processing method. Reading parameters from this object is similar to reading...
argument values from BlockReader or PartitionReader objects: you call a data-type-specific function with the name of the parameter to retrieve its value. For example, in C++:

```cpp
// Get the parameter reader from the ServerInterface to see if there are supplied parameters.
ParamReader paramReader = srvInterface.getParamReader();
// Get the value of an int parameter named constant.
const vint constant = paramReader.getIntRef("constant");
```

**Note:**
String data values do not have any of their escape characters processed before they are passed to your function. Therefore, your function may need to process the escape sequences itself if it needs to operate on unescaped character values.

### Using Parameters in the Factory Class

In addition to using parameters in your UDx function class, you can also access the parameters in the factory class. You may want to access the parameters to let the user control the input or output values of your function in some way. For example, your UDx can have a parameter that lets the user choose to have your UDx return a single- or double-precision value. The process of accessing parameters in the factory class is the same as accessing it in the function class: get a ParamReader object from the ServerInterface's getParamReader() method, them read the parameter values.

### Testing Whether the User Supplied Parameter Values

Unlike its handling of arguments, Vertica does not immediately return an error if a user's function call does not include a value for a parameter defined by your UDx's factory class. This means that your function can attempt to read a parameter value that the user did not supply. If it does so, by default Vertica returns a non-existent parameter warning to the user, and the query containing the function call continues.

If you want your parameter to be optional, you can test whether the user supplied a value for the parameter before attempting to access its value. Your function determines if a value exists for a particular parameter by calling the ParamReader's containsParameter() method with the parameter's name. If this call returns true, your function can safely retrieve the value. If this call returns false, your UDx can use a default value or change its processing in some other way to compensate for not having the parameter value. As long as your UDx does not try to access the non-existent parameter value, Vertica does not generate an error or warning about missing parameters.
Note:
If the user passes your UDx a parameter that it has not defined, by default Vertica issues a warning that the parameter is not used. It still executes the SQL statement, ignoring the parameter. You can change this behavior by altering the StrictUDxParameterChecking configuration parameter.

See C++ Example: Defining Parameters for an example.

Calling UDxs with Parameters

You pass parameters to a UDx by adding a USING PARAMETERS clause in the function call after the last argument.

- Do not insert a comma between the last argument and the USING PARAMETERS clause.
- After the USING PARAMETERS clause, add one or more parameter definitions, in the following form:

  `<parameter name> = <parameter value>`

  - Separate parameter definitions by commas.

Parameter values can be a constant expression (for example 1234 + SQRT(5678)). You cannot use volatile functions (such as RANDOM) in the expression, because they do not return a constant value. If you do supply a volatile expression as a parameter value, by default, Vertica returns an incorrect parameter type warning. Vertica then tries to run the UDx without the parameter value. If the UDx requires the parameter, it returns its own error, which cancels the query.

Calling a UDx with a Single Parameter

The following example demonstrates how you can call the Add2intsWithConstant UDSF example shown in C++ Example: Defining Parameters:

```sql
=> SELECT a, b, Add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' from example;
 a | b  | a+b+42
----+----+---------
 1  | 2  |   45    
 3  | 4  |   49    
 5  | 6  |   53    
```
To remove the first instance of the number 3, you can call the `RemoveSymbol UDSF` example:

```sql
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3');
```

<table>
<thead>
<tr>
<th>original_string</th>
<th>RemoveSymbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>3re3mo3ve3sy3mb3ol</td>
<td>re3mo3ve3sy3mb3ol</td>
</tr>
</tbody>
</table>

(1 row)

### Calling a UDx with Multiple Parameters

The following example shows how you can call a version of the `tokenize UDTF`. This UDTF includes parameters to limit the shortest allowed word and force the words to be output in uppercase. Separate multiple parameters with commas.

```sql
=> SELECT url, tokenize(description USING PARAMETERS minLength=4, uppercase=true) OVER (partition by url) FROM T;
```

<table>
<thead>
<tr>
<th>url</th>
<th>words</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>ONLINE</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>RETAIL</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>MERCHANT</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>PROVIDER</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>CLOUD</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>SERVICES</td>
</tr>
<tr>
<td><a href="http://www.dell.com">www.dell.com</a></td>
<td>LEADING</td>
</tr>
<tr>
<td><a href="http://www.dell.com">www.dell.com</a></td>
<td>PROVIDER</td>
</tr>
<tr>
<td><a href="http://www.dell.com">www.dell.com</a></td>
<td>COMPUTER</td>
</tr>
<tr>
<td><a href="http://www.dell.com">www.dell.com</a></td>
<td>HARDWARE</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>WORLD'S</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>FASTEST</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>ANALYTIC</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>DATABASE</td>
</tr>
</tbody>
</table>

(16 rows)

The following example calls the `RemoveSymbol UDSF`. By changing the value of the optional parameter, `n`, you can remove all instances of the number 3:

```sql
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', n=6);
```

<table>
<thead>
<tr>
<th>original_string</th>
<th>RemoveSymbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>3re3mo3ve3sy3mb3ol</td>
<td>removesymbol</td>
</tr>
</tbody>
</table>

(1 row)
Calling a UDx with Optional or Incorrect Parameters

You can optionally add the Add2intsWithConstant UDSF's constant parameter. Calling this constraint without the parameter does not return an error or warning:

```sql
=> SELECT a, b, Add2intsWithConstant(a, b) AS 'sum' FROM example;
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>11</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>15</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>19</td>
</tr>
</tbody>
</table>
(5 rows)
```

Although calling a UDx with incorrect parameters generates a warning, by default, the query still runs. For further information on setting the behavior of your UDx when you supply incorrect parameters, see Specifying the Behavior of Passing Unregistered Parameters.

```sql
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS wrongparam=42) AS 'result' from example;
WARNING 4332: Parameter wrongparam was not registered by the function and cannot be coerced to a definite data type
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>11</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>15</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>19</td>
</tr>
</tbody>
</table>
(5 rows)
```

Specifying the Behavior of Passing Unregistered Parameters

By default, Vertica issues a warning message when you pass a UDx an unregistered parameter. An unregistered parameter is one that you did not declare in the getParameterType() method.

You can control the behavior of your UDx when you pass it an unregistered parameter by altering the StrictUDxParameterChecking configuration parameter.
Unregistered Parameter Behavior Settings

You can specify the behavior of your UDx in response to one or more unregistered parameters. To do so, set the `StrictUDxParameterChecking` configuration parameter to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Allows unregistered parameters to be accessible to the UDx. The <code>ParamReader</code> class's <code>getType()</code> method determines the data type of the unregistered parameter. Vertica does not display any warning or error message.</td>
</tr>
<tr>
<td>1</td>
<td>[Default Value] Ignores the unregistered parameter and allows the function to run. Vertica displays a warning message.</td>
</tr>
<tr>
<td>2</td>
<td>Returns an error and does not allow the function to run.</td>
</tr>
</tbody>
</table>

Examples

The following examples demonstrate the behavior you can specify using different values with the `StrictUDxParameterChecking` parameter.

View the Current Value of `StrictUDxParameterChecking`

To view the current value of the `StrictUDxParameterChecking` configuration parameter, run the following query:

```
=> \x
Expanded display is on.
=> SELECT * FROM configuration_parameters WHERE parameter_name = 'StrictUDxParameterChecking';
-[-[ RECORD 1 ]-]-
node_name | ALL
parameter_name | StrictUDxParameterChecking
```
Change the Value of StrictUDxParameterChecking

You can change the value of the StrictUDxParameterChecking configuration parameter at the database, node, or session level. For example, you can change the value to '0' to specify that unregistered parameters can pass to the UDx without displaying a warning or error message:

```sql
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
ALERT DATABASE
```

Invalid Parameter Behavior with RemoveSymbol

The following example demonstrates how to call the RemoveSymbol UDSF example. The RemoveSymbol UDSF has a required parameter, symbol, and an optional parameter, n. In this case, you do not use the optional parameter.

If you pass both symbol and an additional parameter called wrongParam, which is not declared in the UDx, the behavior of the UDx changes corresponding to the value of StrictUDxParameterChecking.

When you set StrictUDxParameterChecking to '0', the UDx runs normally without a warning. Additionally, wrongParam becomes accessible to the UDx through the ParamReader object of the ServerInterface object:
When you set `StrictUDxParameterChecking` to '1', the UDx ignores `wrongParam` and runs normally. However, it also issues a warning message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 1;
ALTER DATABASE
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
    original_string   RemoveSymbol
-----------------+-----------------------------------
3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set `StrictUDxParameterChecking` to '2', the UDx encounters an error when it tries to call `wrongParam` and does not run. Instead, it generates an error message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 2;
ALTER DATABASE
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
ERROR 0: Parameter wrongParam was not registered by the function
```

- [Setting Configuration Parameter Values](#)

**User-Defined Session Parameters**

User-defined session parameters allow you to write more generalized parameters than what Vertica provides. You can configure user-defined session parameters in these ways:

- From the client—for example, with `ALTER SESSION`
- Through the UDx itself
A user-defined session parameter can be passed into any type of UDx supported by Vertica. You can also set parameters for your UDx at the session level. By specifying a user-defined session parameter, you can have the state of a parameter saved continuously. Vertica saves the state of the parameter even when the UDx is invoked multiple times during a single session.

The RowCount example uses a user-defined session parameter. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions. See C++ Example: Using Session Parameters and Java Example: Using Session Parameters for implementations.

**Viewing the User-Defined Session Parameter**

Enter the following command to see the value of all session parameters:

```sql
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
----------+------------+-----+-------
(0 rows)
```

No value has been set, so the table is empty. Now, execute the UDx:

```sql
=> SELECT RowCount(5,5);
RowCount
----------
10
(1 row)
```

Again, enter the command to see the value of the session parameter:

```sql
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
----------+------------+-----+-------
public | UDSession | rowcount | 1
(1 row)
```

The library column shows the name of the library containing the UDx. This is the name set with CREATE LIBRARY. Because the UDx has processed one row, the value of the rowcount session parameter is now 1. Running the UDx two more times should increment the value twice.

```sql
=> SELECT RowCount(10,10);
RowCount
----------
20
(1 row)
=> SELECT RowCount(15,15);
```
RowCount
---------
30
(1 row)

You have now executed the UDx three times, obtaining the sum of 5 + 5, 10 + 10, and 15 + 15. Now, check the value of rowcount.

```sql
=> SHOW SESSION UDPARAMETER all;
schema  | library  | key     | value
---------|----------|---------|--------
public   | UDSession| rowcount| 3      
(1 row)
```

**Altering the User-Defined Session Parameter**

You can also manually alter the value of rowcount. To do so, enter the following command:

```sql
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 25;
ALTER SESSION
```

Check the value of RowCount:

```sql
=> SHOW SESSION UDPARAMETER all;
schema  | library  | key     | value
---------|----------|---------|--------
public   | UDSession| rowcount| 25     
(1 row)
```

**Clearing the User-Defined Session Parameter**

**From the client:**

To clear the current value of rowcount, enter the following command:

```sql
=> ALTER SESSION CLEAR UDPARAMETER FOR UDSession rowcount;
ALTER SESSION
```

Verify that rowcount has been cleared:

```sql
=> SHOW SESSION UDPARAMETER all;
schema  | library  | key     | value
---------|----------|---------|--------
(0 rows)
```

**Through the UDx in C++:**
You can set the session parameter to clear through the UDx itself. For example, to clear rowcount when its value reaches 10 or greater, do the following:

1. Remove the following line from the `destroy()` method in the RowCount class:

   ```java
   udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
   ```

2. Replace the removed line from the `destroy()` method with the following code:

   ```java
   if (rowCount < 10) {
     udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
   } else {
     udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
   }
   ```

3. To see the UDx clear the session parameter, set rowcount to a value of 9:

   ```sql
   => ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
   ALTER SESSION
   ```

4. Check the value of rowcount:

   ```sql
   => SHOW SESSION UDPARAMETER all;
   schema | library | key | value
   -----------+-----------+------+-
   public | UDSession | rowcount | 9
   (1 row)
   ```

5. Invoke RowCount so that its value becomes 10:

   ```sql
   => SELECT RowCount(15,15);
   RowCount
   -----------
   30
   (1 row)
   ```

6. Check the value of rowcount again. Because the value has reached 10, the threshold specified in the UDx, expect that rowcount is cleared:

   ```sql
   => SHOW SESSION UDPARAMETER all;
   schema | library | key | value
   -----------+-----------+------+-
   (0 rows)
   ```

   As expected, RowCount is cleared.

**Through the UDx in Java:**
1. Remove the following lines from the `destroy()` method in the `RowCount` class:

```java
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
srvInterface.log("RowNumber processed %d records", count);
```

2. Replace the removed lines from the `destroy()` method with the following code:

```java
if (rowCount < 10) {
    udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
    srvInterface.log("RowNumber processed %d records", count);
} else {
    udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set `rowcount` to a value of 9:

```sql
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
ALTER SESSION
```

4. Check the value of `rowcount`:

```sql
=> SHOW SESSION UDPARAMETER all;
```

```
schema | library | key     | value
----------|---------|---------|---------
 public | UDSession | rowcount | 9
(1 row)
```

5. Invoke `RowCount` so that its value becomes 10:

```sql
=> SELECT RowCount(15,15);
```

```
RowCount
--------
30
(1 row)
```

6. Check the value of `rowcount`. Since the value has reached 10, the threshold specified in the UDx, expect that `rowcount` is cleared:

```sql
=> SHOW SESSION UDPARAMETER all;
```

```
schema | library | key     | value
----------|---------|---------|---------
 (0 rows)
```

As expected, `rowcount` is cleared.
Read-Only and Hidden Session Parameters

If you don't want a parameter to be set anywhere except in the U Dx, you can make it read-only. If, additionally, you don't want a parameter to be visible in the client, you can make it hidden.

To make a parameter read-only, meaning that it cannot be set in the client, but can be viewed, add a single underscore before the parameter's name. For example, to make rowCount read-only, change all instances in the U Dx of "rowCount" to "_rowCount".

To make a parameter hidden, meaning that it cannot be viewed in the client nor set, add two underscores before the parameter's name. For example, to make rowCount hidden, change all instances in the U Dx of "rowCount" to "__rowCount".

Kafka User-Defined Session Parameters

C++ Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the C++ add2ints UDSF example. The getParameterType() function defines a single integer parameter that is named constant.

```cpp
class Add2intsWithConstantFactory : public ScalarFunctionFactory
{
    // Return an instance of Add2ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2ints class instance.
        return vt_createFuncObj(interface.allocator, Add2intsWithConstant);
    }
    // Report the argument and return types to Vertica.
    virtual void getPrototype(ServerInterface &interface,
                               ColumnTypes &argTypes,
                               ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object.
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single int.
    }
};
```
See the Vertica SDK entry for SizedColumnTypes for a full list of the data-type-specific functions you can call to define parameters.

The following code fragment demonstrates using the parameter value. The Add2intsWithConstant class defines a function that adds two integer values. If the user supplies it, the function also adds the value of the optional integer parameter named constant.

```cpp
/**
 * A UDSF that adds two numbers together with a constant value.
 */
class Add2intsWithConstant : public ScalarFunction
{
public:
  // Processes a block of data sent by Vertica.
  virtual void processBlock(ServerInterface &srvInterface,
                         BlockReader &arg_reader,
                         BlockWriter &res_writer)
  {
    try
    {
      // The default value for the constant parameter is 0.
      vint constant = 0;

      // Get the parameter reader from the ServerInterface to see if there are supplied parameters.
      ParamReader paramReader = srvInterface.getParamReader();
      if (paramReader.containsParameter("constant"))
        // There is a parameter, so get its value.
        constant = paramReader.getIntRef("constant");
      while we have input to process:
        do
          { // Read the two integer input parameters by calling the BlockReader.getIntRef class function.
            // Add arguments plus constant.
            res_writer.setInt(a+b+constant);
            // Finish writing the row, and advance to the next output row.
            res_writer.next();
            // Continue looping until there are no more input rows.
          }
    }
  }
};
```

RegisterFactory(Add2intsWithConstantFactory);
C++ Example: Using Session Parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the U Dx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```cpp
#include <string>
#include <sstream>
#include <iostream>
#include "Vertica.h"
#include "VerticaUDx.h"
using namespace Vertica;

class RowCount : public Vertica::ScalarFunction
{
private:
    int rowCount;
    int count;

class RowCount : public Vertica::ScalarFunction
{
private:
    int rowCount;
    int count;

public:

    virtual void setup(Vertica::ServerInterface &srvInterface, const Vertica::SizedColumnTypes &argTypes)
    {
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        std::string rCount = pSessionParams.containsParameter("rowCount")?
            pSessionParams.getStringRef("rowCount").str(): "0";
        rowCount=atoi(rCount.c_str());
    }

    virtual void processBlock(Vertica::ServerInterface &srvInterface, Vertica::BlockReader &arg_reader,
        Vertica::BlockWriter &res_writer) {
        count = 0;
        if(arg_reader.getNumCols() != 2)
            vt_report_error(0, "Function only accepts two arguments, but %zu provided", arg_reader.getNumCols());

        do {
            const Vertica::vint a = arg_reader.getIntRef(0);
            const Vertica::vint b = arg_reader.getIntRef(1);
```
Java Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the Java add2ints UDSF example. The `getParameterType()` method defines a single integer parameter that is named constant.

```java
package com.mycompany.example;
import com.vertica.sdk.*;
public class Add2IntsWithConstantFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType) {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
}
RegisterFactory(Add2IntsWithConstantFactory);
```
ColumnTypes returnType) {
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
}

@Override
public void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) {
    returnType.addInt("sum");
}

// Defines the parameters for this UDSF. Works similarly to defining arguments and return types.
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes) {
    // One INTEGER parameter named constant
    parameterTypes.addInt("constant");
}

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface) {
    return new Add2intsWithConstant();
}

See the Vertica Java SDK entry for SizedColumnTypes for a full list of the data-type-specific methods you can call to define parameters.

Java Example: Using Session Parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

package com.mycompany.example;
import com.vertica.sdk.*;

public class RowCountFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType) {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
}
public class RowCount extends ScalarFunction {

    private Integer count;
    private Integer rowCount;

    // In the setup method, you look for the rowCount parameter. If it doesn't exist, it is created.
    // Look in the default namespace which is "library," but it could be anything else, most likely
    "public" if not "library".
    @Override
    public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes) {
        count = new Integer(0);
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        String rCount = pSessionParams.containsParameter("rowCount")?
            pSessionParams.getString("rowCount"): "0";
        rowCount = Integer.parseInt(rCount);
    }

    @Override
    public void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_writer)
        throws UdfException, DestroyInvocation {
        do {
            ++count;
            long a = arg_reader.getLong(0);
            long b = arg_reader.getLong(1);
            res_writer.setLong(a+b);
            res_writer.next();
        } while (arg_reader.next());
    }

    @Override
    public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes,
        SessionParamWriterMap udParams){
        rowCount = rowCount+count;
        udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
    srvInterface.log("RowNumber processed %d records", count);
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new RowCount();
    }
}

Handling Cancel Requests

Users of your UDX might cancel the operation while it is running. How Vertica handles the
cancellation of the query and your UDX depends on whether your UDX is running in fenced
or unfenced mode:
If your UDx is running in unfenced mode, Vertica either stops the function when it requests a new block of input or output, or waits until your function completes running and discards the results. If your UDx is running in Fenced Mode, Vertica kills the zygote process that is running your function if it continues processing past a timeout.

In addition, you can implement the cancel() method in any UDx to perform any necessary additional work. Vertica calls your function when a query is canceled. This cancellation can occur at any time during your UDx's lifetime, from setup() through destroy().

You can check for cancellation before starting an expensive operation by calling isCanceled().

### Implementing the Cancel Callback

Your UDx can implement a cancel() callback function. Vertica calls this function if the query that invoked the UDx has been canceled.

You usually implement this function to perform an orderly shutdown of any additional processing that your UDx spawned. For example, you can have your cancel() function shut down threads that your UDx has spawned or signal a third-party library that it needs to stop processing and exit. Your cancel() function should leave your UDx's function class ready to be destroyed, because Vertica calls the UDx's destroy() function after the cancel() function has exited.

A UDx's default cancel() behavior is to do nothing.

The contract for cancel() is:

- Vertica will call cancel() at most once per UDx instance.
- Vertica can call cancel() concurrently with any other method of the UDx object except the constructor and destructor.
- Vertica can call cancel() from another thread, so implementations should be thread-safe.
- Vertica will call cancel() for either an explicit user cancellation or an error in the query.
- Vertica does not guarantee that cancel() will run to completion. Long-running cancellations might be aborted.

The call to cancel() is not synchronized in any way with your UDx's other functions. If you need your processing function to exit before your cancel() function performs some
action (killing threads, for example), you must have the two function synchronize their actions.

Vertica always calls destroy() if it called setup(). Cancellation does not prevent destruction.

See C++ Example: Cancelable UDSource for an example that implements cancel().

Checking for Cancellation During Execution

You can call the isCanceled() method to check for user cancellation. Typically you check for cancellation from the method that does the main processing in your UDx before beginning expensive operations. If isCanceled() returns true, the query has been canceled and your method should exit immediately to prevent it from wasting CPU time. If your UDx is not running in Fenced Mode, Vertica cannot halt your function and has to wait for it to finish. If it is running in fenced mode, Vertica eventually kills the side process running it.

See C++ Example: Cancelable UDSource for an example that uses isCanceled().

C++ Example: Cancelable UDSource

The FifoSource example, found in filelib.cpp in the SDK examples, demonstrates use of cancel() and isCanceled(). This source reads from a named pipe. Unlike reads from files, reads from pipes can block. Therefore, we need to be able to cancel a load from this source.

To manage cancellation, the UDx uses a pipe, a data channel used for inter-process communication. A process can write data to the write end of the pipe, and it remains available until another process reads it from the read end of the pipe. This example doesn't pass data through this pipe; rather, it uses the pipe to manage cancellation, as explained further below. In addition to the pipe's two file descriptors (one for each end), the UDx creates a file descriptor for the file to read from. The setup() function creates the pipe and then opens the file.

```cpp
virtual void setup(ServerInterface &srvInterface) {
    // cancelPipe is a pipe used only for checking cancellation
    if (pipe(cancelPipe)) {
        vt_report_error(0, "Error opening control structure");
    }

    // handle to the named pipe from which we read data
```
```c
namedPipeFd = open(filename.c_str(), O_RDONLY | O_NONBLOCK);
if (namedPipeFd < 0) {
    vt_report_error(0, "Error opening fifo [%s]", filename.c_str);
}
```

We now have three file descriptors: namedPipeFd, cancelPipe[PIPE_READ], and cancelPipe[PIPE_WRITE]. Each of these must eventually be closed.

This UDx uses the poll() system call to wait either for data to arrive from the named pipe (namedPipeFd) or for a cancellation (cancelPipe[PIPE_READ]). The process() function polls, checks for results, checks for cancellation, writes output if needed, and returns.

```c
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
    struct pollfd pollfds[2] = {
        { namedPipeFd, POLLIN, 0 },
        { cancelPipe[PIPE_READ], POLLIN, 0 }
    };

    if (poll(pollfds, 2, -1) < 0) {
        vt_report_error(1, "Error reading [%s]", filename.c_str);
    }

    if (pollfds[1].revents & (POLLIN | POLLHUP)) {
        /* This can only happen after cancel() has been called */
        VIAssert(isCanceled);
        return DONE;
    }

    VIAssert(pollfds[PIPE_READ].revents & (POLLIN | POLLHUP));

    const ssize_t amount = read(namedPipeFd, output.buf + output.offset, output.size - output.offset);
    if (amount < 0) {
        vt_report_error(1, "Error reading from fifo [%s]", filename.c_str);
    }

    if (amount == 0 || isCanceled) {
        return DONE;
    } else {
        output.offset += amount;
        return OUTPUT_NEEDED;
    }
}
```

If the query is canceled, the cancel() function closes the write end of the pipe. The next time process() polls for input, it finds no input on the read end of the pipe and exits. Otherwise, it continues. The function also calls isCanceled() to check for cancellation before returning OUTPUT_NEEDED, the signal that it has filled its buffer and is waiting for it to be processed downstream.

The cancel() function does only the work needed to interrupt a call to process(). Cleanup that is always needed, not just for cancellation, is instead done in destroy() or
the destructor. The cancel() function closes the write end of the pipe. (The helper
function will be shown later.)

```c
virtual void cancel(ServerInterface &srvInterface) {
    closeIfNeeded(cancelPipe[PIPE_WRITE]);
}
```

It is not safe to close the named pipe in cancel(), because closing it could create a race
condition if another process (like another query) were to reuse the file descriptor number
for a new descriptor before the UDx finishes. Instead we close it, and the read end of the
pipe, in destroy().

```c
virtual void destroy(ServerInterface &srvInterface) {
    closeIfNeeded(namedPipeFd);
    closeIfNeeded(cancelPipe[PIPE_READ]);
}
```

It is not safe to close the write end of the pipe in destroy(), because cancel() closes it
and can be called concurrently with destroy(). Therefore, we close it in the destructor.

```c
~FifoSource() {
    closeIfNeeded(cancelPipe[PIPE_WRITE]);
}
```

The UDx uses a helper function, closeIfNeeded(), to make sure each file descriptor is
closed exactly once.

```c
void closeIfNeeded(int &fd) {
    if (fd >= 0) {
        close(fd);
        fd = -1;
    }
}
```

**Logging**

All UDxs have an associated instance of ServerInterface. The ServerInterface class
provides a function to write to the Vertica log, and the C++ implementation also provides a
function to log events in a system table.
Writing Messages to the Vertica Log

You can write to log files using the ServerInterface.log() function. The function acts similarly to printf(), taking a formatted string and an optional set of values and writing the string to a log file. Where the message is written depends on whether your function runs in fenced mode or unfenced mode:

- Functions running in unfenced mode write their messages into the vertica.log file in the catalog directory.
- Functions running in fenced mode write their messages into a log file named UDxLogs/UDxFencedProcesses.log in the catalog directory.

To help identify your function's output, Vertica adds the SQL function name bound to your UDx function to the log message.

The following code fragment shows how you can add a call to srvInterface.log in the Add2ints example code's processBlock() function to log its input values:

```c++
const vint a = arg_reader.getIntRef(0);
const vint b = arg_reader.getIntRef(1);
srvInterface.log("got a: %d and b: %d", (int) a, (int) b);
```

This code generates entries in the log file for each row the UDx processes. For example:

```
11-05-06  14:37:20.838  nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 1 and b: 2
11-05-06  14:37:20.838  nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 2 and b: 2
11-05-06  14:37:20.838  nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 3 and b: 2
11-05-06  14:37:20.838  nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 1 and b: 4
11-05-06  14:37:20.838  nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 5 and b: 2
```

See Monitoring the Log Files in the Administrator's Guide for details on viewing the Vertica log files.

Writing Messages to the UDX_EVENTS Table

In the C++ API, you can write messages to the UDX_EVENTS system table instead of or in addition to writing to the log. Writing to a system table allows you to collect events from all nodes in one place.

You can write to this table using the ServerInterface.logEvent() function. The function takes one argument, a map. The map is written into the __RAW__ column of the
table as a Flex VMap. The following example shows how the Parquet exporter creates and logs this map.

```cpp
// Log exported parquet file details to v_monitor.udx_events
std::map<std::string, std::string> details;
details["file"] = escapedPath;
details["created"] = create_timestamp_;
details["closed"] = close_timestamp_;
details["rows"] = std::to_string(num_rows_in_file);
details["row_groups"] = std::to_string(num_row_groups_in_file);
details["size_mb"] = std::to_string((double)outputStream->Tell()/(1024*1024));
srvInterface.logEvent(details);
```

You can select individual fields from the VMap as in the following example.

```sql
=> SELECT __RAW__['file'] FROM UDX_EVENTS;

------------------------------
/tmp/export_tmpzLkrKq3a/450c4213-v_vmart_node0001-139770732459776-0.parquet
/tmp/export_tmpzLkrKq3a/9df1c797-v_vmart_node0001-139770860660480-0.parquet
(2 rows)
```

Alternatively, you can define a view to make it easier to query fields directly, as columns. See Monitoring Exports for an example.

## Debugging Tips

You must thoroughly debug your UDx before deploying it to a production environment. The following tips can help you get your UDx ready for deployment.

### Use a Single Node For Initial Debugging

You can attach to the Vertica process using a debugger such as gdb to debug your UDx code. Doing this in a multi-node environment, however, is very difficult. Therefore, consider setting up a single-node Vertica test environment to initially debug your UDx.

### Use Logging

Each UDx has an associated ServerInterface instance. The ServerInterface provides functions to write to the Vertica log and, in the C++ API only, a system table. See Logging for more information.
Developing with the C++ SDK

The Vertica SDK supports writing both fenced and unfenced UDxs of all types in C++ 11. You can download, compile, and run the examples; see Downloading and Running UDx Example Code. Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

This section covers C++-specific topics that apply to all UDx types. For information that applies to all languages, see Handling Different Numbers and Types of Arguments, UDx Parameters, Handling Cancel Requests and the sections for specific Types of UDxs. For full API documentation, see the C++ SDK Documentation.

Setting Up the C++ SDK

The Vertica C++ Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and header files you need to create your UDx library. For examples that you can compile and run, see Downloading and Running UDx Example Code. For requirements for your development environment, see Setting Up a Development Environment.

The SDK files are located in the sdk subdirectory under the root Vertica server directory (usually, /opt/vertica/sdk). This directory contains a subdirectory, include, which contains the headers and source files needed to compile UDx libraries.

There are two files in the include directory you need when compiling your UDx:
Vertica.h is the main header file for the SDK. Your UDx code needs to include this file in order to find the SDK's definitions.

Vertica.cpp contains support code that needs to be compiled into the UDx library.

Much of the Vertica SDK API is defined in the VerticaUDx.h header file (which is included by the Vertica.h file). If you're curious, you might want to review the contents of this file in addition to reading the API documentation.

**Finding the Current SDK Version**

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsq1:

```
=> SELECT sdk_version();
```

**Running the Examples**

You can download the examples from the GitHub repository (see Downloading and Running UDx Example Code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

To compile all of the examples, including the Java examples, issue the following command in the Java-and-C++ directory under the examples directory:

```
$ make
```

**Note:**
To compile the examples, you must have a g++ development environment installed. To install a g++ development environment on Red Hat systems, run `yum install gcc gcc-c++ make`.

**Compiling Your C++ Library**

GNU g++ is the only supported compiler for compiling UDx libraries. Always compile your UDx code on the same version of Linux that you use on your Vertica cluster.

When compiling your library, you must always:
• Compile with the -std=c++11 flag.
• Pass the -shared and -fPIC flags to the linker. The simplest method is to just pass these flags to g++ when you compile and link your library.
• Use the -Wno-unused-value flag to suppress warnings when macro arguments are not used. If you do not use this flag, you may get "left-hand operand of comma has no effect" warnings.
• Compile sdk/include/Vertica.cpp and link it into your library. This file contains support routines that help your UDX communicate with Vertica. The easiest way to do this is to include it in the g++ command to compile your library. Vertica supplies this file as C++ source rather than a library to limit library compatibility issues.
• Add the Vertica SDK include directory in the include search path using the g++ -I flag.

The SDK examples include a working makefile. See Downloading and Running UDX Example Code.

**Example of Compiling a UDX**

The following command compiles a UDX contained in a single source file named MyUDx.cpp into a shared library named MyUDx.so:

```
g++ -I /opt/vertica/sdk/include -Wall -shared -Wno-unused-value \  
-fPIC -o MyUDx.so MyUDx.cpp /opt/vertica/sdk/include/Vertica.cpp
```

**Important:**
Vertica only supports UDX development on 64-bit architectures.

After you debug your UDX, you are ready to deploy it. Recompile your UDX using the -O3 flag to enable compiler optimization.

You can add additional source files to your library by adding them to the command line. You can also compile them separately and then link them together.

**Tip:**
The examples subdirectory in the Vertica SDK directory contains a make file that you can use as starting point for your own UDX project.
Handling External Libraries

You must link your UDx library to any supporting libraries that your UDx code relies on. These libraries might be either ones you developed or others provided by third parties. You have two options for linking:

- **Statically link** the support libraries into your UDx. The benefit of this method is that your UDx library does not rely on external files. Having a single UDx library file simplifies deployment because you just transfer a single file to your Vertica cluster. This method's main drawback is that it increases the size of your UDx library file.
- **Dynamically link** the library to your UDx. You must sometimes use dynamic linking if a third-party library does not allow static linking. In this case, you must copy the libraries to your Vertica cluster in addition to your UDx library file.

Adding Metadata to C++ Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```
RegisterLibrary(author,
                 library_build_tag,
                 library_version,
                 library_sdk_version,
                 source_url,
                 description,
                 licenses_required,
                 signature);
```

- **author** contains whatever name you want associated with the creation of the library (your own name or your company’s name for example).
library_build_tag is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.

library_version is the version of your library. You can use whatever numbering or naming scheme you want.

library_sdk_version is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

**Note:** This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

source_url is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.

description is a concise description of your library.

licenses_required is a placeholder for licensing information. You must pass an empty string for this value.

signature is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates adding metadata to the Add2Ints example (see C++ Example: Add2Ints).

```cpp
// Include the top-level Vertica SDK file
#include "Vertica.h"
// Using the Vertica namespace means we don't have to prefix all
// class references with Vertica::
using namespace Vertica;
/*
 * ScalarFunction implementation for a UDFS that adds
 * two numbers together.
 *
class Add2Ints : public ScalarFunction
{
 public:
  /*
   * This function does all of the actual processing for the UDF.
   * In this case, it simply reads two integer values and returns
   * their sum.
   *
```
* The inputs are retrieved via arg_reader
* The outputs are returned via arg_writer
*/

virtual void processBlock(ServerInterface &srvInterface,
    BlockReader &arg_reader,
    BlockWriter &res_writer)
{
  // While we have input to process
  do
  {
    // Read the two integer input parameters by calling the
    // BlockReader.getIntRef class function
    const vint a = arg_reader.getIntRef(0);
    const vint b = arg_reader.getIntRef(1);
    // Call BlockWriter.setInt to store the output value, which is the
    // two input values added together
    res_writer.setInt(a + b);
    // Finish writing the row, and advance to the next output row
    res_writer.next();
    // Continue looping until there are no more input rows
  }
  while (arg_reader.next());
}

/*
 * This class provides metadata about the ScalarFunction class, and
 * also instantiates a member of that class when needed.
 */
class Add2IntsFactory : public ScalarFunctionFactory
{
  // return an instance of Add2Ints to perform the actual addition.
  virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
  {
    // Calls the vt_createFuncObj to create the new Add2Ints class instance.
    return vt_createFuncObj(interface.allocator, Add2Ints);
  }

  // This function returns the description of the input and outputs of the
  // Add2Ints class's processBlock function. It stores this information in
  // two ColumnTypes objects, one for the input parameters, and one for
  // the return value.
  virtual void getPrototype(ServerInterface &interface,
      ColumnTypes &argTypes,
      ColumnTypes &returnType)
  {
    // Takes two ints as inputs, so add ints to the argTypes object
    argTypes.addInt();
    argTypes.addInt();
    // returns a single int, so add a single int to the returnType object.
    // Note that ScalarFunctions *always* return a single value.
    returnType.addInt();
  }
};

// Register the factory with Vertica
RegisterFactory(Add2IntsFactory);

// Register the library's metadata.
RegisterLibrary("Whizzo Analytics Ltd.");
Loading the library and querying the `USER_LIBRARIES` system table shows the metadata supplied in the call to `RegisterLibrary()`:

```sql
=> CREATE LIBRARY add2intslib AS '/home/dbadmin/add2ints.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'add2intslib';

### C++ SDK Data Types

The Vertica SDK has typedefs and classes for representing Vertica data types within your UDx code. Using these typedefs ensures data type compatibility between the data your UDx processes and generates and the Vertica database. The following table describes some of the typedefs available. Consult the Vertica C++ SDK Documentation for a complete list, as well as lists of helper functions to convert and manipulate these data types.

<table>
<thead>
<tr>
<th>Type Definition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval</td>
<td>A Vertica interval</td>
</tr>
<tr>
<td>IntervalYM</td>
<td>A Vertica year-to-month interval.</td>
</tr>
<tr>
<td>Type Definition</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Timestamp</td>
<td>A Vertica timestamp</td>
</tr>
<tr>
<td>vint</td>
<td>A standard Vertica 64-bit integer</td>
</tr>
<tr>
<td>vint_null</td>
<td>A null value for integer values</td>
</tr>
<tr>
<td>vbool</td>
<td>A Boolean value in Vertica</td>
</tr>
<tr>
<td>vbool_null</td>
<td>A null value for a Boolean data types</td>
</tr>
<tr>
<td>vfloat</td>
<td>A Vertica floating point value</td>
</tr>
</tbody>
</table>
| VString         | String data types (such as varchar and char)  
|                 | **Note**: Do not use a VString object to hold an intermediate result. Use a std::string or char[] instead. |
| VNumeric        | Fixed-point data types from Vertica |

**Notes**

- When making some Vertica SDK API calls (such as VerticaType::getNumericLength()) on objects, make sure they have the correct data type. To minimize overhead and improve performance, most of the APIs do not check the data types of the objects on which they are called. Calling a function on an incorrect data type can result in an error.
- A NULL Vertica value string data type is converted into an empty C++ string.
- You cannot create instances of VString or VNumeric yourself. You can manipulate the values of existing objects of these classes that Vertica passes to your UDx, and extract values from them. However, only Vertica can instantiate these classes.

**Handling Errors**

If your UDx encounters some sort of error, it can report it back to Vertica using the vt_report_error macro. When called, this macro halts the execution of the UDx and causes the statement that called the function to fail. The macro takes two parameters: an error number and an error message string. Both the error number and message appear in the
error that Vertica reports to the user. The error number is not defined by Vertica. You can use whatever value that you wish.

For example, the following ScalarFunction class divides two integers. To prevent division by zero, it tests the second parameter. If it is zero, the function reports the error back to Vertica.

```cpp
/*
  * Demonstrate reporting an error
  */
class Div2ints : public ScalarFunction
{
public:
  virtual void processBlock(ServerInterface &srvInterface,
                              BlockReader &arg_reader,
                              BlockWriter &res_writer)
  {
    // While we have inputs to process
do{
      const vint a = arg_reader.getIntRef(0);
      const vint b = arg_reader.getIntRef(1);
      if (b == 0)
      {
        vt_report_error(1,"Attempted divide by zero");
      }
      res_writer.setInt(a/b);
      res_writer.next();
    }
    while (arg_reader.next());
  }
};
```

Loading and invoking the function demonstrates how the error appears to the user.

```sql
=> CREATE LIBRARY Div2IntsLib AS '/home/dbadmin/Div2ints.so';
CREATE LIBRARY
=> CREATE FUNCTION div2ints AS LANGUAGE 'C++' NAME 'Div2intsInfo' LIBRARY Div2IntsLib;
CREATE FUNCTION
=> SELECT div2ints(25, 5);
div2ints
---------
 5
(1 row)
=> SELECT * FROM MyTable;
a | b
-----+
12 | 6
7 | 0
12 | 2
18 | 9
(4 rows)
=> SELECT * FROM MyTable WHERE div2ints(a, b) > 2;
ERROR: Error in calling processBlock() for User Defined Scalar Function
div2ints at Div2ints.cpp:21, error code: 1, message: Attempted divide by zero
```
Your function must not allow an exception to be passed back to Vertica. You should use a
top-level try-catch block to catch any stray exceptions that might be thrown by your code
or any functions or libraries your code calls. This is especially important when running a
UDx in unfenced mode. Any errors in an unfenced UDx can result in database instability or
even data loss.
Resource Use for C++ UDxs

Your UDxs consume at least a small amount of memory by instantiating classes and creating local variables. This basic memory usage by UDxs is small enough that you do not need to be concerned about it.

If your UDx needs to allocate more than one or two megabytes of memory for data structures, or requires access to additional resources such as files, you must inform Vertica about its resource use. Vertica can then ensure that the resources your UDx requires are available before running a query that uses it. Even moderate memory use (10MB per invocation of a UDx, for example) can become an issue if there are many simultaneous queries that call it.

**Note:**
If your UDx allocates its own memory, you must make **absolutely sure** it properly frees it. Failing to free even a single byte of allocated memory can have huge consequences if your UDx is called to operate on a multi-million-row table. Instead of having your code allocate its own memory, you should use the C++ `vt_alloc` macro, which uses Vertica’s own memory manager to allocate and track memory. This memory is guaranteed to be properly disposed of when your UDx completes execution. See Allocating Resources for UDxs for more information.

Allocating Resources for UDxs

You have two options for allocating memory and file handles for your user-defined extensions (UDxs):

- Use Vertica SDK macros to allocate resources. This is the best method, since it uses Vertica’s own resource manager, and guarantees that resources used by your UDx are reclaimed. See Allocating Resources with the SDK Macros.
- Allocate resources in your UDxs yourself using standard C++ methods (instantiating objects using `new`, allocating memory blocks using `malloc()`, etc.). You must manually free these resources before your UDx exits.

**Note:**
You must be extremely careful if you choose to allocate your own resources.
in your U Dx. Failing to free resources properly will have significant negative impact, especially if your U Dx is running in unfenced mode.

Whichever method you choose, you usually allocate resources in a function named setup() in your U Dx class. This function is called after your U Dx function object is instantiated, but before Vertica calls it to process data.

If you allocate memory on your own in the setup() function, you must free it in a corresponding function named destroy(). This function is called after your U Dx has performed all of its processing. This function is also called if your U Dx returns an error (see Handling Errors).

Note: Always use the setup() and destroy() functions to allocate and free resources instead of your own constructors and destructors. The memory for your U Dx object is allocated from one of Vertica's own memory pools. Vertica always calls your U Dx's destroy() function before it deallocates the object's memory. There is no guarantee that your U Dx's destructor is will be called before the object is deallocated. Using the destroy() function ensures that your U Dx has a chance to free its allocated resources before it is destroyed.

The following code fragment demonstrates allocating and freeing memory using a setup() and destroy() function.

class MemoryAllocationExample : public ScalarFunction
{
public:
  uint64* myarray;
  // Called before running the UDF to allocate memory used throughout
  // the entire UDF processing.
  virtual void setup(ServerInterface &srvInterface, const SizedColumnTypes &argTypes)
  {
    try
    {
      // Allocate an array. This memory is directly allocated, rather than
      // letting Vertica do it. Remember to properly calculate the amount
      // of memory you need based on the data type you are allocating.
      // This example divides 500MB by 8, since that's the number of
      // bytes in a 64-bit unsigned integer.
      myarray = new uint64[1024 * 1024 * 500 / 8];
    }
    catch (std::bad_alloc &ba)
    {
      // Always check for exceptions caused by failed memory
      // allocations.
      vt_report_error(1, "Couldn't allocate memory:[%s]", ba.what());
    }
};
Allocating Resources with the SDK Macros

The Vertica SDK provides three macros to allocate memory:

- `vt_alloc` allocates a block of memory to fit a specific data type (vint, struct, etc.).
- `vt_allocArray` allocates a block of memory to hold an array of a specific data type.
- `vt_allocSize` allocates an arbitrarily-sized block of memory.

All of these macros allocate their memory from memory pools managed by Vertica. The main benefit of allowing Vertica to manage your UDX's memory is that the memory is automatically reclaimed after your UDX has finished. This ensures there is no memory leaks in your UDX.

Because Vertica frees this memory automatically, do not attempt to free any of the memory you allocate through any of these macros. Attempting to free this memory results in run-time errors.

Informing Vertica of Resource Requirements

When you run your UDX in fenced mode, Vertica monitors its use of memory and file handles. If your UDX uses more than a few megabytes of memory or any file handles, it should tell Vertica about its resource requirements. Knowing the resource requirements of
Vertica allocates, that MemoryAllocationExample getPerInstanceResources The is should 100MB). VResources.scratchMemory structure instance VResources Your bytes Vertica::VResources The resources your Vertica::UDXFactory::getPerInstanceResources getPerInstanceResources Your UDx's Your UDx's UDx's implementation UDx's memory queries, then extrapolate its memory use based on the worst-case scenario it may face in your production environment. In all cases, it's usually a good idea to add a safety margin to the amount of memory you tell Vertica your UDx uses.

**Note:**
The information on your UDx's resource needs that you pass to Vertica is used when planning the query execution. There is no way to change the amount of resources your UDx requests from Vertica while the UDx is actually running.

Your UDx informs Vertica of its resource needs by implementing the getPerInstanceResources() function in its factory class (see Vertica::UDXFactory::getPerInstanceResources() in the SDK documentation). If your UDx's factory class implements this function, Vertica calls it to determine the resources your UDx requires.

The getPerInstanceResources() function receives an instance of the Vertica::VResources struct. This struct contains fields that set the amount of memory and the number of file handles your UDx needs. By default, the Vertica server allocates zero bytes of memory and 100 file handles for each instance of your UDx.

Your implementation of the getPerInstanceResources() function sets the fields in the VResources struct based on the maximum resources your UDx may consume for each instance of the UDx function. So, if your UDx's processBlock() function creates a data structure that uses at most 100MB of memory, your UDx must set the VResources.scratchMemory field to at least 104857600 (the number of bytes in 100MB). Leave yourself a safety margin by increasing the number beyond what your UDx should normally consume. In this example, allocating 115000000 bytes (just under 110MB) is a good idea.

The following ScalarFunctionFactory class demonstrates calling getPerInstanceResources() to inform Vertica about the memory requirements of the MemoryAllocationExample class shown in Allocating Resources for UDxs. It tells Vertica that the UDSF requires 510MB of memory (which is a bit more than the UDSF actually allocates, to be on the safe size).
class MemoryAllocationExampleFactory : public ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    {
        return vt_createFuncObj(srvInterface.allocator, MemoryAllocationExample);
    }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
    // Tells Vertica the amount of resources that this UDF uses.
    virtual void getPerInstanceResources(ServerInterface &srvInterface,
        VResources &res)
    {
        res.scratchMemory += 1024LL * 1024 * 510; // request 510MB of memory
    }
};

**Setting Memory Limits for Fenced-Mode UDxs**

Vertica calls a fenced-mode U Dx's implementation of 
Vertica::UDXFactory::getPerInstanceResources() to determine if there are 
enough free resources to run the query containing the U Dx (see **Informing Vertica of Resource Requirements**). Since these reports are not generated by actual memory use, they 
can be inaccurate. Once started by Vertica, a U Dx could allocate far more memory or file 
handles than it reported it needs.

The FencedUDxMemoryLimitMB configuration parameter lets you create an absolute memory limit for UDxs. Any attempt by a U Dx to allocate more memory than this limit 
results in a bad_alloc exception. For more information on configuration parameters, see **Configuration Parameters** in the Administrator's Guide. For an example of setting 
FencedUDxMemoryLimitMB, see **How Resource Limits Are Enforced**.

**How Resource Limits Are Enforced**

Before running a query, Vertica determines how much memory it requires to run. If the 
query contains a fenced-mode U Dx which implements the getPerInstanceResources() 
function in its factory class, Vertica calls it to determine the amount of memory the U Dx
needs and adds this to the total required for the query. Based on these requirements, Vertica decides how to handle the query:

- If the total amount of memory required (including the amount that the UDxs report that they need) is larger than the session's MEMORYCAP or resource pool's MAXMEMORYSIZE setting, Vertica rejects the query. For more information about resource pools, see Resource Pool Architecture in the Administrator's Guide.
- If the amount of memory is below the limit set by the session and resource pool limits, but there is currently not enough free memory to run the query, Vertica queues it until enough resources become available.
- If there are enough free resources to run the query, Vertica executes it.

**Note:**
Vertica has no other way to determine the amount of resources a UDx requires other than the values it reports using the `getPerInstanceResources()` function. A UDx could use more resources than it claims, which could cause performance issues for other queries that are denied resources. You can set an absolute limit on the amount of memory UDxs can allocate. See Setting Memory Limits for Fenced-Mode UDxs for more information.

If the process executing your UDx attempts to allocate more memory than the limit set by the FencedUDxMemoryLimitMB configuration parameter, it receives a bad_alloc exception. For more information about FencedUDxMemoryLimitMB, see Setting Memory Limits for Fenced-Mode UDxs.

Below is the output of loading a UDSF that consumes 500MB of memory, then changing the memory settings to cause out-of-memory errors. The MemoryAllocationExample UDSF in the following example is just the Add2Ints UDSF example altered as shown in Allocating Resources for UDxs and Informing Vertica of Resource Requirements to allocate 500MB of RAM.

```sql
=> CREATE LIBRARY mylib AS '/home/dbadmin/MemoryAllocationExample.so';
CREATE LIBRARY
=> CREATE FUNCTION usemem AS NAME 'MemoryAllocationExampleFactory' LIBRARY mylib
  => FENCED;
CREATE FUNCTION
=> SELECT usemem(1,2);
  usemem
  -------
  3
(1 row)
```

The following statements demonstrate setting the session's MEMORYCAP to lower than the amount of memory that the UDSF reports it uses. This causes Vertica to return an error before it executes the UDSF.
The resource pool can also prevent a UDx from running if it requires more memory than is available in the pool. The following statements demonstrate the effect of creating and using a resource pool that has too little memory for the UDSF to run. Similar to the session's MAXMEMORYCAP limit, the pool's MAXMEMORYSIZE setting prevents Vertica from executing the query containing the UDSF.

Finally, setting the FencedUDxMemoryLimitMB configuration parameter to lower than the UDx actually allocates results in the UDx throwing an exception. This is a different case than either of the previous two examples, since the query actually executes. The UDx's code needs to catch and handle the exception. In this example, it uses the vt_report_error macro to report the error back to Vertica and exit.

Developing with the Java SDK

The Vertica SDK supports writing Java UDxs of all types except aggregate functions. All Java UDxs are fenced.

You can download, compile, and run the examples; see Downloading and Running UDx Example Code. Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

This section covers Java-specific topics that apply to all UDx types. For information that applies to all languages, see Handling Different Numbers and Types of Arguments, UDx Parameters, Handling Cancel Requests and the sections for specific Types of UDxs. For full API documentation, see the Java SDK Documentation.

Setting Up the Java SDK

The Vertica Java Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and JAR files you need to create your UDx library. For examples that you can compile and run, see Downloading and Running UDx Example Code. For requirements for your development environment, see Setting Up a Development Environment.
To use the SDK you need two files from the Java support package:

- `/opt/vertica/bin/VerticaSDK.jar` contains the Vertica Java SDK and other supporting files.
- `/opt/vertica/sdk/BuildInfo.java` contains version information about the SDK. You must compile this file and include it within your Java UDx JAR files.

If you are not doing your development on a database node, you can copy these two files from one of the database nodes to your development system.

The BuildInfo.java and VerticaSDK.jar files that you use to compile your UDx must be from the same SDK version. Both files must also match the version of the SDK files on your Vertica hosts. Versioning is only an issue if you are not compiling your UDxs on a Vertica host. If you are compiling on a separate development system, always refresh your copies of these two files and recompile your UDxs just before deploying them.

### Finding the Current SDK Version

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:

```sql
=> SELECT sdk_version();
```

### Compiling BuildInfo.java

You need to compile the BuildInfo.java file into a class file, so you can include it in your Java UDx JAR library. If you are using a Vertica node as a development system, you can either:

- Copy the BuildInfo.java file to another location on your host.
- If you have root privileges, compile the BuildInfo.java file in place. (Only the root user has privileges to write files to the /opt/vertica/sdk directory.)

Compile the file using the following command. Replace `path` with the path to the file and `output-directory` with the directory where you will compile your UDxs.

```bash
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
/path/BuildInfo.java -d output-directory
```

If you use an IDE such as Eclipse, you can include the BuildInfo.java file in your project instead of compiling it separately. You must also add the VerticaSDK.jar file to the
project's build path. See your IDE's documentation for details on how to include files and libraries in your projects.

**Running the Examples**

You can download the examples from the GitHub repository (see Downloading and Running UDx Example Code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

If you have not already done so, set the JAVA_HOME environment variable to your JDK (not JRE) directory.

To compile all of the examples, including the Java examples, issue the following command in the Java-and-C++ directory under the examples directory:

```
$ make
```

To compile only the Java examples, issue the following command in the Java-and-C++ directory under the examples directory:

```
$ make JavaFunctions
```

**Note:**

To compile the examples, you must have make installed. To install make on Red Hat systems, run yum install make.

**Compiling and Packaging a Java Library**

Before you can use your Java UDx, you need to compile it and package it into a JAR file.

The SDK examples include a working makefile. See Downloading and Running UDx Example Code.

**Compile Your Java UDx**

You must include the SDK JAR file in the classpath when you compile your Java UDx source files so the Java compiler can resolve the Vertica API calls. If you are using the command-line Java compiler on a host in your database cluster, enter this command:
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar factorySource.java \
[functionSource.java...] -d output-directory

If all of your source files are in the same directory, you can use *.java on the command line instead of listing the files individually.

If you are using an IDE, verify that a copy of the VerticaSDK.jar file is in the build path.

**UDx Class File Organization**

After you compile your UDx, you must package its class files and the BuildInfo.class file into a JAR file.

**Note:**
You can package as many UDxs as you want into the same JAR file. Bundling your UDxs together saves you from having to load multiple libraries.

To use the jar command packaged as part of the JDK, you must organize your UDx class files into a directory structure matching your class package structure. For example, suppose your UDx's factory class has a fully-qualified name of com.mycompany.udfs.Add2ints. In this case, your class files must be in the directory hierarchy com/mycompany/udfs relative to your project's base directory. In addition, you must have a copy of the BuildInfo.class file in the path com/vertica/sdk so that it can be included in the JAR file. This class must appear in your JAR file to indicate the SDK version that was used to compile your Java UDx.

The JAR file for the Add2Ints UDSF example explained in Java Example: Add2Ints has the following directory structure after compilation:

```
com/vertica/sdk/BuildInfo.class
com/mycompany/example/Add2IntsFactory.class
com/mycompany/example/Add2IntsFactory$Add2Ints.class
```

**Package Your UDx Into a JAR File**

To create a JAR file from the command line:

1. Change to the root directory of your project.
2. Use the jar command to package the BuildInfo.class file and all of the classes in your UDx:
When you type this command, *Libname* is the filename you have chosen for your JAR file (choose whatever name you like), and *packagePath* is the path to the directory containing your UDx's class files.

- For example, to package the files from the Add2ints example, you use the command:

  ```
  # jar -cvf Add2intsLib.jar com/vertica/sdk/BuildInfo.class \
  com/mycompany/example/*.class
  ```

- More simply, if you compiled BuildInfo.class and your class files into the same root directory, you can use the following command:

  ```
  # jar -cvf Add2intsLib.jar .
  ```

You must include all of the class files that make up your UDx in your JAR file. Your UDx always consists of at least two classes (the factory class and the function class). Even if you defined your function class as an inner class of your factory class, Java generates a separate class file for the inner class.

After you package your UDx into a JAR file, you are ready to deploy it to your Vertica database.

### Handling Java UDx Dependencies

If your Java UDx relies on one or more external libraries, you can handle the dependencies in one of three ways:

- Bundle the JAR files into your UDx JAR file using a tool such as One-JAR or Eclipse Runnable JAR Export Wizard.
- Unpack the JAR file and then repack its contents in your UDx's JAR file.
- Copy the libraries to your Vertica cluster in addition to your UDx library. Then, use the DEPENDS keyword of the `CREATE LIBRARY` statement to tell Vertica that the UDx library depends on the external libraries. This keyword acts as a library-specific `CLASSPATH` setting. Vertica distributes the support libraries to all of the nodes in the cluster and sets the class path for the UDx so it can find them.

If your UDx depends on native libraries (SO files), use the DEPENDS keyword to specify their path. When you call `System.loadLibrary` in your UDx (which you must do
before using a native library), this function uses the DEPENDS path to find them. You do not need to also set the LD_LIBRARY_PATH environment variable.

**Important:**
In previous versions of Vertica, the JavaClassPathForUDx configuration parameter set the locations of external libraries for all Java UDxs. In Vertica Version 7.1, this configuration parameter is deprecated. It will be removed in a future version. If you upgrade from a previous version of Vertica, switch any existing Java UDxs that rely on support libraries to use the new DEPENDS keyword. To make this switch, use the ALTER LIBRARY statement to recreate the UDx library. In this statement, supply the DEPENDS keyword to specify the directory containing the support libraries.

*External Library Example*

The following example demonstrates using an external library with a Java UDx.

The following sample code defines a simple class, named VowelRemover. It contains a single method, named removevowels, that removes all of the vowels (the letters a, e, i, o u, and y) from a string.

```java
package com.mycompany.libs;

public class VowelRemover {
    public String removevowels(String input) {
        return input.replaceAll("(?i)\[aeiouy\]", "");
    }
}
```

You can compile this class and package it into a JAR file with the following commands:

```bash
$ javac -g com/mycompany/libs/VowelRemover.java
$ jar cf mycompanylibs.jar com/mycompany/libs/VowelRemover.class
```

The following code defines a Java UDSF, named DeleteVowels, that uses the library defined in the preceding example code. DeleteVowels accepts a single VARCHAR as input, and returns a VARCHAR.

```java
package com.mycompany.udx;
// Import the support class created earlier
import com.mycompany.libs.VowelRemover;
// Import the Vertica SDK
import com.vertica.sdk.*;
```
public class DeleteVowelsFactory extends ScalarFunctionFactory {

    @Override
    public ScalarFunction createScalarFunction(ServerInterface arg0) {
        return new DeleteVowels();
    }

    @Override
    public void getPrototype(ServerInterface arg0, ColumnTypes argTypes, ColumnTypes returnTypes) {
        // Accept a single string and return a single string.
        argTypes.addVarchar();
        returnTypes.addVarchar();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) {
        returnType.addVarchar(
            // Output will be no larger than the input.
            argTypes.getColumnType(0).getStringLength(), "RemovedVowels");
    }

    public class DeleteVowels extends ScalarFunction {
        @Override
        public void processBlock(ServerInterface arg0, BlockReader argReader, BlockWriter resWriter) throws UdfException, DestroyInvocation {

            // Create an instance of the VowelRemover object defined in
            // the library.
            VowelRemover remover = new VowelRemover();

            do {
                String instr = argReader.getString(0);
                // Call the removevowels method defined in the library.
                resWriter.setString(remover.removevowels(instr));
                resWriter.next();
            } while (argReader.next());
        }
    }
}

Use the following commands to build the example UDSF and package it into a JAR:

- The first javac command compiles the SDK’s BuildInfo class. Vertica requires all
  UDX libraries to contain this class. The javac command’s -d option outputs the class
  file in the directory structure of your UDSF’s source.
- The second javac command compiles the UDSF class. It adds the previously-created
  mycompanylibs.jar file to the class path so compiler can find the the
  VowelRemover class.
- The jar command packages the BuildInfo and the classes for the UDX library
  together.
To install the UDx library, you must copy both of the JAR files to a node in the Vertica cluster. Then, connect to the node to execute the CREATE LIBRARY statement.

The following example demonstrates how to load the UDx library after you copy the JAR files to the home directory of the dbadmin user. The DEPENDS keyword tells Vertica that the UDx library depends on the mycompanylibs.jar file.

```sql
CREATE LIBRARY DeleteVowelsLib AS '/home/dbadmin/DeleteVowelsLib.jar' DEPENDS '/home/dbadmin/mycompanylibs.jar'
LANGUAGE 'JAVA';
CREATE FUNCTION deleteVowels AS language 'java' NAME 'com.mycompany.udx.DeleteVowelsFactory' LIBRARY DeleteVowelsLib;
SELECT deleteVowels('I hate vowels!');
deleteVowels
-----------
ht vwls!
(1 row)
```

### Java and Vertica Data Types

The Vertica Java SDK converts Vertica's native data types into the appropriate Java data type. The following table lists the Vertica data types and their corresponding Java data types.

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Java Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>long</td>
</tr>
<tr>
<td>FLOAT</td>
<td>double</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>com.vertica.sdk.VNumeric</td>
</tr>
<tr>
<td>DATE</td>
<td>java.sql.Date</td>
</tr>
<tr>
<td>CHAR, VARCHAR, LONG VARCHAR</td>
<td>com.vertica.sdk.VString</td>
</tr>
<tr>
<td>BINARY, VARBINARY, LONG VARBINARY</td>
<td>com.vertica.sdk.VString</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>java.sql.Timestamp</td>
</tr>
</tbody>
</table>
Some Vertica data types are not supported.

**Setting BINARY, VARBINARY, and LONG VARBINARY Values**

The Vertica BINARY, VARBINARY, and LONG VARBINARY data types are converted as the Java UDx SDK's VString class. You can also set the value of a column with one of these data types with a ByteBuffer object (or a byte array wrapped in a ByteBuffer) using the PartitionWriter.setStringBytes() method. See the Java API UDx entry for PartitionWriter.setStringBytes() for more information.

**Timestamps and Time Zones**

When the SDK converts a Vertica timestamp into a Java timestamp, it uses the time zone of the JVM. If the JVM is running in a different time zone than the one used by Vertica, the results can be confusing.

Vertica stores timestamps in the database in UTC. (If a database time zone is set, the conversion is done at query time.) To prevent errors from the JVM time zone, add the following code to the processing method of your UDx:

```
TimeZone.setDefault(TimeZone.getTimeZone("UTC"));
```

**Strings**

The Java SDK contains a class named StringUtils that assists you when manipulating string data. One of its more useful features is its getStringBytes() method. This method extracts bytes from a String in a way that prevents the creation of invalid strings. If you attempt to extract a substring that would split part of a multi-byte UTF-8 character, getStringBytes() truncates it to the nearest whole character.

**Handling NULL Values**

Your UDxs must be prepared to handle NULL values. These values usually must be handled separately from regular values.
**Reading NULL Values**

Your UDx reads data from instances of the BlockReader or PartitionReader classes. If the value of a column is NULL, the methods you use to get data (such as `getLong`) return a Java null reference. If you attempt to use the value without checking for NULL, the Java runtime will throw a null pointer exception.

You can test for null values before reading columns by using the data-type-specific methods (such as `isLongNull`, `isDoubleNull`, and `isBooleanNull`). For example, to test whether the INTEGER first column of your UDx's input is a NULL, you would use the statement:

```java
// See if the Long value in column 0 is a NULL
if (inputReader.isLongNull(0)) {
    // value is null
    ...
}
```

**Writing NULL Values**

You output NULL values using type-specific methods on the BlockWriter and PartitionWriter classes (such as `setLongNull` and `setStringNull`). These methods take the column number to receive the NULL value. In addition, the PartitionWriter class has data-type specific set value methods (such as `setLongValue` and `setStringValue`). If you pass these methods a value, they set the output column to that value. If you pass them a Java null reference, they set the output column to NULL.

**Handling Errors**

If your UDx encounters an unrecoverable error, it should instantiate and throw a `UdfException`. The exception causes the transaction containing the function call to be rolled back.

The `UdfException` constructor takes a numeric code (which can be anything you want since it is just reported in the error message) and an error message string. If you want to report additional diagnostic information about the error, you can write messages to a log file before throwing the exception (see Writing Messages to the Log File).
The following code fragment demonstrates adding error checking to the Add2ints UDSF example (shown in Java Example: Add2Ints). If either of the arguments is NULL, the processBlock() method throws an exception.

```java
@override
public void processBlock(ServerInterface srvInterface, BlockReader argReader, BlockWriter resWriter)
    throws UdfException, DestroyInvocation {
    do {
        // Test for NULL value. Throw exception if one occurs.
        if (argReader.isLongNull(0) || argReader.isLongNull(1) ) {
            // No nulls allowed. Throw exception
            throw new UdfException(1234, "Cannot add a NULL value");
        }
    }
}
```

**Note:**
This example isn't realistic, since you would likely just replace the NULL value with a zero or return a NULL value. Your U Dx should only throw an exception if there is no way to compensate for the error.

When your U Dx throws an exception, the side process running your U Dx reports the error back to Vertica and exits. Vertica displays the error message contained in the exception and a stack trace to the user:

```sql
=> SELECT add2ints(2, NULL);
ERROR 3399: Failure in U Dx RPC call InvokeProcessBlock(): Error in User Defined Object [add2ints], error code: 1234
com.vertica.sdk.UdfException: Cannot add a NULL value
    at com.mycompany.example.Add2IntsFactory$Add2ints.processBlock(Add2IntsFactory.java:37)
    at com.vertica.udxfence.UDxExecContext.processBlock(UDxExecContext.java:700)
    at com.vertica.udxfence.UDxExecContext.run(UDxExecContext.java:173)
    at java.lang.Thread.run(Thread.java:662)
```

## Writing Messages to the Log File

Writing messages to a log is useful when you are debugging your Java U Dxs, or you want to output additional information about an error condition. You can write messages to a log file by calling the `ServerInterface.log()` method, passing it a `printf()`-style String value along with any variables referenced in the string. (See the `java.util.Formatter class documentation` for details of formatting this string value.) An instance of the `ServerInterface` class is passed to the main processing method of every SDK class you can override.

The following code fragment demonstrates how you could log the values passed into the Add2ints UDSF example.

```java
@Override
public void processBlock(ServerInterface srvInterface, BlockReader argReader, BlockWriter resWriter) throws UdfException, DestroyInvocation {
    do {
        // Get the two integer arguments from the BlockReader
        long a = argReader.getLong(0);
        long b = argReader.getLong(1);
        // Log the input values
        srvInterface.log("Got values a=%d and b=%d", a, b);
    }
}
```

The messages are written to a log file stored in the catalog directory's UDxlog subdirectory named UDxFencedProcessesJava.log:

```
$ tail VMart/v_vmart_node0001_catalog/UDxLogs/UDxFencedProcesses.log
2012-12-12 10:23:47.649 [Java-2164] 0x01 UDx side process (Java) started
2012-12-12 10:23:47.871 [Java-2164] 0x0b [UserMessage] add2ints - Got values a=5 and b=6
2012-12-12 10:23:48.598 [Java-2164] 0x0c Exiting UDx side process
```

The SQL name of the UDx is added to the log message, along with the string [UserMessage] to mark the entry as a message added by a call to the log() method. These additions make it easier for you to filter the log to find the messages generated by your UDx.

## Adding Metadata to Java UDx Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

To add metadata to your Java UDx library, you create a subclass of the UDXLibrary class that contains your library's metadata. You then include this class within your JAR file. When you load your class into the Vertica Analytic Database catalog using the CREATE LIBRARY statement, looks for a subclass of UDXLibrary for the library's metadata.

In your subclass of UDXLibrary, you need to implement eight getters that return String values containing the library's metadata. The getters in this class are:
- `getAuthor()` returns the name you want associated with the creation of the library (your own name or your company's name for example).
- `getLibraryBuildTag()` returns whatever String you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `getLibraryVersion()` returns the version of your library. You can use whatever numbering or naming scheme you want.
- `getLibrarySDKVersion()` returns the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

**Note:**
This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `getSourceUrl()` returns a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `getDescription()` returns a concise description of your library.
- `getLicensesRequired()` returns a placeholder for licensing information. You must pass an empty string for this value.
- `getSignature()` returns a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates creating a UDXLibrary subclass to be included in the Add2Ints UDSF example JAR file (see Java Example: Add2Ints).

```java
// Import the UDXLibrary class to hold the metadata
import com.vertica.sdk.UDXLibrary;

public class Add2IntsLibrary extends UDXLibrary
{
    // Return values for the metadata about this library.
    @Override public String getAuthor() {return "Whizzo Analytics Ltd.";}
    @Override public String getLibraryBuildTag() {return "1234";}
    @Override public String getLibraryVersion() {return "1.0";}
    @Override public String getLibrarySDKVersion() {return "7.0.0";}
    @Override public String getSourceUrl() {
        return "http://example.com/add2ints";
    }
    @Override public String getDescription() {
```
return "My Awesome Add 2 Ints Library";
}
@Override
public String getLicensesRequired() {return "";
@Override
public String getSignature() {return "";
}

When the library containing the Add2IntsLibrary class loaded, the metadata appears in the USER_LIBRARY system table:

```
=> CREATE LIBRARY JavaAdd2IntsLib AS :libfile LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION JavaAdd2Ints as LANGUAGE 'JAVA' name 'com.mycompany.example.Add2IntsFactory' library JavaAdd2IntsLib;
CREATE FUNCTION
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARYS WHERE lib_name = 'JavaAdd2IntsLib';
- [ RECORD 1 ]-+-------------------------------------------------------------

```

Java UDx Resource Management

Java Virtual Machines (JVMs) allocate a set amount of memory when they start. This set memory allocation complicates memory management for Java UDxs, because memory cannot be dynamically allocated and freed by the UDx as it is processing data. This is differs from C++ UDxs which can dynamically allocate resources.

To control the amount of memory consumed by Java UDxs, Vertica has a memory pool named jvm that it uses to allocate memory for JVMs. If this memory pool is exhausted, queries that call Java UDxs block until enough memory in the pool becomes free to start a new JVM.

By default, the jvm pool has:
- no memory of its own assigned to it, so it borrows memory from the GENERAL pool.
- its MAXMEMORYSIZE set to either 10% of system memory or 2GB, whichever is smaller.
- its PLANNEDCONCURRENCY set to AUTO, so that it inherits the GENERAL pool's PLANNEDCONCURRENCY setting.

You can view the current settings for the jvm pool by querying the RESOURCE_POOLS table:

```sql
=> SELECT MAXMEMORYSIZE, PLANNEDCONCURRENCY FROM V_CATALOG.RESOURCE_POOLS WHERE NAME = 'jvm';
MAXMEMORYSIZE | PLANNEDCONCURRENCY
-------------- |------------------
10%           | AUTO
```

When a SQL statement calls a Java UDx, Vertica checks if the jvm memory pool has enough memory to start a new JVM instance to execute the function call. Vertica starts each new JVM with its heap memory size set to approximately the jvm pool's MAXMEMORYSIZE parameter divided by its PLANNEDCONCURRENCY parameter. If the memory pool does not contain enough memory, the query blocks until another JVM exits and return their memory to the pool.

If your Java UDx attempts to consume more memory than has been allocated to the JVM's heap size, it exits with a memory error. You can attempt to resolve this issue by:

- increasing the jvm pool's MAXMEMORYSIZE parameter.
- decreasing the jvm pool's PLANNEDCONCURRENCY parameter.
- changing your Java UDx's code to consume less memory.

**Adjusting the jvm Pool**

When adjusting the jvm pool to your needs, you must consider two factors:

- the amount of RAM your Java UDx requires to run
- how many concurrent Java UDx functions you expect your database to run

You can learn the amount of memory your Java UDx needs using several methods. For example, your code can use Java's `Runtime` class to get an estimate of the total memory it has allocated and then log the value using `ServerInterface.log()`. (An instance of this class is passed to your UDx.) If you have multiple Java UDxs in your database, set the jvm pool memory size based on the UDx that uses the most memory.

The number of concurrent sessions that need to run Java UDxs may not be the same as the global PLANNEDCONCURRENCY setting. For example, you may have just a single user who
runs a Java UDX, which means you can lower the jvm pool's PLANNEDCONCURRENCY setting to 1.

When you have an estimate for the amount of RAM and the number of concurrent user sessions that need to run Java UDXs, you can adjust the jvm pool to an appropriate size. Set the pool's MAXMEMORYSIZE to the maximum amount of RAM needed by the most demanding Java UDX multiplied by the number of concurrent user sessions that need to run Java UDXs. Set the pool's PLANNEDCONCURRENCY to the number of simultaneous user sessions that need to run Java UDXs.

For example, suppose your Java UDX requires up to 4GB of memory to run and you expect up to two user sessions use Java UDX's. You would use the following command to adjust the jvm pool:

```
=> ALTER RESOURCE POOL jvm MAXMEMORYSIZE '8G' PLANNEDCONCURRENCY 2;
```

The MEMORYSIZE is set to 8GB, which is the 4GB maximum memory use by the Java UDX multiplied by the 2 concurrent user sessions.

---

**Note:**
The PLANNEDCONCURRENCY value is **not** the number of calls to Java UDX that you expect to happen simultaneously. Instead, it is the number of concurrently open user sessions that call Java UDXs at any time during the session. See below for more information.

See [Managing Workloads](#) in the Administrator's Guide for more information on tuning the jvm and other resource pools.

---

**Freeing JVM Memory**

The first time users call a Java UDX during their session, Vertica allocates memory from the jvm pool and starts a new JVM. This JVM remains running for as long as the user's session is open so it can process other Java UDX calls. Keeping the JVM running lowers the overhead of executing multiple Java UDXs by the same session. If the JVM did not remain open, each call to a Java UDX would require additional time for Vertica to allocate resources and start a new JVM. However, having the JVM remain open means that the JVM's memory remains allocated for the life of the session whether or not it will be used again.

If the jvm memory pool is depleted, queries containing Java UDXs either block until memory becomes available or eventually fail due a lack of resources. If you find queries blocking or failing for this reason, you can allocate more memory to the jvm pool and increase its PLANNEDCONCURRENCY. Another option is to ask users to call the `RELEASE_JVM_MEMORY`
function when they no longer need to run Java UDx. This function closes any JVM belonging to the user's session and returns its allocated memory to the JVM memory pool.

The following example demonstrates querying V_MONITOR.SESSIONS to find the memory allocated to JVMs by all sessions. It also demonstrates how the memory is allocated by a call to a Java UDx, and then freed by calling RELEASE_JVM_MEMORY.

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
user_name | external_memory_kb
-----------+-----------------
dbadmin   | 0
(1 row)

=> -- Call a Java UDx
=> SELECT add2ints(123,456);
add2ints
-----------
579
(1 row)

=> -- JVM is now running and memory is allocated to it.
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
-----------+-----------------
dbadmin   | 79705
(1 row)

=> -- Shut down the JVM and deallocate memory
=> SELECT RELEASE_JVM_MEMORY();
RELEASE_JVM_MEMORY
-----------
Java process killed and memory released
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
-----------+-----------------
dbadmin   | 0
(1 row)
```

In rare cases, you may need to close all JVMs. For example, you may need to free memory for an important query, or several instances of a Java UDx may be taking too long to complete. You can use the RELEASE_ALL_JVM_MEMORY to close all of the JVMs in all user sessions:

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
USER_NAME | EXTERNAL_MEMORY_KB
-----------+-----------------
ExampleUser | 79705
dbadmin     | 79705
(2 rows)

=> SELECT RELEASE_ALL_JVM_MEMORY();
RELEASE_ALL_JVM_MEMORY
```

Vertica Analytic Database (9.3.x)
Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR_SESSIONS;

<table>
<thead>
<tr>
<th>USER_NAME</th>
<th>EXTERNAL_MEMORY_KB</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbadmin</td>
<td>0</td>
</tr>
</tbody>
</table>

(1 row)

**Caution:**
This function terminates all JVMs, including ones that are currently executing Java UDXs. This will cause any query that is currently executing a Java UDX to return an error.

**Notes**

- The jvm resource pool is used only to allocate memory for the Java UDX function calls in a statement. The rest of the resources required by the SQL statement come from other memory pools.
- The first time a Java UDX is called, Vertica starts a JVM to execute some Java methods to get metadata about the UDX during the query planning phase. The memory for this JVM is also taken from the jvm memory pool.

**Developing with the Python SDK**

The Vertica SDK supports writing UDXs of some types in Python 3.

The Python SDK does not require any additional system configuration or header files. This low overhead allows you to develop and deploy new capabilities to your Vertica cluster in a short amount of time.

The following workflow is typical for the Python SDK:
Because Python is an interpreted language, you do not have to compile your program before loading the UDx in Vertica. However, you should expect to do some debugging of your code after you create your function and begin testing it in Vertica.

This section covers Python-specific topics that apply to all UDx types. For information that applies to all languages, see Handling Different Numbers and Types of Arguments, UDx Parameters, Handling Cancel Requests and the sections for specific Types of UDxs. For full API documentation, see the Python SDK Documentation.

**Python Libraries**

Before you can use your Python UDx, you need to verify that it meets the following library requirements:

- Your UDx must import the `vertica_sdk` package in your code. You do not need to download this package. It is included as a part of the Vertica server.

```python
import vertica_sdk
```

- The Vertica Python SDK includes the Python Standard Library. If your UDx depends on other libraries, you must add them as dependencies using `CREATE LIBRARY`. You cannot simply import them.

**Python and Vertica Data Types**

The Vertica Python SDK converts native Vertica data types into the appropriate Python data types, as follows:

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Python Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>int</td>
</tr>
<tr>
<td>FLOAT</td>
<td>float</td>
</tr>
<tr>
<td>NUMERIC</td>
<td><code>decimal.Decimal</code></td>
</tr>
<tr>
<td>DATE</td>
<td><code>datetime.date</code></td>
</tr>
<tr>
<td>CHAR, VARCHAR, LONG VARCHAR</td>
<td>string (UTF-8 encoded)</td>
</tr>
</tbody>
</table>
### Vertica Data Type

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Python Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY, VARBINARY, LONG VARBINARY</td>
<td>binary</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>datetime.datetime</td>
</tr>
<tr>
<td>TIME</td>
<td>datetime.time</td>
</tr>
</tbody>
</table>

**Note:**

Some Vertica Analytic Database data types are not supported in Python.

### Handling Errors

If your UDx encounters an unrecoverable error, it should throw a UdfException. The exception triggers a rollback of the function call. In Python, this function rollback occurs when the UDx raises an exception.

The following code shows how you can add error checking to your UDx. In this example, if one of the arguments is less than 100, then the Python UDx throws an error.

```python
while(True):
    # Example of error checking best practices.
    product_id = block_reader.getInt(2)
    if product_id < 100:
        raise ValueError("Invalid Product ID")
```

When an exception is raised in your Python UDx, the UDx throws a UdfException and generates an error message.

```sql
=> SELECT add2ints(prod_cost, sale_price, product_id) FROM bunch_of_numbers;
ERROR 3399: Failure in UDx RPC call InvokeProcessBlock(): Error calling processBlock() in User Defined Object [add2ints]
at [/scratch_a/release/svrtar11244/vbuild/vertica/OSD/UDxFence/PythonInterface.cpp:168], error code: 0,
message: Error [/scratch_a/release/svrtar11244/vbuild/vertica/OSD/UDxFence/PythonInterface.cpp:385] function ['call_method']
(Python error type ['class 'ValueError']
Traceback (most recent call last):
  File "/home/dbadmin/py_db/v_py_db_node0001_catalog/Libraries/02fc4af0ace6f91eeafa74baecf3ef76000a00000004fc4/pylib_02fc4af0ace6f91eeafa74baecf3ef76000a00000004fc4.py", line 13, in processBlock
    raise ValueError("Invalid Product ID")
ValueError: Invalid Product ID
```
Writing Messages to Log Files

Writing messages to a log can help you when you debug your Python UDxs and want to output additional information about an error condition.

To write a message to the vertica log file, use the `server_interface.log()` function:

```python
def processBlock(self, server_interface, arg_reader, res_writer):
    server_interface.log("Python UDx - Adding 2 ints!")
    while(True):
        first_int = block_reader.getInt(0)
        second_int = block_reader.getInt(1)
        block_writer.setInt(first_int + second_int)
        server_interface.log("Values: first_int is {} second_int is ".format(first_int, second_int))
    block_writer.next()
    if not block_reader.next():
        break
```

Vertica writes the messages to a log file stored in the catalog directory's UDx log subdirectory, which is named UDxFencedProcesses.log:

```bash
$ tail /home/dbadmin/py_db/v_py_db_node0001_catalog/UDxLogs/UDxFencedProcesses.log
07:52:12.862 [Python-v_py_db_node001-7524:0x206c-40575] 0x7f70eee2f780 PythonExecContext::processBlock
07:52:12.862 [Python-v_py_db_node001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Python UDx - Adding 2 ints!
07:52:12.862 [Python-v_py_db_node001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Values: first_int is 100 second_int is 100
```

Vertica adds the SQL name of the UDx to the log message. It also adds the string [UserMessage] to mark the entry as a message added by a call to the `server_interface.log()` function. These additions allow you to filter the log to find the messages generated by your UDx.

Handling Errors
Developing with the R SDK

The Vertica R SDK extends the capabilities of the Vertica Analytic Database so you can leverage additional R libraries. Before you can begin developing User Defined Extensions (UDxs) in R, you must install the R Language Pack for Vertica on each of the nodes in your cluster. The R SDK supports scalar and transform functions in fenced mode. Other UDx types are not supported.

The following workflow is typical for the R SDK:

You can find detailed documentation of all of the classes in the Vertica R SDK API Documentation.

Installing/Upgrading the R Language Pack for Vertica

To create R UDxs in Vertica, install the R Language Pack package that matches your server version. The R Language Pack includes the R runtime and associated libraries for interfacing with Vertica. You must use this version of the R runtime; you cannot upgrade it.

You must install the R Language Pack on each node in the cluster. The Vertica R Language Pack must be the only R Language Pack installed on the node.

Vertica R Language Pack Prerequisites

The R Language Pack package requires a number of packages for installation and execution. The names of these dependencies vary among Linux distributions. For Vertica supported Linux platforms the packages are:

- RHEL/CentOS: libfortran, xz-libs, libgomp
- SUSE Linux Enterprise Server: libfortran3, liblzma5, libgomp1
Debian/Ubuntu: libfortran3, liblzma5, libgomp1
Amazon Linux 2.0: compat-gcc-48-libgfortran, xz-libs, libgomp

**Installing the Vertica R Language Pack**

If you use your operating systems package manager, rather than the rpm or dpkg command, for installation, you do not need to manually install the R Language Pack. The native package managers for each supported Linux version are:

- RHEL/CentOS: yum
- SUSE Linux Enterprise Server: zypper
- Debian/Ubuntu: apt-get
- Amazon Linux 2.0: yum

1. Download the R language package by going to the myVertica portal, clicking the downloads tab, and selecting the vertica-R-lang-_version.rpm (or vertica-R-lang_<version>.deb) file for your server version. The R language package version must match your server version to three decimal points.
2. Install the package as root or using sudo:

   - RHEL/CentOS
     ```bash
     $ yum install vertica-R-lang-<version>.rpm
     ```
   - SUSE Linux Enterprise Server
     ```bash
     $ zypper install vertica-R-lang-<version>.rpm
     ```
   - Debian
     ```bash
     $ apt-get install ./vertica-R-lang_<version>.deb
     ```
   - Amazon Linux 2.0
     ```bash
     $ yum install vertica-R-lang-<version>.AMZN.rpm
     ```

The installer puts the R binary in /opt/vertica/R.

**Upgrading the Vertica R Language Pack**

When upgrading, some R packages you have manually installed may not work and may have to be reinstalled. If you do not update your package(s), then R returns an error if the
package cannot be used. Instructions for upgrading these packages are below.

**Note:**
The R packages provided in the R Language Pack are automatically upgraded and do not need to be reinstalled.

1. You must uninstall the R Language package before upgrading Vertica. Any additional R packages you manually installed remain in /opt/vertica/R and are not removed when you uninstall the package.
2. Upgrade your server package as detailed in [Upgrading Vertica to a New Version](#).
3. After the server package has been updated, install the new R Language package on each host.

If you have installed additional R packages, on each node:

1. As root run /opt/vertica/R/bin/R and issue the command:
   ```
   > update.packages(checkBuilt=TRUE)
   ```
2. Select a CRAN mirror from the list displayed.
3. You are prompted to update each package that has an update available for it. You must update any packages that you manually installed and are not compatible with the current version of R in the R Language Pack.

Do NOT update:
- Rcpp
- RInside

The packages you selected to be updated are installed. Quit R with the command:

```
> quit()
```

Vertica UDx functions written in R do not need to be compiled and you do not need to reload your Vertica-R libraries and functions after an upgrade.

## R Packages

The Vertica R Language Pack includes the following R packages in addition to the default packages bundled with R:

- Rcpp
- RInside
- IpSolve
- IpSolveAPI
You can install additional R packages not included in the Vertica R Language Pack by using one of two methods. You must install the same packages on all nodes.

**Installing R Packages**

You can install additional R packages by using one of the two following methods.

Using the `install.packages()` R command:

```
$ sudo /opt/vertica/R/bin/R
> install.packages("Zelig");
```

Using CMD INSTALL:

```
/opt/vertica/R/bin/R CMD INSTALL <path-to-package-tgz>
```

The installed packages are located in: `/opt/vertica/R/library`.

**R and Vertica Data Types**

The following data types are supported when passing data to/from an R UDx:

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>R Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>logical</td>
</tr>
<tr>
<td>DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP, TIMESTAMPZ, TIMETZ</td>
<td>numeric</td>
</tr>
<tr>
<td>DOUBLE PRECISION, FLOAT, REAL</td>
<td>numeric</td>
</tr>
<tr>
<td>BIGINT, DECIMAL, INT, NUMERIC, NUMBER, MONEY</td>
<td>numeric</td>
</tr>
<tr>
<td>BINARY, VARBINARY</td>
<td>character</td>
</tr>
<tr>
<td>CHAR, VARCHAR</td>
<td>character</td>
</tr>
</tbody>
</table>

NULL values in Vertica are translated to R NA values when sent to the R function. R NA values are translated into Vertica null values when returned from the R function to Vertica.
**Important:**
When specifying LONG VARCHAR or LONG VARBINARY data types, include the space between the two words. For example, datatype = c("long varchar").

### Handling Errors

If your UDx encounters an unrecoverable error, it should throw a UdfException. The error triggers a rollback of the function call. In R, this function rollback occurs when the UDx executes an error action.

The following code shows how you can add error checking to your UDx. In this example, if the third column of the data frame does not match the specified Product ID, then the R UDx throws an error.

```r
Calculate_Cost_w_Tax <- function(input.data.frame) {
  # Must match the Product ID 11444
  if ( !is.numeric(input.data.frame[, 3]) == 11444 ) {
    stop("Invalid Product ID!")
  } else {
    cost_w_tax <- data.frame(input.data.frame[, 1] * input.data.frame[, 2])
  }
  return(cost_w_tax)
}

Calculate_Cost_w_TaxFactory <- function() {
  list(name=Calculate_Cost_w_Tax,
       udxtype=c("scalar"),
       intype=c("float","float", "float"),
       outtype=c("float"))
}
```

When an exception is raised in your R UDx, the UDx throws a UdfException and generates an error message.

```sql
=> SELECT Calculate_Cost_w_Tax(item_price, tax_rate, prod_id) FROM Inventory_Sales_Data;
```

```sql
```

### Adding Metadata to R Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your
function that is deployed on a Vertica Analytic Database cluster and lets third-party users of
your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the RegisterLibrary() function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The RegisterLibrary() function takes eight string parameters:

```
RegisterLibrary(author,  
    library_build_tag,  
    library_version,  
    library_sdk_version,  
    source_url,  
    description,  
    licenses_required,  
    signature);
```

- **author** contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- **library_build_tag** is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- **library_version** is the version of your library. You can use whatever numbering or naming scheme you want.
- **library_sdk_version** is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

**Note:**

This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- **source_url** is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- **description** is a concise description of your library.
- `licenses_required` is a placeholder for licensing information. You must pass an empty string for this value.
- `signature` is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

The following example shows how to add metadata to an R UDx.

```r
RegisterLibrary("Speedy Analytics Ltd.",
"1234",
"1.0",
"8.1.0",
"Sales Tax R Library",
"
")
```

Loading the library and querying the `USER_LIBRARIES` system table shows the metadata supplied in the call to `RegisterLibrary`:

```r
=> CREATE LIBRARY rLib AS '/home/dbadmin/sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'rLib';
- [ RECORD 1 ]-+---------------------------------------------------------------+
| schema_name | public | lib_name | rLib | lib_oid | 45035996273708350 | author | Speedy Analytics Ltd. | owner_id | 45035996273704962 | lib_file_name | rLib_02552872a35d9352b4907d3fcd03cf9700a000000000d3e.R | md5_sum | 30da55537c4d93c352775e4f31332d2 | sdk_version | revision | lib_build_tag | 1234 | lib_version | 1.0 | lib_sdk_version | 8.1.0 | source_url | http://www.example.com/sales_tax_calculator.R | description | Sales Tax R Library | licenses_required | signature | dependencies | | is_valid | t | sal_storage_id | 02552872a35d9352b4907d3fcd03cf9700a000000000d3e |
```

### Setting Null Input and Volatility Behavior for R Functions

Vertica supports defining volatility and null-input settings for UDxs written in R. Both settings aid in the performance of your R function.
Volatility settings describe the behavior of the function to the Vertica optimizer. For example, if you have identical rows of input data and you know the U Dx is immutable, then you can define the U Dx as IMMUTABLE. This tells the Vertica optimizer that it can return a cached value for subsequent identical rows on which the function is called rather than having the function run on each identical row.

To indicate your U D X's volatility, set the volatility parameter of your R factory function to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLATILE</td>
<td>Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.</td>
</tr>
<tr>
<td>IMMUTABLE</td>
<td>Calls to the function with the same arguments always results in the same return value.</td>
</tr>
<tr>
<td>STABLE</td>
<td>Repeated calls to the function with the same arguments <em>within the same statement</em> returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.</td>
</tr>
<tr>
<td>DEFAULT_VOLATILITY</td>
<td>The default volatility. This is the same as VOLATILE.</td>
</tr>
</tbody>
</table>

If you do not define a volatility, then the function is considered to be VOLATILE.

The following example sets the volatility to STABLE in the multiplyTwoIntsFactory function:

```r
multiplyTwoIntsFactory <- function() {
  list(name = multiplyTwoInts,
       udxtype = c("scalar"),
       intype  = c("float","float"),
       outtype = c("float"),
       volatility = c("stable"),
       parameterstypecallback = multiplyTwoIntsParameters)
}
```
**Null Input Behavior**

Null input setting determine how to respond to rows that have null input. For example, you can choose to return null if any inputs are null rather than calling the function and having the function deal with a NULL input.

To indicate how your UDx reacts to NULL input, set the strictness parameter of your R factory function to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLED_ON_NULL_INPUT</td>
<td>The function must be called, even if one or more arguments are NULL.</td>
</tr>
<tr>
<td>RETURN_NULL_ON_NULL_INPUT</td>
<td>The function always returns a NULL value if any of its arguments are NULL.</td>
</tr>
<tr>
<td>STRICT</td>
<td>A synonym for RETURN_NULL_ON_NULL_INPUT</td>
</tr>
<tr>
<td>DEFAULT STRICTNESS</td>
<td>The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.</td>
</tr>
</tbody>
</table>

If you do not define a null input behavior, then the function is called on every row of data regardless of the presence of NULL values.

The following example sets the NULL input behavior to STRICT in the multiplyTwoIntsFactory function:

```r
multiplyTwoIntsFactory <- function() {
  list(name = multiplyTwoInts,
       udtype = c("scalar"),
       intype = c("float","float"),
       outtype = c("float"),
       strictness = c("strict"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```
User-Defined Aggregate Functions

Aggregate functions perform an operation on a set of values and return one value. Vertica provides standard built-in aggregate functions such as AVG, MAX, and MIN. User-defined aggregate functions (UDAFs) provide similar functionality:

- Support a single input column (or set) of values and provide a single output column.
- Support RLE decompression. RLE input is decompressed before it is sent to a UDAF.
- Support use with GROUP BY and HAVING clauses. Only columns appearing in the GROUP BY clause can be selected.

Restrictions

The following restrictions apply to UDAFs:

- Available for C++ only.
- Cannot be used with correlated subqueries.

UDAF Class Overview

You create your UDAF by subclassing two classes defined by the Vertica SDK: AggregateFunction and AggregateFunctionFactory.

AggregateFunction

The AggregateFunction class performs the aggregation. It computes values on each database node where relevant data is stored and then combines the results from the nodes. You must implement the following methods:

- initAggregate() - Initializes the class, defines variables, and sets the starting value for the variables. This function must be idempotent.
- aggregate() - The main aggregation operation, executed on each node.
- combine() - If multiple invocations of aggregate() are needed, Vertica calls combine() to combine all the sub-aggregations into a final aggregation. Although
this method might not be called, you must define it.

- **terminate()** - Terminates the function and returns the result as a column.

**Important:**
The `aggregate()` function might not operate on the complete input set all at once. For this reason, `initAggregate()` must be idempotent.

The `AggregateFunction` class also provides optional methods that you can implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDAF API (see Allocating Resources for UDxs for details).

### AggregateFunctionFactory

The `AggregateFunctionFactory` class specifies metadata information such as the argument and return types of your aggregate function. It also instantiates your `AggregateFunction` subclass. Your subclass must implement the following methods:

- **getPrototype()** - Defines the number of parameters and data types accepted by the function. There is a single parameter for aggregate functions.
- **getIntermediateTypes()** - Defines the intermediate variable(s) used by the function. These variables are used when combining the results of `aggregate()` calls.
- **getParameterType()** - Defines the names and types of parameters that this function uses (optional).
- **getReturnType()** - Defines the type of the output column.

Vertica uses this data when you call the `CREATE AGGREGATE FUNCTION` SQL statement to add the function to the database catalog.

### UDAF Performance in Statements Containing a GROUP BY Clause

You may see slower-than-expected performance from your UDAF if the SQL statement calling it also contains a GROUP BY Clause. For example:

```
=> SELECT a, MYUDAF(b) FROM sampletable GROUP BY a;
```

In statements like this one, Vertica does not consolidate row data together before calling your UDAF's `aggregate()` method. Instead, it calls `aggregate()` once for each row of
data. Usually, the overhead of having Vertica consolidate the row data is greater than the overhead of calling `aggregate()` for each row of data. However, if your UDAF's `aggregate()` method has significant overhead, then you might notice an impact on your UDAF's performance.

For example, suppose `aggregate()` allocates memory. When called in a statement with a `GROUP BY` clause, it performs this memory allocation for each row of data. Because memory allocation is a relatively expensive process, this allocation can impact the overall performance of your UDAF and the query.

There are two ways you can address UDAF performance in a statement containing a `GROUP BY` clause:

- Reduce the overhead of each call to `aggregate()`. If possible, move any allocation or other setup operations to the UDAF's `setup()` function.
- Declare a special parameter that tells Vertica to group row data together when calling a UDAF. This technique is explained below.

**Using the `_minimizeCallCount` Parameter**

Your UDAF can tell Vertica to always batch row data together to reduce the number of calls to its `aggregate()` method. To trigger this behavior, your UDAF must declare an integer parameter named `_minimizeCallCount`. You do not need to set a value for this parameter in your SQL statement. The fact that your UDAF declares this parameter triggers Vertica to group row data together when calling `aggregate()`.

You declare the `_minimizeCallCount` parameter the same way you declare other UDx parameters. See [UDx Parameters](#) for more information.

**Important:**
Always test the performance of your UDAF before and after implementing the `_minimizeCallCount` parameter to ensure that it improves performance. You might find that the overhead of having Vertica group row data for your UDAF is greater than the cost of the repeated calls to `aggregate()`.

**C++ API**

This section provides APIs and examples for the C++ API for UDAFs.
For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

**AggregateFunction and AggregateFunctionFactory C++ Interface**

This section describes information that is specific to the C++ API. See UDAF Class Overview for general information about implementing the AggregateFunction and AggregateFunctionFactory classes.

**AggregateFunction API**

The API provides the following methods for extension by subclasses:

```c++
virtual void setup(ServerInterface &srvInterface,
                   const SizedColumnTypes &argTypes);
virtual void initAggregate(ServerInterface &srvInterface, IntermediateAggs &aggs)=0;
void aggregate(ServerInterface &srvInterface, BlockReader &arg_reader,
               IntermediateAggs &aggs);
virtual void combine(ServerInterface &srvInterface, IntermediateAggs &aggs_output,
                     MultipleIntermediateAggs &aggs_other)=0;
virtual void terminate(ServerInterface &srvInterface, BlockWriter &res_writer,
                       IntermediateAggs &aggs);
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

**AggregateFunctionFactory API**

The API provides the following methods for extension by subclasses:

```c++
virtual AggregateFunction *
    createAggregateFunction(ServerInterface &srvInterface)=0;
virtual void getPrototype(ServerInterface &srvInterface,
                        ColumnTypes &argTypes, ColumnTypes &returnType)=0;
```
virtual void getIntermediateTypes(ServerInterface &srvInterface, 
    const SizedColumnTypes &inputTypes, SizedColumnTypes &intermediateTypeMetaData)=0;

virtual void getReturnType(ServerInterface &srvInterface, 
    const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface, 
    SizedColumnTypes &parameterTypes);

### C++ Example: Average

The **Average** aggregate function created in this example computes the average of values in a column.

You can find the source code used in this example on the [Vertica GitHub page](https://github.com/Vertica/vertica-public).

### Loading the Example

Use **CREATE LIBRARY** and **CREATE AGGREGATE FUNCTION** to declare the function:

```sql
=> CREATE LIBRARY AggregateFunctions AS
    '/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE aggregate function ag_avg AS LANGUAGE 'C++'
    name 'AverageFactory' library AggregateFunctions;
CREATE AGGREGATE FUNCTION
```

### Using the Example

Use the function as part of a **SELECT** statement:

```sql
=> SELECT * FROM average;

id  | count
----+-------
A   | 8
B   | 3
C   | 6
D   | 2
E   | 9
F   | 7
G   | 5
H   | 4
I   | 1
```
(9 rows)
=> SELECT ag_avg(count) FROM average;
ag_avg
--------
5
(1 row)

**AggregateFunction Implementation**

This example adds the input argument values in the `aggregate()` method and keeps a counter of the number of values added. The server runs `aggregate()` on every node and different data chunks, and combines all the individually added values and counters in the `combine()` method. Finally, the average value is computed in the `terminate()` method by dividing the total sum by the total number of values processed.

For this discussion, assume the following environment:

- A three-node Vertica cluster
- A table column that contains nine values that are evenly distributed across the nodes.

Schematically, the nodes look like the following figure:
Node 1
Values 1,2,3

Node 2
Values 4,5,6

Node 3
Values 7,8,9
The function uses sum and count variables. *Sum* contains the sum of the values, and *count* contains the count of values.

First, `initAggregate()` initializes the variables and sets their values to zero.

```cpp
virtual void initAggregate(ServerInterface &srvInterface,
                            IntermediateAggs &aggs)
{
    try {
        VNumeric &sum = aggs.getNumericRef(0);
        sum.setZero();

        vint &count = aggs.getIntRef(1);
        count = 0;
    } catch(std::exception &e) {
        vt_report_error(0, "Exception while initializing intermediate aggregates: [% s]", e.what());
    }
}
```

The `aggregate()` function reads the block of data on each node and calculates partial aggregates.

```cpp
void aggregate(ServerInterface &srvInterface,
               BlockReader &argReader,
               IntermediateAggs &aggs)
{
    try {
        VNumeric &sum = aggs.getNumericRef(0);
        vint &count = aggs.getIntRef(1);

        do {
            const VNumeric &input = argReader.getNumericRef(0);
            if (!input.isNull()) {
                sum.accumulate(&input);
                count++;
            }
        } while (argReader.next());
    } catch(std::exception &e) {
        vt_report_error(0, "Exception while processing aggregate: [% s]", e.what());
    }
}
```

Each completed instance of the `aggregate()` function returns multiple partial aggregates for sum and count. The following figure illustrates this process using the `aggregate()` function:
Node 1
Values 1,2,3

aggregate()
sum = 6; count = 3

initAggregate()
sum = 0; count = 0

Node 2
Values 4,5,6

aggregate()
sum = 15; count = 3

Node 3
Values 7,8,9

aggregate()
sum = 24; count = 3
The combine() function puts together the partial aggregates calculated by each instance of the average function.

```cpp
virtual void combine(ServerInterface &srvInterface,
                      IntermediateAggs &aggs,
                      MultipleIntermediateAggs &aggsOther)
{
    try {
        VNumeric &mySum = aggs.getNumericRef(0);
        vint &myCount = aggs.getIntRef(1);
        do {
            const VNumeric &otherSum = aggsOther.getNumericRef(0);
            const vint &otherCount = aggsOther.getIntRef(1);
            mySum.accumulate(&otherSum);
            myCount += otherCount;
        } while (aggsOther.next());
    } catch(std::exception &e) {
        vt_report_error(0, "Exception while combining intermediate aggregates: [%s]", e.what());
    }
}
```

The following figure shows how each partial aggregate is combined:
After all input has been evaluated by the `aggregate()` function Vertica calls the `terminate()` function. It returns the average to the caller.
virtual void terminate(ServerInterface &srvInterface,
    BlockWriter &resWriter,
    IntermediateAggs &aggs)
{
    try {
        const int32 MAX_INT_PRECISION = 20;
        const int32 prec = Basics::getNumericWordCount(MAX_INT_PRECISION);
        uint64 words[prec];
        VNumeric count(words,prec,0/*scale*/);
        count.copy(aggs.getIntRef(1));
        VNumeric &out = resWriter.getNumericRef();
        if (count.isZero()) {
            out.setNull();
        } else {
            const VNumeric &sum = aggs.getNumericRef(0);
            out.div(&sum, &count);
        }
    }
}

The following figure shows the implementation of the terminate() function:
AggregateFunctionFactory Implementation

The `getPrototype()` function allows you to define the variables that are sent to your aggregate function and returned to Vertica after your aggregate function runs. The following example accepts and returns a numeric value:

```cpp
virtual void getPrototype(ServerInterface &srvfloaterface,
                        ColumnTypes &argTypes,
                        ColumnTypes &returnType)
{
    argTypes.addNumeric();
    returnType.addNumeric();
}
```

The `getIntermediateTypes()` function defines any intermediate variables that you use in your aggregate function. *Intermediate variables* are values used to pass data among multiple invocations of an aggregate function. They are used to combine results until a final result can be computed. In this example, there are two results - total (numeric) and count (int).

```cpp
virtual void getIntermediateTypes(ServerInterface &srvInterface,
                               const SizedColumnTypes &inputTypes,
                               SizedColumnTypes &intermediateTypeMetaData)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    intermediateTypeMetaData.addNumeric(inType.getNumericScale());
    intermediateTypeMetaData.addInt();
}
```

The `getReturnType()` function defines the output data type:

```cpp
virtual void getReturnType(ServerInterface &srvfloaterface,
                         const SizedColumnTypes &inputTypes,
                         SizedColumnTypes &outputTypes)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    outputTypes.addNumeric(inType.getNumericPrecision(),
                           inType.getNumericScale());
}
```
Analytic Functions (UDAnFs)

User-defined analytic functions (UDAnFs) are used for analytics. See SQL Analytics for an overview of Vertica's built-in analytics. Like user-defined scalar functions (UDSFs), UDAnFs must output a single value for each row of data read and can have no more than 1600 arguments.

Unlike UDSFs, the UDAnF's input reader and output reader can be advanced independently. This feature lets you create UDAnF's where the output value is calculated over multiple rows of data. By advancing the reader and writer independently, you can create functions similar to the built-in analytic functions such as LAG, which uses data from prior rows to output a value for the current row.

UDAnF Class Overview

You create your UDAnF by subclassing two classes defined by the Vertica SDK: AnalyticFunction and AnalyticFunctionFactory.

AnalyticFunction

The AnalyticFunction subclass performs the analytic processing. Your subclass must define the processPartition() method to perform the operation. It may define methods to set up and tear down the function.

Performing the Operation

The processPartition() method reads a partition of data, performs some sort of processing, and outputs a single value for each input row.

Vertica calls processPartition() once for each partition of data. It supplies the partition using an AnalyticPartitionReader object from which you read its input data. In addition, there is a unique method on this object named isNewOrderByKey(), which returns a Boolean value indicating whether your function has seen a row with the same ORDER BY key (or keys). This method is very useful for analytic functions (such as the
example RANK function) which need to handle rows with identical ORDER BY keys differently than rows with different ORDER BY keys.

Note:
You can specify multiple ORDER BY columns in the SQL query you use to call your UDAnF. The isNewOrderByKey method returns true if any of the ORDER BY keys are different than the previous row.

Once your method has finished processing the row of data, you advance it to the next row of input by calling next() on AnalyticPartitionReader.

Your method writes its output value using an AnalyticPartitionWriter object that Vertica supplies as a parameter to processPartition(). This object has data-type-specific methods to write the output value (such as setInt()). After setting the output value, call next() on AnalyticPartitionWriter to advance to the next row in the output.

Note:
You must be sure that your function produces a row of output for each row of input in the partition. You must also not output more rows than are in the partition, otherwise the zygote size process (if running in Fenced Mode) or Vertica itself could generate an out of bounds error.

Setting Up and Tearing Down

The AnalyticFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy(). You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

AnalyticFunctionFactory

The AnalyticFunctionFactory class tells Vertica metadata about your UDAnF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of AnalyticFunction.

Your AnalyticFunctionFactory subclass must implement the following methods:

- getPrototype() describes the input parameters and output value of your function. You set these values by calling functions on two ColumnTypes objects that are
passed to your method.
- `createAnalyticFunction()` supplies an instance of your `AnalyticFunction` that Vertica can call to process a UDAnF function call.
- `getReturnType()` provides details about your function's output. This method is where you set the width of the output value if your function returns a variable-width value (such as VARCHAR) or the precision of the output value if it has a settable precision (such as TIMESTAMP).

**C++ API**

This section provides APIs and examples for the C++ API for UDAnFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

**AnalyticFunction and AnalyticFunctionFactory C++ Interface**

This section describes information that is specific to the C++ API. See UDAnF Class Overview for general information about implementing the AnalyticFunction and AnalyticFunctionFactory classes.

**AnalyticFunction API**

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
                    const SizedColumnTypes &argTypes);

virtual void processPartition (ServerInterface &srvInterface,
                                AnalyticPartitionReader &input_reader,
                                AnalyticPartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```
AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

```cpp
virtual AnalyticFunction * createAnalyticFunction (ServerInterface &srvInterface)=0;
virtual void getPrototype(ServerInterface &srvInterface,
ColumnTypes &argTypes, ColumnTypes &returnType)=0;
virtual void getReturnType(ServerInterface &srvInterface,
const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;
virtual void getParameterType(ServerInterface &srvInterface,
SizedColumnTypes &parameterTypes);
```

C++ Example: Rank

The Rank analytic function ranks rows based on how they are ordered.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.so library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```sql
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
   NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named an_rank, is:

```sql
=> SELECT * FROM hits;
  site        | date       | num_hits
---------------+------------+-----------
www.example.com | 2012-01-02 | 97        
www.vertica.com | 2012-01-01 | 343435     
www.example.com | 2012-01-01 | 123       
www.example.com | 2012-01-04 | 112       
www.vertica.com | 2012-01-02 | 503695     
www.vertica.com | 2012-01-03 | 490387     
www.example.com | 2012-01-03 | 123       
```
As with the built-in **Rank** analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

**AnalyticFunction Implementation**

The following code defines an `AnalyticFunction` subclass named `Rank`. It is based on example code distributed in the examples directory of the SDK.

```c++
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 */
class Rank : public AnalyticFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
                                  AnalyticPartitionReader &inputReader,
                                  AnalyticPartitionWriter &outputWriter)
    {
        // Always use a top-level try-catch block to prevent exceptions from
        // leaking back to Vertica or the fenced-mode side process.
        try {
            rank = 1; // The rank to assign a row
            rowCount = 0; // Number of rows processed so far
            do {
                rowCount++;
                // Do we have a new order by row?
                if (inputReader.isNewOrderByKey()) {
                    // Yes, so set rank to the total number of rows that have been
                    // processed. Otherwise, the rank remains the same value as
                    // the previous iteration.
                    rank = rowCount;
                }
                // Write the rank
                outputWriter.setInt(0, rank);
            }
        }
```
In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It does not need to read data; it just counts the rows that have been read and determine whether those rows have the same `ORDER BY` key as the previous row. If the current row is a new `ORDER BY` key, then the rank is set to the total number of rows that have been processed. If the current row has the same `ORDER BY` value as the previous row, then the rank remains the same.

Note that the function has a top-level try-catch block. All of your UDx functions should always have one to prevent stray exceptions from being passed back to Vertica (if you run the function unfenced) or the side process.

### AnalyticFunctionFactory Implementation

The following code defines the `AnalyticFunctionFactory` that corresponds with the Rank analytic function.

```cpp
class RankFactory : public AnalyticFunctionFactory
{
    virtual void getPrototype(ServerInterface &srvInterface,
                               ColumnTypes &argTypes,
                               ColumnTypes &returnType)
    {
        returnType.addInt();
    }
    virtual void getReturnType(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes,
                                SizedColumnTypes &outputTypes)
    {
        outputTypes.addInt();
    }
    virtual AnalyticFunction *createAnalyticFunction(ServerInterface &srvInterface)
    {
        return vt_createFuncObj(srvInterfaceallocator, Rank); }
};
```

The first method defined by the `RankFactory` subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAnF does not read input, it does not define
any arguments by calling methods on the ColumnTypes object passed in the argTypes parameter.

The next method is getReturnType(). If your function returns a data type that needs to define a width or precision, your implementation of the getReturnType() method calls a method on the SizedColumnType object passed in as a parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls addInt() to report its output data type.

Finally, RankFactory defines the createAnalyticFunction() method that returns an instance of the AnalyticFunction class that Vertica can call. This code is mostly boilerplate. All you need to do is add the name of your analytic function class in the call to vt_createFuncObj(), which takes care of allocating the object for you.

Java API

This section provides APIs and examples for the Java API for UDAnFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

AnalyticFunction and AnalyticFunctionFactory Java Interface

This section describes information that is specific to the Java API. See UDAnF Class Overview for general information about implementing the AnalyticFunction and AnalyticFunctionFactory classes.

AnalyticFunction API

The API provides the following methods for extension by subclasses:

```java
class AnalyticFunction {
    public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

    public abstract void processPartition (ServerInterface srvInterface,
                                             AnalyticPartitionReader input_reader, AnalyticPartitionWriter output_writer)
                                             throws UdfException, DestroyInvocation;

    protected void cancel(ServerInterface srvInterface);
}
```
public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);

**AnalyticFunctionFactory API**

The API provides the following methods for extension by subclasses:

```java
public abstract AnalyticFunction createAnalyticFunction (ServerInterface srvInterface);
public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);
public abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException;
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

**Java Example: Rank**

The Rank analytic function ranks rows based on how they are ordered.

**Loading and Using the Example**

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.jar library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```sql
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.jar';
=> CREATE LIBRARY AnalyticFunctions;
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'Java'
    NAME 'RankFactory' LIBRARY AnalyticFunctions;
=> CREATE ANALYTIC FUNCTION an_rank;
```

An example of running this rank function, named an_rank, is:

```sql
=> SELECT * FROM hits;
<table>
<thead>
<tr>
<th>site</th>
<th>date</th>
<th>num_hits</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.example.com">www.example.com</a></td>
<td>2012-01-02</td>
<td>97</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>2012-01-01</td>
<td>343435</td>
</tr>
<tr>
<td><a href="http://www.example.com">www.example.com</a></td>
<td>2012-01-01</td>
<td>123</td>
</tr>
<tr>
<td><a href="http://www.example.com">www.example.com</a></td>
<td>2012-01-04</td>
<td>112</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>2012-01-02</td>
<td>503695</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>2012-01-03</td>
<td>490387</td>
</tr>
</tbody>
</table>
```
As with the built-in `RANK` analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

**AnalyticFunction Implementation**

The following code defines an `AnalyticFunction` subclass named `Rank`. The code can be found in the SDK examples directory.

```java
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 *
 */
public class Rank extends AnalyticFunction {
    private int rank, numRowsWithSameOrder;

    @Override
    public void processPartition(ServerInterface srvInterface,
                                  AnalyticPartitionReader inputReader,
                                  AnalyticPartitionWriter outputWriter)
        throws UdfException, DestroyInvocation {
        rank = 0;
        numRowsWithSameOrder = 1;
        do{
            if (!inputReader.isNewOrderByKey()){
                ++numRowsWithSameOrder;
            }else {
                rank += numRowsWithSameOrder;
                numRowsWithSameOrder = 1;
            }
            outputWriter.setLong(0, rank);
            outputWriter.next();
        }while(inputReader.next());
    }
```
In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It just needs to count the number of rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

**AnalyticFunctionFactory Implementation**

The following code defines the `AnalyticFunctionFactory` that corresponds with the Rank analytic function.

```java
public class RankFactory extends AnalyticFunctionFactory {

@Override
    public void getPrototype(ServerInterface srvInterface,
            ColumnTypes argTypes,
            ColumnTypes returnType) {
        returnType.addInt();
    }

@Override
    public void getReturnType(ServerInterface srvInterface,
            SizedColumnTypes argTypes,
            SizedColumnTypes returnType) throws UdfException {
        returnType.addInt();
    }

@Override
    public AnalyticFunction createAnalyticFunction(ServerInterface srvInterface) {
        return new Rank();
    }
}
```

The first method defined by the `RankFactory` subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAf does not read input, it does not define any arguments by calling methods on the `ColumnTypes` object passed in the `argTypes` parameter.

The next method is `getReturnType()`. If your analytic function returns a data type that needs to define a width or precision, your implementation of the `getReturnType` function calls a method on the `SizedColumnTypes` parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an `INTEGER`) so it does not need to set the precision or width of its output; it just calls `addInt()` to report its output data type.
Finally, RankFactory defines the `createAnalyticFunction()` method that returns an instance of the `AnalyticFunction` class that Vertica can call.
Scalar Functions (UDSFs)

A user-defined scalar function (UDSF) returns a single value for each row of data it reads. You can use a UDSF anywhere you can use a built-in Vertica function. You usually develop a UDSF to perform data manipulations that are too complex or too slow to perform using SQL statements and functions. UDSFs also let you use analytic functions provided by third-party libraries within Vertica while still maintaining high performance.

Your UDSF must return a value for every input row (unless it generates an error; see Handling Errors for details). Failure to return a value for a row results in incorrect results and potentially destabilizes the Vertica server if not run in Fenced Mode.

A UDSF cannot have more than 1600 arguments.

UDSF Class Overview

You create your UDSF by subclassing two classes defined by the Vertica SDK: ScalarFunction and ScalarFunctionFactory.

ScalarFunction

The ScalarFunction class is the heart of a UDSF. Your subclass must define the processBlock() method to perform the scalar operation. It may define methods to set up and tear down the function.

Performing the Operation

The processBlock() method carries out all of the processing that you want your UDSF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to processBlock().

The input and output of the processBlock() method are supplied by objects of the BlockReader and BlockWriter classes. They define methods that you use to read the input data and write the output data for your UDSF.
The majority of the work in developing a UDSF is writing `processBlock()`. This is where all of the processing in your function occurs. Your UDSF should follow this basic pattern:

- Read in a set of parameters from the `BlockReader` object using data-type-specific methods.
- Process the data in some manner.
- Output the resulting value using one of the `BlockWriter` class's data-type-specific methods.
- Advance to the next row of output and input by calling `BlockWriter.next()` and `BlockReader.next()`.

This process continues until there are no more rows of data to be read (`BlockReader.next()` returns `false`).

You must make sure that `processBlock()` reads all of the rows in its input and outputs a single value for each row. Failure to do so can corrupt the data structures that Vertica reads to get the output of your UDSF. The only exception to this rule is if your `processBlock()` function reports an error back to Vertica (see Handling Errors). In that case, Vertica does not attempt to read the incomplete result set generated by the UDSF.

### Setting Up and Tearing Down

The `ScalarFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDx for details).

### Notes

- While the name you choose for your `ScalarFunction` subclass does not have to match the name of the SQL function you will later assign to it, Vertica considers making the names the same a best practice.
- Do not assume that your function will be called from the same thread that instantiated it.
- The same instance of your `ScalarFunction` subclass can be called on to process multiple blocks of data.
- The rows of input sent to `processBlock()` are not guaranteed to be in any particular order.
- Writing too many output rows can cause Vertica to emit an out-of-bounds error.
**ScalarFunctionFactory**

The `ScalarFunctionFactory` class tells Vertica metadata about your UDSF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `ScalarFunction`.

**Methods**

You must implement the following methods in your `ScalarFunctionFactory` subclass:

- `createScalarFunction()` instantiates a `ScalarFunction` subclass. If writing in C++, you can call the `vt_createFuncObj` macro with the name of the `ScalarFunction` subclass. This macro takes care of allocating and instantiating the class for you.
- `getPrototype()` tells Vertica about the parameters and return type for your UDSF. In addition to a `ServerInterface` object, this method gets two `ColumnType`s objects. All you need to do in this function is to call class functions on these two objects to build the list of parameters and the single return value type.

After defining your factory class, you need to call the `RegisterFactory` macro. This macro instantiates a member of your factory class, so Vertica can interact with it and extract the metadata it contains about your UDSF.

**Declaring Return Values**

If your function returns a sized column (a return data type whose length can vary, such as a VARCHAR) or a value that requires precision, you must implement `getReturnType()`. This method is called by Vertica to find the length or precision of the data being returned in each row of the results. The return value of this method depends on the data type your `processBlock()` method returns:

- CHAR or VARCHAR return the maximum length of the string.
- NUMERIC types specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone) specify precision.
- INTERVAL YEAR TO MONTH specifies range.
- INTERVAL DAY TO SECOND specifies precision and range.
If your UDSF does not return one of these data types, it does not need a `getReturnType()` method.

The input to the `getReturnType()` method is a `SizedColumnTypes` object that contains the input argument types along with their lengths. This object will be passed to an instance of your `processBlock()` function. Your implementation of `getReturnType()` must extract the data types and lengths from this input and determine the length or precision of the output rows. It then saves this information in another instance of the `SizedColumnTypes` class.

**Setting Null Input and Volatility Behavior**

Normally, Vertica calls your UDSF for every row of data in the query. There are some cases where Vertica can avoid executing your UDSF. You can tell Vertica when it can skip calling your function and just supply a return value itself by changing your function's volatility and strictness settings.

- Your function's **volatility** indicates whether it always returns the same output value when passed the same arguments. Depending on its behavior, Vertica can cache the arguments and the return value. If the user calls the UDSF with the same set of arguments, Vertica returns the cached value instead of calling your UDSF.
- Your function's **strictness** indicates how it reacts to NULL arguments. If it always returns NULL when *any* argument is NULL, Vertica can just return NULL without having to call the function. This optimization also saves you work, because you do not need to test for and handle null arguments in your UDSF code.

You indicate the volatility and null handling of your function by setting the `vol` and `strict` fields in your `ScalarFunctionFactory` class's constructor.

**Volatility Settings**

To indicate your function's volatility, set the `vol` field to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLATILE</td>
<td>Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.</td>
</tr>
<tr>
<td>IMMUTABLE</td>
<td>Calls to the function with the same arguments always results in the</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>same return value.</td>
<td></td>
</tr>
<tr>
<td>STABLE</td>
<td>Repeated calls to the function with the same arguments within the same statement returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.</td>
</tr>
<tr>
<td>DEFAULT_VOLATILITY</td>
<td>The default volatility. This is the same as VOLATILE.</td>
</tr>
</tbody>
</table>

**C++ Example**

The following example shows a version of the Add2ints example factory class that makes the function immutable.

```cpp
class Add2intsImmutableFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                                Vertica::ColumnTypes &argTypes,
                                Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    public:
    Add2intsImmutableFactory() { vol = IMMUTABLE; }
};
RegisterFactory(Add2intsImmutableFactory);
```

**Java Example**

The following example demonstrates setting the Add2IntsFactory's vol field to IMMUTABLE to tell Vertica it can cache the arguments and return value.

```java
public class Add2IntsFactory extends ScalarFunctionFactory {

    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType){
```
argTypes.addInt();
argTypes.addInt();
returnType.addInt();
}

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface){
    return new Add2Ints();
}

// Class constructor
public Add2IntsFactory() {
    // Tell Vertica that the same set of arguments will always result in the
    // same return value.
    vol = volatility.IMMUTABLE;
}

### Null Input Behavior

To indicate how your function reacts to NULL input, set the `strictness` field to one of the following values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLED_ON_NULL_INPUT</td>
<td>The function must be called, even if one or more arguments are NULL.</td>
</tr>
<tr>
<td>RETURN_NULL_ON_NULL_INPUT</td>
<td>The function always returns a NULL value if any of its arguments are NULL.</td>
</tr>
<tr>
<td>STRICT</td>
<td>A synonym for RETURN_NULL_ON_NULL_INPUT</td>
</tr>
<tr>
<td>DEFAULT STRICTNESS</td>
<td>The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.</td>
</tr>
</tbody>
</table>

### C++ Example

The following example demonstrates setting the null behavior of Add2ints so Vertica does not call the function with NULL values.

class Add2intsNullOnNullInputFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
```cpp
{ return vt_createFuncObj(srvInterface.allocator, Add2ints); }

virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                           Vertica::ColumnTypes &argTypes,
                           Vertica::ColumnTypes &returnType)
{
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
}

public:
    Add2intsNullOnNullInputFactory() { strict = RETURN_NULL_ON_NULL_INPUT; }
};
RegisterFactory(Add2 intsNullOnNullInputFactory);
```

### Java Example

The following example demonstrates setting the strictness setting of the Add2Ints example to STRICT. This means that if either of the two values to be added is NULL, Vertica can set the return value to NULL without having to call the Add2Ints function.

```java
public class Add2IntsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType){
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new Add2Ints();
    }

    public Add2IntsFactory() {
        // Tell Vertica that any NULL arguments results in a NULL return value
        strict = strictness.RETURN_NULL_ON_NULL_INPUT;
    }
}
```

### C++API

This section provides APIs and examples for the C++ API for UDSFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.
ScalarFunction and ScalarFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDSF Class Overview for general information about implementing the ScalarFunction and ScalarFunctionFactory classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
                    const SizedColumnTypes &argTypes);

virtual void processBlock(ServerInterface &srvInterface,
                            BlockReader &arg_reader, BlockWriter &res_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface,
                      const SizedColumnTypes &argTypes);
```

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

```cpp
virtual ScalarFunction * createScalarFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
                            ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
                             const SizedColumnTypes &argTypes, SizedColumnTypes &returnType);

virtual void getParameterType(ServerInterface &srvInterface,
                                SizedColumnTypes &parameterTypes);
```

C++ Example: Add2Ints

The following example shows a very basic subclass of ScalarFunction called Add2Ints. As the name implies it adds two integers together, returning a single integer result. It also
demonstrates including the main Vertica SDK header file (Vertica.h) and using the Vertica namespace. While not required, using the namespace saves you from having to prefix every Vertica SDK class reference with Vertica::.

**ScalarFunction Implementation**

```cpp
// Include the top-level Vertica SDK file
#include "Vertica.h"

// Using the Vertica namespace means we don't have to prefix all
// class references with Vertica::
using namespace Vertica;

/*
 * ScalarFunction implementation for a UDSF that adds
 * two numbers together.
 */
class Add2Ints : public ScalarFunction
{
 public:
  /*
   * This function does all of the actual processing for the UDF.
   * In this case, it simply reads two integer values and returns
   * their sum.
   *
   * The inputs are retrieved via arg_reader
   * The outputs are returned via arg_writer
   */
  virtual void processBlock(ServerInterface &srvInterface, BlockReader &arg_reader, BlockWriter &res_writer)
  {
    // While we have input to process
    do {
      // Read the two integer input parameters by calling the
      // BlockReader.getIntRef class function
      const vint a = arg_reader.getIntRef(0);
      const vint b = arg_reader.getIntRef(1);
      // Call BlockWriter.setInt to store the output value, which is the
      // two input values added together
      res_writer.setInt(a+b);
      // Finish writing the row, and advance to the next output row
      res_writer.next();
      // Continue looping until there are no more input rows
    } while (arg_reader.next());
  }
};
```

**ScalarFunctionFactory Implementation**

```cpp
/*
 * This class provides metadata about the ScalarFunction class, and
```
* also instantiates a member of that class when needed. */

class Add2IntsFactory : public ScalarFunctionFactory
{
    // return an instance of Add2Ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2Ints class instance.
        return vt_createFuncObj(interface.allocator, Add2Ints);
    }
    // This function returns the description of the input and outputs of the
    // Add2Ints class’s processBlock function. It stores this information in
    // two ColumnTypes objects, one for the input parameters, and one for
    // the return value.
    virtual void getPrototype(ServerInterface &interface,
        ColumnTypes &argTypes,
        ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object
        argTypes.addInt();
        argTypes.addInt();
        // returns a single int, so add a single int to the returnType object.
        // Note that ScalarFunctions *always* return a single value.
        returnType.addInt();
    }
};

The RegisterFactory Macro

Use the RegisterFactory macro to register a ScalarFunctionFactory subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

RegisterFactory(Add2IntsFactory);

C++ Example: Calling a UDSF from a Check Constraint

This example shows you the C++ code needed to create a UDSF that can be called by a check constraint. The name of the sample function is LargestSquareBelow. The sample function determines the largest number whose square is less than the number in the subject column. For example, if the number in the column is 1000, the largest number whose square is less than 1000 is 31 (961).

Important: A UDSF used within a check constraint must be immutable, and the constraint must handle null values properly. Otherwise, the check constraint
might not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated, so consider performance in writing your function.

For information on check constraints, see Check Constraints the Administrator's Guide.

For information about implementing the ScalarFunction and ScalarFunctionFactory classes, see UDSF Class Overview.

## Loading and Using the Example

The following example shows how you can create and load a library named MySqLib, using CREATE LIBRARY. Adjust the library path in this example to the absolute path and file name for the location where you saved the shared object LargestSquareBelow.

```sql
=> CREATE OR REPLACE LIBRARY MySqLib AS '/home/dbadmin/LargestSquareBelow.so';
```

1. After you create and load the library, add the function to the catalog using the CREATE FUNCTION (Scalar) statement.

```sql
=> CREATE OR REPLACE FUNCTION largestSqBelow AS LANGUAGE 'C++' NAME 'LargestSquareBelowInfo' LIBRARY MySqLib;
```

2. Next, include the UDSF in a check constraint.

```sql
=> CREATE TABLE squaretest(
    ceiling INTEGER UNIQUE,
    CONSTRAINT chk_sq CHECK (largestSqBelow(ceiling) < ceiling*ceiling)
);
```

3. Add data to the table, squaretest.

```sql
=> COPY squaretest FROM stdin DELIMITER ',' NULL 'null';
-1
null
0
1
1000
100000
10000001
.
```

Your output should be similar to the following sample, based upon the data you use:

```sql
SELECT ceiling, largestSqBelow(ceiling) FROM squaretest ORDER BY ceiling;
```
ScalarFunction Implementation

This ScalarFunction implementation does the processing work for a UDSF that determines the largest number whose square is less than the number input.

```cpp
#include "Vertica.h"
/*
 * ScalarFunction implementation for a UDSF that
determines the largest number whose square is less than
 * the number input.
 */
class LargestSquareBelow : public Vertica::ScalarFunction
{
public:
    /*
    * This function does all of the actual processing for the UDSF.
    * The inputs are retrieved via arg_reader
    * The outputs are returned via arg_writer
    */
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                              Vertica::BlockReader &arg_reader,
                              Vertica::BlockWriter &res_writer)
    {
        if (arg_reader.getNumCols() != 1)
            vt_report_error(0, "Function only accept 1 argument, but %zu provided", arg_reader.getNumCols());
        // While we have input to process
        do {
            // Read the input parameter by calling the
            // BlockReader.getIntRef class function
            const Vertica::vint a = arg_reader.getIntRef(0);
            Vertica::vint res;
            // Determine the largest square below the number
            if ((a != Vertica::vint_null) && (a > 0))
                {
                    res = (Vertica::vint)sqrt(a - 1);
                }
            else
                res = Vertica::vint_null;
            // Call BlockWriter.setInt to store the output value,
            // which is the largest square
            res_writer.setInt(res);
```
ScalarFunctionFactory Implementation

This ScalarFunctionFactory implementation does the work of handling input and output, and marks the function as immutable (a requirement if you plan to use the UDSF within a check constraint).

class LargestSquareBelowInfo : public Vertica::ScalarFunctionFactory
{
    //return an instance of LargestSquareBelow to perform the computation.
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface) {
        //Call the vt_createFuncObj to create the new LargestSquareBelow class instance.
        //return Vertica::vt_createFuncObject<LargestSquareBelow>(srvInterface.allocator);
        return Vertica::vt_createFuncObject<decltype(this)>(srvInterface.allocator);
    }

    /*
     * This function returns the description of the input and outputs of the
     * LargestSquareBelow class's processBlock function. It stores this information in
     * two ColumnTypes objects, one for the input parameter, and one for
     * the return value.
     */
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                             Vertica::ColumnTypes &argTypes,
                             Vertica::ColumnTypes &returnType)
    {
        // Takes one int as input, so adds int to the argTypes object
        argTypes.addInt();
        // Returns a single int, so add a single int to the returnType object.
        returnType.addInt();
    }

public:
    // the function cannot be called within a check constraint unless the U Dx author
    // certifies that the function is immutable:
    LargestSquareBelowInfo() { verticab::IMMUTABLE; }
};

The RegisterFactory Macro

Use the RegisterFactory macro to register a ScalarFunctionFactory subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.
RegisterFactory(LargestSquareBelowInfo);

Java API

This section provides APIs and examples for the Java API for UDSFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

*ScalarFunction and ScalarFunctionFactory Java Interface*

This section describes information that is specific to the Java API. See UDSF Class Overview for general information about implementing the ScalarFunction and ScalarFunctionFactory classes.

**ScalarFunction API**

The API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);
public abstract void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_writer) throws UdfException, DestroyInvocation;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

**ScalarFunctionFactory API**

The API provides the following methods for extension by subclasses:

```java
public abstract ScalarFunction createScalarFunction(ServerInterface srvInterface);
public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);
```
Java Example: Add2Ints

The Add2Ints scalar function adds two integers together, returning a single integer result.

Loading and Using the Example

Use CREATE LIBRARY to load the jar file containing the function, and then use CREATE FUNCTION (Scalar) to declare the function as in the following example:

```
=> CREATE FUNCTION add2ints AS LANGUAGE 'Java' NAME 'com.mycompany.example.Add2intsFactory' LIBRARY add2intslib;
```

The following example shows how to use this function.

```
=> SELECT Add2Ints(27,15);
Add2ints
--------
42
(1 row)
=> SELECT * FROM MyTable;
a | b
-----
7 | 0
12 | 2
12 | 6
18 | 9
1 | 1
58 | 4
450 | 15
(7 rows)
=> SELECT * FROM MyTable WHERE Add2Ints(a, b) > 20;
a | b
-----
18 | 9
58 | 4
450 | 15
(3 rows)
```
Implementation

The following code example is the full source of the Java Add2ints example. To simplify handling the source code, the ScalarFunction class is defined as an inner class of the ScalarFunctionFactory class.

```java
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.example;
// Import all of the Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{
  @Override
  public void getPrototype(ServerInterface srvInterface,
      ColumnTypes argTypes,
      ColumnTypes returnType)
  {
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }

  // This ScalarFunction is defined as an inner class of
  // its ScalarFunctionFactory class. This gets around having
  // to have a separate source file for this public class.
  public class Add2ints extends ScalarFunction
  {
    @Override
    public void processBlock(ServerInterface srvInterface,
        BlockReader argReader,
        BlockWriter resWriter)
        throws UdfException, DestroyInvocation
    {
      do {
        // The input and output objects have already loaded
        // the first row, so you can start reading and writing
        // values immediately.

        // Get the two integer arguments from the BlockReader
        long a = argReader.getLong(0);
        long b = argReader.getLong(1);

        // Process the arguments and come up with a result. For this
        // example, just add the two arguments together.
        long result = a+b;

        // Write the integer output value.
        resWriter.setLong(result);

        // Advance the output BlockWriter to the next row.
        resWriter.next();

        // Continue processing input rows until there are no more.
    }
```

Vertica Documentation
Extending Vertica
Python API

This section provides APIs and examples for the Python SDK for UDSFs.

For more information on setting up a Python development environment, see Developing with the Python SDK.

ScalarFunction and ScalarFunctionFactory Python Interface

This section describes information that is specific to the Python API. See UDSF Class Overview for general information about implementing the ScalarFunction and ScalarFunctionFactory classes. See Python SDK Documentation for detailed reference documentation for all API classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:

- `setup(self, server_interface, col_types)`
- `processBlock(self, server_interface, block_reader, block_writer)`
- `destroy(self, server_interface, col_types)`

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:
**Python Example: add2ints**

The `add2ints` scalar function adds two integers together, returning a single integer result.

You can find more U Dx examples in the Vertica Github repository, [https://github.com/vertica/UDx-Examples](https://github.com/vertica/UDx-Examples).

**UDSF Python Code**

```python
import vertica_sdk

class add2ints(vertica_sdk.ScalarFunction):
    """Return the sum of two integer columns""
    def __init__(self):
        pass
    def setup(self, server_interface, col_types):
        pass
    def processBlock(self, server_interface, arg_reader, res_writer):
        server_interface.log("Python UDx - Adding 2 ints!")
        while(True):
            # Example of error checking best practices.
            if arg_reader.isNull(0) or arg_reader.isNull(1):
                raise ValueError("I found a NULL!")
            else:
                first_int = arg_reader.getInt(0)  # Input column
                second_int = arg_reader.getInt(1)  # Input column
                res_writer.setInt(first_int + second_int)  # Sum of input columns.
                res_writer.next()  # Read the next row.
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break
    def destroy(self, server_interface, col_types):
        pass

class add2ints_factory(vertica_sdk.ScalarFunctionFactory):
    def createScalarFunction(self, srv):
        return add2ints()
```
def getPrototype(self, srv_interface, arg_types, return_type):
    arg_types.addInt()
    arg_types.addInt()
    return_type.addInt()

def getReturnType(self, srv_interface, arg_types, return_type):
    return_type.addInt()

Load the Function and Library

Create the library and the function.

=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/add2ints/add2ints.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION add2ints AS LANGUAGE 'Python' NAME 'add2ints_factory' LIBRARY pylib fenced;
CREATE FUNCTION

Querying Data with the Function

The following shows how to run a query with the UDSF.

=> SELECT add2ints(10, 10);
add2ints
--------
20
(1 row)

You can query on a table with two integer columns as follows:

=> SELECT nums_1, nums_2, add2ints(nums_1, nums_2) AS add2ints_sum
FROM bunch_of_numbers;
nums_1  | nums_2  | add2ints_sum
--------+--------+----------------
10      | 10     | 20             
1       | 4      | 5              
6       | 6      | 12             
30      | 144    | 174            
(4 rows)

Python Example: currency_convert

The currency_convert scalar function reads two values from a table, a currency and a value. It then converts the item's value to USD, returning a single float result.
Vertica Documentation
Extending Vertica
You can find more UDx examples in the Vertica Github repository,

UDSF Python Code
import vertica_sdk
import decimal
rates2USD = {'USD':
'EUR':
'GBP':
'INR':
'AUD':
'CAD':
'ZAR':
'XXX':

1.000,
0.89977,
0.68452,
67.0345,
1.39187,
1.30335,
15.7181,
-1.0000}

class currency_convert(vertica_sdk.ScalarFunction):
"""Converts a money column to another currency
Returns a value in USD.
"""
def __init__(self):
pass
def setup(self, server_interface, col_types):
pass
def processBlock(self, server_interface, block_reader, block_writer):
while(True):
currency = block_reader.getString(0)
try:
rate = decimal.Decimal(rates2USD[currency])
except KeyError:
server_interface.log("ERROR: {} not in dictionary.".format(currency))
# Scalar functions always need a value to move forward to the
# next input row. Therefore, we need to assign it a value to
# move beyond the error.
currency = 'XXX'
rate = decimal.Decimal(rates2USD[currency])
starting_value = block_reader.getNumeric(1)
converted_value = decimal.Decimal(starting_value
block_writer.setNumeric(converted_value)
block_writer.next()
if not block_reader.next():
break

/ rate)

def destroy(self, server_interface, col_types):
pass
class currency_convert_factory(vertica_sdk.ScalarFunctionFactory):
def createScalarFunction(self, srv):

Vertica Analytic Database (9.3.x)

Page 4618 of 6246


return currency_convert()

def getPrototype(self, srv_interface, arg_types, return_type):
    arg_types.addVarchar()
    arg_types.addNumeric()
    return_type.addNumeric()

def getReturnType(self, srv_interface, arg_types, return_type):
    return_type.addNumeric(9,4)

Load the Function and Library

Create the library and the function.

=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/currency_convert/currency_convert.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION currency_convert AS LANGUAGE 'Python' NAME 'currency_convert_factory' LIBRARY pylib fenced;
CREATE FUNCTION

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

=> SELECT product, currency_convert(currency, value) AS cost_in_usd
    FROM items;

Product   | Cost in USD
----------|-------------
Shoes      | 133.4008
Soccer Ball| 110.2817
Coffee     | 13.5190
Surfboard  | 176.2593
Hockey Stick| 76.7177
Car        | 17000.0000
Software   | 10.4424
Hamburger  | 7.5000
Fish       | 130.4272
Cattle     | 269.2367

Python Example: validate_url

The validate_url scalar function reads a string from a table, a URL. It then validates if the URL is responsive, returning a status code or a string indicating the attempt failed.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

UDSF Python Code

```python
import vertica_sdk
import urllib.request
import time

class validate_url(vertica_sdk.ScalarFunction):
    """Validates HTTP requests.
    Returns the status code of a webpage. Pages that cannot be accessed return "Failed to load page.""
    
    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Validating webpage accessibility - UDx")
        
        while(True):
            url = arg_reader.getString(0)
            try:
                status = urllib.request.urlopen(url).getcode()
                # Avoid overwhelming web servers -- be nice.
                time.sleep(2)
            except (ValueError, urllib.error.HTTPError, urllib.error.URLError):
                status = 'Failed to load page'
                res_writer.setString(str(status))
                res_writer.next()
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break

    def destroy(self, server_interface, col_types):
        pass

class validate_url_factory(vertica_sdk.ScalarFunctionFactory):
```
def createScalarFunction(self, srv):
    return validate_url()

def getPrototype(self, srv_interface, arg_types, return_type):
    arg_types.addVarchar()
    return_type.addChar()

def getReturnType(self, srv_interface, arg_types, return_type):
    return_type.addChar(20)

Load the Function and Library

Create the library and the function.

CREATE OR REPLACE LIBRARY pylib AS 'webpage_tester/validate_url.py' LANGUAGE 'Python';
CREATE OR REPLACE FUNCTION validate_url AS LANGUAGE 'Python' NAME 'validate_url_factory' LIBRARY pylib fenced;

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

SELECT url, validate_url(url) AS url_status FROM webpages;

<table>
<thead>
<tr>
<th>url</th>
<th>url_status</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.vertica.com/documentation/vertica/">http://www.vertica.com/documentation/vertica/</a></td>
<td>200</td>
</tr>
<tr>
<td><a href="http://www.google.com/">http://www.google.com/</a></td>
<td>200</td>
</tr>
<tr>

<td>200</td>
</tr>
</tbody>
</table>

R API

This section provides APIs and examples for the R API for UDSFs.

For information on setting up an R development environment and compiling and packaging libraries, see Developing with the R SDK.
Scalar Function and Scalar Function Factory R Interface

This section describes information that is specific to the R API. See R SDK API Documentation for general information about implementing Scalar functions.

Scalar Function API

The API provides the following framework for extension by R function:

```r
FunctionName <- function(input.data.frame, parameters.data.frame) {
  # Computations
  # The function must return a data frame.
  return(output.data.frame)
}
```

Scalar Function Factory API

The API provides the following framework for extension by R function:

```r
FunctionNameFactory <- function() {
  list(name = FunctionName,
       udxtype = c("scalar"),
       intype = c("int"),
       outtype = c("int"))
}
```

For a complete list of factory options, see the R API documentation for Factory Function.

R Example: SalesTaxCalculator

The SalesTaxCalculator scalar function reads a float and a varchar from a table, an item's price and the state abbreviation. It then uses the state abbreviation to find the sales tax rate from a list and calculates the item's price including the state's sales tax, returning the total cost of the item.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.
Load the Function and Library

Create the library and the function.

```sql
=> CREATE OR REPLACE LIBRARY rLib AS 'sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION SalesTaxCalculator AS LANGUAGE 'R' NAME 'SalesTaxCalculatorFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```sql
=> SELECT item, state_abbreviation,
    price, SalesTaxCalculator(price, state_abbreviation) AS Price_with_sales_tax
FROM inventory;
```

<table>
<thead>
<tr>
<th>Item</th>
<th>State Abbreviation</th>
<th>Price</th>
<th>Price with sales tax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scarf</td>
<td>AZ</td>
<td>6.88</td>
<td>7.53016</td>
</tr>
<tr>
<td>Software</td>
<td>MA</td>
<td>88.31</td>
<td>96.655295</td>
</tr>
<tr>
<td>Soccer Ball</td>
<td>MS</td>
<td>12.55</td>
<td>13.735975</td>
</tr>
<tr>
<td>Beads</td>
<td>LA</td>
<td>0.99</td>
<td>1.083555</td>
</tr>
<tr>
<td>Baseball</td>
<td>TN</td>
<td>42.42</td>
<td>46.42869</td>
</tr>
<tr>
<td>Cheese</td>
<td>WI</td>
<td>20.77</td>
<td>22.732765</td>
</tr>
<tr>
<td>Coffee Mug</td>
<td>MA</td>
<td>8.99</td>
<td>9.839555</td>
</tr>
<tr>
<td>Shoes</td>
<td>TN</td>
<td>23.99</td>
<td>26.257055</td>
</tr>
</tbody>
</table>

(8 rows)

UDSF R Code

```r
SalesTaxCalculator <- function(input.data.frame) {
  # Not a complete list of states in the USA, but enough to get the idea.
  state.sales.tax <- list(ma = 0.0625,
                           az = 0.087,
                           la = 0.0891,
                           tn = 0.0945,
                           wi = 0.0543,
                           ms = 0.0707)

  for (state_abbreviation in input.data.frame[, 2]) {
    # Ensure state abbreviations are lowercase.
    lower_state <- tolower(state_abbreviation)
    # Check if the state is in our state.sales.tax list.
    if (is.null(state.sales.tax[[lower_state]])) {
      stop("State is not in our small sample!")
    }
```

Vertica Analytic Database (9.3.x)
```r
} else {
    sales.tax.rate <- state.sales.tax[[lower_state]]
    item.price <- input.data.frame[, 1]
    # Calculate the price including sales tax.
    price.with.sales.tax <- (item.price) + (item.price * sales.tax.rate)
}
}
return(price.with.sales.tax)
}
SalesTaxCalculatorFactory <- function()
{
  list(name = SalesTaxCalculator,
       udxtype = c("scalar"),
       intype = c("float", "varchar"),
       outtype = c("float"))
}

R Example: kmeans

The KMeans_User scalar function reads any number of columns from a table, the observations. It then uses the observations and the two parameters when applying the kmeans clustering algorithm to the data, returning an integer value associated with the cluster of the row.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```r
=> CREATE OR REPLACE LIBRARY rLib AS 'kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION KMeans_User AS LANGUAGE 'R' NAME 'KMeans_UserFactory' LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```r
=> SELECT spec,
    KMeans_User(sl, sw, pl, pw USING PARAMETERS clusters = 3, nstart = 20)
```
FROM iris;  
  spec | KMeans_User
  -------------+----------------------------------
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
     Iris-setosa | 2  
(150 rows)

UdSF R Code

```r
KMeans_User <- function(input.data.frame, parameters.data.frame) {
  # Take the clusters and nstart parameters passed by the user and assign them
  # to variables in the function.
  if (is.null(parameters.data.frame[['clusters']])) {
    stop("NULL value for clusters! clusters cannot be NULL.")
  } else {
    clusters.value <- parameters.data.frame[['clusters']]
  }
  if (is.null(parameters.data.frame[['nstart']])) {
    stop("NULL value for nstart! nstart cannot be NULL.")
  } else {
    nstart.value <- parameters.data.frame[['nstart']]
  }
  # Apply the algorithm to the data.
  kmeans.clusters <- kmeans(input.data.frame[, 1:length(input.data.frame)],
                            clusters.value, nstart = nstart.value)
  final.output <- data.frame(kmeans.clusters$cluster)
  return(final.output)
}

KMeans_UserFactory <- function() {
  list(name = KMeans_User,
       udxtype = c("scalar"),
       # Since this is a polymorphic function the intype must be any
       intype = c("any"),
       outtype = c("int"),
       parametertypecallback=KMeansParameters)
}

KMeansParameters <- function() {
  parameters <- list(datatype = c("int", "int"),
                     length = c("NA", "NA"),
                     scale = c("NA", "NA"),
                     name = c("clusters", "nstart"))
```

Vertica Analytic Database (9.3.x)
return(parameters)
}
Transform Functions (UDTFs)

A user-defined transform function (UDTF) lets you transform a table of data into another table. It reads one or more arguments (treated as a row of data), and returns zero or more rows of data consisting of one or more columns. A UDTF can produce any number of rows as output. However, each row it outputs must be complete. Advancing to the next row without having added a value for each column produces incorrect results.

The schema of the output table does not need to correspond to the schema of the input table—they can be totally different. The UDTF can return any number of output rows for each row of input.

UDTFs can only be used in the SELECT list that contains just the UDTF call and a required OVER clause. A multi-phase UDTF can make use of partition columns (PARTITION BY), but other UDTFs cannot.

UDTFs are run after GROUP BY, but before the final ORDER BY, when used in conjunction with GROUP BY and ORDER BY in a statement. The ORDER BY clause may contain only columns or expressions that are in a window partition clause (see Window Partitioning).

UDTFs can take up to 1600 parameters (input columns). Attempting to pass more parameters to a UDTF results in an error.

UDTF Class Overview

You create your UDTF by subclassing two classes defined by the Vertica SDK: TransformFunction and TransformFunctionFactory.

The TransformFunctionFactory performs two roles:

- It provides the number of parameters and their and data types accepted by the UDTF and the number of output columns and their data types UDTF's output. Vertica uses this data when you call the CREATE TRANSFORM FUNCTION SQL statement to add the function to the database catalog.
- It returns an instance of the UDTF function's TransformFunction subclass that Vertica can call to process data.
**TransformFunction**

The TransformFunction class is where you perform the data-processing, transforming input rows into output rows. Your subclass must define the `processPartition()` method. It may define methods to set up and tear down the function.

**Performing the Transformation**

The `processPartition()` method carries out all of the processing that you want your UDTF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to `processPartition()`.

The input and output of the `processPartition()` method are supplied by objects of the `PartitionReader` and `PartitionWriter` classes. They define methods that you use to read the input data and write the output data for your UDTF.

A UDTF does not necessarily operate on a single row the way a UDSF does. A UDTF can read any number of rows and write output at any time.

Consider the following guidelines when implementing `processPartition()`:

- Extract the input parameters by calling data-type-specific functions in the `PartitionReader` object to extract each input parameter. Each of these functions takes a single parameter: the column number in the input row that you want to read. Your function might need to handle NULL values.
- When writing output, your UDTF must supply values for all of the output columns you defined in your factory. Similarly to reading input columns, the `PartitionWriter` object has functions for writing each type of data to the output row.
- Use `PartitionReader.next()` to determine if there is more input to process, and exit when the input is exhausted.
- In some cases, you might want to determine the number and types of parameters using `PartitionReader's` `getNumCols()` and `getTypeMetaData()` functions, instead of just hard-coding the data types of the columns in the input row. This is useful if you want your TransformFunction to be able to process input tables with different schemas. You can then use different `TransformFunctionFactory` classes to define multiple function signatures that call the same `TransformFunction` class. See [Handling Different Numbers and Types of Arguments](#) for more information.
Setting Up and Tearing Down

The TransformFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy(). You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

TransformFunctionFactory

The TransformFunctionFactory class tells Vertica metadata about your UDTF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of TransformFunction.

You must implement the following methods in your TransformFunctionFactory:

- `getPrototype()` returns two ColumnTypes objects that describe the columns your UDTF takes as input and returns as output.
- `getReturnType()` tells Vertica details about the output values: the width of variable-sized data types (such as VARCHAR) and the precision of data types that have settable precision (such as TIMESTAMP). You can also set the names of the output columns using this function. While this method is optional for UDxs that return single values, you must implement it for UDTFs.
- `createTransformFunction()` instantiates your TransformFunction subclass.

Creating Multi-Phase UDTFs

Creating Multi-Phase UDTFs

Multi-phase UDTFs let you break your data processing into multiple steps. Using this feature, your UDTFs can perform processing in a way similar to Hadoop or other MapReduce frameworks. You can use the first phase to break down and gather data, and then use subsequent phases to process the data. For example, the first phase of your UDTF
could extract specific types of user interactions from a web server log stored in the column of a table, and subsequent phases could perform analysis on those interactions.

Multi-phase UDTFs also let you decide where processing should occur: locally on each node, or throughout the cluster. If your multi-phase UDTF is like a MapReduce process, you want the first phase of your multi-phase UDTF to process data that is stored locally on the node where the instance of the UDTF is running. This prevents large segments of data from being copied around the Vertica cluster. Depending on the type of processing being performed in later phases, you may choose to have the data segmented and distributed across the Vertica cluster.

Each phase of the UDTF is the same as a traditional (single-phase) UDTF: it receives a table as input, and generates a table as output. The schema for each phase's output does not have to match its input, and each phase can output as many or as few rows as it wants.

You create a subclass of TransformFunction to define the processing performed by each stage. If you already have a TransformFunction from a single-phase UDTF that performs the processing you want a phase of your multi-phase UDTF to perform, you can easily adapt it to work within the multi-phase UDTF.

What makes a multi-phase UDTF different from a traditional UDTF is the factory class you use. You define a multi-phase UDTF using a subclass of MultiPhaseTransformFunctionFactory, rather than the TransformFunctionFactory. This special factory class acts as a container for all of the phases in your multi-step UDTF. It provides Vertica with the input and output requirements of the entire multi-phase UDTF (through the getPrototype() function), and a list of all the phases in the UDTF.

Within your subclass of the MultiPhaseTransformFunctionFactory class, you define one or more subclasses of TransformFunctionPhase. These classes fill the same role as the TransformFunctionFactory class for each phase in your multi-phase UDTF. They define the input and output of each phase and create instances of their associated TransformFunction classes to perform the processing for each phase of the UDTF. In addition to these subclasses, your MultiPhaseTransformFunctionFactory includes fields that provide a handle to an instance of each of the TransformFunctionPhase subclasses.

### Partitioning Options for Processing Local Data

UDTFs typically process data that is partitioned in a specific way. For example, a UDTF that processes a web server log file to count the number of hits referred by each partner web
site needs to have its input partitioned by a referrer column. Each instance of the UDTF sees the hits referred by a particular partner site so it can count them.

In cases like this, the window partitioning clause should use a PARTITION BY clause. Each node in the cluster partitions the data it stores, sends some of these partitions off to other nodes, and then consolidates the partitions it receives from other nodes and runs an instance of the UDTF to process them.

In other cases, a UDTF might not need to partition input data in a particular way—for example, a UDTF that parses data out of an Apache log file. In this case, you can specify that each UDTF instance process only the data that is stored locally by the node on which it is running. By eliminating the overhead of partitioning data, processing can be much more efficient.

You can tell a UDTF to process only local data with one of the following window partitioning options:

- PARTITION BEST: For thread-safe UDTFs only, optimizes performance through multi-threaded queries across multiple nodes.
- PARTITION NODES: Optimizes performance of single-threaded queries across multiple nodes.

The query must specify a source table that is replicated across all nodes and contains a single row (similar to the DUAL table). For example, the following statements call a UDTF that parses locally-stored Apache log files:

```sql
=> CREATE TABLE rep (dummy INTEGER) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO rep VALUES (1);
OUTPUT
--------
 1
(1 row)
=> SELECT ParseLogFile('/data/apache/log*') OVER (PARTITION BEST) FROM rep;
```

**C++ API**

This section provides APIs and examples for the C++ API for UDTFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.
**TransformFunction and TransformFunctionFactory C++ Interface**

This section describes information that is specific to the C++ API. See UDTF Class Overview for general information about implementing the TransformFunction and TransformFunctionFactory classes.

**TransformFunction API**

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
        const SizedColumnTypes &argTypes);

virtual void processPartition(ServerInterface &srvInterface,
        PartitionReader &input_reader, PartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface,
        const SizedColumnTypes &argTypes);
```

The PartitionReader and PartitionWriter classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

**TransformFunctionFactory API**

The API provides the following methods for extension by subclasses:

```cpp
virtual TransformFunction *
        createTransformFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
        ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
        const SizedColumnTypes &argTypes,
        SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
        SizedColumnTypes &parameterTypes);
```
MultiPhaseTransformFunctionFactory API

The `MultiPhaseTransformFunctionFactory` class extends `TransformFunctionFactory`. The API provides the following additional methods for extension by subclasses:

```cpp
virtual void getPhases(ServerInterface &srvInterface,
    std::vector< TransformFunctionPhase * > &phases)=0;
```

If using this factory you must also extend `TransformFunctionPhase`. See the SDK reference documentation.

**C++ Example: String Tokenizer**

The following example shows a subclass of `TransformFunction` named `StringTokenizer`. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

**Loading and Using the Example**

The following example shows how to load the function into Vertica. It assumes that the `TransformFunctions.so` library that contains the function has been copied to the `dbadmin` user's home directory on the initiator node.

```
=> CREATE LIBRARY TransformFunctions AS
    '/home/dbadmin/TransformFunctions.so';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize
    AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use it from SQL statements, for example:
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
OUTPUT
--------
 1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
OUTPUT
--------
 1
(1 row)
=> COMMIT;
COMMIT
=> -- Invoke the UDTF
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
         url    | words
-----------|----------
www.amazon.com | Online
www.amazon.com | retail
www.amazon.com | merchant
www.amazon.com | and
www.amazon.com | provider
www.amazon.com | of
www.amazon.com | cloud
www.amazon.com | services
www.vertica.com | World's
www.vertica.com | fastest
www.vertica.com | analytic
www.vertica.com | database
(12 rows)

Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

TransformFunction Implementation

The following code shows the StringTokenizer class.

class StringTokenizer : public TransformFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
                                   PartitionReader &inputReader,
                                   PartitionWriter &outputWriter)
    {
        try {
            if (inputReader.getNumCols() != 1)
                vt_report_error(0, "Function only accepts 1 argument, but %zu provided",
                                inputReader.getNumCols());
            do {
                const VString &sentence = inputReader.getStringRef(0);
// If input string is NULL, then output is NULL as well
if (sentence.isNull())
{
    VString &word = outputWriter.getStringRef(0);
    word.setNull();
    outputWriter.next();
} else {
    // Otherwise, let's tokenize the string and output the words
    std::string tmp = sentence.str();
    std::istringstream ss(tmp);
    do {
        std::string buffer;
        ss >> buffer;
        // Copy to output
        if (!buffer.empty()) {
            VString &word = outputWriter.getStringRef(0);
            word.copy(buffer);
            outputWriter.next();
        }
    } while (ss);
}

The processPartition() function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row and checking for cancellation before advancing. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, processPartition() first extracts the VString containing the text from the PartitionReader object. The VString class represents a Vertica string value (VARCHAR or CHAR). If there is input, it then tokenizes it and adds it to the output using the PartitionWriter object.

Similarly to reading input columns, the PartitionWriter class has functions for writing each type of data to the output row. In this case, the example calls the PartitionWriter object's getStringRef() function to allocate a new VString object to hold the token to output for the first column, and then copies the token's value into the VString.
TranformFunctionFactory Implementation

The following code shows the factory class.

```cpp
class TokenFactory : public TransformFunctionFactory
{
    // Tell Vertica that we take in a row with 1 string, and return a row with 1 string
    virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
    {
        argTypes.addVarchar();
        returnType.addVarchar();
    }

    // Tell Vertica what our return string length will be, given the input string length
    virtual void getReturnType(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes,
                                SizedColumnTypes &outputTypes)
    {
        // Error out if we’re called with anything but 1 argument
        if (inputTypes.getColumnCount() != 1)
            vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputTypes.getColumnCount());

        int input_len = inputTypes.getColumnType(0).getStringLength();

        // Our output size will never be more than the input size
        outputTypes.addVarchar(input_len, "words");
    }

    virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
    {
        return vt_createFuncObject<StringTokenizer>(srvInterface.allocator);
    }
};
```

In this example:

- The UDTF takes a VARCHAR column as input. To define the input column, `getPrototype()` calls `addVarchar()` on the ColumnTypes object that represents the input table.
- The UDTF returns a VARCHAR as output. The `getPrototype()` function calls `addVarchar()` to define the output table.

This example must return the maximum length of the VARCHAR output column. It sets the length to the length of the input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "words".
Note:
You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, getReturnType() sets the column name to "". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the createTransformFunction() function in the example is boilerplate code. It just calls the vt_returnFuncObj macro with the name of the TransformFunction class associated with this factory class. This macro takes care of instantiating a copy of the TransformFunction class that Vertica can use to process data.

The RegisterFactory Macro

The final step in creating your UDTF is to call the RegisterFactory macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The RegisterFactory macro just takes the name of your factory class:

```
RegisterFactory(TokenFactory);
```

C++ Example: Multi-Phase Transform Function

The following code fragment is from the InvertedIndex UDTF example distributed with the Vertica SDK. It demonstrates subclassing the MultiPhaseTransformFunctionFactory including two TransformFunctionPhase subclasses that define the two phases in this UDTF.

```
class InvertedIndexFactory : public MultiPhaseTransformFunctionFactory
{
public:
/**
 * Extracts terms from documents.
 */
class ForwardIndexPhase : public TransformFunctionPhase
```
virtual void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &inputTypes, SizedColumnTypes &outputTypes) {

// Sanity checks on input we've been given.
// Expected input: (doc_id INTEGER, text VARCHAR)
vector<size_t> argCols;
inputTypes.getArgumentColumns(argCols);
if (argCols.size() != 2) {
    !inputTypes.getColumnType(argCols.at(0)).isInt() ||
    !inputTypes.getColumnType(argCols.at(1)).isVarchar() ||
    vt_report_error(0, "Function expects an argument (INTEGER) with 
    "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
}

// Output of this phase is:
// (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER).
outputTypes.addVarchar(inputTypes.getColumnType(pByCols.at(0)).getStringLength(), "term");
outputTypes.addInt("doc_id");
}

virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface) {
return vt_createFuncObj(srvInterface.allocator, ForwardIndexBuilder); }
*/
/**
* Constructs terms' posting lists.
*/
class InvertedIndexPhase : public TransformFunctionPhase {

virtual void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &inputTypes, SizedColumnTypes &outputTypes) {

// Sanity checks on input we've been given.
// Expected input: (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
vector<size_t> argCols;
inputTypes.getArgumentColumns(argCols);
vector<size_t> pByCols;
inputTypes.getPartitionByColumns(pByCols);
vector<size_t> oByCols;
inputTypes.getOrderByColumns(oByCols);
if (argCols.size() != 1 || pByCols.size() != 1 || oByCols.size() != 1) {
    !inputTypes.getColumnType(argCols.at(0)).isInt() ||
    !inputTypes.getColumnType(pByCols.at(0)).isVarchar() ||
    !inputTypes.getColumnType(oByCols.at(0)).isInt())
    vt_report_error(0, "Function expects an argument (INTEGER) with 
    "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
}

// Output of this phase is:
// (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER).
outputTypes.addVarchar(inputTypes.getColumnType(pByCols.at(0)).getStringLength(), "term");
outputTypes.addInt("doc_id");
}

}
Most of the code in this example is similar to the code in a TransformFunctionFactory class:

- Both TransformFunctionPhase subclasses implement the `getReturnType()` function, which describes the output of each stage. This is similar to the `getReturnType()` function from the TransformFunctionFactory class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF.

The first phase calls `SizedColumnTypes::addVarCharPartitionColumn()` (rather than just `addVarCharColumn()`) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls `SizedColumnTypes::addOrderColumn()` to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as `addIntOrderColumn()`) so it can pass the data type of the original column through to the output column.
**Note:**
Any order by column or partition by column set by the final phase of the UDTF in its `getReturnType()` function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

- The `MultiPhaseTransformFunctionFactory` class implements the `getPrototype()` function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the `TransformFunctionFactory::getPrototype()` function.

The unique function implemented by the `MultiPhaseTransformFunctionFactory` class is `getPhases()`. This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.

The `MultiPhaseTransformFunctionFactory.getPhases()` function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.

**Note:**
Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the `TransformFunctionPhase::setPrepass()` function of the first phase's `TransformFunctionPhase` instance from within the `getPhase()` function.

**Notes**

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each `TransformFunctionPhase::getReturnType()` implementation performs a sanity check on its input and output schemas. Your `TransformFunction` subclasses can also perform these checks in their `processPartition()` function.
- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode,
Vertica may terminate UDTFs that use too much memory. See Resource Use for C++ UDxs.

Java API

This section provides APIs and examples for the Java API for UDTFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

TransformFunction and TransformFunctionFactory

Java Interface

This section describes information that is specific to the Java API. See UDTF Class Overview for general information about implementing the TransformFunction and TransformFunctionFactory classes.

TransformFunction API

The API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

public abstract void processPartition(ServerInterface srvInterface,
    PartitionReader input_reader, PartitionWriter input_writer)
    throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

The PartitionReader and PartitionWriter classes provide getters and setters for column values, along with next() to iterate through partitions. See the API reference documentation for details.
TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```java
public abstract TransformFunction createTransformFunction(ServerInterface srvInterface);
public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);
public abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException;
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

MultiPhaseTransformFunctionFactory API

The MultiPhaseTransformFunctionFactory class extends TransformFunctionFactory The API provides the following additional methods for extension by subclasses:

```java
public abstract void getPhases(ServerInterface srvInterface, Vector<TransformFunctionPhase> phases);
```

If using this factory you must also extend TransformFunctionPhase. See the SDK reference documentation.

Java Example: String Tokenizer

The following example shows a subclass of TransformFunction named StringTokenizer. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

You can then use it from SQL statements, for example:

```sql
=> CREATE TABLE T (url varchar(30), description varchar(2000));
```
TransformFunction Implementation

The following code defines the StringTokenizer class.

To make code management simpler, the TransformFunction class is defined as an inner class of the TransformFactoryClass.

```java
// You will need to specify the full package when creating functions based on // the classes in your library.
package com.mycompany.example;
// Import the entire Vertica SDK
import com.vertica.sdk.*;

public class TokenFactory extends TransformFunctionFactory {
    // Set the number and data types of the columns in the input and output rows.
    @Override
    public void getPrototype(ServerInterface srvInterface,
                              ColumnTypes argTypes, ColumnTypes returnType)
    {
        // Define two input columns: an INTEGER and a VARCHAR
        argTypes.addInt(); // Row id
        argTypes.addVarchar(); // Line of text
    }
}
```
// Define the output columns
returnType.addVarchar(); // The token
returnType.addInt(); // The row in which this token occurred
returnType.addInt(); // The position in the row of the token
}

// Set the width of any variable-width output columns, and also name
// them.
@Override
public void getReturnType(ServerInterface srvInterface,
        SizedColumnTypes inputTypes, SizedColumnTypes outputTypes)
{
    // Set the maximum width of the token return column to the width
    // of the input text column and name the output column "Token"
    outputTypes.addVarchar(inputTypes.getColumnType(1).getStringLength(), "token");
    // Name the two INTEGER output columns
    outputTypes.addInt("row_id");
    outputTypes.addInt("token_position");
}

// Inner class that actually performs work.
public class TokenizeString extends TransformFunction
{
    @Override
    public void processPartition(ServerInterface srvInterface,
        PartitionReader inputReader, PartitionWriter outputWriter)
            throws UdfException, DestroyInvocation
    {
        try {
            // Loop over all rows passed in in this partition.
            do {
                // Test if the row ID is null. If so, then do not
                // process any further. Skip to next row of input.
                if(inputReader.isLongNull(0)) {
                    srvInterface.log("Skipping row with null id.");
                    continue; // Move on to next row of input
                }
                // Get the row ID now that we know it has a value
                long rowId = inputReader.getLong(0);

                // Test if the input string is NULL. If so, return NULL
                // for token and string position.
                if (inputReader.isStringNull(1)) {
                    outputWriter.setStringNull(0);
                    outputWriter.setLong(1, rowId);
                    outputWriter.setLongNull(2);
                    outputWriter.next(); // Move to next line of output
                } else {
                    // Break string into tokens. Output each word as its own
                    // value.
                    String[] tokens = inputReader.getString(1).split("\s+");
                    // Output each token on a separate row.
                    for (int i = 0; i < tokens.length; i++) {
                        outputWriter.getStringWriter(0).copy(tokens[i]);
                        outputWriter.setLong(1, rowId);
                        outputWriter.setLong(2, i);
                    }
                }
            } while (inputReader.hasNext());
        } finally {
            outputWriter.close(); // Close output writer
        }
    }
}
outputWriter.next(); // Advance to next row of output

// Loop until there are no more input rows in partition.
while (inputReader.next());

// Prevent exceptions from bubbling back up to server. Uncaught
// exceptions will cause a transaction rollback.
catch (Exception e) {
  // Use more robust error handling in your own
  // UDTFs. This example just sends a message to the log.
  srvInterface.log("Exception: " + e.getClass().getSimpleName()
      + "Message: " + e.getMessage());
}

@Override
public TransformFunction createTransformFunction(ServerInterface srvInterface)
{ return new TokenizeString(); }

---

**Java Example: Multi-Phase Transform Function**

The following code is excerpted from the `InvertedIndexFactory` SDK example. You can find the complete code in
`/opt/vertica/sdk/examples/JavaUDx/TransformFunctions`.

```java
public class InvertedIndexFactory extends MultiPhaseTransformFunctionFactory {

  public class ForwardIndexPhase extends TransformFunctionPhase {
    // ...
  }

  public class InvertedIndexPhase extends TransformFunctionPhase {

    @Override
    public TransformFunction createTransformFunction(ServerInterface srvInterface) {
      return new InvertedIndexBuilder();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface,
      SizedColumnTypes inputTypes,
      SizedColumnTypes outputTypes) {
      // Sanity checks on input we've been given.
      // Expected input:
      // {term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
      ArrayList<Integer> argCols = new ArrayList<Integer>();
      inputTypes.getArgumentColumns(argCols);

      ArrayList<Integer> pByCols = new ArrayList<Integer>();

      // ...
    }
  }
}
```
inputTypes.getPartitionByColumns(pByCols);

ArrayList<Integer> oByCols = new ArrayList<Integer>();
inputTypes.getOrderByColumns(oByCols);

if (argCols.size() != 1 || pByCols.size() != 1
    || oByCols.size() != 1
    || !inputTypes.getColumnType(argCols.get(0)).isInt()
    || !inputTypes.getColumnType(pByCols.get(0)).isVarchar()
    || !inputTypes.getColumnType(oByCols.get(0)).isInt()) {
    throw new UdfException(0,
        "Function expects an argument (INTEGER) with " +
        "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
}

// Output of this phase is:
// (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER).
outputTypes.addVarchar(inputTypes.getColumnType(pByCols.get(0)).
    getStringLength(), "term");
outputTypes.addInt("doc_id");

// Number of times term appears within the document.
outputTypes.addInt("term_freq");

// Number of documents where the term appears in.
outputTypes.addInt("corp_freq");

@Override
public void getPhases(ServerInterface srvInterface,
    Vector<TransformFunctionPhase> phases) {
    ForwardIndexPhase fwardIdxPh;
    InvertedIndexPhase invIdxPh;
    fwardIdxPh = new ForwardIndexPhase();
    invIdxPh = new InvertedIndexPhase();

    fwardIdxPh.setPrepass();
    phases.add(fwardIdxPh);
    phases.add(invIdxPh);
}

@Override
public void getPrototype(ServerInterface srvInterface,
    ColumnTypes argTypes, ColumnTypes returnTypes) {

    // Expected input: (doc_id INTEGER, text VARCHAR).
    argTypes.addInt();
    argTypes.addVarchar();

    // Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
    returnTypes.addVarchar();
    returnTypes.addInt();
    returnTypes.addInt();
    returnTypes.addInt();
    returnTypes.addInt();
Most of the code in this example is similar to the code in a TransformFunctionFactory class. The getReturnType method is similar, but in a TransformFunctionPhase it can also partition and order the data. The partitions and order are used by the next phase, but they are ignored after the final phase.

The MultiPhaseTransformFunctionFactory class adds the getPhases method. This method defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute. You should also indicate the first phase by calling setPrepass() on it. Doing so can lead to better performance.

There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. Vertica might terminate UDTFs that use too much memory.

**Python API**

This section provides APIs and examples for the Python SDK for UDTFs.

For more information on setting up a Python development environment, see Developing with the Python SDK.

**UDTF Python Interface**

This section describes information that is specific to the Python API. See UDTF Class Overview for general information about implementing the TransformFunction and TransformFunctionFactory classes. See Python SDK Documentation for detailed reference documentation for all API classes.

**TransformFunction API**

The API provides a single method for extension by subclasses:
setup(self, server_interface, col_types)

processPartition(self, server_interface, partition_reader, partition_writer)

destroy(self, server_interface, col_types)

The PartitionReader and PartitionWriter classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

**TransformFunctionFactory API**

The API provides the following methods for extension by subclasses:

- `createTransformFunction(self, srv)`
- `getPrototype(self, srv_interface, arg_types, return_type)`
- `getReturnType(self, srv_interface, arg_types, return_type)`
- `getParameterType(self, srv_interface, parameterTypes)`

**MultiPhaseTransformFunctionFactory and TransformFunctionPhase API**

The MultiPhaseTransformFunctionFactory class extends TransformFunctionFactory. For each phase, the factory must define a class that extends TransformFunctionPhase. For more about using phases, see Creating Multi-Phase UDTFs.

The factory adds the following method:

- `getPhase(cls, srv)`

TransformFunctionPhase has the following methods:

- `createTransformFunction(cls, srv)`
- `getReturnType(self, srv_interface, input_types, output_types)`
**Python Example: String Tokenizer**

The following example shows a transform function that breaks an input string into tokens (based on whitespace). It is similar to the tokenizer examples for C++ and Java.

**Loading and Using the Example**

Create the library and function:

```sql
=> CREATE LIBRARY pyudtf AS '/home/dbadmin/udx/tokenize.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize AS NAME 'StringTokenizerFactory' LIBRARY pyudtf;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```sql
=> CREATE TABLE words (w VARCHAR);
CREATE TABLE
=> COPY words FROM STDIN;
COPY
Enter data to be copied followed by a newline. Enter with a backslash and a period on a line by itself.
>> this is a test of the python udtf
>> .

=> SELECT tokenize(w) OVER () FROM words;
    token
----------
  this
 is
  a
 test
 of
 the
 python
 udtf
(8 rows)
```

**UDTF Python Code**

The following code defines the tokenizer and its factory.

```python
class StringTokenizer(vertica_sdk.TransformFunction):
    """
    Transform function which tokenizes its inputs.
    """
```
For each input string, each of the whitespace-separated tokens of that string is produced as output.

```
def processPartition(self, server_interface, input, output):
    while True:
        for token in input.getString(0).split():
            output.setString(0, token)
            output.next()
        if not input.next():
            break
```

class StringTokenizerFactory(vertica_sdk.TransformFunctionFactory):
    def getPrototype(self, server_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addVarchar()
    def getReturnType(self, server_interface, arg_types, return_type):
        return_type.addColumn(arg_types.getColumnType(0), "tokens")
    def createTransformFunction(cls, server_interface):
        return StringTokenizer()

**Python Example: Multi-Phase Calculation**

The following example shows a multi-phase transform function that computes the average value on a column of numbers in an input table. It first defines two transform functions, and then defines a factory that creates the phases using them.

See AvgMultiPhaseUDT.py in the examples distribution for the complete code.

**Loading and Using the Example**

Create the library and function:

```
=> CREATE LIBRARY pylib_avg AS '/home/dbadmin/udx/AvgMultiPhaseUDT.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION myAvg AS NAME 'MyAvgFactory' LIBRARY pylib_avg;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SELECT statements:

```
=> CREATE TABLE IF NOT EXISTS numbers(num FLOAT);
CREATE TABLE
=> COPY numbers FROM STDIN delimiter ',' DIRECT;
  1
  2
  3
  4
```
\[
\]

=> SELECT myAvg(num) OVER() FROM numbers;

<table>
<thead>
<tr>
<th>average</th>
<th>ignored_rows</th>
<th>total_rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.5</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>

(1 row)

**Setup**

All Python UDxs must import the Vertica SDK. This example also imports another library.

```python
import vertica_sdk
import math
```

**Component Transform Functions**

A multi-phase transform function must define two or more `TransformFunction` subclasses to be used in the phases. This example uses two classes: `LocalCalculation`, which does calculations on local partitions, and `GlobalCalculation`, which aggregates the results of all `LocalCalculation` instances to calculate a final result.

In both functions, the calculation is done in the `processPartition()` function:

```python
class LocalCalculation(vertica_sdk.TransformFunction):
    
    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase0")
        self.local_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase0")

        while True:
            self.total_rows += 1

            if input.isNull() or math.isinf(input.getFloat(0)) or math.isnan(input.getFloat(0)):
                # Null, Inf, or Nan is ignored
                self.ignored_rows += 1
            else:
                self.local_sum += input.getFloat(0)
```
class GlobalCalculation(vertica_sdk.TransformFunction):
    """
    This class is the second phase and aggregates the values for sum, ignored_rows and total_rows.
    """
    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase1")
        self.global_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase1")
        while True:
            self.global_sum += input.getFloat(0)
            self.ignored_rows += input.getInt(1)
            self.total_rows += input.getInt(2)

            if not input.next():
                break

        average = self.global_sum / (self.total_rows - self.ignored_rows)

        output.setFloat(0, average)
        output.setInt(1, self.ignored_rows)
        output.setInt(2, self.total_rows)
        output.next()

Multi-Phase Factory

A MultiPhaseTransformFunctionFactory ties together the individual functions as phases. The factory defines a TransformFunctionPhase for each function. Each phase defines createTransformFunction(), which calls the constructor for the corresponding TransformFunction, and getReturnType().

The first phase, LocalPhase, follows.
number_of_cols = input_types.getColumnCount()
if (number_of_cols != 1 or not input_types.getColumnType(0).isFloat()):
    raise ValueError("Function only accepts one argument (FLOAT))")
output_types.addFloat("local_sum");
output_types.addInt("ignored_rows");
output_types.addInt("total_rows");
def createTransformFunction(cls, server_interface):
    return LocalCalculation()

The second phase, GlobalPhase, does not check its inputs because the first phase already did. As with the first phase, createTransformFunction merely constructs and returns the corresponding TransformFunction.

class GlobalPhase(vertica_sdk.TransformFunctionPhase):
    """ Phase 2 """
    def getReturnType(self, server_interface, input_types, output_types):
        output_types.addFloat("average");
        output_types.addInt("ignored_rows");
        output_types.addInt("total_rows");
    def createTransformFunction(cls, server_interface):
        return GlobalCalculation()

After defining the TransformFunctionPhase subclasses, the factory instantiates them and chains them together in getPhases().

ph0Instance = LocalPhase()
ph1Instance = GlobalPhase()
def getPhases(cls, server_interface):
    cls.ph0Instance.setPrepass()
    phases = [cls.ph0Instance, cls.ph1Instance]
    return phases

R API

This section provides APIs and examples for the R API for UDTFs.

For information on setting up an R development environment and compiling and packaging libraries, see Developing with the R SDK.
**Transform Function and Transform Function Factory R Interface**

This section describes information that is specific to the R API. See [R SDK API Documentation](https://github.com/vertica/UDx-Examples) for general information about implementing transform functions.

**Transform Function API**

The API provides the following framework for extension by R function:

```r
FunctionName <- function(input.data.frame, parameters.data.frame) {
  # Computations
  # The function must return a data frame.
  return(output.data.frame)
}
```

**Transform Function Factory API**

The API provides the following framework for extension by R function:

```r
FunctionNameFactory <- function() {
  list(name = FunctionName,
       udxtype = c("transform"),
       intype = c("int"),
       outtype = c("int"))
}
```

**R Example: Log Tokenizer**

The LogTokenizer transform function reads a varchar from a table, a log message. It then tokenizes each of the log messages, returning each of the tokens.

You can find more UDx examples in the Vertica Github repository, [https://github.com/vertica/UDx-Examples](https://github.com/vertica/UDx-Examples).
**Load the Function and Library**

Create the library and the function.

```sql
=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```

**Querying Data with the Function**

The following query shows how you can run a query with the UDTF.

```sql
=> SELECT machine, LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)
     FROM error_logs;
```

<table>
<thead>
<tr>
<th>machine</th>
<th>Token</th>
</tr>
</thead>
<tbody>
<tr>
<td>node001</td>
<td>ERROR</td>
</tr>
<tr>
<td>node001</td>
<td>345</td>
</tr>
<tr>
<td>node001</td>

UDTF R Code

LogTokenizer <- function(input.data.frame, parameters.data.frame) {
  # Take the spliton parameter passed by the user and assign it to a variable
  # in the function so we can use that as our tokenizer.
  if (is.null(parameters.data.frame[['spliton']])) {
    stop("NULL value for spliton! Token cannot be NULL.")
  } else {
    split.on <- as.character(parameters.data.frame[['spliton']])
  }
  # Tokenize the string.
  tokens <- vector(length=0)
  for (string in input.data.frame[, 1]) {
    tokenized.string <- strsplit(string, split.on)
    for (token in tokenized.string) {
      tokens <- append(tokens, token)
    }
  }
  final.output <- data.frame(tokens)
  return(final.output)
}

LogTokenizerFactory <- function()
{
  list(name = LogTokenizer,
       udxtype = c("transform"),
       intype = c("varchar"),
       outtype = c("varchar"),
       outtypecallback=LogTokenizerReturn,
       parametertypecallback=LogTokenizerParameters)
}

LogTokenizerParameters <- function()
{
  parameters <- list(datatype = c("varchar"),
                     length = c("NA"),
                     scale = c("NA"),
                     name = c("spliton"))
  return(parameters)
}

LogTokenizerReturn <- function(arg.data.frame, parm.data.frame)
{
  output.return.type <- data.frame(datatype = rep(NA,1),
                                   length = rep(NA,1),
                                   scale = rep(NA,1),
                                   name = rep(NA,1))
  output.return.type$datatype <- c("varchar")
  output.return.type$name <- c("Token")
  return(output.return.type)
}
User-Defined Load (UDL)

COPY offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The user-defined load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process.

You use three types of UDL functions during development, one for each stage of the data-load process:

- **User-defined source** (UDSource): Controls how COPY obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.

  API support: C++, Java

- **User-defined filter** (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple user-defined filters together, for example unzipping and then converting.

  API support: C++, Java, Python

- **User-defined parser** (UDParser): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a user-defined chunker (UDChunker, C++ only), to have the parser perform parallel parsing.

  API support: C++, Java, Python

After the final step, COPY inserts the data into a table, or rejects it if the format is incorrect.

User-Defined Source

A user-defined source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a user-defined source to access the data from an HTTP source using cURL. While a given COPY statement can use specify only one user-defined source statement, the source function itself can pull data from multiple sources.
The **UDSource** class acquires data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a UDSource, you must also implement a corresponding **SourceFactory**.

**UDSource Class**

You can subclass the UDSource class when you need to load data from a source type that COPY does not already support.

Each instance of your UDSource subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

**UDSource Methods**

The UDSource class defines the following methods. Your subclass must override `process()` . You can optionally override the others.

For the signatures of these methods and language-specific information, see [Source Classes (C++)](https://www.vertica.com/documentation/vertica/毛巾/9.3.x/) and [Source Classes (Java)](https://www.vertica.com/documentation/vertica/毛巾/9.3.x/).

**Setting Up**

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the UDSource can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

**Processing a Source**

COPY calls `process()` repeatedly during query execution to read data and write it to the DataBuffer passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value `StreamState.OUTPUT_NEEDED`. When Vertica gets this return value, it will call the
method again. This second call occurs after the output buffer has been processed by the next stage in the data-load process. Returning StreamState.DONE indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.

**Tearing Down**

COPY calls destroy() after the last time that process() is called. This method frees any resources reserved by the setup() or process() methods, such as file handles or network connections that the setup() method allocated.

**Accessors**

A source can define two accessors, getSize() and getUri().

COPY might call getSize() to estimate the number of bytes of data to be read before calling process(). This value is an estimate only and is used to indicate the file size in the LOAD_STREAMS table. Because Vertica can call this method before calling setup(), getSize() must not rely on any resources allocated by setup().

This method should not leave any resources open. For example, do not save any file handles opened by getSize() for use by the process() method. Doing so can exhaust the available resources, because Vertica calls getSize() on all instances of your UDSource subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system's supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls getUri() during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this UDSource.

**SourceFactory Class**

If you write a source, you must also write a source factory. Your subclass of the SourceFactory class is responsible for:
Performing the initial validation of the parameters passed to your UDSource.

Setting up any data structures your UDSource instances need to perform their work. This information can include recording which nodes will read which data source.

Creating one instance of your UDSource subclass for each data source (or portion thereof) that your function reads on each host.

The simplest source factory creates one UDSource instance per data source per executor node. You can also use multiple concurrent UDSource instances on each node. This behavior is called concurrent load. To support both options, SourceFactory has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

**SourceFactory Methods**

The SourceFactory class defines several methods. Your class must override prepareUDSources(); it may override the other methods.

**Setting Up**

Vertica calls plan() once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the COPY statement and provide error messages if there are any issues. You can read the parameters by getting a ParamReader object from the instance of ServerInterface passed into the plan() method.
- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's file system, can be read only by a single specified host.

You store the list of hosts to read the data source by calling the setTargetNodes() method on the NodeSpecifyingPlanContext object. This object is passed into your plan() method.

- Store any information that the individual hosts need to process the data sources in the NodeSpecifyingPlanContext instance passed to the plan() method. For
example, you could store assignments that tell each host which data sources to process. The \texttt{plan()} method runs only on the initiator node, and the \texttt{prepareUDSources()} method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the \texttt{NodeSpecifyingPlanContext} by getting a \texttt{ParamWriter} object from the \texttt{getWriter()} method. You then write parameters by calling methods on the \texttt{ParamWriter} such as \texttt{setString()}.

\begin{quote}
\textbf{Note:} \\
\texttt{ParamWriter} offers the ability to store only simple data types. For complex types, you must serialize the data in some manner and store it as a string or long string.
\end{quote}

### Creating Sources

Vertica calls \texttt{prepareUDSources()} on all hosts that the \texttt{plan()} method selected to load data. This call instantiates and returns a list of \texttt{UDSource} subclass instances. If you are not using concurrent load, return one \texttt{UDSource} for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an \texttt{ExecutorPlanContext} as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

\begin{quote}
\textbf{Note:} \\
In the C++ API, the function that supports concurrent load is named \texttt{prepareUDSourcesExecutor()}. In the Java API the class provides two overloads of \texttt{prepareUDSources()}. \\
\end{quote}

For concurrent load, you can find out how many threads are available on the node to run \texttt{UDSource} instances by calling \texttt{getLoadConcurrency()} on the \texttt{ExecutorPlanContext} that is passed in.

### Defining Parameters

Implement \texttt{getParameterTypes()} to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing
parameters. While you should define the types and parameters for your function, you are not required to override this method.

### Requesting Threads for Concurrent Load

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement `getDesiredThreads()`. Vertica calls this method before it calls `prepareUDSources()`, so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The `FilePortionSourceFactory` example implements this method; see Source Example: Concurrent Load.

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing `isSourceApportionable()`. Returning `true` from this method does not guarantee that the source will apportion the load. However, returning `false` indicates that it will not try to do so. See Apportioned Load for more information.

Often, a `SourceFactory` that implements `getDesiredThreads()` also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without apportioning.

### User-Defined Filter

User-defined filter functions allow you to manipulate data obtained from a source in various ways. For example, a filter can:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.

You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a `UDFilter`, you must also implement a corresponding `FilterFactory`. See `UDFilter Class` and `FilterFactory Class` for API details.
**UDFilter Class**

The **UDFilter** class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A **UDFilter** is instantiated by a corresponding **FilterFactory** on each host in the Vertica cluster that is performing filtering for the data source.

**UDFilter Methods**

The **UDFilter** class defines the following methods. Your subclass must override `process()`. You can optionally override the other methods.

For the signatures of these methods and language-specific information, see Filter Classes (C++), Filter Classes (Java), and Filter Classes (Python).

**Setting Up**

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

**Filtering Data**

COPY calls `process()` repeatedly during query execution to filter data. The method receives two instances of the **DataBuffer** class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The `process()` method should process data until it either runs out
of data to read or runs out of space in the output buffer. When one of these conditions
occurs, your method should return one of the following values defined by StreamState:

- OUTPUT_NEEDED if the filter needs more room in its output buffer.
- INPUT_NEEDED if the filter has run out of input data (but the data source has not yet
  been fully processed).
- DONE if the filter has processed all of the data in the data source.
- KEEP_GOING if the filter cannot proceed for an extended period of time. The method
  will be called again, so do not block indefinitely. If you do, then you prevent your user
  from canceling the query.

Before returning, your process() method must set the offset property in each
DataBuffer. In the input buffer, set it to the number of bytes that the method
successfully read. In the output buffer, set it to the number of bytes the method wrote.
Setting these properties allows the next call to process() to resume reading and writing
data at the correct points in the buffers.

Your process() method also needs to check the InputState object passed to it to
determine if there is more data in the data source. When this object is equal to END_OF_ FILE,
then the data remaining in the input data is the last data in the data source. Once it
has processed all of the remaining data, process() must return DONE.

## Tearing Down

COPY calls destroy() after the last time it calls process(). This method frees any
resources reserved by the setup() or process() methods. Vertica calls this method after
the process() method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call
setup() on the object again. On subsequent calls Vertica directs the method to filter the
data in a new data stream. Therefore, your destroy() method should leave an object of
your UDFilter subclass in a state where the setup() method can prepare it to be reused.

### FilterFactory Class

If you write a filter, you must also write a filter factory to produce filter instances. To do so,
subclass the FilterFactory class.

Your subclass performs the initial validation and planning of the function execution and
instantiates UDFilter objects on each host that will be filtering data.
Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

**FilterFactory Methods**

The `FilterFactory` class defines the following methods. Your subclass must override the `prepare()` method. It may override the other methods.

**Setting Up**

Vertica calls `plan()` once on the initiator node, to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into your `plan()` method.

- Store any information that the individual hosts need in order to filter data in the `PlanContext` instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The `plan()` method runs only on the initiator node, and the `prepare()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the `PlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString`.

**Note:**

`ParamWriter` offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

**Creating Filters**

Vertica calls `prepare()` to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to
complete the work based on available resources. You cannot specify the nodes on which the work is done.

## Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

## User-Defined Parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use user-defined parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you can load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

`COPY` supports a single user-defined parser that you can use with a [user-defined source](#) and zero or more instances of a [user-defined filter](#). If you implement a [UDParser class](#), you must also implement a corresponding [ParserFactory](#).

Sometimes, you can improve the performance of your parser by adding a *chunker*. A chunker divides up the input and uses multiple threads to parse it. Chunkers are available only in the C++ API. For details, see [Cooperative Parse](#) and [UDChunker Class](#). Under special circumstances you can further improve performance by using [apportioned load](#), an approach where multiple Vertica nodes parse the input.

### UDParser Class

You can subclass the `UDParser` class when you need to parse data that is in a format that the `COPY` statement's native parser cannot handle.
During parser execution, Vertica always calls three methods: setup(), process(), and destroy(). It might also call getRejectedRecord().

**UDParser Methods**

The UDParse class defines the following methods. Your subclass must override the process() and getRejectedRecord() methods. You can optionally override the other methods.

For the signatures of these methods and language-specific information, see [Parser Classes (C++)](#) and [Parser Classes (Java)](#).

**Note:**
The UDParse class performs important initialization required by all subclasses, including initializing the StreamWriter object used by the parser. Therefore, your constructor must call super().

**Setting Up**

COPY calls setup() before the first time it calls process(). Use setup() to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the process() method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

**Parsing**

COPY calls process() repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by InputState:

- **OK**: currently at the start of or in the middle of a stream
- **END_OF_FILE**: no further data is available.
- **END_OF_CHUNK**: the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.
• **START** _OF**_ **_PORTION:** the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load. You can use the `getPortion()` method to access the offset and size of the portion.

• **END** _OF**_ **_PORTION:** the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.

The `process()` method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is not automatically null-terminated.

A parser has an associated `StreamWriter` object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on `StreamWriter` to write that value to the output stream. See [Writing Data](#) for more information about these methods.

A single call to `process()` might write several rows of data. When your parser finishes processing a row of data, it must call `next()` on its `StreamWriter` to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your `process()` method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by `StreamState`:

• **INPUT** _NEEDED:** the parser has reached the end of the buffer and needs more data to parse.
• **DONE:** the parser has reached the end of the input data stream.
• **REJECT:** the parser has rejected the last row of data it read (see [Rejecting Rows](#)).

**Tearing Down**

`COPY` calls `destroy()` after the last time that `process()` is called. It frees any resources reserved by the `setup()` or `process()` method.

Vertica calls this method after the `process()` method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might remain. In such cases, Vertica might later call `setup()` on the object again and have it
parse the data in a new data stream. Therefore, write your `destroy()` method so that it leaves an instance of your `UDParser` subclass in a state where `setup()` can be safely called again.

**Reporting Rejections**

If `process()` rejects a row, Vertica calls `getRejectedRecord()` to report it. Usually, this method returns an instance of the `RejectedRecord` class with details of the rejected row.

**Writing Data**

A parser has an associated `StreamWriter` object, which you access by calling `getStreamWriter()`. In your `process()` implementation, use the `setType()` methods on the `StreamWriter` object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type `long` to the fourth column (index 3) in the current row:

```java
StreamWriter writer = getStreamWriter();
...
writer.setLongValue(3, 98.6);
```

`StreamWriter` provides methods for all the basic types, such as `setBooleanValue()`, `setStringValue()`, and so on. See the API documentation for a complete list of `StreamWriter` methods, including options that take primitive types or explicitly set entries to null.

The Java API supports additional options for writing data. See [Parser Classes](#).

**Rejecting Rows**

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a `RejectedRecord` object, or in fields on your `UDParser` subclass, until they are needed.
2. Updating the row's position in the input buffer by updating `input.offset` so it can resume parsing with the next row.
3. Signaling that it has rejected a row by returning with the value `StreamState.REJECT`.
4. Returning an instance of the `RejectedRecord` class with the details about the rejected row.

**Breaking Up Large Loads**

Vertica provides two ways to break up large loads. `Apportioned Load` allows you to distribute a load among several database nodes. `Cooperative Parse` (C++ only) allows you to distribute a load among several threads on one node.

**UDChunker Class**

You can subclass the `UDChunker` class to allow your parser to support Cooperative Parse. This class is available only in the C++ API.

Fundamentally, a `UDChunker` is a very simplistic parser. Like `UDParser`, it has the following three methods: `setup()`, `process()`, and `destroy()`. You must override `process()`; you may override the others. This class has one additional method, `alignPortion()`, which you must implement if you want to enable `Apportioned Load` for your `UDChunker`.

For the signatures of these methods, see `Parser Classes`.

**Setting Up and Tearing Down**

As with `UDParser`, you can define initialization and cleanup code for your chunker. Vertica calls `setup()` before the first call to `process()` and `destroy()` after the last call to `process()`. Your object might be reused among multiple load sources, so make sure that `setup()` completely initializes all fields.

**Chunking**

Vertica calls `process()` to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:
• OK: the input buffer begins at the start of or in the middle of a stream.
• END_OF_FILE: no further data is available.
• END_OF_PORTION: the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is END_OF_FILE, the chunker should set the input.offset marker to input.size and return DONE. Returning INPUT_NEEDED is an error.

If the input state is OK, the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the input.offset marker with the byte after the end of the last record in the buffer and return CHUNK_ALIGNED. For example, if the input is "abc~def" and "~" is a record terminator, this method should set input.offset to 4, the position of "d". If process() reaches the end of the input without finding a record boundary, it should return INPUT_NEEDED.

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is END_OF_PORTION, the chunker should behave as it does for an input state of OK, except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The process() method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return KEEP_GOING. Failing to return KEEP_GOING has several consequences, such as preventing your user from being able to cancel the query.

See Chunker Example: Delimited Parser and Chunker for an example of the process() method using chunking.

### Aligning Portions

If your chunker supports apportioned load, implement the alignPortion() method. Vertica calls this method one or more times, before calling process(), to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

• START_OF_PORTION: the beginning of the buffer corresponds to the start of the portion. You can use the getPortion() method to access the offset and size of the
The method should scan from the beginning of the buffer to the start of the first complete record. It should set `input.offset` to this position and return one of the following values:

- **DONE**, if it found a chunk. `input.offset` is the first byte of the chunk.
- **INPUT_NEEDED**, if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of **END_OF_FILE**.
- **REJECT**, if the portion (not buffer) does not contain the start of any chunk.

**ParserFactory Class**

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the **ParserFactory** class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The **ParserFactory** class defines the following methods. Your subclass must override the `prepare()` method. It may override the other methods.

**Setting Up**

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into your `plan()` method.
- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the `PlanContext` instance passed through the `planCtxt` parameter. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.
You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString.

**Note:**
ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

## Creating Parsers

Vertica calls prepare() on each node to create and initialize your parser, using data stored by the plan() method.

## Defining Parameters

Implement getParameterTypes() to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

## Defining Parser Outputs

Implement getParserReturnType() to define the data types of the table columns that the parser outputs. If applicable, getParserReturnType() also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the argType and perColumnParamReader arguments and verifies that it can output the appropriate data types. If getParserReturnType() is prepared to output the data types, it calls methods on the SizedColumnTypes object passed in the returnType argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as CHAR, VARCHAR, and LONG VARBINARY), specify its maximum length.
- For NUMERIC types, specify its precision and scale.
• For Time/Timestamp types (with or without time zone), specify its precision (-1 means unspecified).
• For all other types, no length or precision specification is required.

Supporting Cooperative Parse

To support Cooperative Parse, implement prepareChunker() and return an instance of your UDChunker subclass. If isChunkerApportionable() returns true, then it is an error for this method to return null.

Cooperative parse is currently supported only in the C++ API.

Supporting Apportioned Load

To support Apportioned Load, your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement isParserApportionable() and return true. To indicate that the chunker can apportion a load, implement isChunkerApportionable() and return true.

The isChunkerApportionable() method takes a ServerInterface as an argument, so you have access to the parameters supplied in the COPY statement. You might need this information if the user can specify a record delimiter, for example. Return true from this method if and only if the factory can create a chunker for this input.

Load Parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

• Distributed load: Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.
• Cooperative parse: A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See Cooperative Parse.
• Apportioned load: Vertica divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load
divides the load at planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See Apportioned Load.

You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See Combining Cooperative Parse and Apportioned Load.

**Cooperative Parse**

By default, Vertica parses a data source in a single thread on one database node. You can optionally use cooperative parse to parse a source using multiple threads on a node. More specifically, data from a source passes through a chunker that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDxs. (See Fenced Mode.)

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.

Chunkers are created by parser factories. At load time, Vertica first calls the UDChunker to divide the input into chunks and then calls the UDParser to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See Combining Cooperative Parse and Apportioned Load.

**How Vertica Divides a Load**

When Vertica receives data from a source, it calls the chunker's process() method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the process() method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the process() method on the parser.

**Implementing Cooperative Parse**

To implement cooperative parse, perform the following actions:
Subclass `UDChunker` and implement `process()`. 
In your `ParserFactory`, implement `prepareChunker()` to return a `UDChunker`.

See Chunker Example: Delimited Parser and Chunker for a `UDChunker` that also supports apportioned load.

**Apportioned Load**

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as *apportioned load*. Some of the parsers built into Vertica support apportioned load.

Apportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

It is possible for a parser to not support apportioned load directly but to have a chunker that supports apportioning.

You can use apportioned load and cooperative parse independently or together. See Combining Cooperative Parse and Apportioned Load.

**How Vertica Apportions a Load**

If both the parser and its source support apportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The `SourceFactory` breaks the input into portions and assigns them to execution nodes. Each `Portion` consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a `UDSource` for the given portion.

The `UDParser` first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.

The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that begin in the assigned portion, regardless of where they end. Most of this work occurs within the `process()` method of the parser.

Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses **Cooperative Parse**, then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

### Implementing Apportioned Load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

**In your `SourceFactory` subclass:**

- Implement `isSourceApportionable()` and return `true`.
- Implement `plan()` to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter writer on the plan context (`PlanContext::getWriter()`).
- Implement `prepareUDSources()`. Vertica calls this method on each execution node with the plan context created by the factory. This method returns the `UDSource` instances to be used for this node's assigned portions.
- If sources can take advantage of parallelism, you can implement `getDesiredThreads()` to request a number of threads for each source. See `SourceFactory Class` for more information about this method.

**In your `UDSource` subclass**, implement `process()` as you would for any other source, using the assigned portion. You can retrieve this portion with `getPortion()`.

**In your `ParserFactory` subclass:**
Implement `isParserApportionable()` and return `true`.
If your parser uses a UDChunker that supports apportioned load, implement `isChunkerApportionable()`.

In your UDParser subclass:

- Write your UDParser subclass to operate on portions rather than whole sources. You can do so by handling the stream states `PORTION_START` and `PORTION_END`, or by using the ContinuousUDPParser API. Your parser must scan for the beginning of the portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.
- Handle the special case of a portion containing no record start by returning without writing any output.

In your UDChunker subclass, implement `alignPortion()`. See Aligning Portions.

Example

The SDK provides a C++ example of apportioned load in the ApportionLoadFunctions directory:

- `FilePortionSource` is a subclass of `UDSource`.
- `DelimFilePortionParser` is a subclass of `ContinuousUDPParser`.

Use these classes together. You could also use `FilePortionSource` with the built-in delimited parser.

The following example shows how you can load the libraries and create the functions in the database:

```sql
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';
=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';
=> CREATE SOURCE FilePortionSource AS
  LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;
=> CREATE PARSER DelimFilePortionParser AS
  LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```sql
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSER DelimFilePortionParser(delimiter = '|'),
```
Combining Cooperative Parse and Apportioned Load

You can enable both Cooperative Parse and Apportioned Load in the same parser, allowing Vertica to decide how to load data.

Deciding How to Divide a Load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires SourceFactory support. Given a suitable UDSource, at planning time Vertica calls the isParserApportionable() method on the ParserFactory. If this method returns true, Vertica apports the load.

If isParserApportionable() returns false but isChunkerApportionable() returns true, then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apports the load.

If neither of these methods returns true, then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.

If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but prepareChunker() does not return a UDChunker instance, Vertica reports an error.
Executing Apportioned, Cooperative Loads

If a load uses both apportioned load and cooperative parse, Vertica uses the SourceFactory to break the input into portions. It then assigns the portions to execution nodes. See How Vertica Apportions a Load.

On the execution node, Vertica calls the chunker's alignPortion() method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's process() method repeatedly. See How Vertica Divides a Load.

The chunks found by the chunker are then sent to the parser's process() method for processing in the usual way.

Continuous Load

The ContinuousUDSource, ContinuousUDFilter, and ContinuousUDParser classes allow you to write and process data as needed instead of having to iterate through the data. The Python API does not support continuous load.

Each class includes the following functions:

- initialize() - Invoked before run(). You can optionally override this function to perform setup and initialization.
- run() - Processes the data.
- deinitialize() - Invoked after run() has returned. You can optionally override this function to perform tear-down and destruction.

Do not override the setup(), process(), and destroy() functions that are inherited from parent classes.

You can use the yield() function to yield control back to the server during idle or busy loops so the server can check for status changes or query cancellations.

These three classes use associated ContinuousReader and ContinuousWriter classes to read input data and write output data.
C++ API

This section provides APIs and examples for the C++ API for UDLs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

Requirements for C++ UDLs

C++ UDLs:

- Can run in Fenced Mode. Vertica enables fenced mode by default when you create a source, filter, or parser function, in Vertica unless you explicitly state otherwise.
- Must not permit an exception to be passed back to Vertica. Doing so could lead to issues such as memory leaks caused by the memory allocated by the exception never being freed. Your UDL should always contain a top-level try-catch block to catch any stray exceptions caused by your code or libraries that your code calls.
- Must properly free any resources that the UDL function allocates. Even a single byte of allocated memory that is not freed can become an issue in a UDL that is called over millions of rows. Instead of allocating memory directly, your function should use the memory allocation macros in the Vertica SDK. See Allocating Resources for UDxs for details.

The header files that define the majority of classes and methods are VerticaUDx.h and VerticaUDl.h. These header files, along with the main Vertica.h header file, are available in /opt/vertica/sdk/include.

Source Classes

See User-Defined Source for general information about implementing the UDSource and SourceFactory classes. This section describes information that is specific to the C++ API.

In addition to the examples in this section, see C++ Example: Cancelable UDSource.
**UDSource API**

The API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface);
virtual StreamState process(ServerInterface &srvInterface,
                              DataBuffer &output)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface);
virtual vint getSize();
virtual std::string getUri();
```

**ContinuousUDSource API**

The `ContinuousUDSource` class extends `UDSource` and adds the following methods for extension by subclasses:

```cpp
virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);
```

**SourceFactory API**

The API provides the following methods for extension by subclasses:

```cpp
virtual void plan(ServerInterface &srvInterface, NodeSpecifyingPlanContext &planCtxt);
// must implement exactly one of prepareUDSources() or prepareUDSourcesExecutor()
virtual std::vector<UDSource *> prepareUDSources(ServerInterface &srvInterface,
                                                NodeSpecifyingPlanContext &planCtxt);
virtual std::vector<UDSource *> prepareUDSourcesExecutor(ServerInterface &srvInterface,
                                                         ExecutorPlanContext &planCtxt);
virtual void getParameterType(ServerInterface &srvInterface,
                               SizedColumnTypes &parameterTypes);
virtual bool isSourceApportionable();
```
After creating your SourceFactory, you must register it with the RegisterFactory macro.

**Filter Classes**

This section describes information that is specific to the C++ API. See User-Defined Filter for general information about implementing the UDFilter and FilterFactory classes.

**UDFilter API**

The API provides the following methods for extension by subclasses:

```c
virtual void setup(ServerInterface &srvInterface);
virtual StreamState process(ServerInterface & srvInterface, DataBuffer &input,
                              InputState input_state, DataBuffer &output)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface);
```

**ContinuousUDFilter API**

The ContinuousUDFilter class extends UDFilter and adds the following methods for extension by subclasses:

```c
virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);
```

**FilterFactory API**

The API provides the following methods for extension by subclasses:
After creating your FilterFactory, you must register it with the RegisterFactory macro.

**Parser Classes**

This section describes information that is specific to the C++ API. See User-Defined Parser for general information about implementing the UDParser and ParserFactory classes.

**UDParser API**

The API provides the following methods for extension by subclasses:

- virtual void setup(ServerInterface &srvInterface, SizedColumnTypes &returnType);
- virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state)=0;
- virtual void cancel(ServerInterface &srvInterface);
- virtual void destroy(ServerInterface &srvInterface, SizedColumnTypes &returnType);
- virtual RejectedRecord getRejectedRecord();

**Rejecting Records**

The `process()` method might need to reject input. To reject data, you must do two things:

- Create a `getRejectedRecord()` method on your UDParser subclass that returns an object of type `Vertica::RejectedRecord`. This record contains the data that you want to reject, a string describing the reason for rejection, the size of the data, and the terminator string. See `RejectedRecord` in `VerticaUDI.h` or the SDK documentation for details.
Reject a row by returning `REJECT` from `process()`. Vertica then calls `getRejectedRecord()` to process the rejected record before the next call to `process()`.

You can fulfill these requirements by including code in your parser class such as:

```cpp
Vertica::RejectedRecord myRejRec;
Vertica::RejectedRecord getRejectedRecord() {
    return myRejRec;
}
```

In your `process()` method, add code such as:

```cpp
if (some rejection condition) {
    RejectedRecord rr("Bad Record!", "foo data", 8, "\n");
    myRejRec = rr;
    return Vertica::REJECT;
}
```

### ContinuousUDParser API

The `ContinuousUDParser` class extends `UDParser` and adds the following methods for extension by subclasses:

```cpp
virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);
```

### UDChunker API

The `UDChunker` API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
                    SizedColumnTypes &returnType);
virtual StreamState alignPortion(ServerInterface &srvInterface,
                                   DataBuffer &input, InputState state);
virtual StreamState process(ServerInterface &srvInterface,
                           DataBuffer &input, InputState input_state=0);
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface,
                      Vertica::RejectedRecord myRejRec;
                      Vertica::RejectedRecord getRejectedRecord() {
                          return myRejRec;
                      }

In your process() method, add code such as:

```cpp
if (some rejection condition) {
    RejectedRecord rr("Bad Record!", "foo data", 8, "\n");
    myRejRec = rr;
    return Vertica::REJECT;
}

### ContinuousUDParser API

The ContinuousUDParser class extends UDParse and adds the following methods for extension by subclasses:

```cpp
virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);
```

### UDChunker API

The UDChunker API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
                    SizedColumnTypes &returnType);
virtual StreamState alignPortion(ServerInterface &srvInterface,
                                   DataBuffer &input, InputState state);
virtual StreamState process(ServerInterface &srvInterface,
                           DataBuffer &input, InputState input_state=0);
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface,
                      Vertica::RejectedRecord myRejRec;
                      Vertica::RejectedRecord getRejectedRecord() {
                          return myRejRec;
                      }

In your process() method, add code such as:

```cpp
if (some rejection condition) {
    RejectedRecord rr("Bad Record!", "foo data", 8, "\n");
    myRejRec = rr;
    return Vertica::REJECT;
}
```
ParserFactory API

The API provides the following methods for extension by subclasses:

```c++
virtual void plan(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
                   PlanContext &planCtxt);
virtual UDFParser * prepare(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
                             PlanContext &planCtxt, const SizedColumnTypes &returnType)=0;
virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
virtual void getParserReturnType(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
                                   PlanContext &planCtxt, const SizedColumnTypes &argTypes,
                                   SizedColumnTypes &returnType);
virtual bool isParserApportionable();

// C++ API only:
virtual bool isChunkerApportionable(ServerInterface &srvInterface);
virtual UDFChunker * prepareChunker(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
                                    PlanContext &planCtxt, const SizedColumnTypes &returnType);
```

If you are using **Apportioned Load** to divide a single input into multiple load streams, implement `isParserApportionable()` and/or `isChunkerApportionable()` and return `true`. Returning `true` from these methods does not guarantee that Vertica will apportion the load. However, returning `false` from both indicates that it will not try to do so.

If you are using **Cooperative Parse**, implement `prepareChunker()` and return an instance of your UDFChunker subclass. Cooperative parse is supported only for the C++ API.

Vertica calls the `prepareChunker()` method **only for unfenced functions.** This method is not available when you use the function in fenced mode.

If you want your chunker to be available for apportioned load, implement `isChunkerApportionable()` and return `true`.

After creating your `ParserFactory`, you must register it with the `RegisterFactory` macro.
DataBuffer Class

The DataBuffer is the handle to the raw data stream for all UDL functions. It has a pointer to a buffer and size, and an offset indicating how much of the stream has been consumed.

DataBuffer API

```c
/**
 * A contiguous in-memory buffer of char *
 */
struct DataBuffer {
  /// Pointer to the start of the buffer
  char * buf;

  /// Size of the buffer in bytes
  size_t size;

  /// Number of bytes that have been processed by the UDL
  size_t offset;
};
```

Source Example: CurlSource

The CurlSource example allows you to use cURL to open and read in a file over HTTP. The example provided is part of:
```
/opt/vertica/sdk/examples/SourceFunctions/cURL.cpp
```

Source Implementation

This example uses the helper library available in
```
/opt/vertica/sdk/examples/HelperLibraries/
```

CurlSource loads the data in chunks. If the parser encounters an EndOfFile marker, then the `process()` method returns DONE. Otherwise, the method returns OUTPUT_NEEDED and processes another chunk of data. The functions included in the helper library (such as `url_fread()` and `url_fopen()`) are based on examples that come with the libcurl library. For an example, see [http://curl.haxx.se/libcurl/c/fopen.html](http://curl.haxx.se/libcurl/c/fopen.html).
The `setup()` function opens a file handle and the `destroy()` function closes it. Both use functions from the helper library.

class CurlSource : public UDSource {private:
    URL_FILE *handle;
    std::string url;
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
        output.offset = url_fread(output.buf, 1, output.size, handle);
        return url_feof(handle) ? DONE : OUTPUT_NEEDED;
    }
public:
    CurlSource(std::string url) : url(url) {}
    void setup(ServerInterface &srvInterface) {
        handle = url_fopen(url.c_str(), "r");
    }
    void destroy(ServerInterface &srvInterface) {
        url_fclose(handle);
    }
};//

Factory Implementation

CurlSourceFactory produces CurlSource instances.

class CurlSourceFactory : public SourceFactory {public:
    virtual void plan(ServerInterface &srvInterface,
                      NodeSpecifyingPlanContext &planCtxt) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (args.size() != 1 || find(args.begin(), args.end(), "url") == args.end()) {
            vt_report_error(0, "You must provide a single URL.");
        }
        /* Populate planData */
        planCtxt.getWriter().getStringRef("url").copy(srvInterface.getParamReader().getStringRef("url"));
        /* Assign Nodes */
        std::vector<std::string> executionNodes = planCtxt.getClusterNodes();
        while (executionNodes.size() > 1) executionNodes.pop_back();
        // Only run on the first node in the list.
        planCtxt.setTargetNodes(executionNodes);
    }
    virtual std::vector<UDSource*> prepareUDSources(ServerInterface &srvInterface,
                                                   NodeSpecifyingPlanContext &planCtxt) {
        std::vector<UDSource*> retVal;
        retVal.push_back(vt_createFuncObj(srvInterface.allocator, CurlSource,
                                           planCtxt.getWriter().getStringRef("url").str()));
        return retVal;
    }
    virtual void getParameterType(ServerInterface &srvInterface,
                                   SizedColumnTypes &parameterTypes) {
        parameterTypes.addVarchar(65000, "url");
    }
};
RegisterFactory(CurlSourceFactory);

**Source Example: Concurrent Load**

The FilePortionSource example demonstrates the use of concurrent load. This example is a refinement of the FileSource example. Each input file is divided into portions and distributed to FilePortionSource instances. The source accepts a list of offsets at which to break the input into portions; if offsets are not provided, the source divides the input dynamically.

Concurrent load is handled in the factory, so this discussion focuses on FilePortionSourceFactory. The full code for the example is located in /opt/vertica/sdk/examples/ApportionLoadFunctions. The distribution also includes a Java version of this example.

**Loading and Using the Example**

Load and use the FilePortionSource example as follows.

```sql
=> CREATE LIBRARY FilePortionLib AS '/home/dbadmin/FP.so';
=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++'
   => NAME 'FilePortionSourceFactory' LIBRARY FilePortionLib;
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat', nodes='initiator,e0,e1', offsets = '0,380000,820000');
=> COPY t WITH SOURCE FilePortionSource(file='g2/*.dat', nodes='e0,e1,e2', local_min_portion_size = 2097152);
```

**Implementation**

Concurrent load affects the source factory in two places, getDesiredThreads() and prepareUDSourcesExecutor().
getDesiredThreads()

The getDesiredThreads() member function determines the number of threads to request. Vertica calls this member function on each executor node before calling prepareUDSourcesExecutor().

The function begins by breaking an input file path, which might be a glob, into individual paths. This discussion omits those details. If apportioned load is not being used, then the function allocates one source per file.

```
virtual ssize_t getDesiredThreads(ServerInterface &srvInterface,
     ExecutorPlanContext &planCtxt) {
    const std::string filename = srvInterface.getParamReader().getStringRef("file").str();
    std::vector<std::string> paths;
    // expand the glob - at least one thread per source.
    ...
    // figure out how to assign files to sources
    const std::string nodeName = srvInterface.getCurrentNodeName();
    const size_t nodeId = planCtxt.getWriter().getIntRef(nodeName);
    const size_t numNodes = planCtxt.getTargetNodes().size();

    if (!planCtxt.canApportionSource()) {
      /* no apportioning, so the number of files is the final number of sources */
      std::vector<std::string> *expanded =
          vt_createFuncObject<std::vector<std::string> >>(srvInterface.allocator, paths);
      /* save expanded paths so we don't have to compute expansion again */
      planCtxt.getWriter().setPointer("expanded", expanded);
      return expanded->size();
    }
    // ...

    if the source can be apportioned, then getDesiredThreads() uses the offsets that were passed as arguments to the factory to divide the file into portions. It then allocates portions to available nodes. This function does not actually assign sources directly; this work is done to determine how many threads to request.

    else if (srvInterface.getParamReader().containsParameter("offsets")) {
      // if the offsets are specified, then we will have a fixed number of portions per file.
      // Round-robin assign offsets to nodes.
      // ...

      /* Construct the portions that this node will actually handle.
      * This isn't changing (since the offset assignments are fixed),
      * so we'll build the Portion objects now and make them available
      * to prepareUDSourcesExecutor() by putting them in the ExecutorContext.
    }
```
We don't know the size of the last portion, since it depends on the file size. Rather than figure it out here we will indicate it with -1 and defer that to prepareUDSourcesExecutor().

```cpp
std::vector<Portion> *portions =
    vt_createFuncObject<std::vector<Portion>>(srvInterface.allocator);
for (std::vector<size_t>::const_iterator offset = offsets.begin();
    offset != offsets.end(); ++offset) {
    Portion p(*offset);
    p.is_first_portion = (offset == offsets.begin());
    p.size = (offset + 1 == offsets.end() ? -1 : (*offset) - *offset);
    if (((offset - offsets.begin()) % numNodes == nodeId) {
        portions->push_back(p);
        srvInterface.log("FilePortionSource: assigning portion %ld: [offset = %lld, size =
%lld]",
            offset - offsets.begin(), p.offset, p.size);
    } }
```

The function now has all the portions and thus the number of portions:

```cpp
planCtxt.getWriter().setPointer("portions", portions);
/* total number of threads we want is the number of portions per file, which is fixed */
return portions->size() * expanded->size();
} // end of "offsets" parameter
```

If offsets were not provided, the function divides the file into portions dynamically, one portion per thread. This discussion omits the details of this computation. There is no point in requesting more threads than are available, so the function calls getMaxAllowedThreads() on the PlanContext (an argument to the function) to set an upper bound:

```cpp
if (portions->size() >= planCtxt.getMaxAllowedThreads()) {
    return paths.size();
}
```

See the full example for the details of how this function divides the file into portions.

This function uses the vt_createFuncObject template to create objects. Vertica calls the destructors of returned objects created using this macro, but it does not call destructors for other objects like vectors. You must call these destructors yourself to avoid memory leaks. In this example, these calls are made in prepareUDSourcesExecutor().
prepareUDSourcesExecutor()

The `prepareUDSourcesExecutor()` member function, like `getDesiredThreads()`, has separate blocks of code depending on whether offsets are provided. In both cases, the function breaks input into portions and creates `UDSource` instances for them.

If the function is called with offsets, `prepareUDSourcesExecutor()` calls `prepareCustomizedPortions()`. This function follows.

```cpp
/* prepare portions as determined via the "offsets" parameter */
void prepareCustomizedPortions(ServerInterface &srvInterface,
                                ExecutorPlanContext &planCtx,
                                std::vector<UDSource *> &sources,
                                const std::vector<std::string> &expandedPaths,
                                std::vector<Portion> &portions) {
    for (std::vector<std::string>::const_iterator filename = expandedPaths.begin();
        filename != expandedPaths.end(); ++filename) {
        /*
         * the "portions" vector contains the portions which were generated in
         * `getDesiredThreads`
         */
        const size_t fileSize = getFileSize(*filename);
        for (std::vector<Portion>::const_iterator portion = portions.begin();
            portion != portions.end(); ++portion) {
            Portion fportion(*portion);
            if (fportion.size == -1) {
                /* as described above, this means from the offset to the end */
                fportion.size = fileSize - portion->offset;
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                    *filename, fportion));
            } else if (fportion.size > 0) {
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                    *filename, fportion));
            }
        }
    }
}
```

If `prepareUDSourcesExecutor()` is called without offsets, then it must decide how many portions to create.

The base case is to use one portion per source. However, if extra threads are available, the function divides the input into more portions so that a source can process them concurrently. Then `prepareUDSourcesExecutor()` calls `prepareGeneratedPortions()` to create the portions. This function begins by calling `getLoadConcurrency()` on the plan context to find out how many threads are available.
```
void prepareGeneratedPortions(ServerInterface &srvInterface,
    ExecutorPlanContext &planCtxt,
    std::vector<UDSource *> &sources,
    std::map<std::string, Portion> initialPortions) {

    if ((ssize_t) initialPortions.size() >= planCtxt.getLoadConcurrency()) { /* all threads will be used, don’t bother splitting into portions */
        for (std::map<std::string, Portion>::const_iterator file = initialPortions.begin(); file != initialPortions.end(); ++file) {
            sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                file->first, file->second));
        } // for
        return;
    } // if

    // Now we can split files to take advantage of potentially-unused threads. // First sort by size (descending), then we will split the largest first.
    // details elided...
}
```

### For More Information

See the source code for the full implementation of this example.

**Filter Example: Converting Encoding**

The following example shows how you can convert encoding for a file from one type to another by converting UTF-16 encoded data to UTF-8. You can find this example in the SDK at `/opt/vertica/sdk/examples/FilterFunctions/IConverter.cpp`.

### Filter Implementation

```
class IConverter : public UDFilter{
private:
    std::string fromEncoding, toEncoding;
    iconv_t cd; // the conversion descriptor opened
    uint converted; // how many characters have been converted
protected:
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
        InputState input_state, DataBuffer &output)
    {
        char *input_buf = (char *)input.buf + input.offset;
```
char *output_buf = (char *)output.buf + output.offset;
size_t inBytesLeft = input.size - input.offset, outBytesLeft = output.size - output.offset;
// end of input
if (input_state == END_OF_FILE && inBytesLeft == 0)
{
    // Gnu libc iconv doc says, it is good practice to finalize the
    // outbuffer for stateful encodings (by calling with null inbuffer).
    iconv(cd, NULL, NULL, &output.buf, &outBytesLeft);
    // output buffer can be updated by this operation
    output.offset = output.size - outBytesLeft;
    return DONE;
}
size_t ret = iconv(cd, &input_buf, &inBytesLeft, &output_buf, &outBytesLeft);
// if conversion is successful, we ask for more input, as input has not reached EOF.
StreamState retStatus = INPUT_NEEDED;
if (ret == (size_t)(-1))
{
    // seen an error
    switch (errno)
    {
    case E2BIG:
        // input size too big, not a problem, ask for more output.
        retStatus = OUTPUT_NEEDED;
        break;
    case EINVAL:
        // input stops in the middle of a byte sequence, not a problem, ask for more input
        retStatus = input_state == END_OF_FILE ? DONE : INPUT_NEEDED;
        break;
    case EILSEQ:
        // invalid sequence seen, throw
        // TODO: reporting the wrong byte position
        vt_report_error(1, "Invalid byte sequence when doing %u-th conversion", converted);
        break;
    case EBADF:
        // something wrong with descriptor, throw
        vt_report_error(0, "Invalid descriptor");
        break;
    default:
        vt_report_error(0, "Uncommon Error");
        break;
    }
}
else converted += ret;
// move position pointer
input.offset = input.size - inBytesLeft;
output.offset = output.size - outBytesLeft;
return retStatus;
}

public:
Iconverter(const std::string &from, const std::string &to)
    : fromEncoding(from), toEncoding(to), converted(0)
{
    // note "to encoding" is first argument to iconv...
    cd = iconv_open(to.c_str(), from.c_str());
    if (cd == (iconv_t)(-1))
    {
        // error when creating converters.
        vt_report_error(0, "Error initializing iconv: %m");
    }
}
Factory Implementation

class IconverterFactory : public FilterFactory{
public:
    virtual void plan(ServerInterface &srvInterface,
                      PlanContext &planCtxt) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if ((args.size() == 0 || (args.size() == 1 && find(args.begin(), args.end(), "from_encoding") != args.end())
            && find(args.begin(), args.end(), "from_encoding") != args.end())
            && find(args.begin(), args.end(), "to_encoding") != args.end())) {
            vt_report_error(0, "Invalid arguments. Must specify either no arguments, or "
            "'from_encoding' alone, or 'from_encoding' and 'to_encoding'.");
        }
        /* Populate planData */
        // By default, we do UTF16->UTF8, and x->UTF8
        VString from_encoding = planCtxt.getWriter().getStringRef("from_encoding");
        VString to_encoding = planCtxt.getWriter().getStringRef("to_encoding");
        from_encoding.copy("UTF-16");
        to_encoding.copy("UTF-8");
        if (args.size() == 2) {
            from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
            to_encoding.copy(srvInterface.getParamReader().getStringRef("to_encoding"));
        } else if (args.size() == 1) {
            from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
        }
        if (!from_encoding.length()) {
            vt_report_error(0, "The empty string is not a valid from_encoding value");
        }
        if (!to_encoding.length()) {
            vt_report_error(0, "The empty string is not a valid to_encoding value");
        }
    }

    virtual UDFilter* prepare(ServerInterface &srvInterface,
                               PlanContext &planCtxt) {
        return vt_createFuncObj(srvInterface.allocator, Iconverter,
                                planCtxt.getReader().getStringRef("from_encoding").str(),
                                planCtxt.getReader().getStringRef("to_encoding").str());
    }

    virtual void getParameterType(ServerInterface &srvInterface,
                                   SizedColumnTypes &parameterTypes) {
        parameterTypes.addVarchar(32, "from_encoding");
        parameterTypes.addVarchar(32, "to_encoding");
    }
};
Parser Example: BasicIntegerParser

The BasicIntegerParser example parses a string of integers separated by non-numeric characters. For a version of this parser that uses continuous load, see Parser Example: ContinuousIntegerParser.

Loading and Using the Example

Load and use the BasicIntegerParser example as follows.

```sql
=> CREATE LIBRARY BasicIntegerParserLib AS '/home/dbadmin/BIP.so';
=> CREATE PARSER BasicIntegerParser AS LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;
=> CREATE TABLE t (i integer);
=> COPY t FROM stdin WITH PARSER BasicIntegerParser();
0
1
2
3
4
5
.
```

Implementation

The BasicIntegerParser class implements only the process() method from the API. (It also implements a helper method for type conversion.) This method processes each line of input, looking for numbers on each line. When it advances to a new line it moves the input.offset marker and checks the input state. It then writes the output.

```cpp
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
   InputState input_state) {
   // WARNING: This implementation is not trying for efficiency.
   // It is trying for simplicity, for demonstration purposes.
   size_t start = input.offset;

```
In the factory, the `plan()` method is a no-op; there are no parameters to check. The `prepare()` method instantiates the parser using the macro provided by the SDK:

```cpp
virtual UDParse* prepare(ServerInterface &srvInterface,
               PerColumnParamReader &perColumnParamReader,
               PlanContext &planCtx,
               const SizedColumnTypes &returnType)
{
    return vt_createFuncObject<BasicIntegerParser>(srvInterface.allocator);
}
```

The `getParserReturnType()` method declares the single output:

```cpp
virtual void getParserReturnType(ServerInterface &srvInterface,
               PerColumnParamReader &perColumnParamReader,
               PlanContext &planCtx,
               const sizedColumnTypes &argTypes,
               sizedColumnTypes &returnType)
{
    // We only and always have a single integer column
    returnType.addInt(argTypes.getColumnName(0));
}
```
As for all U Dx s written in C++, the example ends by registering its factory:

```cpp
RegisterFactory(BasicIntegerParserFactory);
```

**Parser Example: ContinuousIntegerParser**

The ContinuousIntegerParser example is a variation of BasicIntegerParser. Both examples parse integers from input strings. ContinuousIntegerParser uses Continuous Load to read data.

**Loading and Using the Example**

Load the ContinuousIntegerParser example as follows.

```sql
=> CREATE LIBRARY ContinuousIntegerParserLib AS '/home/dbadmin/CIP.so';

=> CREATE PARSER ContinuousIntegerParser AS
   LANGUAGE 'C++' NAME 'ContinuousIntegerParserFactory'
   LIBRARY ContinuousIntegerParserLib;
```

Use it in the same way that you use BasicIntegerParser. See Parser Example: BasicIntegerParser.

**Implementation**

ContinuousIntegerParser is a subclass of ContinuousUDParser. Subclasses of ContinuousUDParser place the processing logic in the run() method.

```cpp
virtual void run() {
    // This parser assumes a single-column input, and
    // a stream of ASCII integers split by non-numeric characters.
    size_t pos = 0;
    size_t reserved = cr.reserve(pos+1);
    while (!cr.isEof() || reserved == pos + 1) {
        while (reserved == pos + 1 && isdigit(*ptr(pos))) {
            pos++;
            reserved = cr.reserve(pos + 1);
        }

        std::string st(ptr(), pos);
        writer->setInt(0, strToInt(st));
        writer->next();
    }
}
```
while (reserved == pos + 1 && !isdigit(*ptr(pos))) {
    pos++;
    reserved = cr.reserve(pos + 1);
}
    cr.seek(pos);
    pos = 0;
    reserved = cr.reserve(pos + 1);
};

For a more complex example of a ContinuousUDParser, see ExampleDelimitedParser in the examples. (See Downloading and Running UDx Example Code.) ExampleDelimitedParser uses a chunker; see Chunker Example: Delimited Parser and Chunker.

**Chunker Example: Delimited Parser and Chunker**

The ExampleDelimitedUDChunker class divides an input at delimiter characters. You can use this chunker with any parser that understands delimited input. ExampleDelimitedParser is a ContinuousUDParser subclass that uses this chunker.

**Loading and Using the Example**

Load and use the example as follows.

```sql
=> CREATE LIBRARY ExampleDelimitedParserLib AS '/home/dbadmin/EDP.so';

=> CREATE PARSER ExampleDelimitedParser AS
    LANGUAGE 'C++' NAME 'DelimitedParserFrameworkExampleFactory'
    LIBRARY ExampleDelimitedParserLib;

=> COPY t FROM stdin WITH PARSER ExampleDelimitedParser();
0
1
2
3
4
5
6
7
8
9

\.
```
**Chunker Implementation**

This chunker supports apportioned load. The `alignPortion()` method finds the beginning of the first complete record in the current portion and aligns the input buffer with it. The record terminator is passed as an argument and set in the constructor.

```cpp
StreamState ExampleDelimitedUDChunker::alignPortion(
    ServerInterface &srvInterface, 
    DataBuffer &input, InputState state)
{
    /* find the first record terminator. Its record belongs to the previous portion */
    void *buf = reinterpret_cast<void *>(input.buf + input.offset);
    void *term = memchr(buf, recordTerminator, input.size - input.offset);

    if (term) {
        /* record boundary found. Align to the start of the next record */
        const size_t chunkSize = reinterpret_cast<size_t>(term) - reinterpret_cast<size_t>(buf);
        input.offset += chunkSize
        + sizeof(char) /* length of record terminator */;

        /* input.offset points at the start of the first complete record in the portion */
        return DONE;
    } else if (state == END_OF_FILE || state == END_OF_PORTION) {
        return REJECT;
    } else {
        VIAssert(state == START_OF_PORTION || state == OK);
        return INPUT_NEEDED;
    }
}
```

The `process()` method has to account for chunks that span portion boundaries. If the previous call was at the end of a portion, the method set a flag. The code begins by checking for and handling that condition. The logic is similar to that of `alignPortion()`, so the example calls it to do part of the division.

```cpp
StreamState ExampleDelimitedUDChunker::process(
    ServerInterface &srvInterface, 
    DataBuffer &input, 
    InputState input_state)
{
    const size_t termLen = 1;
    const char *terminator = &recordTerminator;

    if (pastPortion) {
        /*
        * Previous state was END_OF_PORTION, and the last chunk we will produce
        * extends beyond the portion we started with, into the next portion.
        * To be consistent with alignPortion(), that means finding the first
        * record boundary, and setting the chunk to be at that boundary.
        * Fortunately, this logic is identical to aligning the portion (with
        * some slight accounting for END_OF_FILE)!
        */
```
const StreamState findLastTerminator = alignPortion(srvInterface, input);

switch (findLastTerminator) {
    case DONE:
        return DONE;
    case INPUT_NEEDED:
        if (input_state == END_OF_FILE) {
            /* there is no more input where we might find a record terminator */
            input_offset = input.size;
            return DONE;
        }
        return INPUT_NEEDED;
    default:
        VIAssert("Invalid return state from alignPortion()");
}
return findLastTerminator;

Now the method looks for the delimiter. If the input began at the end of a portion, it sets the flag.

size_t ret = input.offset, term_index = 0;
for (size_t index = input.offset; index < input.size; ++index) {
    const char c = input.buf[index];
    if (c == terminator[term_index]) {
        ++term_index;
        if (term_index == termLen) {
            ret = index + 1;
            term_index = 0;
        }
        continue;
    } else if (term_index > 0) {
        index -= term_index;
    }
    term_index = 0;
}

if (input_state == END_OF_PORTION) {
    /*
    * Regardless of whether or not a record was found, the next chunk will extend
    * into the next portion.
    */
    pastPortion = true;
}

Finally, process() moves the input offset and returns.

// if we were able to find some rows, move the offset to point at the start of the next
(potential) row, or end of block
if (ret > input.offset) {
    input_offset = ret;
    return CHUNKAligned;
}

if (input_state == END_OF_FILE) {
    input_offset = input.size;
}
Factory Implementation

The file ExampleDelimitedParser.cpp defines a factory that uses this UDChunker. The chunker supports apportioned load, so the factory implements isChunkerApportionable():

```cpp
virtual bool isChunkerApportionable(ServerInterface &srvInterface) {
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("d
isable_chunker")) {
        return false;
    } else {
        return true;
    }
}
```

The prepareChunker() method creates the chunker:

```cpp
virtual UDChunker* prepareChunker(ServerInterface &srvInterface,
    PerColumnParamReader &perColumnParamReader,
    PlanContext &planCtx,
    const SizedColumnTypes &returnType) {
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("d
isable_chunker")) {
        return NULL;
    }

    std::string recordTerminator("\n");
    ParamReader args(srvInterface.getParamReader());
    if (args.containsParameter("record_terminator")) {
        recordTerminator = args.getStringRef("record_terminator").str();
    }

    return vt_createFuncObject<ExampleDelimitedUDChunker>(srvInterface.allo\ctor,
        recordTerminator[0]);
```
Java API

The Vertica Java SDK supports developing UDLs. The Java SDK enables you to create sources, filters, and parsers, but not chunkers.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

Source Classes

This section describes information that is specific to the Java API. See User-Defined Source for general information about implementing the UDSource and SourceFactory classes.

UDSource API

The API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface) throws UdfException;
public abstract StreamState process(ServerInterface srvInterface, DataBuffer output) throws UdfException;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface) throws UdfException;
public Integer getSize();
public String getUri();
```

SourceFactory API

The API provides the following methods for extension by subclasses:

```java
public void plan(ServerInterface srvInterface, NodeSpecifyingPlanContext planCtxt) throws UdfException;
```
// must implement one overload of prepareUDSources()
public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface,
                                              NodeSpecifyingPlanContext planCtxt)
    throws UdfException;

public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface,
                                              ExecutorPlanContext planCtxt)
    throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

public boolean isSourceApportionable();

public int getDesiredThreads(ServerInterface srvInterface,
                              ExecutorPlanContext planCtxt)
    throws UdfException;

Filter Classes

This section describes information that is specific to the Java API. See User-Defined Filter for general information about implementing the UDFilter and FilterFactory classes.

UDFilter API

The API provides the following methods for extension by subclasses:

  public void setup(ServerInterface srvInterface) throws UdfException;
  public abstract StreamState process(ServerInterface srvInterface,
                                        DataBuffer input,
                                        InputState input_state,
                                        DataBuffer output)
      throws UdfException;
  protected void cancel(ServerInterface srvInterface);
  public void destroy(ServerInterface srvInterface) throws UdfException;

FilterFactory API

The API provides the following methods for extension by subclasses:

  public void plan(ServerInterface srvInterface, PlanContext planCtxt)
      throws UdfException;
  public abstract UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt)
Parser Classes

This section describes information that is specific to the Java API. See User-Defined Parser for general information about implementing the UDParse and ParserFactory classes.

UDParser API

The API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes returnType) throws UdfException;
public abstract StreamState process(ServerInterface srvInterface,
                                      DataBuffer input, InputState input_state)
                                      throws UdfException, DestroyInvocation;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface, SizedColumnTypes returnType)
                       throws UdfException;
public RejectedRecord getRejectedRecord() throws UdfException;
```

A UDParse uses a StreamWriter to write its output. StreamWriter provides methods for all the basic types, such as setBooleanValue(), setValue(), and so on. In the Java API this class also provides the setValue() method, which automatically sets the data type.

The methods described so far write single column values. StreamWriter also provides a method to write a complete row from a map. The setRowFromMap() method takes a map of column names and values and writes all the values into their corresponding columns. This method does not define new columns but instead writes values only to existing columns. The JsonParser example uses this method to write arbitrary JSON input. (See Parser Example: JSON Parser.)

Note:
The setRowFromMap() method does not automatically advance the input to the next line; you must call next(). You can thus read a row and then override selected column values.
setRowsFromMap() also populates any VMap ("_raw_") column of Flex Tables (see Using Flex Tables) with the entire provided map. For most cases, setRowsFromMap() is the appropriate way to populate a Flex Table. However, you can also generate a VMap value into a specified column using setVMap(), similar to other setValue() methods.

The setRowFromMap() method automatically coerces the input values into the types defined for those columns using an associated TypeCoercion. In most cases, using the default implementation (StandardTypeCoercion) is appropriate.

TypeCoercion uses policies to govern its behavior. For example, the FAIL_INVALID_INPUT_VALUE policy means invalid input is treated as an error instead of using a null value. Errors are caught and handled as rejections (see "Rejecting Rows" in User-Defined Parser). Policies also govern whether input that is too long is truncated. Use the setPolicy() method on the parser's TypeCoercion to set policies. See the API documentation for supported values.

You might need to customize type coercion beyond setting these policies. To do so, subclass one of the provided implementations of TypeCoercion and override the asType() methods. Such customization could be necessary if your parser reads objects that come from a third-party library. A parser handling geo-coordinates, for example, might override asLong to translate inputs like "40.4397N" into numbers. See the Vertica API documentation for a list of implementations.

ContinuousUDParser API

The ContinuousUDParser class extends UDPParser and adds the following methods for extension by subclasses:

```java
public void initialize(ServerInterface srvInterface, SizedColumnTypes returnType);
public abstract void run() throws UdfException;
public void deinitialize(ServerInterface srvInterface, SizedColumnTypes returnType);
```

See the API documentation for additional utility methods.

ParserFactory API

The API provides the following methods for extension by subclasses:

```java
public void plan(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext planCtxt)
```
DataBuffer Classes

The DataBuffer is the handle to the raw data stream for all UDL functions. Java is a language whose strings require attention to character encodings. The UDX must decode or encode buffers provided by Vertica. A parser can interact with the stream by accessing the buffer directly.

DataBuffer API

Source Example: FileSource

The example shown in this section is a simple UDL Source function named FileSource, This function loads data from files stored on the host's file system (similar to the standard COPY statement). To call FileSource, you must supply a parameter named file that
contains the absolute path to one or more files on the host file system. You can specify multiple files as a comma-separated list.

The FileSource function also accepts an optional parameter, named nodes, that indicates which nodes should load the files. If you do not supply this parameter, the function defaults to loading data on the initiator node only. Because this example is simple, the nodes load only the files from their own file systems. Any files in the file parameter must exist on all of the hosts in the nodes parameter. The FileSource UDSource attempts to load all of the files in the file parameter on all of the hosts in the nodes parameter.

### Generating Files

You can use the following Python script to generate files and distribute them to hosts in your Vertica cluster. With these files, you can experiment with the example UDSource function. Running the function requires passwordless-SSH logins to copy the files to the other hosts. Therefore, you must run the script using the database administrator account on one of your database hosts.

```python
#!/usr/bin/python
# Save this file as UDLDaGen.py
import string
import random
import sys
import os

# Read in the dictionary file to provide random words. Assumes the words
# file is located in /usr/share/dict/words
wordFile = open("/usr/share/dict/words")
wordDict = []
for line in wordFile:
    if len(line) > 6:
        wordDict.append(line.strip())

MAXSTR = 4  # Maximum number of words to concatenate
NUMROWS = 1000  # Number of rows of data to generate
FILEPATH = '/tmp/UDLdata.txt'  # Final filename to use for UDL source
TMPFILE = '/tmp/UDLtemp.txt'  # Temporary filename.

def randomWords():
    words = [random.choice(wordDict) for n in xrange(random.randint(1, MAXSTR))]
    sentence = " ".join(words)
    return sentence

def generateFile(node):
    outFile = open(TMPFILE, 'w')
    for line in xrange(NUMROWS):
```
```python
outFile.write(''.format(line, randomWords(), node))
outFile.close()

# Copy the temporary file to a node. Only works if passwordless SSH login
# is enabled, which it is for the database administrator account on
# Vertica hosts.
def copyFile(fileName, node):
    os.system('scp "%s" "%s:%s" % (TMPFILE, node, fileName) )

# Loop through the comma-separated list of nodes given in the first
# parameter, creating and copying data files whose full comma-separated
# paths are passed in the second parameter
for node in [x.strip() for x in sys.argv[1].split(',')]:
    for fileName in [y.strip() for y in sys.argv[2].split(',')]:
        print "generating file", fileName, "for", node
        generateFile(node)
        print "Copying file to", node
        copyFile(fileName, node)
```

You call this script by giving it a comma-separated list of hosts to receive the files and a comma-separated list of absolute paths of files to generate. For example:

```bash
python UDLDataGen.py v_vmart_node0001,v_vmart_node0002,v_vmart_node0003 /tmp/UDLdata01.txt,/tmp/UDLdata02.txt,\ UDLdata03.txt
```

This script generates files that contain a thousand rows of columns delimited with the pipe character (|). These columns contain an index value, a set of random words, and the node for which the file was generated, as shown in the following output sample:

```
0|megabits embanks|v_vmart_node0001
1|unneatly|v_vmart_node0001
2|self-precipitation|v_vmart_node0001
3|antihistamine scalados Vatter|v_vmart_node0001
```

### Loading and Using the Example

**Load and use the FileSource UDSourc**e as follows:

```sql
=> --Load library and create the source function
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLlib.jar'
=> LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE SOURCE File as LANGUAGE 'JAVA' NAME
=> 'com.mycompany.UDL.FileSourceFactory' LIBRARY JavaLib;
CREATE SOURCE FUNCTION
=> --Create a table to hold the data loaded from files
=> CREATE TABLE t (i integer, text VARCHAR, node VARCHAR);
CREATE TABLE
=> -- Copy a single file from the currently host using the FileSource
```
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt');
  Rows Loaded
  --------------
     1000
  (1 row)

=> --See some of what got loaded.
=> SELECT * FROM t WHERE i < 5 ORDER BY i;
  i | text                      | node
-------------------------------
  0 | megabits embanks           | v_vmart_node0001
  1 | unneatly                   | v_vmart_node0001
  2 | self-precipitation         | v_vmart_node0001
  3 | antihistamine scalados Vatter | v_vmart_node0001
  4 | fate-menaced toilworn      | v_vmart_node0001
  (5 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE
=> -- Now load a file from three hosts. All of these hosts must have a file
=> -- named /tmp/UDLdata01.txt, each with different data
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt',
  -> nodes='v_vmart_node0001,v_vmart_node0002,v_vmart_node0003');
  Rows Loaded
  --------------
     3000
  (1 row)

=> --Now see what has been loaded
=> SELECT * FROM t WHERE i < 5 ORDER BY i,node ;
  i | text                      | node
-------------------------------
  0 | megabits embanks           | v_vmart_node0001

     9000
  (1 row)
Parser Implementation

The following code shows the source of the FileSource class that reads a file from the host file system. The constructor, which is called by FileSourceFactory.prepareUDSources(), gets the absolute path for the file containing the data to be read. The setup() method opens the file and the destroy() method closes it. The process() method reads from the file into a buffer provided by the instance of the DataBuffer class passed to it as a parameter. If the read operation filled the output buffer, it returns OUTPUT_NEEDED. This value tells Vertica to call the method again after the next stage of the load has processed the output buffer. If the read did not fill the output buffer, then process() returns DONE to indicate it has finished processing the data source.

```java
package com.mycompany.UDL;

import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileReader;
import java.io.IOException;
import java.io.RandomAccessFile;
import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSource extends UDSource {

    private String filename; // The file for this UDSource to read
    private RandomAccessFile reader; // handle to read from file

    // The constructor just stores the absolute filename of the file it will // read.
```
public FileSource(String filename) {
    super();
    this.filename = filename;
}

// Called before Vertica starts requesting data from the data source.
// In this case, setup needs to open the file and save to the reader
// property.
@Override
public void setup(ServerInterface srvInterface) throws UdfException{
    try {
        reader = new RandomAccessFile(new File(filename), "r");
    } catch (FileNotFoundException e) {
        // In case of any error, throw a UDFException. This will terminate
        // the data load.
        String msg = e.getMessage();
        throw new UdfException(0, msg);
    }
}

// Called after data has been loaded. In this case, close the file handle.
@Override
public void destroy(ServerInterface srvInterface) throws UdfException {
    if (reader != null) {
        try {
            reader.close();
        } catch (IOException e) {
            String msg = e.getMessage();
            throw new UdfException(0, msg);
        }
    }
}

@Override
public StreamState process(ServerInterface srvInterface, DataBuffer output)
    throws UdfException {
    // Read up to the size of the buffer provided in the DataBuffer.buf
    // property. Here we read directly from the file handle into the
    // buffer.
    long offset;
    try {
        offset = reader.read(output.buf, output.offset,
            output.buf.length-output.offset);
    } catch (IOException e) {
        // Throw an exception in case of any errors.
        String msg = e.getMessage();
        throw new UdfException(0, msg);
    }

    // Update the number of bytes processed so far by the data buffer.
    output.offset += offset;

    // See end of data source has been reached, or less data was read
    // than can fit in the buffer
    if(offset == -1 || offset < output.buf.length) {
        // No more data to read.
        return StreamState.DONE;
    } else {
        // Tell Vertica to call again when buffer has been emptied
Factory Implementation

The following code is a modified version of the example Java UDsource function provided in the Java UDx support package. You can find the full example in /opt/vertica/sdk/examples/JavaUDx/UDLFuctions/com/vertica/JavaLibs/FileSourceFactory.java. Its override of the plan() method verifies that the user supplied the required file parameter. If the user also supplied the optional nodes parameter, this method verifies that the nodes exist in the Vertica cluster. If there is a problem with either parameter, the method throws an exception to return an error to the user. If there are no issues with the parameters, the plan() method stores their values in the plan context object.

```java
package com.mycompany.UDL;
import java.util.ArrayList;
import java.util.Vector;
import com.vertica.sdk.NodeSpecifyingPlanContext;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.SourceFactory;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;
public class FileSourceFactory extends SourceFactory {
    // Called once on the initiator host to do initial setup. Checks
    // parameters and chooses which nodes will do the work.
    @Override
    public void plan(ServerInterface srvInterface,
                     NodeSpecifyingPlanContext planCtxt) throws UdfException {
        String nodes; // stores the list of nodes that will load data
        // Get copy of the parameters the user supplied to the UDSource
        // function call.
        ParamReader args = srvInterface.getParamReader();
        // A list of nodes that will perform work. This gets saved as part
        // of the plan context.
        ArrayList<String> executionNodes = new ArrayList<String>();
        // First, ensure the user supplied the file parameter
        if (!args.containsParameter("file")) {
            // Without a file parameter, we cannot continue. Throw an
```
// exception that will be caught by the Java U Dx framework.
throw new UdfException(0, "You must supply a file parameter");
}

// If the user specified nodes to read the file, parse the
// comma-separated list and save. Otherwise, assume just the
// Initiator node has the file to read.
if (args.containsParameter("nodes")) {
    nodes = args.getString("nodes");

    // Get list of nodes in cluster, to ensure that the node the
    // user specified actually exists. The list of nodes is available
    // from the planCtx (plan context) object,
    ArrayList<String> clusterNodes = planCtx.getClusterNodes();

    // Parse the string parameter "nodes" which
    // is a comma-separated list of node names.
    String[] nodeNames = nodes.split(",");

    for (int i = 0; i < nodeNames.length; i++) {
        // See if the node the user gave us actually exists
        if (clusterNodes.contains(nodeNames[i]))
            // Node exists. Add it to list of nodes.
            executionNodes.add(nodeNames[i]);
        else {
            // User supplied node that doesn't exist. Throw an
            // exception so the user is notified.
            String msg = String.format("Specified node '%s' but no" +
                " node by that name is available. Available nodes " +
                "are \"%s\".",
                nodeNames[i], clusterNodes.toString());
            throw new UdfException(0, msg);
        }
    }
} else {
    // User did not supply a list of node names. Assume the initiator
    // is the only host that will read the file. The srvInterface
    // instance passed to this method has a getter for the current
    // node.
    executionNodes.add(srvInterface.getCurrentNodeName());
}

// Set the target node(s) in the plan context
planCtx.addTargetNodes(executionNodes);

// Set parameters for each node reading data that tells it which
// files it will read. In this simple example, just tell it to
// read all of the files the user passed in the file parameter
String files = args.getString("file");

// Get object to write parameters into the plan context object.
ParamWriter nodeParams = planCtx.getWriter();

// Loop through list of execution nodes, and add a parameter to plan
// context named for each node performing the work, which tells it the
// list of files it will process. Each node will look for a
// parameter named something like "filesForV_vmart_node0002" in its
// prepareUDSources() method.
for (int i = 0; i < executionNodes.size(); i++) {
    nodeParams.setString("filesFor" + executionNodes.get(i), files);
Called on each host that is reading data from a source. This method returns an array of UDSource objects that process each source.

```java
@Override
public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface, 
                                             NodeSpecifyingPlanContext planCtxt) throws UdfException {

    // An array to hold the UDSource subclasses that we instantiate
    ArrayList<UDSource> retVal = new ArrayList<UDSource>();

    // Get the list of files this node is supposed to process. This was
    // saved by the plan() method in the planContext
    String myName = srvInterface.getCurrentNodeName();
    ParamReader params = planCtxt.getReader();
    String fileNames = params.getString("filesFor" + myName);

    // Note that you can also be lazy and directly grab the parameters
    // the user passed to the UDSource function in the COPY statement directly
    // by getting parameters from the ServerInterface object. I.e.:
    // String fileNames = srvInterface.getParamReader().getString("file");

    String[] fileList = fileNames.split(",");
    for (int i = 0; i < fileList.length; i++) {
        // Instantiate a FileSource object (which is a subclass of UDSource)
        // to read each file. The constructor for FileSource takes the
        // file name of the
        retVal.add(new FileSource(fileList[i]));
    }

    // Return the collection of FileSource objects. They will be called,
    // in turn, to read each of the files.
    return retVal;
}
```

// Declares which parameters that this factory accepts.
@Override
public void getParameterType(ServerInterface srvInterface, 
                             SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(65000, "file");
    parameterTypes.addVarchar(65000, "nodes");
}
```

**Filter Example: ReplaceCharFilter**

The example in this section demonstrates creating a UDFilter that replaces any occurrences of a character in the input stream with another character in the output stream. This example is highly simplified and assumes the input stream is ASCII data.
Always remember that the input and output streams in a UDFilter are actually binary data. If you are performing character transformations using a UDFilter, convert the data stream from a string of bytes into a properly encoded string. For example, your input stream might consist of UTF-8 encoded text. If so, be sure to transform the raw binary being read from the buffer into a UTF string before manipulating it.

Loading and Using the Example

The example UDFilter has two required parameters. The from_char parameter specifies the character to be replaced, and the to_char parameter specifies the replacement character. Load and use the ReplaceCharFilter UDFilter as follows:

```sql
-> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLlib.jar'
-> LANGUAGE 'JAVA';
CREATE LIBRARY
-> CREATE FILTER ReplaceCharFilter as LANGUAGE 'JAVA'
-> name 'com.mycompany.UDL.ReplaceCharFilterFactory' library JavaLib;
CREATE FILTER FUNCTION
-> CREATE TABLE t (text VARCHAR);
CREATE TABLE
-> COPY t FROM STDIN WITH FILTER ReplaceCharFilter(from_char='a', to_char='z');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
-> Mary had a little lamb
-> a man, a plan, a canal, Panama
-> 
-> SELECT * FROM t;
   text
---------------------
 Mzry hzd z little lzmb
 z mzn, z plzn, z cznzl, Pznzmz
(2 rows)
```

```
=> -- Calling the filter with incorrect parameters returns errors
=> COPY t from stdin with filter ReplaceCharFilter();
ERROR 3999: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined Object [ReplaceCharFilter], error code: 0
com.vertica.sdk.UdfException: You must supply two parameters to ReplaceChar: 'from_char' and 'to_char'

```
Parser Implementation

The ReplaceCharFilter class reads the data stream, replacing each occurrence of a user-specified character with another character.

```java
package com.vertica.JavaLibs;
import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.InputState;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDFilter;
public class ReplaceCharFilter extends UDFilter {
    private byte[] fromChar;
    private byte[] toChar;

    public ReplaceCharFilter(String fromChar, String toChar){
        // Stores the from char and to char as byte arrays. This is
        // not a robust method of doing this, but works for this simple
        // example.
        this.fromChar= fromChar.getBytes();
        this.toChar=toChar.getBytes();
    }
    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input, InputState input_, DataBuffer output) {
        // Check if there is no more input and the input buffer has been completely
        // processed. If so, filtering is done.
        if (input_.state == InputState.END_OF_FILE && input.buf.length == 0) {
            return StreamState.DONE;
        } // Get current position in the input buffer
        int offset = output.offset;

        // Determine how many bytes to process. This is either until input
        // buffer is exhausted or output buffer is filled
        int limit = Math.min((input.buf.length - input.offset),
                                (output.buf.length - output.offset));

        for (int i = input.offset; i < limit; i++) {
            // This example just replaces each instance of from_char
            // with to_char. It does not consider things such as multi-byte
            // UTF-8 characters.
            if (input.buf[i] == fromChar[0]) {
                output.buf[i+offset] = toChar[0];
            } else {
                // Did not find from_char, so copy input to the output
                output.buf[i+offset]=input.buf[i];
            }
        }
    }
}
```
input.offset += limit;
output.offset += input.offset;

if (input.buf.length - input.offset < output.buf.length - output.offset) {
    return StreamState.INPUT_NEEDED;
} else {
    return StreamState.OUTPUT_NEEDED;
}

Factory Implementation

ReplaceCharFilterFactory requires two parameters (from_char and to_char). The plan() method verifies that these parameters exist and are single-character strings. The method then stores them in the plan context. The prepare() method gets the parameter values and passes them to the ReplaceCharFilter objects, which it instantiates, to perform the filtering.

```java
package com.vertica.JavaLibs;
import java.util.ArrayList;
import java.util.Vector;
import com.vertica.sdk.FilterFactory;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDFilter;
import com.vertica.sdk.UdfException;

public class ReplaceCharFilterFactory extends FilterFactory {
    // Run on the initiator node to perform varification and basic setup.
    @Override
    public void plan(ServerInterface srvInterface, PlanContext planCtx) throws UdfException {
        ArrayList<String> args = srvInterface.getParamReader().getParamNames();

        // Ensure user supplied two arguments
        if (!args.contains("from_char") && args.contains("to_char")) {
            throw new UdfException(0, "You must supply two parameters" + " to ReplaceChar: 'from_char' and 'to_char'");
        }

        // Verify that the from_char is a single character.
        String fromChar = srvInterface.getParamReader().getString("from_char");
        if (fromChar.length() != 1) {
            String message = String.format("Replacechar expects a single " + "character in the 'from_char' parameter. Got length %d", fromChar.length());
            throw new UdfException(0, message);
        }
    }
}
```

```java
// Save the from character in the plan context, to be read by
// prepare() method.
planCtxt.getWriter().setString("fromChar",fromChar);

// Ensure to character parameter is a single character
String toChar = srvInterface.getParamReader().getString("to_char");
if (toChar.length() != 1) {
    String message = String.format("ReplaceChar expects a single 
    + "character in the 'to_char' parameter. Got length %d",
    toChar.length());
    throw new UdfException(0, message);
}
// Save the to character in the plan data
planCtxt.getWriter().setString("toChar",toChar);
}

// Called on every host that will filter data. Must instantiate the
// UDFilter subclass.
@Override
public UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt)
    throws UdfException {
    // Get data stored in the context by the plan() method.
    String fromChar = planCtxt.getWriter().getString("fromChar");
    String toChar = planCtxt.getWriter().getString("toChar");

    // Instantiate a filter object to perform filtering.
    return new ReplaceCharFilter(fromChar, toChar);
}

// Describe the parameters accepted by this filter.
@Override
public void getParameterType(ServerInterface srvInterface,
    SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "from_char");
    parameterTypes.addVarchar(1, "to_char");
}
```

**Parser Example: Numeric Text**

This NumericTextParser example parses integer values spelled out in words rather than digits (for example "one two three" for one-hundred twenty three). The parser:

- Accepts a single parameter to set the character that separates columns in a row of data. The separator defaults to the pipe (|) character.
- Ignores extra spaces and the capitalization of the words used to spell out the digits.
- Recognizes the digits using the following words: zero, one, two, three, four, five, six, seven, eight, nine.
- Assumes that the words spelling out an integer are separated by at least one space.
• Rejects any row of data that cannot be completely parsed into integers.
• Generates an error, if the output table has a non-integer column.

Loading and Using the Example

Load and use the parser as follows:

```sql
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE PARSER NumericTextParser AS LANGUAGE 'java'
  -> NAME 'com.myCompany.UDParser.NumericTextParserFactory'
  -> LIBRARY JavaLib;
CREATE PARSER FUNCTION

=> CREATE TABLE t (i INTEGER);
CREATE TABLE
=> COPY t FROM STDIN WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
  >> One
  >> Two
  >> One Two Three
  >> \.
  => SELECT * FROM t ORDER BY i;
  1
  ----- 1
  2
  123
(3 rows)
  => DROP TABLE t;
DROP TABLE
  => -- Parse multi-column input
  => CREATE TABLE t (i INTEGER, j INTEGER);
CREATE TABLE
  => COPY t FROM stdin WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
  >> One | Two
  >> Two | Three
  >> One Two Three | Four Five Six
  >> \.
  => SELECT * FROM t ORDER BY i;
  i | j
  -----------
  1 | 2
  2 | 3
  123 | 456
(3 rows)
  => TRUNCATE TABLE t;
TRUNCATE TABLE
  => -- Use alternate separator character
  => COPY t FROM STDIN WITH PARSER NumericTextParser(separator='*');
```
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

```plaintext
>> Five * Six
>> seven * eight
>> nine * one zero
>> \
=> SELECT * FROM t ORDER BY i;
i | j
---+----
  5 | 6
  7 | 8
  9 | 10
(3 rows)
```

```sql
=> TRUNCATE TABLE t;
TRUNCATE TABLE
```

```plaintext
=> -- Rows containing data that does not parse into digits is rejected.
=> DROP TABLE t;
DROP TABLE
=> CREATE TABLE t (i INTEGER);
CREATE TABLE
=> COPY t FROM STDIN WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

```plaintext
>> One Zero Zero
>> Two Zero Zero
>> Three Zed Zed
>> Four Zero Zero
>> Five Zed Zed
>> \
SELECT * FROM t ORDER BY i;
i |-----
   | 100
   | 200
   | 400
(3 rows)
```

```plaintext
=> -- Generate an error by trying to copy into a table with a non-integer column
=> DROP TABLE t;
DROP TABLE
=> CREATE TABLE t (i INTEGER, j VARCHAR);
CREATE TABLE
=> COPY t FROM STDIN WITH PARSER NumericTextParser();
vsq1:UDParse.sql:94: ERROR 3399: Failure in UDx RPC call

Parser Implementation

The following code implements the parser.

```
package com.myCompany.UDParser;

import java.util.Arrays;
import java.util.List;
import java.util.regex.Pattern;
import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.DestroyInvocation;
import com.vertica.sdk.RejectedRecord;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.InputState;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.StreamWriter;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;

public class NumericTextParser extends UDParser {

    private String separator; // Holds column separator character
    // List of strings that we accept as digits.
    private List<String> numbers = Arrays.asList("zero", "one",
        "two", "three", "four", "five", "six", "seven",
        "eight", "nine");

    // Hold information about the last rejected row.
    private String rejectedReason;
    private String rejectedRow;

    // Constructor gets the separator character from the Factory's prepare() method.
    public NumericTextParser(String sepparam) {
        super();
        this.separator = sepparam;
    }

    // Called to perform the actual work of parsing. Gets a buffer of bytes to turn into tuples.
    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input,
        InputState input_state) throws UdfException, DestroyInvocation {

        int i = input.offset; // Current position in the input buffer
        // Flag to indicate whether we just found the end of a row.
        boolean lastCharNewline = false;
        // Buffer to hold the row of data being read.
        StringBuffer line = new StringBuffer();

        // Continue reading until end of buffer.
        for(; i < input.buf.length; i++){
            // Loop through input until we find a linebreak: marks end of row
```
char inchar = (char) input.buf[i];
// Note that this isn't a robust way to find rows. It should
// accept a user-defined row separator. Also, the following
// assumes ASCII line break methods, which isn't a good idea
// in the UTF world. But it is good enough for this simple example.
if (inchar != '\n' & & inchar != '\r') {
    // Keep adding to a line buffer until a full row of data is read
    line.append(inchar);
    lastCharNewline = false; // Last character not a new line
} else {
    // Found a line break. Process the row.
    lastCharNewline = true; // indicate we got a complete row
    // Update the position in the input buffer. This is updated
    // whether the row is successfully processed or not.
    input.offset = i+1;
    // Call processRow to extract values and write tuples to the
    // output. Returns false if there was an error.
    if (!processRow(line)) {
        // Processing row failed. Save bad row to rejectedRow field
        // and return to caller indicating a rejected row.
        rejectedRow = line.toString();
        // Update position where we processed the data.
        return StreamState.REJECT;
    }
    line.delete(0, line.length()); // clear row buffer
}

// At this point, process() has finished processing the input buffer.
// There are two possibilities: need to get more data
// from the input stream to finish processing, or there is
// no more data to process. If at the end of the input stream and
// the row was not terminated by a linefeed, it may need
// to process the last row.
if (input_state == InputState.END_OF_FILE & & lastCharNewline) {
    // End of input and it ended on a newline. Nothing more to do
    return StreamState.DONE;
} else if (input_state == InputState.END_OF_FILE & & !lastCharNewline) {
    // At end of input stream but didn't get a final newline. Need to
    // process the final row that was read in, then exit for good.
    if (line.length() == 0) {
        // Nothing to process. Done parsing.
        return StreamState.DONE;
    }
    // Need to parse the last row, not terminated by a linefeed. This
    // can occur if the file being read didn't have a final line break.
    if (processRow(line)) {
        return StreamState.DONE;
    } else {
        // Processing last row failed. Save bad row to rejectedRow field
        // and return to caller indicating a rejected row.
        rejectedRow = line.toString();
        // Tell Vertica the entire buffer was processed so it won't
        // call again to have the line processed.
        input.offset = input.buf.length;
        return StreamState.REJECT;
    }
} else {
    // Stream is not fully read, so tell Vertica to send more. If
Vertica Documentation
Extending Vertica

// process() didn't get a complete row before it hit the end of the
// input buffer, it will end up re-processing that segment again
// when more data is added to the buffer.
return StreamState.INPUT_NEEDED;
}

// Breaks a row into columns, then parses the content of the
// columns. Returns false if there was an error parsing the
// row, in which case it sets the rejected row to the input
// line. Returns true if the row was successfully read.
private boolean processRow(StringBuffer line)
throws UdfException, DestroyInvocation {

String[] columns = line.toString().split(Pattern.quote(separator));
// (Loop through the columns, decoding their contents)
for (int col = 0; col < columns.length; col++) {
    // Call decodeColumn to extract value from this column
    Integer colval = decodeColumn(columns[col]);
    if (colval == null) {
        // Could not parse one of the columns. Indicate row should
        // be rejected.
        return false;
    }
}
// Column parsed OK. Write it to the output. writer is a field
// provided by the parent class. Since this parser only accepts
// integers, there is no need to verify that data type of the parsed
// data matches the data type of the column being written. In your
// UDParsers, you may want to perform this verification.
writer.setLong(col, colval);
}
// Done with the row of data. Advance output to next row.

// Note that this example does not verify that all of the output columns
// have values assigned to them. If there are missing values at the
// end of a row, they get automatically get assigned a default value
// (0 for integers). This isn't a robust solution. Your UDParse
// should perform checks here to handle this situation and set values
// (such as null) when appropriate.
writer.next();
return true; // Successfully processed the row.
}

// Gets a string with text numerals, i.e. "One Two Five Seven" and turns
// it into an integer value, i.e. 1257. Returns null if the string could not
// be parsed completely into numbers.
private Integer decodeColumn(String text) {
    int value = 0; // Hold the value being parsed.

    // Split string into individual words. Eat extra spaces.
    String[] words = text.toLowerCase().trim().split("\s+");

    // Loop through the words, matching them against the list of
    // digit strings.
    for (int i = 0; i < words.length; i++) {
        if (numbers.contains(words[i])) {
            // Matched a digit. Add it to the value.
            int digit = numbers.indexOf(words[i]);
            value = (value * 10) + digit;
        } else {
            // The string didn't match one of the accepted string values
            break;
        }
    }
    return value;
}
ParserFactory Implementation

The following code implements the parser factory.

NumericTextParser accepts a single optional parameter named separator. This parameter is defined in the getParameterType() method, and the plan() method stores its value. NumericTextParser outputs only integer values. Therefore, if the output table contains a column whose data type is not integer, the getParserReturnType() method throws an exception.

```java
package com.myCompany.UDParser;
import java.util.regex.Pattern;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ParserFactory;
import com.vertica.sdk.PerColumnParamReader;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;
import com.vertica.sdk.VerticaType;
```
public class NumericTextParserFactory extends ParserFactory {

    // Called once on the initiator host to check the parameters and set up the
    // context data that hosts performing processing will need later.
    @Override
    public void plan(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext planCtxt) {
        String separator = "|"; // assume separator is pipe character
        // See if a parameter was given for column separator
        ParamReader args = srvInterface.getParamReader();
        if (args.containsParameter("separator")) {
            separator = args.getString("separator");
            if (separator.length() > 1) {
                throw new UdfException(0, "Separator parameter must be a single character");
            }
            if (Pattern.quote(separator).matches("[a-zA-Z]")) {
                throw new UdfException(0, "Separator parameter cannot be a letter");
            }
        }
        // Save separator character in the Plan Data
        ParamWriter context = planCtxt.getWriter();
        context.setString("separator", separator);
    }

    // Define the data types of the output table that the parser will return.
    // Mainly, this just ensures that all of the columns in the table which
    // is the target of the data load are integer.
    @Override
    public void getParserReturnType(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext planCtxt, SizedColumnTypes argTypes, SizedColumnTypes returnType) {
        // Get access to the output table's columns
        for (int i = 0; i < argTypes.getColumnCount(); i++) {
            if (argTypes.getColumnType(i).isInt()) {
                // Column is integer... add it to the output
                returnType.addInt(argTypes.getColumnName(i));
            } else {
                // Column isn't an int, so throw an exception.
                // Technically, not necessary since the
                // Udx framework will automatically error out when it sees a
                // Discrepancy between the type in the target table and the
                // types declared by this method. Throwing this exception will
                // provide a clearer error message to the user.
                String message = String.format("Column %d of output table is not an Int", i + 1);
                throw new UdfException(0, message);
            }
        }
    }

    // Instantiate the UDF parser subclass named NumericTextParser. Passes the
public UDFParser prepare(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext planCtxt, SizedColumnTypes returnType) throws UdfException {
    // Get the separator character from the context
    String separator = planCtxt.getReader().getString("separator");
    return new NumericTextParser(separator);
}

// Describe the parameters accepted by this parser.
@Override
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "separator");
}
=> COPY mountains FROM '/opt/vertica/packages/flextable/examples/mountains.json'
-> WITH PARSER JsonParser();
- [ RECORD 1 ] --
Rows Loaded | 2

=> SELECT * from mountains;
- [ RECORD 1 ] ---------
name | Everest
type | mountain
height | 29029
- [ RECORD 2 ] ---------
name | Mt St Helens
type | volcano
height | 

The data file contains a value (hike_safety) that was not loaded because the table definition did not include that column. The data file follows:

```json
{
  "name": "Everest", "type": "mountain", "height": 29029, "hike_safety": 34.1
}
{
  "name": "Mt St Helens", "type": "volcano", "hike_safety": 15.4
}
```

**Implementation**

The following code shows the `process()` method from `JsonParser.java`. The parser attempts to read the input into a `Map`. If the read is successful, the JSON Parser calls `setRowFromMap()`:

```java
@override
public StreamState process(ServerInterface srvInterface, DataBuffer input,
InputState inputState) throws UdfException, DestroyInvocation {
    clearReject();
    StreamWriter output = getStreamWriter();

    while (input.offset < input.buf.length) {
        ByteBuffer lineBytes = consumeNextLine(input, inputState);

        if (lineBytes == null) {
            return StreamState.INPUT_NEEDED;
        }

        String lineString = StringUtils.newString(lineBytes);

        try {
            Map<String, Object> map = gson.fromJson(lineString, parseType);

            if (map == null) {
                continue;
            }
```

Vertica Analytic Database (9.3.x)
output.setRowFromMap(map);
// No overrides needed, so just call next() here.
output.next();
} catch (Exception ex) {
    setReject(lineString, ex);
    return StreamState.REJECT;
}
}

The factory, JsonParserFactory.java, instantiates and returns a parser in the prepare() method. No additional setup is required.

## Developing UDLs in Python

### Python API

The Vertica Python SDK supports developing UDLs. The Python SDK enables you to create filters and parsers.

For information on setting up a Python development environment and compiling and packaging libraries, see Developing with the Python SDK.

### Filter Classes

This section describes information that is specific to the Python API. See User-Defined Filter for general information about implementing the UDFilter and FilterFactory classes.

### UDFilter API

The API provides the following methods for extension by subclasses:

class PyUDFilter(vertica_sdk.UDFilter):
    def __init__(self):
        pass
    def setup(self, srvInterface):
        pass
    def process(self, srvInterface, inputbuffer, outputbuffer, inputstate):
        # User process data here, and put into outputbuffer.
In Python, the `process()` method requires both an input buffer as well as a corresponding output buffer. The input buffer represents the source of the information that you want to filter. The output buffer delivers the filtered information to Vertica.

**FilterFactory API**

The API provides the following methods for extension by subclasses:

```python
class PyFilterFactory(vertica_sdk.SourceFactory):
    def __init__(self):
        pass
    def plan(self):
        pass
    def prepare(self, planContext):
        # User implement the function to create PyUDSources.
        pass
```

**Parser Classes**

This section describes information that is specific to the Python API. See User-Defined Parser for general information about implementing the UDPARSER and ParserFactory classes.

**UDParser API**

The API provides the following methods for extension by subclasses:

```python
class PyUDParser(vertica_sdk.UDSource):
    def __init__(self):
        pass
    def setup(srvInterface, returnType):
        pass
    def process(self, srvInterface, inputbuffer, inputstate, streamwriter):
        # User implement process function.
        # User reads data from inputbuffer and parse the data.
        # Rows are emitted via the streamwriter argument
        return StreamState.DONE
```
In Python, the `process()` method requires both an **input buffer** as well as a corresponding **output buffer**. The input buffer represents the source of the information that you want to parse. The output buffer delivers the filtered information to Vertica.

In the event the filter rejects a record, use the method `REJECT()` to identify the rejected data and the reason for the rejection.

**ParserFactory API**

The API provides the following methods for extension by subclasses:

```python
class PyParserFactory(vertica_sdk.SourceFactory):
    def __init__(self):
        pass
    def plan(self):
        pass
    def prepareUDSources(self, srvInterface):
        # User implement the function to create PyUDParser.
        pass
```

**InputBuffer Class**

The `InputBuffer` class decodes and translates raw data streams depending on the specified encoding. Python natively supports a **wide range of languages and codecs**. The `InputBuffer` is an argument to the `process()` method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the `InputBuffer`.

If you do not specify a value for `setEncoding()`, Vertica assumes a value of **NONE**.

```python
class InputBuffer:
    def getSize(self):
        ...
    def getOffset(self):
        ...

    def setEncoding(self, encoding):
        """
        Set the encoding of the data contained in the underlying buffer
        """
        pass

    def peek(self, length = None):
        """
        Copy data from the input buffer into Python.
        If no encoding has been specified, returns a Bytes object containing raw data.
        Otherwise, returns data decoded into an object corresponding to the specified encoding
        (for example, 'utf-8' would return a string).
        """
        pass
```
If length is None, returns all available data. If length is not None then the length of the returned object is at most what is requested. This method does not advance the buffer offset.

```python
def read(self, length = None):
    """
    See peek(). This method does the same thing as peek(), but it also advances the buffer offset by the number of bytes consumed.
    """
    pass
```

# Advances the DataBuffer offset by a number of bytes equal to the result # of calling "read" with the same arguments.
# def advance(self, length = None):
#     """
#     Advance the buffer offset by the number of bytes indicated by the length and encoding arguments. See peek().
#     """
#     pass

OutputBuffer Class

The OutputBuffer class encodes and outputs data from Python to Vertica. The OutputBuffer is an argument to the process() method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the OutputBuffer to manipulate and encode data.

The write() method transfers all data from the Python client to Vertica. The output buffer can accept any size object. If a user writes an object to the OutputBuffer larger than Vertica can immediately process, Vertica stores the overflow. During the next call to process(), Vertica checks for leftover data. If there is any, Vertica copies it to the DataBuffer before determining whether it needs to call process() from the Python UDL.

If you do not specify a value for setEncoding(), Vertica assumes a value of NONE.

```python
class OutputBuffer:
    def setEncoding(self, encoding):
        """
        Specify the encoding of the data which will be written to the underlying buffer
        """
        pass
    def write(self, data):
        """
        Transfer bytes from the data object into Vertica.
        If an encoding was specified via setEncoding(), the data object will be converted to bytes using the specified encoding.
        """
```
Otherwise, the data argument is expected to be a Bytes object and is copied to the underlying buffer.
Connecting to Vertica

This book explains several methods of connecting to Vertica, including:

- Directly connecting to Vertica using the vsql client application.
- Installing and configuring the Vertica client libraries to allow client applications to access Vertica.
- Developing your own client applications using the Vertica client libraries.

**Using vsql**

vsq1 is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.

If you are using the vsq1 client installed on the server, then you can connect from the:

- Administration Tools
- Linux command line

You can also install the vsq1 client for other supported platforms.
General Notes

- SQL statements can be spread over several lines for clarity.
- vsql can handle input and output in UTF-8 encoding. The terminal emulator running vsql must be set up to display the UTF-8 characters correctly. The following example shows the settings in PuTTY:

![PuTTY Reconfiguration](image)

See also Best Practices for Working with Locales.

- Cancel SQL statements by typing Ctrl+C.
- Traverse command history by typing Ctrl+R.
- When you disconnect a user session, any transactions in progress are automatically rolled back.
- To view wide result sets, use the Linux less utility to truncate long lines.

1. Before connecting to the database, specify that you want to use less for query output:
2. Connect to the database.
3. Query a wide table:

   => select * from wide_table;

4. At the less prompt, type:

   -S

   - If a shell running vsql fails (crashes or freezes), the vsql processes continue to run even if you stop the database. In that case, log in as root on the machine on which the shell was running and manually kill the vsql process. For example:

   ```
   # ps -ef | grep vertica
   =>
   fred 2401 1 0 06:02 pts/1 00:00:00 /opt/vertica/bin/vsql -p 5433 -h test01_site01 quick_start_single
   =>
   # kill -9 2401
   ```
Installing the vsql Client

The vsql client is installed as part of the Vertica server rpm. It is also available as a download for other Unix-based systems.

Unix Installation

1. Download the appropriate vsql client for your system.

   **Important:**
   Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and vsql.

2. Extract the tarball. The tarball is structured to extract into /opt/vertica if you extract it at the root (/) of the drive.
3. (Optional) Add the vsql client's directory to your PATH.
4. Make the vsql client executable. For example, to allow all users to execute vsql:

   ```bash
   $ chmod ugo+x vsql_version
   ```
5. Set your shell locale to a locale supported by vsql. For example, in your .profile, add: `export LANG=en_US.UTF-8`

Windows Installation

vsql on Windows is installed as part of the Windows Client Driver package. For installation details, see The Vertica Client Drivers and Tools for Windows.

See Using vsql for Windows Users for details on using vsql in a Windows console.
Connecting From the Administration Tools

You can use the Administration Tools to connect to a database using vsq1 on any node in the cluster.

1. Log in as the database administrator user; for example, dbadmin.

   Note:
   Vertica does not allow users with root privileges to connect to a database for security reasons.

2. Run the Administration Tools.
   /opt/vertica/bin/admintools

3. On the Main Menu, select Connect to Database.

   Main Menu
   1. View Database Cluster State
   2. Connect to Database
   3. Start Database
   4. Stop Database
   5. Restart Vertica on Host
   6. Configuration Menu
   7. Advanced Menu
   8. Help Using the Administration Tools
   E. Exit

4. Supply the database password if asked:

   Password:

   When you create a new user with the CREATE USER command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the ALTER USER command.

5. The Administration Tools connect to the database and transfer control to vsq1.
Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit

Note:
See Meta-Commands for the various commands you can run while connected to the database through the Administration Tools.
Connecting from the Command Line

You can connect to a database using vsqI from the command line on multiple client platforms.

If the connection cannot be made for any reason—for example, you have insufficient privileges, or the server is not running on the targeted host—vsqI returns an error and terminates.

Syntax

```
/opt/vertica/bin/vsql [-h host] [ option...] [ dbname [ username ] ]
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>host</code></td>
<td>Optional if you connect to a local server. You can provide an IPv4 or IPv6 IP address or a host name. For Vertica servers that have both IPv4 and IPv6 addressed and you have provided a host name instead of an IP address, you can prefer to use an IPv4 address with the -4 option and to use the IPv6 address with the -6 option if the DNS is configured to provide both IPv4 and IPv6 addresses. If you are using IPv6 and provide an IP address, you must append the address with an <code>%interface name</code>.</td>
</tr>
<tr>
<td><code>option</code></td>
<td>One or more vsqI Command-Line Options If the database is password protected, you must specify the -w or --password command line option.</td>
</tr>
<tr>
<td><code>dbname</code></td>
<td>The name of the target database, by default your Linux user name.</td>
</tr>
<tr>
<td><code>username</code></td>
<td>A database username, by default your Linux user name.</td>
</tr>
</tbody>
</table>
Exit Codes

`vsql` returns 0 to the shell when it terminates normally. Otherwise, it returns one of the following:

- 1: A fatal error occurred—for example, out of memory or file not found.
- 2: The connection to the server went bad and the session was not interactive
- 3: An error occurred in a script and the variable `ON_ERROR_STOP` was set.
- Unrecognized words in the command line might be interpreted as database or user names.

Examples

The following example shows how to capture error messages by redirecting `vsql` output to the output file `retail_queries.out`:

```
$ vsql --echo-all < retail_queries.sql > retail_queries.out 2>&1
```

Command-Line Options

This section contains the command-line options for `vsql`.

**General Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--command</code></td>
<td>Runs one command and exits. This command is useful in shell scripts.</td>
</tr>
<tr>
<td><code>--dbname</code></td>
<td>Specifies the name of the database to which you want to connect. Using this command is equivalent to specifying <code>dbname</code> as the first non-option argument on the command line.</td>
</tr>
<tr>
<td><code>--file</code></td>
<td>Uses the <code>filename</code> as the source of commands instead of</td>
</tr>
</tbody>
</table>
**-f filename**  
Reading commands interactively. After the file is processed, vsql terminates.

**--help**  
Displays help about vsql command line arguments and exits.

**--timing**  
Enables the `\timing` meta-command.

**--list**  
Returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command `\list`.

**--set assignment --variable assignment**  
Performs a variable assignment, like the vsql command `\set`.

**--version**  
Prints the vsql version and exits.

**--no-vsqlr**  
Disables all command line editing and history functionality.

## Connection Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-4</td>
<td>When resolving hostnames in dual stack environments, prefer IPv4 addresses.</td>
</tr>
<tr>
<td>-6</td>
<td>When resolving hostnames in dual stack environments, prefer IPv6 addresses.</td>
</tr>
<tr>
<td>-B server:port[,]...</td>
<td>Sets connection backup server/port. Use comma-separated multiple hosts (default: not set). If using an IPv6 address, enclose the address in brackets ([, ]) and place the port outside of the brackets. For example <code>\B [2620:0:a13:8a4:9d9f:e0e3:1181:7f51]:5433</code></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>--host</strong> hostname</td>
<td>Specifies the host name of the machine on which the server is running.</td>
</tr>
<tr>
<td><strong>-h hostname</strong></td>
<td></td>
</tr>
<tr>
<td><strong>-k krb-service</strong></td>
<td>Provides the service name portion of the Kerberos principal (default: vertica). Using -k is equivalent to using the drivers' KerberosServiceName connection string.</td>
</tr>
<tr>
<td><strong>-K krb-host</strong></td>
<td>Provides the instance or host name portion of the Kerberos principal. -K is equivalent to the drivers' KerberosHostName connection string.</td>
</tr>
<tr>
<td><strong>--sslmode</strong></td>
<td>Specifies the policy for making SSL connections to the server. Options are require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.</td>
</tr>
<tr>
<td><strong>-m</strong></td>
<td></td>
</tr>
<tr>
<td><strong>--port</strong> port</td>
<td>Specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.</td>
</tr>
<tr>
<td><strong>-p port</strong></td>
<td></td>
</tr>
<tr>
<td><strong>--username</strong> username</td>
<td>Connects to the database as the user username instead of the default.</td>
</tr>
<tr>
<td><strong>-U username</strong></td>
<td></td>
</tr>
<tr>
<td><strong>-w password</strong></td>
<td>Specifies the password for a database user.</td>
</tr>
<tr>
<td><strong>--password</strong></td>
<td></td>
</tr>
<tr>
<td><strong>-W</strong></td>
<td>Forces vsql to prompt for a password before connecting to a database. The password is not displayed on the screen.</td>
</tr>
</tbody>
</table>

**Note:**
You can only use load balancing with one address family in dual stack environments. For example, if you've configured load balancing for IPv6 addresses, then when an IPv4 client connects and requests load balancing the server does not allow it.

**Note:**
Using this command-line option displays the database password in plain text. Use it with care, particularly if you are connecting as the database administrator, to avoid exposing sensitive information.
This option remains set for the entire session, even if you change the database connection with the meta-command `\connect`.

### Output Formatting

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--no-align</code> -A</td>
<td>Switches to unaligned output mode. (The default output mode is aligned.)</td>
</tr>
<tr>
<td>-b</td>
<td>Beep on command completion.</td>
</tr>
<tr>
<td><code>--field-separator</code> separator <code>-F separator</code></td>
<td>Specifies the field separator for unaligned output (default: &quot;</td>
</tr>
<tr>
<td><code>--html</code> -H</td>
<td>Turns on HTML tabular output. Using this command is equivalent to using the <code>\pset</code> format html or the <code>\H</code> command.</td>
</tr>
<tr>
<td><code>--pset assignment</code> <code>-P assignment</code></td>
<td>Lets you specify printing options in the style of <code>\pset</code> on the command line. You must separate the name and value with an equals (=) sign instead of a space. Thus, to set the output format to LaTeX, you could write <code>-P format=latex</code>.</td>
</tr>
<tr>
<td>-Q</td>
<td>Turns on trailing record separator. Use <code>\pset trailingrecordsep</code> to toggle the trailing record separator on or off.</td>
</tr>
<tr>
<td><code>--record-separator</code> separator <code>-R separator</code></td>
<td>Uses separator as the record separator. Using this command is equivalent to using the <code>\pset</code> recordsep command.</td>
</tr>
<tr>
<td><code>--tuples-only</code> -t</td>
<td>Disables printing of column names, result row count footers, and so on. This is equivalent to the <code>vsql</code> meta-command <code>\t</code>.</td>
</tr>
<tr>
<td><code>--table-attr options</code></td>
<td>Allows you to specify options to be placed within the table.</td>
</tr>
</tbody>
</table>
**-T options**

HTML table tag. See \pset for details.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--expanded</td>
<td>Enables extended table formatting mode. This is equivalent to the vsql meta-command \x.</td>
</tr>
</tbody>
</table>

**Input and Output Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--echo-all</td>
<td>Prints all input lines to standard output as they are read. This approach is more useful for script processing than interactive mode. It is the same as setting the variable ECHO to all.</td>
</tr>
<tr>
<td>-a</td>
<td></td>
</tr>
<tr>
<td>--echo-queries</td>
<td>Copies all SQL commands sent to the server to standard output. Using this command is equivalent to setting the variable ECHO to queries.</td>
</tr>
<tr>
<td>-e</td>
<td></td>
</tr>
<tr>
<td>-E</td>
<td>Displays queries generated by internal commands.</td>
</tr>
<tr>
<td>-n</td>
<td>Disables command line editing.</td>
</tr>
<tr>
<td>--output filename</td>
<td>Writes all query output to filename. Using this command is equivalent to using the vsql meta-command \o.</td>
</tr>
<tr>
<td>-o filename</td>
<td></td>
</tr>
<tr>
<td>--quiet</td>
<td>Specifies that vsql do its work quietly (without informational output, such as welcome messages). This command is useful with the -c option. Within vsql you can also set the QUIET variable to achieve the same effect.</td>
</tr>
<tr>
<td>-q</td>
<td></td>
</tr>
<tr>
<td>--single-step</td>
<td>Runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.</td>
</tr>
<tr>
<td>-s</td>
<td></td>
</tr>
<tr>
<td>--single-line</td>
<td>Runs in single-line mode where a newline terminates a SQL command, as if you are using a semicolon.</td>
</tr>
<tr>
<td>-S</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**

This mode is provided only by customer request.
Vertica recommends that you not use single-line mode in cases where you mix SQL and meta-commands on a line. In single-line mode, the order of execution might be unclear to the inexperienced user.

- **-A --no-align**

- A or --no-align switches to unaligned output mode. The default output mode is aligned.

- **-a --echo-all**

- a or --echo-all prints all input lines to standard output as they are read. This is more useful for script processing than interactive mode. It is equivalent to setting the variable ECHO to all.

- **-c --command**

- c command or --command command runs one command and exits. This is useful in shell scripts.

Use either:

- A command string that can be completely parsed by the server that does not contain features specific to vsq
- A single meta-command

You cannot mix SQL and vsq meta-commands. You can, however, pipe the string into vsq as shown:

```bash
echo "\\timing\\select * from t"  |  ./Linux64/bin/vsql
Timing is on.
i | c | v
-------
(0 rows)
```
Note:
If you use double quotes (") with `echo`, you must double the backslashes (\).

-d --dbname

-d `db-name` or --dbname `db-name` specifies the name of the database to connect to. This is equivalent to specifying `db-name` as the first non-option argument on the command line.

-E

-E displays queries generated by internal commands.

-e --echo-queries

-e --echo-queries copies all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable ECHO to queries.

-F --field-separator

-F `separator` or --field-separator `separator` specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See -A --no-align.) This is equivalent to `\pset fieldsep` or \f.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as \t for tab), or a backslash (\) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (\t), vertical tab (\v) and the octal value of vertical tab (\013).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6
```
-f --file

-f filename or --file filename uses filename as the source of commands instead of reading commands interactively. After the file is processed, vsq1 terminates.

If filename is a hyphen (-), standard input is read.

Using this option is different from writing vsq1 < filename. Using -f enables some additional features such as error messages with line numbers. Conversely, the variant using the shell's input redirection should always yield exactly the same output that you would have gotten had you entered everything manually.

? --help

-? --help displays help about vsq1 command line arguments and exits.

-H --html

-H --html turns on HTML tabular output. This is equivalent to \pset format html or the \H command.
-h --host

-h hostname or --host hostname specifies the host name of the machine on which the server is running. Use this flag to connect to Vertica remotely.

The following requirements and restrictions apply:

- If you use client authentication with a Kerberos connection method of either gss or krb5, you must specify -h hostname.
- Use the -h option if you want to connect to Vertica from a local connection, but want to use the an authentication record with the access method HOST (rather than LOCAL).

-i -- timing

Enables the \timing meta-command. You can only use this command with the -c --command and -f --file commands:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

You can only use -i with the -c (command) and -f (filename) commands. For more information see Command-Line Options.

From the command line enter the -i option before running a session to turn timing on. For example:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql

$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -c "SELECT user_name, ssl_state, authentication_method, client_authentication_name, client_type FROM sessions WHERE session_id=(SELECT session_id FROM current_session);"
```

-l --list

-l or --list returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command \list.
-m --sslmode

-m or --sslmode specifies the policy for making SSL connections to the server. Options are verify_full, verify_ca require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.

For information on these modes see Configuring TLS for ODBC Clients.

-n

-n disables command line editing.

-o --output

-o filename or --output filename writes all query output into file filename. This is equivalent to the vsql meta-command \o.

-P --pset

-P assignment or --pset assignment lets you specify printing options in the style of \pset on the command line. Note that you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write -P format=latex.

-p --port

-p port or --port port specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.

-q --quiet

-q or --quiet specifies that vsql do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this appears. This is useful with the -c option. Within vsql you can also set the QUIET variable to achieve the same effect.

-R --record-separator

-R separator or --record-separator separator specifies separator as the record separator. This is equivalent to the \pset recordsep command.

-S --single-line

-S --single-line runs in single-line mode where a newline terminates a SQL command, like the semicolon does.

Note:
This mode is provided for those who insist on it, but you are not necessarily encouraged to use it, particularly if you mix SQL and meta-commands on a line. The order of execution might not always be clear to the inexperienced user.

-s --single-step

-s --single-step runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.

-T --table-attr

-T table-options or --table-attr table-options lets you specify options to be placed within the HTML table tag. See \pset for details.
**-t --tuples-only**

-t or --tuples-only disables printing of column names, result row count footers, and so on. This is equivalent to the `vsql meta-command \t`.

**-V --version**

-V or --version prints the vsql version and exits.

**-v --variable --set**

-v `assignment`, --variable `assignment`, and --set `assignment` perform a variable assignment, like the `vsql meta-command \set`.

**Note:**
You must separate name and value, if any, by an equals sign (=) on the command line.

To unset a variable, omit the equal sign. To set a variable without a value, use the equals sign but omit the value. Make these assignments at a very early stage of start-up, so that variables reserved for internal purposes can get overwritten later.

**-X --no-vsqr**

-X or --no-vsqr prevents the start-up file from being read: the system-wide vsqr file or the user's `~/.vsqr` file.

**-x --expanded**

-x or --expanded enables extended table formatting mode. This is equivalent to the `vsql meta-command \x`. 
Connecting From a Non-Cluster Host

You can use the Vertica `vsql` executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the `vsql` executable. See [Installing the Client RPM on Red Hat and SUSE](#) for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

  ```
  $ scp host01:/opt/vertica/bin/vsql .
  $ ./vsql
  ```

- If the non-cluster host is running a different version of Linux than your cluster hosts, and that operating system is not Red Hat version 5 64-bit or SUSE 10/11 64-bit, you must install the Vertica server RPM in order to get `vsql`. Download the appropriate rpm package from the Download tab of the [myVertica portal](#) then log into the non-cluster host as root and install the rpm package using the command:

  ```
  # rpm -Uvh filename
  ```

  In the above command, `filename` is the package you downloaded. Note that you do not have to run the `install_Vertica` script on the non-cluster host in order to use `vsql`.

**Notes**

- Use the same [Command-Line Options](#) that you would on a cluster host.
- You cannot run `vsql` on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run `vsql`.  

Meta-Commands

Anything you enter in vsql that begins with an unquoted backslash is a vsql meta-command that is processed by vsql itself. These commands help make vsql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a vsql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you can quote it with a single quote. To include a single quote into such an argument, precede it by a backslash. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \digits, \0digits, and \0xdigits (the character with the given decimal, octal, or hexadecimal code).

If an unquoted argument begins with a colon (:), it is taken as a vsql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes (`) are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.

Some commands take a SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes ("") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, FOO"BAR"BAZ is interpreted as fooBARbaz, and "A weird"" name" becomes A weird" name.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence `\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and vsql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.
## Meta-Commands Quick Reference

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Summary</th>
<th>Command-line Options</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\! [cmd]</code></td>
<td>Executes a command in a Linux shell (passing arguments as entered) or starts an interactive shell.</td>
<td></td>
</tr>
<tr>
<td><code>\?</code></td>
<td>Displays help information about all meta-commands, the same as <code>\h</code>.</td>
<td><code>?</code></td>
</tr>
<tr>
<td><code>\a</code></td>
<td>Toggles output format alignment. For details, see <code>\pset format aligned</code>.</td>
<td><code>-A  -no-align</code></td>
</tr>
<tr>
<td><code>\b</code></td>
<td>Toggles beep on command completion.</td>
<td></td>
</tr>
<tr>
<td><code>\c[connect] [db [user-name]]</code></td>
<td>Establishes a connection to database <em>db</em>, under the specified user <em>user-name</em>. For details, see <code>\connect</code>.</td>
<td></td>
</tr>
<tr>
<td><code>\c ['title-str']</code></td>
<td>Sets a title <em>title-str</em> that precedes query result output. For details, see <code>\pset title title-str</code>.</td>
<td></td>
</tr>
<tr>
<td><code>\cd [dir]</code></td>
<td>Changes the current working directory to <em>dir</em>, changes to your home directory if you omit specifying a directory.</td>
<td></td>
</tr>
<tr>
<td><code>\d commands</code></td>
<td>See <code>\d Meta-Commands</code></td>
<td></td>
</tr>
<tr>
<td><code>\edit [file]</code></td>
<td>Edits the query buffer (or specified file) with an external editor. For details, see <code>\edit</code>.</td>
<td></td>
</tr>
<tr>
<td><code>\echo [str]</code></td>
<td>Writes <em>str</em> to standard output.</td>
<td></td>
</tr>
<tr>
<td><code>\f [str]</code></td>
<td>Sets the field separator for unaligned output.</td>
<td><code>-F</code></td>
</tr>
</tbody>
</table>

**Tip:**
Use `\qecho` to redirect query output to the query output stream, as set by `\o`.
<table>
<thead>
<tr>
<th>Syntax</th>
<th>Summary</th>
<th>Command-line Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>\g [ file-name</td>
<td>shell-command]</td>
<td>Sends the query in the input buffer (see \p) to the server. You can send query results to file-name, or pipe results to shell-comand; otherwise, \g sends query results to standard output.</td>
</tr>
<tr>
<td>\H</td>
<td>Renders output in HTML markup as a table. For details, see \pset_format aligned.</td>
<td>-H --html</td>
</tr>
<tr>
<td>\h[elp]</td>
<td>Displays help information about the meta-commands, the same as ?.</td>
<td>- --help</td>
</tr>
<tr>
<td>\i file</td>
<td>Reads and executes input from filename.</td>
<td>-f --file</td>
</tr>
<tr>
<td>\l \list</td>
<td>Lists available databases and owners.</td>
<td>-l --list</td>
</tr>
<tr>
<td>\locale [locale]</td>
<td>Displays the current locale setting or sets a new locale for the session. For details, see \locale.</td>
<td></td>
</tr>
<tr>
<td>\o [ file-name</td>
<td>shell-command]</td>
<td>Controls where vsql directs query output. You can send query results to file-name, or pipe results to shell-comand; otherwise, \o sends query results to standard output.</td>
</tr>
<tr>
<td>\p</td>
<td>Prints the current query buffer to standard output.</td>
<td></td>
</tr>
<tr>
<td>\password [user-name]</td>
<td>Starts the password change process. Superusers can specify a user name to change that user's password; otherwise, users can only change their own passwords.</td>
<td></td>

<tr>
<td><code>output-option</code></td>
<td>formats query result output. For details, see <code>\pset</code>.</td>
<td><code>--pset</code></td>
</tr>
<tr>
<td><code>\q</code></td>
<td>Quits the vsql program</td>
<td></td>
</tr>
<tr>
<td><code>\qecho</code> <code>[str]</code></td>
<td>Writes <code>str</code> to the query output stream, as specified by <code>\o</code>.</td>
<td></td>
</tr>
<tr>
<td><code>\r</code></td>
<td>Clears (resets) the query buffer</td>
<td></td>
</tr>
<tr>
<td><code>\s</code> <code>[file]</code></td>
<td>Valid only if vsql is configured to use the GNU Readline library, prints or saves the command line history to <code>file</code>, or to standard output if no file name is supplied.</td>
<td></td>
</tr>
<tr>
<td><code>\set</code> <code>[var]</code> <code>[value]…</code></td>
<td>Sets internal variable <code>var</code> to <code>value</code>. If you specify multiple values, <code>var</code> is set to their concatenated values. If no values are specified, <code>var</code> is set to no value.</td>
<td><code>--set</code> <code>-v</code></td>
</tr>
<tr>
<td><code>-t</code></td>
<td>Toggles between tuples only and full display. For details, see <code>\pset format tuples only</code>.</td>
<td><code>-t</code> <code>--tuples-only</code></td>
</tr>
<tr>
<td><code>-T</code> <code>html-attribute</code> <code>[…]</code></td>
<td>Specifies attributes to be placed inside the HTML table tag—for example, <code>cellpadding</code> or <code>bgcolor</code>, the same as <code>\pset tableattr html-attribute […]</code>. For sample usage, see Output Formatting Examples.</td>
<td><code>-T</code> <code>--table-attr</code></td>
</tr>
<tr>
<td><code>\timing</code></td>
<td>If set to on, returns how long (in milliseconds) each SQL statement runs. For details, see <code>\timing</code>.</td>
<td><code>-i</code> <code>-- timing</code></td>
</tr>
<tr>
<td><code>\unset</code> <code>var</code></td>
<td>Deletes internal variable <code>var</code> that was set by the meta-command <code>\set</code>.</td>
<td></td>
</tr>
<tr>
<td><code>\w</code> <code>file-name</code></td>
<td>Outputs the current query buffer to file <code>file-name</code>.</td>
<td></td>
</tr>
</tbody>
</table>
### Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Summary</th>
<th>Command-line Options</th>
</tr>
</thead>
</table>
| \x     | Toggles between regular and expanded format. For details, see \pset format expanded. | -x
|        |         | --expanded          |
| \z     | Returns a summary of privileges on all objects in system table `v_catalog.grants`: grantee, grantor, privileges, schema, and object name (equivalent to `dp`). \z supports the same options as `dp` for filtering output by schema and object name patterns, . For example: |  |

```
> \z *."myseq*  
    Access privileges for database  
    "dbadmin"  
    Grantee | Grantor | Privileges | Schema |  
    Name    |         |------------|---------|  
    +----------+-------------+-----------|---------|  
    +----------+-------------+-----------|---------|  
    dbadmin  | dbadmin     | SELECT*   | public |  
    mySeq    |             |           |         |  
    dbadmin  | dbadmin     | SELECT*   | public |  
    mySeq2   |             |           |         |  
    (2 rows) |             |           |         |  
```

### \connect

Establishes a connection to database `db`, under the specified user `user-name`. The previous connection is closed. If you omit specifying a database name, Vertica connects to the current database. If you omit specifying a user name argument, Vertica assumes the current user.

**Syntax**

```
\c [connect] [db [user-name]]
```
Error Handling

Errors that prevent execution include specifying an unknown user and denial of access to the specified database. Vertica handles errors differently, depending on whether this command is executed interactively in vsq1, or in a script:

- VSQL handling: The current connection is maintained.
- Script: Processing immediately stops with an error. This is prevents scripts from acting on the wrong database.

\d Meta-Commands

Vertica supports a number of \d commands, which return information on different categories of database objects. For a full list, see \d Reference below.

Syntax

Unless otherwise noted, \d commands generally conform to the following syntax:

\dCommand [ [schema.]pattern ]

Arguments

You can supply most \d commands with a string pattern argument, which filters the results that the command returns. The pattern can optionally be qualified by a schema name.

<table>
<thead>
<tr>
<th>schema</th>
<th>Valid for most \d commands, specifies to return only database objects in schema. For example, the following \dp command obtains privileges information for all V_MONITOR tables that contain the string resource:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>=&gt; \dp V_MONITOR.<em>resource</em></td>
</tr>
<tr>
<td></td>
<td>Access privileges for database &quot;dbadmin&quot;</td>
</tr>
<tr>
<td></td>
<td>Grantee</td>
</tr>
<tr>
<td></td>
<td>public</td>
</tr>
<tr>
<td></td>
<td>public</td>
</tr>
<tr>
<td></td>
<td>public</td>
</tr>
<tr>
<td></td>
<td>public</td>
</tr>
<tr>
<td></td>
<td>public</td>
</tr>
<tr>
<td></td>
<td>public</td>
</tr>
<tr>
<td></td>
<td>public</td>
</tr>
</tbody>
</table>
### Pattern

Returns only the database objects that match the specified string. Pattern strings can include one or more of two wildcards:

<table>
<thead>
<tr>
<th>Wildcard character</th>
<th>Represents...</th>
</tr>
</thead>
<tbody>
<tr>
<td>* (asterisk)</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>? (question mark)</td>
<td>Any single character</td>
</tr>
</tbody>
</table>

For example, the following `\dt` command returns tables that start with the string `store`:

```
=> \dt store*

<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Kind</th>
<th>Owner</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>store_orders</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>store_orders_2018</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>store_overseas</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_dimension</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_sales_fact</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
</tbody>
</table>
```

(6 rows)

### d Reference

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\d</td>
<td>Unqualified by a pattern argument, returns all tables with their schema names, owners, and comments. If qualified by a pattern argument, \d returns all matching tables and all columns in each table, with details about each column, such as data type, size, and default value.</td>
</tr>
<tr>
<td>\df</td>
<td>Returns all function names, the function return data type, and the function argument data type. Also returns the procedure names and arguments for all procedures that are available to the user.</td>
</tr>
<tr>
<td>\dj</td>
<td>Returns all projections showing the schema, projection name, owner, and node. The returned rows include superprojections, live aggregate projections,</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>Top-K projections, and projections with expressions.</td>
<td></td>
</tr>
<tr>
<td>\dn</td>
<td>Returns the schema names and schema owner.</td>
</tr>
<tr>
<td>\dp</td>
<td>Returns a summary of privileges on all objects in system table V_CATALOG.GRANTS: grantee, grantor, privileges, schema, and object name (equivalent to \z).</td>
</tr>
<tr>
<td>\dS</td>
<td>Unqualified by a pattern argument, returns all V_CATALOG and V_MONITOR system tables. To obtain system tables for just one schema, qualify the command with the schema name, as follows: \dS { V_CATALOG</td>
</tr>
<tr>
<td>Unqualified by a pattern argument, returns all views with their schema names, owners, and comments. If qualified by a pattern argument, \dv returns all matching views and the columns in each view, with each column’s data type and size.</td>
<td></td>
</tr>
<tr>
<td>\dt</td>
<td>Returns the same information as an unqualified \d command. If qualified by a pattern argument, \dt returns matching tables with the same level of detail as an unqualified \d command.</td>
</tr>
<tr>
<td>\dv</td>
<td>Returns tables and views.</td>
</tr>
<tr>
<td>\du</td>
<td>Returns database users and whether they are superusers.</td>
</tr>
</tbody>
</table>

\edit

Edits the query buffer (or specified file) with an external editor. When the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.
The new query buffer is then re-parsed according to the normal rules of vsq1, where the whole buffer up to the first semicolon is treated as a single line. (Thus you cannot make scripts this way. Use \i for that.) If there is no semicolon, vsq1 waits for one to be entered (it does not execute the query buffer).

Tip:
vsq1 searches the environment variables VSQL_EDITOR, EDITOR, and VISUAL (in that order) for an editor to use. If all of them are unset, vi is used on Linux systems, notepad.exe on Windows systems.

Syntax
\e[dit] [ file ]

\i

Reads and executes input from the specified file.

Note:
To see the lines on the screen as they are read, set the variable ECHO to all.

Syntax
\i filename

Examples
The Vertica vsq1 client on Linux supports backquote (backtick) expansion. For example:

1. Set an environment variable to a path that contains scripts you want to run:
   $ export MYSCRIPTS=/home/dbadmin/testscripts

2. Issue the vsq1 command.
   $ vsq1

3. Use backquote expansion to include the path for running an existing script—for example, sample.sql.
   => \i `echo $MYSCRIPTS/sample.sql`
\locale

Displays or sets the locale setting for the current session.

**Note:**
This command does not alter the default locale for all database sessions. To change the default for all sessions, set configuration parameter `DefaultSessionLocale`.

### Syntax
\locale [locale-identifier]

### Arguments

| **locale-identifier** | Specifies the ICU locale identifier to use, by default set to: en_US@collation=binary  
If set to an empty string, Vertica sets locale to en_US_POSIX.  
If you omit this argument, \locale returns the current locale setting.  
For details on identifier options, see About Locale in the Administrator's Guide. For a complete list of locale identifiers, see the ICU Project. |

### Examples

**View the current locale setting:**

```
=> \locale
en_US@collation=binary
```

**Change the default locale for this session:**

```
=> \locale en_GBINFO:
INFO 2567: Canonical locale: 'en_GBINFO:'  
Standard collation: 'LEN'  
English (GBINFO:)
```
Notes

The server locale settings impact only the collation behavior for server-side query processing. The client application is responsible for ensuring that the correct locale is set in order to display the characters correctly. Below are the best practices recommended by Vertica to ensure predictable results:

- The locale setting in the terminal emulator for vsq1 (POSIX) should be set to be equivalent to session locale setting on server side (ICU) so data is collated correctly on the server and displayed correctly on the client.
- The vsq1 locale should be set using the POSIX LANG environment variable in terminal emulator. Refer to the documentation of your terminal emulator for how to set locale.
- Server session locale should be set using the set as described in Specify the Default Locale for the Database.
- All input data for vsq1 should be in UTF-8 and all output data is encoded in UTF-8.
- Non UTF-8 encodings and associated locale values are not supported.

\pset

Sets options that control how Vertica formats query result output.

Syntax

\pset output-option

Output Options

Note:

Unless otherwise specified, output options are valid for all formats.

<table>
<thead>
<tr>
<th>format</th>
<th>format-option</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Sets output format, where format-option is one of the following:</td>
</tr>
<tr>
<td></td>
<td>• u[naligned] writes all column data of each row on a single line, where each field is separated only by the</td>
</tr>
</tbody>
</table>
current separator character. Use this output for use as input to other programs—for example, comma-delimited fields for CSV input.

- a[lined] (default): Renders column-aligned output.
- h[tml]: Renders output in HTML markup as a table.
- l[atex]: Renders output in LaTex markup.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>border int</td>
<td>Valid only if output format is set to h[tml], specifies the table border, where int specifies the border type.</td>
</tr>
<tr>
<td>expanded</td>
<td>Toggles between regular and expanded format. When expanded format is enabled, all output has two columns with the column name on the left and the data on the right. This mode is especially useful for wide tables.</td>
</tr>
<tr>
<td>fieldsep 'arg'</td>
<td>Valid only if output format is set to unaligned, specifies the field separator, by default</td>
</tr>
<tr>
<td>footer</td>
<td>Toggles display of the default footer:</td>
</tr>
<tr>
<td>null 'string'</td>
<td>Specifies to represent column null values as string. By default, Vertica renders null values as an empty field, which might be mistaken as an empty string. For example:</td>
</tr>
<tr>
<td>pager [always]</td>
<td>Toggles use of a pager for query and vsql help output. If the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used. When the pager is off, the pager is not used. When the pager is on, the pager is used only when appropriate; that is, the output is to a terminal and does not fit on the screen. (vsql does not do a perfect job of estimating when to use the</td>
</tr>
</tbody>
</table>
If qualified with the argument always, the pager is always used.

<table>
<thead>
<tr>
<th>PSET command</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td>\pset expanded</td>
<td>\x</td>
</tr>
<tr>
<td>\pset fieldsep 'arg'</td>
<td>\f</td>
</tr>
<tr>
<td>\pset format aligned</td>
<td>\a</td>
</tr>
<tr>
<td>\pset format html</td>
<td>\H</td>
</tr>
<tr>
<td>\pset tableattr html-attribute[...]</td>
<td>\T html-attribute[...]</td>
</tr>
<tr>
<td>\pset title title-str</td>
<td>\C ['title-str']</td>
</tr>
<tr>
<td>\pset tuples_only</td>
<td>\t</td>
</tr>
</tbody>
</table>
Examples

See Output Formatting Examples.

\set

Sets an internal variable to one or more values. If multiple values are specified, they are concatenated. An unqualified \set command lists all internal variables.

To unset a variable, use vsql meta-command \unset.

Syntax

\set [var [value]...]

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>var</td>
<td>The name of an internal variable to set. Valid variable names are case sensitive and can contain characters, digits, and underscores. vsql treats several variables as special, which are described in Variables.</td>
</tr>
<tr>
<td>value</td>
<td>A value to set in variable var. If no value is specified, the variable is set to no value. If set to an empty string, the variable is set to no value. If you omit this argument, \set returns all internal variables.</td>
</tr>
</tbody>
</table>

If no arguments are supplied, \set returns all internal variables. For example:

```
=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%# '
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```
\textbf{\texttt{\textbackslash timing}}

If set to on, returns how long (in milliseconds) each SQL statement runs. Results include:

- Length of time required to fetch the first block of rows
- Total time until the last block is formatted.

Unqualified, \texttt{\textbackslash timing} toggles timing on and off. You can explicitly turn timing on and off by qualifying the command with options ON and OFF, respectively.

\textbf{Note:}

You can also enable \texttt{\textbackslash timing} from the command line using the \texttt{vsql -i} command.

\section*{Syntax}

\texttt{\textbackslash timing [ON | OFF]}

\section*{Examples}

The following unqualified \texttt{\textbackslash timing} commands toggle timing on and off:

\begin{verbatim}
=> \texttt{\textbackslash timing}
Timing is on
=> \texttt{\textbackslash timing}
Timing is off
\end{verbatim}

The following example shows a SQL command with timing on:

\begin{verbatim}
=> \texttt{\textbackslash timing}
Timing is on.
=> \texttt{SELECT user\_name, ssl\_state, authentication\_method, client\_authentication\_name, client\_type FROM sessions WHERE session\_id=(SELECT session\_id FROM current\_session);}

<table>
<thead>
<tr>
<th>user_name</th>
<th>ssl_state</th>
<th>authentication_method</th>
<th>client_authentication_name</th>
<th>client_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbadmin</td>
<td>None</td>
<td>ImpTrust</td>
<td>default: Implicit Trust</td>
<td>vsql</td>
</tr>
</tbody>
</table>

(1 row)

Time: First fetch (1 row): 73.684 ms. All rows formatted: 73.770 ms
\end{verbatim}
Variables

VSQL provides variable substitution features similar to common Linux command shells. Variables are name/value pairs, where the value can be a string of any length. To set variables, use the vsql meta-command \set. For example, the following statement sets the variable fact to the value dim:

```
=> \set fact dim
```

If you call \set on a variable and supply no value, the variable is set to an empty string.

**Note:**
The arguments of \set are subject to the same substitution rules as with other commands. For example, \set dim :fact is a valid way to copy a variable.

Getting Variables

To retrieve the content of a given variable, precede the name with a colon and use it as the argument of any slash command. For example:

```
=> \echo :fact
dim
```

An unqualified \set command returns all current variables and their values:

```
dbadmin=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%# '
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```
Deleting Variables

To unset (or delete) a variable, use the `vsql meta-command \unset`.

Variable Naming Conventions

`vsql` internal variable names can contain letters, numbers, and underscores in any order and any number. Some variables are treated specially by `vsql`. They indicate certain option settings that can be changed at run time by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended. By convention, all specially treated variables consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

SQL Interpolation

You can substitute ("interpolate") `vsql` variables into regular SQL statements. You do so by prepending the variable name with a colon (:``). For example, the following statements query the table `my_table`:

```
=> \set fact 'my_table'
=> SELECT * FROM :fact;
```

The value of the variable is copied literally, so it can even contain unbalanced quotes or backslash commands. Make sure that it makes sense where you put it. Variable interpolation is not performed into quoted SQL entities. One exception applies: the contents of backquoted strings (```) are passed to a system shell, and replaced with the shell's output. See Using Backquotes to Read System Variables below.

Using Backquotes to Read System Variables

In `vsql`, the contents of backquotes are passed to the system shell to be interpreted (the same behavior as many UNIX shells). This is particularly useful in setting internal `vsql` variables, since you may want to access UNIX system variables (such as HOME or TMPDIR) rather than hard-code values.
For example, to set an internal variable to the full path for a file in your UNIX user directory, you can use backquotes to get the content of the system HOME variable, which is the full path to your user directory:

```
=> \set inputfile `echo $HOME`/myinput.txt
/home/dbadmin/myinput.txt
```

The contents of the backquotes are replaced with the results of running the contents in a system shell interpreter. In this case, the `echo $HOME` command returns the contents of the HOME system variable.

## AUTOCOMMIT

When AUTOCOMMIT is set 'on', each SQL command is automatically committed upon successful completion; for example:

```
\set AUTOCOMMIT on
```

To postpone COMMIT in this mode, set the value as off.

```
\set AUTOCOMMIT off
```

If AUTOCOMMIT is empty or defined as off, SQL commands are not committed unless you explicitly issue COMMIT.

## Notes

- AUTOCOMMIT is off by default.
- AUTOCOMMIT must be in uppercase, but the values, on or off, are case insensitive.
- In autocommit-off mode, you must explicitly abandon any failed transaction by entering ABORT or ROLLBACK.
- If you exit the session without committing, your work is rolled back.
- Validation on vsql variables is done when they are run, not when they are set.
- The COPY statement, by default, commits on completion, so it does not matter which AUTOCOMMIT mode you use, unless you issue COPY NO COMMIT. Please note that DDL statements are autocommitted.
- To tell if AUTOCOMMIT is on or off, issue the set command:

```
$ \set...
AUTOCOMMIT = 'off'
```
• AUTOCOMMIT is off if a SELECT * FROM LOCKS shows locks from the statement you just ran.

```
$ \set AUTOCOMMIT off
$ \set ...
AUTOCOMMIT = 'off'
...
SELECT COUNT(*) FROM customer_dimension;
count
--------
50000
(1 row)
SELECT node_names, object_name, lock_mode, lock_scope
FROM LOCKS;
node_names | object_name | lock_mode | lock_scope
--------- | ----------- | --------- | ------------
site01    | Table:customer_dimension | S         | TRANSACTION
(1 row)
```

### DBNAME

The name of the database to which you are currently connected. DBNAME is set every time you connect to a database (including program startup), but it can be unset.

### ECHO

If set to all, all lines entered from the keyboard or from a script are written to the standard output before they are parsed or run.

To select this behavior on program start-up, use the switch -a. If set to queries, vsql merely prints all queries as they are sent to the server. The switch for this is -e.

### ECHO_HIDDEN

When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the Vertica internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch -E.)
If you set the variable to the value noexec, the queries are just shown but are not actually sent to the server and run.

**ENCODING**

The current client character set encoding.

**HISTCONTROL**

If this variable is set to ignorespace, lines that begin with a space are not entered into the history list. If set to a value of ignoredups, lines matching the previous history line are not entered. A value of ignoreboth combines the two options. If unset, or if set to any other value than those previously mentioned, all lines read in interactive mode are saved on the history list.

*Source: Bash.*

**HISTSIZE**

Sets the amount of space to store the command history. This value roughly approximates the number of commands vsq1 will store in its command history buffer. This value only impacts the number of lines stored by the current vsq1 session. It does not affect the history stored in the .vsq1_history file.

The default value is 500.

*Note:*

vsq1 multiplies the HISTSIZE value by 50 bytes (an approximation of the average length of a SQL statement) to arrive at the amount of memory to set aside for the command history. Depending on the actual length of your SQL statements, vsq1 may be able to store more or less commands than the value you set in HISTSIZE.

*Source: Bash.*
HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program startup), but can be unset.

IGNOREEOF

If unset, sending an EOF character (usually Control+D) to an interactive session of vsql terminates the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

Source: Bash.

ON_ERROR_STOP

By default, if a script command results in an error, for example, because of a malformed command or invalid data format, processing continues. If you set ON_ERROR_STOP to ON in a script and an error occurs during processing, the script terminates immediately.

For example:

=> \set ON_ERROR_STOP ON

Note:
If you invoke the script on Linux with vsql -f, vsql returns with error code 3 to indicate that an error occurred in the script.

PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.
These specify what the prompts vsql issues look like. See Prompting for details.

This variable is equivalent to the command line option -q. It is probably not too useful in interactive mode.

ROWS_AT_A_TIME

ROWS_AT_A_TIME is set by default to 1000, and retrieves results as blocks of rows of that size. The column formatting for the first block is used for all blocks, so in later blocks some entries could overflow.

When formatting results, Vertica buffers ROWS_AT_A_TIME rows in memory to calculate the maximum column widths. It is possible that rows after this initial fetch are not properly aligned if any of the field values are longer than those see in the first ROWS_AT_A_TIME rows. ROWS_AT_A_TIME can be unset with vsql meta-command \unset to guarantee perfect alignment. However, this requires re-buffering the entire result set in memory and might cause vsql to fail if the result set is too big.

This variable is equivalent to the command line option -S.

This variable is equivalent to the command line option -s.
**USER**

The database user you are currently connected as. This is set every time you connect to a database (including program startup), but can be unset.

**VERBOSITY**

This variable can be set to the values default, verbose, or terse to control the verbosity of error reports.

**VSQL_HOME**

By default, the vsql program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.

In the following example, vsql reads configuration information out of /tmp/jsmith rather than out of ~.

```
# Make an alternate configuration file in /tmp/jsmith
mkdir -p /tmp/jsmith
echo "\echo Using VSQLRC in tmp/jsmith" > /tmp/jsmith/.vsqlrc
# Note that nothing is echoed when invoked normally
vsql
# Note that the .vsqlrc is read and the following is
displayed before the vsql prompt
#
# Using VSQLRC in tmp/jsmith
VSQL_HOME=/tmp/jsmith vsql
```

**VSQL_SSLMODE**

VSQL_SSLMODE specifies how (or whether) clients (like admintools) use SSL when connecting to servers. The default value is prefer, meaning to use SSL if the server offers it. Legal values are require, prefer, allow, and disable. This variable is equivalent to the command-line `-m` option (or `--sslmode`).
**Prompting**

The prompts vsql issues can be customized to your preference. The three variables PROMPT1, PROMPT2, and PROMPT3 contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when vsql requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run a SQL COPY command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

| %M | The full host name (with domain name) of the database server, or [local] if the connection is over a socket, or [local:/dir/name], if the socket is not at the compiled in default location. |
| %m | The host name of the database server, truncated at the first dot, or [local]. |
| %> | The port number at which the database server is listening. |
| %n | The database session user name. |
| %/ | The name of the current database. |
| %~ | Like %/, but the output is ~ (tilde) if the database is your default database. |
| %# | If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.) |
| %R | In prompt 1 normally =, but ^ if in single-line mode, and ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 the sequence is replaced by -, *, a single quote, a double quote, or a dollar sign, depending on whether vsql expects more input because the command wasn't terminated yet, because you are inside a /* ... */ comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything. |
| %x | Transaction status: an empty string when not in a transaction block, or * |
when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

<table>
<thead>
<tr>
<th>%digits</th>
<th>The character with the indicated numeric code is substituted. If digits starts with 0x the rest of the characters are interpreted as hexadecimal; otherwise if the first digit is 0 the digits are interpreted as octal; otherwise the digits are read as a decimal number.</th>
</tr>
</thead>
<tbody>
<tr>
<td>%:name:</td>
<td>The value of the vsql variable name. See the section Variables for details.</td>
</tr>
<tr>
<td>%<code>command</code></td>
<td>The output of command, similar to ordinary &quot;back- tick&quot; substitution.</td>
</tr>
</tbody>
</table>
| %[ ... %] | Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[ and %]. Multiple pairs of these may occur within the prompt. The following example results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals:

testdb=> \set PROMPT1 ' [%033[1;33;40m]%n@%/%R%%[%033 [0m%] ' |

To insert a percent sign into your prompt, write %. The default prompts are '%/%R%#' for prompts 1 and 2, and '>> ' for prompt 3.

**Note:** See the [specification for terminal control sequences](https://www.gnu.org/software/readline/manual/html_node/Terminal-Control-Sequences.html) (applicable to gnome-terminal and xterm).

---

## Command Line Editing

vsql supports the tecla library for convenient line editing and retrieval.

The command history is automatically saved when vsql exits and is reloaded when vsql starts up. Tab-completion is also supported, although the completion logic makes no claim to be a SQL parser. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.teclarc` in your home directory:

```
bind ^I
```

Read the tecla documentation for further details.
Notes

The vsql implementation of the tecla library deviates from the tecla documentation as follows:

- Recalling Previously Typed Lines

  Under pure tecla, all new lines are appended to a list of historical input lines maintained within the GetLine resource object. In vsql, only different, non-empty lines are appended to the list of historical input lines.

- History Files

  tecla has no standard name for the history file. In vsql, the file name is called ~/.vsql_hist.

- International Character Sets (Meta keys and locales)

  In vsql, 8-bit meta characters are no longer supported. Make sure that meta characters send an escape by setting their EightBitInput X resource to False. You can do this in one of the following ways:

  - Edit the ~/.Xdefaults file by adding the following line:

    ```
    XTerm*EightBitInput: False
    ```

  - Start an xterm with an -xrm '*EightBitInput: False' command-line argument.

- Key Bindings:

- The following key bindings are specific to vsql:

  - *Insert switches between insert mode (the default) and overwrite mode.
  - *Delete deletes the character to the right of the cursor.
  - *Home moves the cursor to the front of the line.
  - *End moves the cursor to the end of the line.
  - *^R Performs a history backwards search.

vsql Environment Variables

Set one or more of the following environment variables to be used by the defined properties automatically, each time you start vsql:
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAGER</td>
<td>If the query results do not fit on the screen, they are piped through this command. Typical values are more or less. The default is platform-dependent. Use the \pset command to enable/disable the pager.</td>
</tr>
<tr>
<td>VSQL_DATABASE</td>
<td>The database to which you are connecting. For example, VMar\t.</td>
</tr>
<tr>
<td>TMPDIR</td>
<td>Directory for storing temporary files. The default is platform-dependent. On Unix-like systems the default is /tmp.</td>
</tr>
<tr>
<td>VSQL_EDITOR</td>
<td>Editor used by the \e command. The variables are examined in the order listed; the first that is set is used.</td>
</tr>
<tr>
<td>VSQL_EDITION</td>
<td>Editor used by the \e command. The variables are examined in the order listed; the first that is set is used.</td>
</tr>
<tr>
<td>VSQL_HOME</td>
<td>By default, the vsql program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.</td>
</tr>
<tr>
<td>VSQL_HOST</td>
<td>Host name or IP address of the Vertica node.</td>
</tr>
<tr>
<td>VSQL_PASSWORD</td>
<td>The database password. Using this environment variable increases site security by precluding the need to enter the database password on the command line.</td>
</tr>
<tr>
<td>VSQL_PORT</td>
<td>Port to use for the connection.</td>
</tr>
<tr>
<td>VSQL_SSMODE</td>
<td>Specifies whether and how clients such as admintools use SSL when connecting to servers.</td>
</tr>
<tr>
<td>VSQL_USER</td>
<td>User name to use for the connection.</td>
</tr>
</tbody>
</table>

**Locales**

The default terminal emulator under Linux is gnome-terminal, although xterm can also be used.

Vertica recommends that you use gnome-terminal with vsql in UTF-8 mode, which is its default.
To Change Settings on Linux

1. From the tabs at the top of the vsql screen, select Terminal.
2. Click Set Character Encoding.
3. Select Unicode (UTF-8).

Note: This works well for standard keyboards. xterm has a similar UTF-8 option.

To Change Settings on Windows Using PuTTy

1. Right click the vsql screen title bar and select Change Settings.
2. Click Window and click Translation.
3. Select UTF-8 in the drop-down menu on the right.

Notes

- vsql has no way of knowing how you have set your terminal emulator options.
- The tecla library is prepared to do POSIX-type translations from a local encoding to UTF-8 on interactive input, using the POSIX LANG, etc., environment variables. This could be useful to international users who have a non-UTF-8 keyboard. See the tecla documentation for details.

Vertica recommends the following (or whatever other .UTF-8 locale setting you find appropriate):

```
export LANG=en_US.UTF-8
```

- The vsql \locale command invokes and tracks the server SET LOCALE TO command, described in the SQL Reference Manual. vsql itself currently does nothing with this locale setting, but rather treats its input (from files or from tecla), all its output, and all its interactions with the server as UTF-8. vsql ignores the POSIX locale variables, except for any "automatic" uses in printf, and so on.
## Entering Data with vsqli

You often need to insert literal data when using vsqli. For example:

- Adding a row of data to a table using an `INSERT` statement.
- Adding multiple rows of data through a `COPY` FROM STDIN statement.

The following table lists the data types that Vertica supports, and the format you use to enter that data in queries when using vsqli.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Inserting to vsqli using</th>
<th>Example Use in INSERT INTO <em>table</em>...</th>
<th>For More Information See...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary types, such as BINARY and VARBINARY</td>
<td>Helper functions such as HEX_TO_BINARY, octal strings, specified data format in COPY statements, casting string values to binary.</td>
<td>VALUES(HEX_TO_BINARY('0x3D'), '\141\337');</td>
<td>• Binary Data Types</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Loading Binary (Native) Data</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>Literal values TRUE and FALSE or strings such as 'y', 't', 'true', or 'false'.</td>
<td>VALUES(TRUE, 'f');</td>
<td>Boolean Data Type</td>
</tr>
<tr>
<td>Character data types such as CHAR or LONG VARCHAR</td>
<td>Strings enclosed in single quotes.</td>
<td>VALUES('my string');</td>
<td>Character Data Types</td>
</tr>
<tr>
<td>Date and time data types, such as TIMESTAMPTZ</td>
<td>Formatted text string</td>
<td>VALUES('16:43:00', '2016-09-15 04:55:00 PDT');</td>
<td>• Date/Time Data Types</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Date/Time Expressions</td>
</tr>
</tbody>
</table>
### Numeric Data Types

<table>
<thead>
<tr>
<th>Description</th>
<th>Literal numeric values, including scientific notation, hexadecimal, and BINARY scaling.</th>
<th>VALUES(3.1415, 42, 6.0221409e23);</th>
</tr>
</thead>
</table>

**UUID**

<table>
<thead>
<tr>
<th>Description</th>
<th>Formatted text string</th>
<th>VALUES('12345678-1234-1234-1234-123456789012');</th>
</tr>
</thead>
</table>

### Files

Before starting up, vsq1 attempts to read and execute commands from the system-wide `vsqlrc` file and the user's `~/.vsqlrc` file. The command-line history is stored in the file `~/.vsql_history`.

**Tip:**

If you want to save your old history file, open another terminal window and save a copy to a different file name.

### Exporting Data Using vsq1

You can use vsq1 for simple data-export tasks by changing its output format options so the output is suitable for importing into other systems (tab-delimited or comma-separated files, for example). These options can be set either from within an interactive vsq1 session, or through command-line arguments to the vsq1 command (making the export process suitable for automation through scripting). After you have set vsq1's options so it outputs the data in a format your target system can read, you run a query and capture the result in a text file.

The following table lists the meta-commands and command-line options that are useful for changing the format of vsq1's output.

<table>
<thead>
<tr>
<th>Description</th>
<th>Meta-command</th>
<th>Command-line Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable padding used to align output.</td>
<td>\a</td>
<td>-A or --no-align</td>
</tr>
</tbody>
</table>

---

Vertica Analytic Database (9.3.x)
<table>
<thead>
<tr>
<th>Description</th>
<th>Meta-command</th>
<th>Command-line Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show only tuples, disabling column headings and row counts.</td>
<td>\t</td>
<td>-t or --tuples-only</td>
</tr>
<tr>
<td>Set the field separator character.</td>
<td>\pset fieldsep</td>
<td>-F or --field-separator</td>
</tr>
<tr>
<td>Send output to a file.</td>
<td>\o</td>
<td>-o or --output</td>
</tr>
<tr>
<td>Specify a SQL statement to execute.</td>
<td>N/A</td>
<td>-c or --command</td>
</tr>
</tbody>
</table>

The following example demonstrates disabling padding and column headers in the output, and setting a field separator to dump a table to a tab-separated text file within an interactive session.

```
=> SELECT * FROM my_table;
 a  |  b  |  c
---+---+---
 a  | one | 1
 b  | two | 2
 c  | three | 3
 d  | four | 4
 e  | five | 5
(5 rows)
=> \a
Output format is unaligned.
=> \t
Showing only tuples.
=> \pset fieldsep '\t'
Field separator is "
=> \o dumpfile.txt
=> select * from my_table;
=> \o
=> ! cat dumpfile.txt
 a  | one | 1
 b  | two | 2
 c  | three | 3
 d  | four | 4
 e  | five | 5
```

**Note:**
You could encounter issues with empty strings being converted to NULLs or the reverse using this technique. You can prevent any confusion by explicitly setting null values to output a unique string such as NULLNULLNULL (for example, `\pset null 'NULLNULLNULL'`). Then, on the import end, convert the unique string back to a null value. For example, if you are copying the file back into a Vertica database, you would give the argument...
When logged into one of the database nodes, you can create the same output file directly from the command line by passing the right parameters to vsql:

```
$ vsql -U username -F '$\t' -At -o dumpfile.txt -c "SELECT * FROM my_table;"
Password:
$ cat dumpfile.txt
A|1|2|3
B|4|5|6
```

If you want to convert null values to a unique string as mentioned earlier, you can add the argument `-P null='NULLNULLNULL'` (or whatever unique string you choose).

By adding the `-w` vsql command-line option to the example command line, you could use the command within a batch script to automate the data export. However, the script would contain the database password as plain text. If you take this approach, you should prevent unauthorized access to the batch script, and also have the script use a database user account that has limited access.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as \t for tab), or a backslash (\) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (\t), vertical tab (\v) and the octal value of vertical tab (\013).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F '$\t' -At -c "SELECT * FROM testtable;"
A   1  2  3
B   4  5  6

$ vsql -F '$\v' -At -c "SELECT * FROM testtable;"
A   1
   2
   3
B   4
   5
   6

$ vsql -F '$\013' -At -c "SELECT * FROM testtable;"
A
   1
   2
   3
B
   4
   5
   6
```
Copying Data Using vsqql

You can use vsqql to copy data between two Vertica databases. This technique is similar to the technique explained in Exporting Data Using vsqql, except instead of having vsqql save data to a file for export, you pipe one vsqql's output to the input of another vsqql command that runs a COPY statement from STDIN. This technique can also work for other databases or applications that accept data from an input stream.

**Note:**

The following technique only works for individual tables. To copy an entire database to another cluster, see Copying the Database to Another Cluster in the Administrator's Guide.

The easiest way to copy using vsqql is to log in to a node of the target database, then issue a vsqql command that connects to the source Vertica database to dump the data you want. For example, the following command copies the store.store_sales_fact table from the vmart database on node testdb01 to the vmart database on the node you are logged into:

```
vsqql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact" \ | vsqql -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '\|';"
```

**Note:**

The above example copies the data only, not the table design. The target table for the data copy must already exist in the target database. You can export the design of the table using EXPORT_OBJECTS or EXPORT_CATALOG.

If you are using the Bash shell, you can escape special delimiter characters. For example, DELIMITER E '\t' specifies tab. Shells other than Bash may have other string-literal syntax.
Monitoring Progress (optional)

You may want some way of monitoring progress when copying large amounts of data between Vertica databases. One way of monitoring the progress of the copy operation is to use a utility such as Pipe Viewer that pipes its input directly to its output while displaying the amount and speed of data it passes along. Pipe Viewer can even display a progress bar if you give it the total number of bytes or lines you expect to be processed. You can get the number of lines to be processed by running a separate vsq1 command that executes a SELECT COUNT query.

Note:
Pipe Viewer isn't a standard Linux command, so you will need to download and install it yourself. See the Pipe Viewer page for download packages and instructions. Vertica does not support Pipe Viewer. Install and use it at your own risk.

The following command demonstrates how you can use Pipe Viewer to monitor the progress of the copy shown in the prior example. The command is complicated by the need to get the number of rows that will be copied, which is done using a separate vsq1 command within a Bash backquote string, which executes the string's contents and inserts the output of the command into the command line. This vsq1 command just counts the number of rows in the store.store_sales_fact table.

```
vsq1 -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact" \ | pv -lpetr -s `vsq1 -U username -w passwd -h testdb01 -d vmart -At -c "SELECT COUNT (*) FROM store.store_sales_fact;"` \ | vsq1 -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

While running, the above command displays a progress bar that looks like this:

```
0:00:39 [12.6M/s] [==================================] 50% ETA 00:00:40
```

Output Formatting Examples

By default, Vertica formats query output as follows:

```
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
category_description
```
You can control the format of query output in various ways with the `\pset` command—for example, change the border:

```
=> \pset border 2
Border style is 2.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
+--------------------------+
| category_description     |
+--------------------------+
| Food                     |
| Medical                  |
| Misc                     |
| Non-food                 |
+--------------------------+
(4 rows)
=> \pset border 0
Border style is 0.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
+--------------------------+
| category_description     |
+--------------------------+
| Food                     |
| Medical                  |
| Misc                     |
| Non-food                 |
+--------------------------+
(4 rows)
```

The following sequence of `pset` commands change query output in several ways:

- Set border style to 1.
- Remove column alignment.
- Change the field separator to a comma.
- Remove column headings

```
=> \pset border 1
Border style is 1.
=> \pset format unaligned
Output format is unaligned.
=> \pset fieldsep ','
Field separator is ",".
=> \pset tuples_only
Showing only tuples.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
1,Brand #2 bagels,Food
1,Brand #1 butter,Food
2,Brand #6 chicken noodle soup,Food
3,Brand #11 vanilla ice cream,Food
4,Brand #14 chocolate chip cookies,Food
```
The following example uses meta-commands to toggle output format—in this case, \a (alignment), \t (tuples only), and -x (extended display):

```
=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is off.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
```

```
<table>
<thead>
<tr>
<th>product_key</th>
<th>product_description</th>
<th>category_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Brand #2 bagels</td>
<td>Food</td>
</tr>
<tr>
<td>1</td>
<td>Brand #1 butter</td>
<td>Food</td>
</tr>
<tr>
<td>2</td>
<td>Brand #6 chicken noodle soup</td>
<td>Food</td>
</tr>
<tr>
<td>3</td>
<td>Brand #11 vanilla ice cream</td>
<td>Food</td>
</tr>
<tr>
<td>4</td>
<td>Brand #14 chocolate chip cookies</td>
<td>Food</td>
</tr>
<tr>
<td>4</td>
<td>Brand #12 rash ointment</td>
<td>Medical</td>
</tr>
<tr>
<td>6</td>
<td>Brand #18 bananas</td>
<td>Food</td>
</tr>
<tr>
<td>7</td>
<td>Brand #25 basketball</td>
<td>Misc</td>
</tr>
<tr>
<td>8</td>
<td>Brand #27 french bread</td>
<td>Food</td>
</tr>
<tr>
<td>9</td>
<td>Brand #32 clams</td>
<td>Food</td>
</tr>
</tbody>
</table>
```

(10 rows)

The following example sets output format to HTML, so Vertica renders query results in HTML markup as a table:

```
=> \pset format html
Output format is html.
=> \pset tableattr 'border="2" cellpadding="3"'
Table attribute is "border="2" cellpadding="3"".
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 2;
```

```
<table border="1">
<tr>
<th>product_key</th>
<th>product_description</th>
<th>category_description</th>
</tr>
<tr>
<td align="right">1</td>
<td>Brand #2 bagels</td>
<td>Food</td>
</tr>
<tr>
<td align="right">1</td>
<td>Brand #1 butter</td>
<td>Food</td>
</tr>
</table>
```

(2 rows)
Client Libraries

The Vertica client driver libraries provide interfaces for connecting your client applications (or third-party applications such as Cognos and MicroStrategy) to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- Open Database Connectivity (ODBC)—the most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- Java Database Connectivity (JDBC)—used by clients written in the Java programming language.
- ActiveX Data Objects for .NET (ADO.NET)—used by clients developed using Microsoft's .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Client Driver Standards

The Vertica client drivers are compatible with the following driver standards:

- The ODBC driver complies with version 3.5.1 of the ODBC standard.
- Vertica's JDBC driver is a type 4 driver that complies with the JDBC 3.0 standard. It is compiled using JDK version 1.5, and is compatible with client applications compiled using JDK versions 1.5 and 1.6.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

The drivers do not support some of the optional features in the standards. See ODBC Feature Support and JDBC Feature Support and Using ADO.NET for details.
Client Driver and Server Version Compatibility

Usually, each version of the Vertica server is compatible with previous versions of the client drivers. This compatibility lets you upgrade your Vertica server without having to immediately upgrade your client software. However, some new features of the new server version may not be available through the old drivers.

Note:
Vertica ODBC client drivers are backwards compatible to all Vertica server versions 7.1 and later. JDBC and ADO.NET client drivers are backwards compatible to all Vertica server versions 7.2 and later.

The following tables summarize the compatibility of each recent version of the client drivers with the Vertica server versions.

The following table indicates that, in general, all clients are forward compatible.

<table>
<thead>
<tr>
<th>Client</th>
<th>Client Driver Version</th>
<th>Compatible Server Versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Clients</td>
<td>6.1.x</td>
<td>6.1.x, 7.0.x, 7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x</td>
</tr>
<tr>

Vertica ODBC/JDBC Client Installers

The ODBC/JDBC client drivers are a separate installation from the ADO.NET drivers. (ADO.NET support is not available in Community Edition.) As noted in the compatibility table, the 6.x ODBC/JDBC client drivers do not support access to a non Vertica 6.x database and above. For example, you cannot use the new 6.x ODBC/JDBC client drivers to access a Vertica 5.x database. If you plan on having a mixed Vertica environment supporting both 5.x and 6.x Vertica database, consider keeping the 5.x drivers installed.

ODBC/JDBC Multiple Version Installations

The following ODBC/JDBC drivers are supported on a single machine:

- 4.x and 5.x ODBC/JDBC drivers can be installed on the same machine.
- 4.x and 6.x ODBC/JDBC drivers can be installed on the same machine.

It is not possible to have both 5.x and 6.x ODBC drivers on a single machine. If you install the 6.x version, it automatically overlays the existing 5.x installation, and any DSN defined against a 5.x Vertica database is not supported.

Vertica ADO.NET Client Installers

Prior to version 6.x, ADO.Net drivers must be uninstalled prior to installing a later version of the driver. The 6.x ADO.Net drivers require the Vertica database to be 6.0.0 or above. The ADO.NET 6.x driver only supports access to a Vertica 6.x server. The ADO.NET 4.x plug-in does not work with a Vertica 6.x server. If you plan on also using the ODBC bridge and you need to access both Vertica 5.x and 6.x databases, consider keeping the 5.x versions of the ODBC/JDBC drivers for the reasons stated previously.
Client Drivers

You must install the Vertica client drivers to access Vertica from your client application. The drivers create and maintain connections to the database and provide APIs that your applications use to access your data. The client drivers support connections using JDBC, ODBC, and ADO.NET.

Client Driver Standards

The client drivers support the following standards:

- ODBC drivers conform to ODBC 3.5.1 specifications.
- JDBC drivers conform to JDK 5 specifications.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

Installing the Client Drivers

How you install client drivers depends on the client's operating system:

- For Linux and UNIX clients, you must first install a Linux driver manager. After you have installed the driver manager, there are two different ways to install the client drivers:
  
  - On Red Hat Enterprise Linux 5, 64-bit and SUSE Linux Enterprise Server 10/11 64-bit, you can use the Vertica client RPM package to install the ODBC and JDBC drivers as well as the vsq1 client.
  - On other Linux platforms and UNIX-like platforms you can download the ODBC and JDBC drivers and install them individually.

Note:
The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica Analytics Platform on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java
CLASSPATH. (The JDBC client driver is not available on FIPS-compliant systems.)

- On Mac OS X clients, download the ODBC client driver .pkg file. The driver is compatible with both 32-bit and 64-bit applications.
- On Windows clients, download the 32-bit or 64-bit client installer. The installer provides the ODBC client driver, the ADO.NET client driver, the OLE DB client driver, the vsq1 client, the Microsoft Connectivity Pack, and the Visual Studio plug-in.
- There is a cross-platform JDBC client driver .jar file available for installation on all platforms.

The remainder of this section explain the requirements for the Vertica client drivers, and the procedure for downloading, installing, and configuring them.

Driver Prerequisites

The following topics describe the system requirements for the client drivers. You need to ensure that your client system meets these requirements before installing and using the client drivers.

ODBC Prerequisites

There are several requirements your client systems must meet before you can install the Vertica ODBC drivers.

Operating System

The Vertica ODBC driver requires a supported platform. The list of currently-supported platforms can be found at Vertica 9.3.x Client Drivers.

ODBC Driver Manager

The Vertica ODBC driver requires that the client system have a supported driver manager. See Installing Driver Managers on Linux and Other UNIX-like Platforms for details.
UTF-8, UTF-16 and UTF-32 Support

The Vertica ODBC driver is a universal driver that supports UTF-8, UTF-16, and UTF-32 encoding. The default setting depends on the client platform. For details, see Required ODBC Driver Configuration Settings for Linux and UNIX.

When using the driver with the DataDirect Connect driver manager, DataDirect Connect adapts to the ODBC driver’s text encoding settings. You should configure the ODBC driver to use the encoding method that your application requires. This allows strings to be passed between the driver and the application without intermediate conversion.

- Client Drivers
- Programming ODBC Client Applications
- Creating an ODBC Data Source Name (DSN)

ADO.NET Prerequisites

The Vertica driver for ADO.NET requires the following software and hardware components:

Operating System

The Vertica ADO.NET driver requires a supported Windows operating system. The list of supported platforms can be found in the Supported Platforms document at http://www.vertica.com/docs.

Memory

Vertica suggests a minimum of 512MB of RAM.
.NET Framework

The requirements for the .NET framework for ADO.NET in Vertica can be found in the Supported Platforms document at http://www.vertica.com/docs.

See Also

- Programming ADO.NET Applications

Python Prerequisites

Python is a free, agile, object-oriented, cross-platform programming language designed to emphasize rapid development and code readability. Python has been released under several different open source licenses.

Vertica’s ODBC driver is tested with multiple versions of Python. See Perl and Python Requirements for details.

Python Driver

Vertica requires the Vertica Python Client or the pyodbc driver module. See your system’s Python documentation for installation and configuration information.

Supported Operating Systems

The Vertica ODBC driver requires one of the operating systems listed in ODBC Prerequisites.

For usage and examples, see Programming Python Client Applications.

Perl Prerequisites

Perl is a free, stable, open source, cross-platform programming language licensed under its Artistic License, or the GNU General Public License (GPL).
Your Perl scripts access Vertica through its ODBC driver, using the Perl Database Interface (DBI) module with the ODBC Database Driver (DBD::ODBC). The Vertica ODBC driver is known to be compatible with these versions of Perl:

- 5.8
- 5.10

Later Perl versions may also work.

**Perl Drivers**

The following Perl driver modules have been tested with the Vertica ODBC driver:

- The DBI driver module, version 1.609
- The DBD::ODBC driver module, version 1.22

Other versions may also work.

**Supported Client Systems**

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC Prerequisites.

**PHP Prerequisites**

PHP is a widely-used general-purpose scripting language that is especially suited for Web development and can be embedded into HTML. PHP is licensed under the PHP License, an open-source BSD-style license certified by the Open Source Initiative.

**PHP Modules**

The following PHP modules are required:

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbc (if you are using the iODBC driver)
Supported Client Systems

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC Prerequisites.

Upgrading the Client Drivers

The Vertica client drivers are usually updated for each new release of the Vertica server. The client driver installation packages include the version number of the corresponding Vertica server release. Usually, the drivers are forward-compatible with the next release, so your client applications are still able to connect using the older drivers after you upgrade to the next version of Vertica Analytics Platform server. See Client Driver and Server Version Compatibility for details on which client driver versions work with each version of Vertica server.

Note:
Vertica ODBC client drivers are backwards compatible to all Vertica server versions 7.1 and later. JDBC and ADO.NET client drivers are backwards compatible to all Vertica server versions 7.2 and later.

You should upgrade your clients as soon as possible after upgrading your server, to take advantage of new features and to maintain maximum compatibility with the server.

To upgrade your drivers, follow the same procedure you used to install them in the first place. The new installation will overwrite the old. See the specific instructions for installing the drivers on your client platform for any special instructions regarding upgrades.

Note:
Installing new ODBC drivers does not alter existing DSN settings. You may need to change the driver settings in either the DSN or in the odbcinst.ini file, if your client system uses one. See Creating an ODBC Data Source Name for details.
Setting a Client Connection Label

You can set a client connection label when you connect to a Vertica database. You can also set or return the client connection label using the SET_CLIENT_LABEL and GET_CLIENT_LABEL functions.

Set the client connection label:

```
=> SELECT SET_CLIENT_LABEL('py_data_load_application');
---------
client_label set to py_data_load_application
(1 row)
```

Return the current client connection label:

```
=> SELECT GET_CLIENT_LABEL();
---------
py_data_load_application
(1 row)
```

JDBC

The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions GET_CLIENT_LABEL and SET_CLIENT_LABEL.

When you use these two methods, make sure you pass the string value APPLICATIONNAME to both the setter and getter methods.

Use setClientInfo() to create a client label, and use getClientInfo() to return the client label:

```java
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        myProp.put("loginTimeout", "35");
        Connection conn;
        try {
            conn = DriverManager.getConnection(  
```
When you run this method, it prints the following result to the standard output:

```
Connected!
New Conn Label: JDBC Client - Data Load
```

### Additional Parameter Settings

The following parameters can be set for the Vertica client drivers.

#### Logging Settings

These parameters control how messages between the client and server are logged. None of these settings are required. If they are not set, then the client library does not log any messages. They apply to both ADO.NET and ODBC.

- **LogLevel**—The severity of messages that are logged between the client and the server. The valid values are:
  - 0—No logging
  - 1—Fatal errors
  - 2—Errors
3—Warnings
4—Info
5—Debug
6—Trace (all messages)

The value you specify for this setting sets the minimum severity for a message to be logged. For example, setting LogLevel to 3 means that the client driver logs all warnings, errors, and fatal errors.

**Note:**
On a Windows client, you have the option of directing ODBC or OLE DB log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. See Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs. for ODBC, or Register the OLE DB Driver as a Windows Event Log Provider, and Enable the Logs for OLE DB.

- **LogPath**—The absolute path of a directory to store log files. For example: /var/log/verticaodbc
- **LogNamespace**—Limits logging to messages generated by certain objects in the client driver.

**Note:**
These settings are also available for the Vertica JDBC driver through connection properties. See [Connection Properties](#) for details.

**ODBC-specific Settings**

The following settings are used only by the Vertica ODBC client driver.

- **DriverManagerEncoding**—The UTF encoding standard that the driver manager uses. This setting needs to match the encoding the driver manager expects. The available values for this setting are:
  - UTF-8
  - UTF-16 (usually used by unixODBC)
  - UTF-32 (usually used by iODBC)

See the documentation for your driver manager to find the correct value for this setting.
**Note:**
While both UTF-16 and UTF-8 are valid settings for DataDirect, Vertica recommends that you set the DataDirect driver manager encoding to UTF-16.

If you do not set this parameter, the ODBC driver defaults to the value shown in the following table. If your driver manager uses a different encoding, you must set this value for the ODBC driver to be able to work.

<table>
<thead>
<tr>
<th>Client Platform</th>
<th>Default Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux 32-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Linux 64-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Linux Itanium 64-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>OS X</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Windows 32-bit</td>
<td>UTF-16</td>
</tr>
<tr>
<td>Windows 64-bit</td>
<td>UTF-16</td>
</tr>
</tbody>
</table>

- **ErrorMessagesPath**—The absolute path to the parent directory that contains the Vertica client driver's localized error message files. These files are usually stored in the same directory as the Vertica ODBC driver files.

**Note:**
This setting is required. If you do not set it, then any error the ODBC driver encounters will result in an error message about a missing ODBCMessages.xml file.

- **ODBCInstLib**—The absolute path to the file containing the ODBC installer library (ODBCInst). This setting is required if the directory containing this library is not set in the LD_LIBRARY_PATH or LIB_PATH environment variables. The library files for the major driver manager are:
  - UnixODBC: libodbcinst.so
  - iODBC: libiodbcinst.so (libiodbcinst.2.dylib on OS X)
  - DataDirect: libodbcinst.so
**ADO.NET-specific Settings**

This setting applies only to the ADO.NET client driver:

**C#PreloadLogging**—Tells the Vertica ADO.NET driver to begin logging as soon as possible, before the driver has fully loaded itself. Normally, logging only starts after the driver has fully loaded. Valid values for this setting are:

- 0—Do not start logging before the driver has loaded.
- 1—Start logging as soon as possible.

**Using Legacy Drivers**

The Vertica server supports connections from previous versions of the client drivers. For detailed information the compatibility between versions of the Vertica server and Vertica client, see [Client Driver and Server Version Compatibility](#).

**Modifying the Java CLASSPATH**

The CLASSPATH environment variable contains the list of directories where the Java run time looks for library class files. For your Java client code to access Vertica, you need to add the directory where the Vertica JDBC .jar file is located.

**Note:**

In your CLASSPATH, use the symbolic link `vertica-jdbc-x.x.x.jar` (where `x.x.x` is a version number) that points to the JDBC library .jar file, rather than the .jar file itself. Using the symbolic link ensures that any updates to the JDBC library .jar file (which will use a different filename) will not invalidate your CLASSPATH setting, since the symbolic link's filename will remain the same. You just need to update the symbolic link to point at the new .jar file.
**Linux and OS X**

If you are using the Bash shell, use the `export` command to define the CLASSPATH variable:

```bash
# export CLASSPATH=/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If environment variable CLASSPATH is already defined, use the following command to prevent it from being overwritten:

```bash
# export CLASSPATH=$CLASSPATH:/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If you are using a shell other than Bash, consult its documentation to learn how to set environment variables.

You need to either set the CLASSPATH environment variable for every login session, or insert the command to set the variable into one of your startup scripts (such as `~/.profile` or `/etc/profile`).

**Windows**

Provide the class paths to the .jar, .zip, or .class files.

```cmd
C:> SET CLASSPATH=classpath1;classpath2...
```

For example:

```cmd
C:> SET CLASSPATH=C:\java\MyClasses\vertica-jdbc-x.x.x.jar
```

As with the Linux/UNIX settings, this setting only lasts for the current session. To set the CLASSPATH permanently, set an environment variable:

1. On the Windows Control Panel, click **System**.
2. Click **Advanced or Advanced Systems Settings**.
3. Click **Environment Variables**.
4. Under User variables, click **New**.
5. In the Variable name box, type CLASSPATH.
6. In the Variable value box, type the path to the Vertica JDBC .jar file on your system (for example, `C:\Program Files (x86)\Vertica\JDBC\vertica-jdbc-x.x.x.jar`)
Specifying the Library Directory in the Java Command

There is an alternative way to tell the Java run time where to find the Vertica JDBC driver other than changing the CLASSPATH environment variable: explicitly add the directory containing the .jar file to the java command line using either the -cp or -classpath argument. For example, on Linux, start your client application using:

```
# java -classpath /opt/vertica/java/lib/vertica-jdbc-x.x.x.jar myapplication.class
```

Your Java IDE may also let you add directories to your CLASSPATH, or let you import the Vertica JDBC driver into your project. See your IDE documentation for details.

Installing the Client Drivers on Linux and UNIX-Like Platforms

This topic explains how to install the client drivers on Linux and UNIX-like platforms.

Installing Driver Managers on Linux and Other UNIX-like Platforms

If your client platform does not already have an ODBC driver manager, you need to install one before you can use the Vertica ODBC client driver. The driver manager provides an interface between your client operating system and the ODBC drivers. See Vertica 9.3.x Client Drivers for a list of driver managers that are supported on each of the client platforms.

Driver managers can be downloaded from your operating system specific repository and from the links below.

Vertica does not provide instructions for installing and configuring these third-party binaries. For download and configuration information, see the respective driver manager websites for installation and configuration information:

- UnixODBC: http://www.unixodbc.org/
- iODBC: http://www.iodbc.org
Installing the Client RPM on Red Hat and SUSE

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client driver RPM that installs both the ODBC and JDBC driver libraries and the vsql client.

**Important:**
Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and vsql.

To install the client driver RPM package:

1. Open a Web browser and log in to the myVertica portal.
2. Click Downloads, and choose Client Drivers.
3. Download the client RPM file that matches your client platform's architecture.

**Note:**
The 64-bit client driver RPM installs both the 64-bit and 32-bit ODBC driver libraries on non-FIPS compliant systems.

4. If you did not directly download the RPM on the client system, transfer the file to the client.
5. Log in to the client system as root.
6. Install the RPM package you downloaded:

```
# rpm -Uvh package_name.rpm
```

**Note:**
You receive one or more conflict error messages if there are existing Vertica client driver files on your system. This can happen if you are trying to install the client driver package on a system that has the server package installed, since the server package also includes the client drivers. In this case, you don't need to install the client drivers, and can instead use the drivers installed by the server package. If the conflict arises from an old driver installation or from a server installation for an older version, you can use the rpm command's `--force` switch to force it to overwrite the existing
files with the files in the client driver package.

Once you have installed the client package, you need to create a DSN (see Creating an ODBC DSN for Linux) and set some additional configuration parameters (see Required ODBC Driver Configuration Settings for Linux and UNIX) to use ODBC. To use JDBC, you need to modify your class path (see Modifying the Java CLASSPATH) before you can use JDBC.

You may also want to add the vsq1 client to your PATH environment variable so that you do not need to enter its full path to run it. You add it to your path by adding the following to the .profile file in your home directory or the global /etc/profile file:

```
export PATH=$PATH:/opt/vertica/bin
```

Installing JDBC Driver on Linux

**Note:**
The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica Analytics Platform on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)

**Note:**
For additional details about supported platforms, see Supported Platforms.

The JDBC driver is available for download from myVertica portal. There is a single .jar file that works on all platforms and architectures. To download and install the file:

1. Open a Web browser and log in to myVertica portal.
2. Click the Download tab and locate and download the JDBC driver.
3. You need to copy the .jar file you downloaded to a directory in your Java CLASSPATH on every client system with which you want to access Vertica. You can either:
   - Copy the .jar file to its own directory (such as /opt/vertica/java/lib) and then add that directory to your CLASSPATH (recommended). See Modifying the Java CLASSPATH for details.
• Copy the .jar file to directory that is already in your CLASSPATH (for example, a directory where you have placed other .jar files on which your application depends).

**Note:**
In the directory where you copied the .jar file, you should create a symbolic link named vertica_jdk_5.jar to the .jar file. You can reference this symbolic link anywhere you need to use the name of the JDBC library without having to worry any future upgrade invalidating the file name. This symbolic link is automatically created on server installs. On clients, you need to create and manually maintain this symbolic link yourself if you installed the driver manually. The Installing the Client RPM on Red Hat and SUSE create this link when they install the JDBC library.

**Installing ODBC Drivers on Linux**

**Note:**
For additional details about supported platforms, see [Supported Platforms](#).

Read [Driver Prerequisites](#) before you proceed.

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client RPM that installs both the ODBC and JDBC driver and the vsq1 client. See Installing the Client RPM on Red Hat and SUSE.

**Note:**
The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica Analytics Platform on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see [Creating an ODBC DSN for Linux](#)). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see [Modifying the Java CLASSPATH](#)). (The JDBC client driver is not available on FIPS-compliant systems.)

The ODBC driver installation packages are broken down by client platform on the [myVertica portal](#). The package's filename is named based on its operating system and architecture (for example, vertica_9.3.xx_odbc_x86_64_linux.tar.gz)
**Important:**
Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, *Installing the FIPS Client Driver for ODBC and vsql.*

### Installation Procedure

1. Open a Web browser and log in to [myVertica portal](https://my.vertica.com).
2. Click the Download tab and locate and download the driver package that corresponds to your client system.
3. If you did not directly download to the client system, transfer the downloaded file to it.
4. Log in to the client system as root.
5. If the directory `/opt/vertica/` does not exist, create it:

   ```
   # mkdir -p /opt/vertica/
   ```

6. Copy the downloaded file to the `/opt/vertica/` directory. For example:

   ```
   # cp vertica_9.3.xx_odbc_x86_64_linux.tar.gz /opt/vertica/
   ```

7. Change to the `/opt/vertica/` directory:

   ```
   # cd /opt/vertica/
   ```

8. Uncompress the file you downloaded. For example:

   ```
   $ tar vzxvf vertica_9.3.xx_odbc_x86_64_linux.tar.gz
   ```

   Two folders are created: one for the include file, and one for the library files. The path of the library file depends on the processor architecture: `lib` for 32-bit libraries, and `lib64` for 64-bit libraries. So, a 64-bit driver client download creates the directories:

   - `/opt/vertica/include`, which contains the header file
   - `/opt/vertica/lib64`, which contains the library file
Post Driver Installation Configuration

You must configure the ODBC driver before you can use it. There are two required configuration files:

- The `odbc.ini` configuration file defines the Data Source Names (DSNs) that tell the ODBC how to access your Vertica databases. See [Creating an ODBC Data Source Name](#) for instructions to create this file.
- The `vertica.ini` configuration file defines some Vertica-specific settings required by the drivers. See [Required ODBC Driver Configuration Settings for Linux and UNIX](#) for instructions to create this file.

**Note:**

If you are upgrading your ODBC driver, you must either update your DSNs to point to the newly-installed driver or create new DSNs. If your `odbc.ini` file references drivers defined in an `odbcinst.ini` file, you just need to update the `odbcinst.ini` file. See [Creating an ODBC Data Source Name (DSN)](#) for details.

**Required ODBC Driver Configuration Settings for Linux and UNIX**

In addition to DSN settings, Vertica provides additional ODBC client driver configuration parameters. These settings control the following:

- The text encoding used by the driver manager (for example, UTF-8 or UTF-16).
- The location of the directory containing the Vertica ODBC driver's error message files.
- Whether and how the ODBC driver logs messages.

On Linux and UNIX platforms, you must provide these additional settings manually so that the ODBC driver can function properly. To do so, edit the `vertica.ini` file to supply the necessary additional configuration settings. You specify where the ODBC driver can find the `vertica.ini` file using an environment variable named `VERTICAINI`. See [Required Settings](#).
Setting ODBC Driver Settings on Linux and UNIX-Like Platforms

Driver settings specific to Vertica are stored in a text file named vertica.ini (although you may choose a different file name). On Linux and UNIX platforms, you must edit the vertica.ini file to supply additional configuration settings before the ODBC driver can function properly. You tell the Vertica ODBC driver where to find the vertica.ini file using an environment variable named VERTICAINI.

Required Settings

On Linux and UNIX platforms, you must configure two settings in order for the ODBC driver to work correctly:

- ErrorMessagesPath
- ODBCInstLib (unless the driver manager's installation library is in a directory listed in the LD_LIBRARY_PATH or LIB_PATH environment variables).

If your driver manager does not use UTF-8 encoding, you need to set DriverManagerEncoding to the proper encoding.

Create a vertica.ini File

There is no standard location for the vertica.ini file—you can store the file anywhere that it is convenient for you on your client system. One possible location is in the /etc directory if you have multiple users on your client system that need to access it. You can also have a vertica.ini file in each user's home directory so users can alter their own settings. Wherever you store it, be sure users have read access to the file.

The format of the vertica.ini file is similar to the odbc.ini file, with a section followed by parameter definitions. Unlike the odbc.ini file, vertica.ini contains a single section named Driver:

```
[Driver]
```

Following the section definition, you add setting definitions, one per line. A setting definition consists of the setting name, followed by an equal sign (=), followed by the value. The value does not need quotes. For example, to set the ODBCInstLib setting, you add a line like this:
ODBCInstLib=/usr/lib64/libodbcinst.so

See Additional Parameter Settings for a list of the additional settings.

**Set the VERTICAINI Environment Variable**

You must set an environment variable named VERTICAINI to the absolute path of the vertica.ini file. The Vertica ODBC driver uses this variable to find the settings.

Where you set this variable depends on whether users on your client system need to have separate vertica.ini files. If you want to have a single, system-wide vertica.ini file, you can add a command to set VERTICAINI in /etc/profile or some other system-wide environment file. For example:

```bash
export VERTICAINI=/etc/vertica.ini
```

If users need individual vertica.ini files, set VERTICAINI in their ~/.profile or similar configuration file. For example:

```bash
export VERTICAINI=~/.vertica.ini
```

**Example vertica.ini File**

The following example vertica.ini file configures the ODBC driver to:

- use the 64-bit UNIXODBC driver manager.
- get its error messages from the standard Vertica 64-bit ODBC driver installation directory.
- log all warnings and more severe messages to log files stored in the temporary directory.

```ini
[Driver]
DriverManagerEncoding=UTF-16
ODBCInstLib=/usr/lib64/libodbcinst.so
ErrorMessagePath=/opt/vertica
LogLevel=4
LogPath=/tmp
```

**Installing the FIPS Client Drivers**

This topic details how to install the FIPS client drivers for JDBC and ODBC.
Installing the FIPS Client Driver for ODBC and vsq1

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 9.3. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 9.3.x-xxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstall Vertica 9.2.x.

Vertica 9.2.x offers a FIPS client for FIPS-compatible systems. A FIPS-compatible system is FIPS-enabled and includes the OpenSSL libraries.

The FIPS client supports ODBC and vsq1 and is offered in 64-bit only.

Prerequisites

Verify that your host system is running a FIPS-compliant operating system that Vertica supports.

The FIPS client installer checks your host system for the value of the sysctl parameter, crypto.fips_enabled. You must set this parameter to 1 (enabled). If your host is not enabled, the client does not install.

For other prerequisites, related specifically to ODBC, see ODBC Prerequisites.

Installing the FIPS Client

To install the FIPS client driver package:

1. Download the FIPS client package from the myVertica portal.
2. Log in to the client system as root.
3. Install the RPM package that you downloaded:

   # rpm -Uvh package_name.rpm

For ODBC, once you have installed the client package, you need to create a DSN and set some additional configuration parameters. For more information, see:
- Creating an ODBC DSN for Linux
- Required ODBC Driver Configuration Settings for Linux and UNIX

You may also want to add the vsq1 client to your PATH environment variable so that you do not need to enter its full path to run it. To do so, add the following to the .profile file in your home directory or the global /etc/profile file:

```bash
export PATH=$PATH:/opt/vertica/bin
```

## Client Searches for OpenSSL Libraries

When you launch the client application to connect to the server, the client searches for and loads the OpenSSL libraries libcrypto.so.10 and libssl.so.10 for supported OpenSSL versions:

- The client first checks to see if LD_LIBRARY_PATH is set.
- If the LD_LIBRARY_PATH location does not include the libraries, it checks RunPath, either /opt/vertica/lib or within the ODBC or vsq1 directory structure (../lib).

### Important:

The LD_LIBRARY_PATH, if set, directs the search path for the OpenSSL libraries. Be aware that the client loads the libraries from any set or preset LD_LIBRARY_PATH location.

The following figure depicts the search for the OpenSSL libraries:
Vertica offers a JDBC client driver that is compliant with the Federal Information Processing Standard (FIPS). Use this JDBC client driver to access systems that are FIPS-compatible. For more information on FIPS in Vertica, see Federal Information Processing Standard.
Implementing FIPS on a JDBC client requires a third-party JRE extension called BouncyCastle, a collection of APIs used for cryptography. Use BouncyCastle APIs with JDK 1.7 and 1.8, and a FIPS-compliant operating system that Vertica supports.

**Important:**
When using the JDBC FIPS-compliant client, expect some time lag for the client to connect efficiently and securely. If necessary, increase your system's entropy to ensure a fast and secure connection.

You need to add the FIPS BouncyCastle jar as the JVM JSSE provider, as follows:

1. Download the BouncyCastle FIPS jar file bc-fips-1.0.0.jar from the BouncyCastle download page.
2. Add bc-fips-1.0.0.jar as a JRE library extension:

   ```
   <path to jre>/lib/ext/bc-fips-1.0.0.jar
   ```
3. Add BouncyCastle as an SSL security provider in <path to jre>/lib/security/java.security:

   ```
   security.provider.1=org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
   security.provider.2=com.sun.net.ssl.internal.ssl.Provider
   BCFIPS
   security.provider.3=sun.security.provider.Sun
   ```
4. Use the following JVM java -D system property command arguments to set the KeyStore and TrustStore files to BCFIPS:

   ```
   export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.keyStoreProvider=BCFIPS
   export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.trustStoreProvider=BCFIPS
   ```

   For information on setting the SSL Keystore and Truststore, see Configuring TLS for JDBC Clients.

5. Set the default type for the KeyStore implementation to BCFKS in <path to jre>/lib/security/java.security:

   ```
   keystore type=BCFKS
   ssl.keystore.type=BCFKS
   ```

**Note:**
If you are using FIPS with BouncyCastle, you must create all client keys and
certificates with the BCFKS store type, including the Vertica->Kafka key/certs.

6. On the command line, run the following command from `<path to jre>/lib/ext` to create the keystore and truststore. Make sure you use the BCFKS type:

7. Enter the keystore password when prompted. The following message appears:

   "Certificate was added to the keystore"

8. Run the Java program with SSL DB:

   1. Copy the `vertica.kafka.keystore.bcfks` keyStore from `<path to jre>/lib/ext/` to the java program folder.

   2. Convert the Vertica server certificate to a form that java understands:

      i. openssl x509 -in server.crt -out server.crt.der -outform der

      ii. `<java bin path>/keytool -keystore verticastore -keystore password -importkeystore -noprompt -alias verticasql -import -file server.crt.der

   3. Download the latest vertica JDBC driver from the [Vertica download page](#).

9. After creation of verticastore, keyStore, and download jar, execute the following command to run Java with debugging to test the implementation:

   $ java -Djavax.net.debug=ssl -Djavax.net.ssl.keyStore='vertica.kafka.keystore.bcfks' -Djavax.net.ssl.keyStorePassword='password' -Djavax.net.ssl.trustStore='<path to verticastore>/verticastore' -Djavax.net.ssl.trustStorePassword='password' -cp .:vertica-jdbc-8.1.0-0.jar FIPSTest
Installing the Client Drivers and Tools on Windows

This section details how to install the client drivers and tools on Windows.

For connectivity through a JDBC connection, see Installing the JDBC Client Driver for Windows. For all other client drivers and tools, see The Vertica Client Drivers and Tools for Windows.

Installing the JDBC Client Driver for Windows

To install the Vertica JDBC driver on your Windows client system, you must first download the cross-platform JDBC driver .jar file to your system. Then, choose the method that the Windows Java installation will use to find it.

Important:
If you are using Vertica client drivers for Windows that were released before Vertica 7.2.3, you must first uninstall the older drivers. This is true for the separate JDBC client driver download (the .jar file). This is also true for the client drivers included in the package, Client Drivers and Tools for Windows (an .exe file), which includes ODBC, vsqI, ADO.NET, OLEDB, the Visual Studio plugin, and SQL Server integration components. Once you have installed client versions 7.2.3, you do not need to uninstall for upgrades that follow. For example, upgrading from 8.1.x to 9.3.x would not require that you uninstall before upgrade.

Download the JDBC Driver for Windows

1. On your Windows client system, open a browser, and log in to the myVertica portal.
2. Install the Vertica JDBC driver for Windows:
   a. Navigate to the Downloads tab, and scroll to the Client Software section.
   b. Click the download link for the JDBC Driver for Windows installer.
3. Accept the license agreement, and wait for the download to complete.
Choose How Java Locates the JDBC Driver Library

For your Java client application to use the Vertica JDBC driver, the Java interpreter must be able to find the driver’s library file. Choose one of these methods to tell the Java interpreter where to look for the library:

- Copy the JDBC .jar file you downloaded to the system-wide Java Extensions folder (C:\Windows\Sun\Java).
- Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).
- Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java command line.

The Vertica Client Drivers and Tools for Windows

You can obtain the Vertica Client Drivers and Tools for Windows installer through the myVertica portal. You can run the installer on either a 32-bit or 64-bit system, either as a regular Windows installer or silently.

Components

The Vertica Client Drivers and Tools for Windows installs the following components on your system:

- The ODBC Client Driver for Windows
- The OLE DB Client Driver for Windows
- The vsql Client for Windows
- The ADO.NET Driver for Windows
- The Microsoft Connectivity Pack for Windows
- The Visual Studio Plug-in for Windows

Read Fully Update Your System before you proceed.
System Prerequisites

The Vertica Client Drivers and Tools for Windows released with Vertica Release 7.2. or later has basic system prerequisite requirements. The pack also requires that specific Microsoft components be installed for full integration.

For a list of all prerequisites, see Vertica 9.3.x Client Drivers in the Supported Platforms document.

Important:
If you are using Vertica client drivers for Windows that were released before Vertica 7.2.3, you must first uninstall the older drivers. This is true for the separate JDBC client driver download (the .jar file). This is also true for the client drivers included in the package, Client Drivers and Tools for Windows (an .exe file), which includes ODBC, vsql, ADO.NET, OLEDB, the Visual Studio plugin, and SQL Server integration components. Once you have installed client versions 7.2.3, you do not need to uninstall for upgrades that follow. For example, upgrading from 8.1.x to 9.3.x would not require that you uninstall before upgrade.

Fully Update Your System

Before you install the Vertica driver package, verify that your system is fully up to date with all Windows updates and patches. See the documentation for your version of Windows for instructions on how to run Windows update. The Vertica client libraries and vsql executable install updated Windows libraries that depend on Windows service packs. Be sure to resolve any issues that block the installation of Windows updates.

If your system is not fully up-to-date, you may receive error messages about missing libraries such as api-ms-win-crt-runtime-l1-1-0.dll when starting vsql.
.NET Framework

The .NET framework is not bundled into the Vertica Client Drivers and Tools for Windows. However, during installation, a web installer launches if Microsoft .NET 3.5 SP1 is not detected on your system. You then have the opportunity to download the framework. Also, if your operating system version includes .NET 3.5 SP1, but it is not turned on, the installer turns on the feature.

If you have Visual Studio 2010 or 2012 installed, your system already includes Microsoft .NET Framework 4.0 or 4.5, respectively. You also need Microsoft .NET 3.5 SP1 to use the Vertica Client Drivers and Tools for Windows integration features.

Use the following links to download the appropriate version of .NET framework directly from Microsoft:

- For .NET Framework 3.5 SP1:
  

- For .NET Framework 4.0:
  

- For .NET Framework 4.5:
  
Microsoft Visual Studio

**Important:** You must have Visual Studio and the matching SDK installed to use the Visual Studio plug-in.

After installing the plug-in, you can use it to access your Vertica database from within Visual Studio. If you do not have the SDK installed, download the SDK specific to your version of Visual Studio.

**Note:**
For Visual Studio 2015, you do not need to download the SDK separately as it is included as an installation option with the Visual Studio installation. For more information, refer to the [Microsoft documentation](http://www.microsoft.com/en-us/download/details.aspx?id=508).

- For the Microsoft Visual Studio 2008 SDK:
- For the Microsoft Visual Studio 2008 SP1 SDK:
- For the Microsoft Visual Studio 2010 SDK:
- For the Microsoft Visual Studio 2010 SP1 SDK:
- For the Microsoft Visual Studio 2012 SDK:
- For the Microsoft Visual Studio 2013 SDK:

If the Microsoft Visual Studio SDK is missing when you begin the installation, a dialog box opens to tell you so. You can choose to ignore this dialog box.
Configuring BIDS or SSDT-BI Integration

The Vertica Client Drivers and Tools for Windows installer provides BIDS (Visual Studio 2008) or SSDT-BI (Visual Studio 2010, 2012, 2013, or 2015) integration. To use BIDS or SSDT-BI, follow this process:

1. Install the BIDS or SSDT-BI development tool add-on for Visual Studio.
2. Verify that SQL Server is installed on the same or a different machine.
3. Verify that the SQL Server Shared Features for BIDS or SSDT-BI have been activated.

You can then develop packages using BIDS or SSDT-BI, creating your projects using SQL Server’s SSIS, SSAS, SSRS features. To use these features, you must connect to Vertica through the Vertica ADO.NET driver (for SSIS and SSRS) or the OLE DB driver (for SSAS).

For more information, see Microsoft Components.
Microsoft SQL Server

Use SQL Server 2012, 2014 or 2016. The Vertica Client Drivers and Tools for Windows installer enables support for the following:

- **SQL Server 2012, 2014, and 2016:**
  - SQL Server Integration Services (SSIS)
  - SQL Server Reporting Services (SSRS)
  - SQL Server Analysis Services (SSAS)

- **SQL Server using Visual Studio 2010, 2012, 2013, and 2015**—SQL Server Data Tool - Business Intelligence (SSDT-BI)

**Note:**
For SQL Server 2012, you can use either SQL Server 2012 or SQL Server 2012 SP1.

To use the enhanced Vertica .NET support, you must first install SQL Server. Then, you can install the Client Drivers and Tools for Windows. The following components must be installed on the SQL server:

<table>
<thead>
<tr>
<th>For...</th>
<th>Install...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSAS</td>
<td>The Analysis Services Instance Feature.</td>
</tr>
<tr>
<td>SSRS</td>
<td>The Reporting Services Instance Feature.</td>
</tr>
<tr>
<td>SSIS (Data Type Mappings)</td>
<td>The SQL Server Integration Services Shared Feature.</td>
</tr>
</tbody>
</table>
Download the Client Drivers and Tools for Windows

The Vertica driver downloads page has the client drivers for all currently-supported versions of Vertica. The installation package works on both 32-bit and 64-bit versions of Windows.

Install or Upgrade the Client Drivers and Tools for Windows

As the Windows Administrator, double-click the installer to start the installation. Follow the prompts as the wizard guides you through each step of the process.

By default, the installer installs the client drivers and tools in C:\Program Files\Vertica Systems\ . You have the option of changing this location during installation.

Note:
The install wizard allows you to choose the components you want to install. Under your Windows Control Panel, the installer adds a program for each installed component. Among the programs the installer adds is a program named, Vertica Client Installer. You can right-click on the installer to modify, repair, or uninstall the Vertica client.

Important:
The Vertica Microsoft Connectivity Pack is included as part of the Vertica Client Drivers and Tools for Windows. If you plan to use the Microsoft Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.

Upgrading the Client Drivers and Tools for Windows

You do not need to uninstall the Client Drivers and Tools for Windows before upgrading. The installation program upgrades the existing drivers and tools in place.

Important:
If you are using Vertica client drivers for Windows that were released before
Vertica 7.2.3, you must first uninstall the older drivers. This is true for the separate JDBC client driver download (the .jar file). This is also true for the client drivers included in the package, Client Drivers and Tools for Windows (an .exe file), which includes ODBC, vsqi, ADO.NET, OLEDB, the Visual Studio plugin, and SQL Server integration components. Once you have installed client versions 7.2.3, you do not need to uninstall for upgrades that follow. For example, upgrading from 8.1.x to 9.3.x would not require that you uninstall before upgrade.

Silently Install or Upgrade the Client Drivers and Tools for Windows

1. As a Windows Administrator, open a command-line session, and change directory to the folder that contains the installer.
2. Run the command:

   VerticaSetup.exe -q -install InstallFolder="C:\Program Files\Vertica Systems"

The client drivers and tools are silently installed in C:\Program Files\Vertica Systems\.

Upgrading the Client Drivers and Tools for Windows

You do not need to uninstall the Client Drivers and Tools for Windows before upgrading. The installation program upgrades the existing drivers and tools in place.

Important:
If you are using Vertica client drivers for Windows that were released before Vertica 7.2.3, you must first uninstall the older drivers. This is true for the separate JDBC client driver download (the .jar file). This is also true for the client drivers included in the package, Client Drivers and Tools for Windows (an .exe file), which includes ODBC, vsqi, ADO.NET, OLEDB, the Visual Studio plugin, and SQL Server integration components. Once you have installed client versions 7.2.3, you do not need to uninstall for upgrades that follow. For example, upgrading from 8.1.x to 9.3.x would not require that you uninstall before upgrade.
Post-Installation Steps for ODBC Driver and vsq1 Client

After you install the Vertica Client Drivers and Tools for Windows, there are additional steps you must take for the ODBC driver and vsq1 client to function correctly.

- **ODBC Driver** — After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Windows Clients.
- **vsq1 Client** — The vsq1 client does not have a shortcut. Before you can start using vsq1, you must add the vsq1 executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating system you are running. To start vsq1 and show the help list, open a command window, and type `vsq1 -?` at the command prompt. See Using vsq1 for Windows Users for important details about using vsq1 in a Windows console.

Uninstalling, Modifying, or Repairing the Client Drivers and Tools

To uninstall, modify, or repair the client drivers and tools, run the Client Drivers and Tools for Windows installer.

The installer provides three options:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify</td>
<td>Remove installed client drivers and tools or install missing client drivers and tools.</td>
</tr>
<tr>
<td>Repair</td>
<td>Reinstall already-installed client drivers and tools.</td>
</tr>
<tr>
<td>Uninstall</td>
<td>Uninstall all of the client drivers and tools.</td>
</tr>
</tbody>
</table>
Silently Uninstall the Client Drivers and Tools

1. As a Windows Administrator, open a command-line session, and change directory to the folder that contains the installer.
2. Run the command:

   ```
   VerticaSetup.exe -q -uninstall
   ```

The client drivers and tools are silently uninstalled.

Components of the Client Drivers and Tools on Windows

The following sections describe the components in the Client Drivers and Tools for Windows in more detail:

- The ODBC Client Driver for Windows
- The \texttt{vsql} Client for Windows
- The Microsoft Connectivity Pack for Windows
- The OLE DB Client Driver for Windows
- The ADO.NET Driver for Windows
- The Visual Studio Plug-in for Windows

The ODBC Client Driver for Windows

The Vertica ODBC driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the Client Drivers downloads page.

After Installing the ODBC Driver

After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Windows Clients.
**ODBC Driver Settings on Windows**

ODBC driver settings are automatically configured using the Vertica Client Drivers and Tools installer on Windows. The values for the settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver. It is not necessary to configure additional ODBC driver settings on Windows platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings using the Windows ODBC Data Source Configuration window.

See Additional Parameter Settings for a list of additional settings for the ODBC client driver. See Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs for information on how to send ODBC log entries to Event Tracing for Windows (ETW).

**Diverting ODBC Log Entries to ETW**

On Windows clients, you can direct Vertica to send ODBC log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

**Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs**

To use ETW logging, you must register the ODBC driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

**Important:**

If you do not both register the driver and enable the logs, output is directed to stdout.
1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

   **Important:**
   You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.
   
   1. For the 64-bit ODBC driver, run:
      
      ```
      wevtutil im "c:\Program Files\Vertica Systems\ODBC64\lib\VerticaODBC64.man"
      /resourceFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
      /messageFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
      ```
   
   2. For the 32-bit ODBC driver, run:
      
      ```
      wevtutil im "c:\Program Files (x86)\Vertica Systems\ODBC32\lib\VerticaODBC32.man"
      /resourceFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
      /messageFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
      ```

3. Run the command `wevtutil sl` to enable the logs.
   
   1. For 64-bit ODBC driver logs, run:
      
      ```
      wevtutil sl VerticaODBC64/e:true
      ```
   
   2. For the 32-bit ODBC driver logs, run:
      
      ```
      wevtutil sl VerticaODBC32/e:true
      ```

   **Note:**
   Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.
Add the String Value LogType

By default, Vertica does not send ODBC log entries to ETW. To activate ETW, add the string LogType to your Windows registry, and set its value to ETW.

1. Start the registry editor by typing regedit.exe in the Windows Run command box.
2. Navigate to the correct location in the registry.

```
HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver
```

3. Right-click in the right pane of the Registry Editor window. Select New and then select String Value.
4. Change the name of the string value from New Value #1 to LogType.
5. Double-click the new LogType entry. When prompted for a new value, enter ETW.
6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

Event Viewer Log Levels

The LogLevel parameter setting is described in the section, Additional Parameter Settings. The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

<table>
<thead>
<tr>
<th>Vertica LogLevel Setting</th>
<th>Vertica LogLevel Description</th>
<th>Entries are sent to Event Viewer as log level...</th>
<th>Event Viewer Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(No logging)</td>
<td>0</td>
<td>(No logging)</td>
</tr>
<tr>
<td>1</td>
<td>Fatal Errors</td>
<td>1</td>
<td>Critical</td>
</tr>
<tr>
<td>2</td>
<td>Errors</td>
<td>2</td>
<td>Error</td>
</tr>
<tr>
<td>3</td>
<td>Warnings</td>
<td>3</td>
<td>Warning</td>
</tr>
</tbody>
</table>
### Vertica LogLevel Setting

<table>
<thead>
<tr>
<th>Vertica LogLevel Setting</th>
<th>Vertica LogLevel Description</th>
<th>Entries are sent to Event Viewer as log level...</th>
<th>Event Viewer Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Info</td>
<td>4</td>
<td>Information</td>
</tr>
<tr>
<td>5</td>
<td>Debug</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Trace (all messages)</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

### Where to Find Logs in Event Viewer

1. Launch the **Windows Event Viewer**.
2. From **Event Viewer (Local)**, expand **Applications and Services Logs**.
3. Expand the folder that contains the log you want to review (for example, **VerticaODBC64**).
4. Select the Vertica ODBC log under the folder. Entries appear in the right pane.

### Event Log Entry: Event ID

Once you have chosen an ODBC log in Event Viewer, note the value in the **Event ID** field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

### The vsqI Client for Windows

The Vertica vsqI client for Windows is installed as part of the Client Drivers and Tools for Windows.

There is no shortcut for the vsqI client. Before you can start using vsqI, you must add the vsqI executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating system.
system you are running. After you have made the change to your PATH environment variable, start a command window and type `vsql -?` at the command prompt to start `vsql` and show the help list.

For information about editing the Window PATH environment variable, see [How do I set or change the PATH system variable?](#)

For important details about using `vsql` in a Windows console, see [Using vsql for Windows Users](#).

## Using vsql for Windows Users

### Font

The default raster font does not work well with the ANSI code page. Set the console font to "Lucida Console."

### Console Encoding

`vsql` is built as a "console application." The Windows console windows use a different encoding than the rest of the system, so take care when you use 8-bit characters within `vsql`. If `vsql` detects a problematic console code page, it warns you at startup.

To change the console code page, set the code page by entering `cmd.exe /c chcp 1252`.

**Note:**

1252 is a code page that is appropriate for European languages. Replace it with your preferred locale code page.

### Running Under Cygwin

Verify that your cygwin.bat file does not include the "tty" flag. If the "tty" flag is included in your cywgin.bat file, then banners and prompts are not displayed in `vsql`.

To verify, enter:

```
set CYGWIN=binmode tty ntsec
```

To remove the "tty" flag, enter:
set CYGWIN=binmode ntsec

Additionally, when running under Cygwin, vsq1 uses Cygwin shell conventions as opposed to Windows console conventions.

**Tab Completion**

Tab completion is a function of the shell, not vsq1. Because of this, tab completion does not work the same way in Windows vsq1 as it does on Linux versions of vsq1.

On Windows, instead of using tab-completion, press F7 to pop-up a history window of commands. You can also press F8 after typing a few letters of a command to cycle through commands in the history buffer which begin with the same letters.

**The Microsoft Connectivity Pack for Windows**

The Vertica Microsoft Connectivity Pack for Windows provides a configuration file for you to access Microsoft Business Intelligence tools. The Connectivity Pack is installed as part of the Client Drivers and Tools for Windows.

To learn about which Microsoft components are configured with the Microsoft Connectivity Pack, see [Microsoft Components](#).

**Microsoft Components**

This section describes the Microsoft Business Intelligence components you can use with Microsoft Visual Studio and Microsoft SQL Server. After configuration, you can use these Microsoft components to develop business solutions using your Vertica server.

**Important:**

The Vertica Microsoft Connectivity Pack is included as part of the Vertica Client Drivers and Tools for Windows. If you plan to use the Microsoft Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.
Microsoft Component Configuration

The Vertica ADO.NET driver, the Visual Studio plug-in, and the OLE DB driver allow you to integrate your Vertica server with an environment that includes Microsoft components previously installed on your system. Additional tools are also available for integration with Microsoft SQL Server.

The available drivers provide integration with the following Microsoft components:

- **Business Intelligence Development Studio (BIDS) for Visual Studio 2008** for use with SQL Server 2012. BIDS is a client-based application used to develop business intelligence solutions based on the Microsoft Visual Studio development environment. It includes additional project types specific to SQL Server Business Intelligence. As a developer, you can use BIDS to develop business solutions.
- **SQL Server Analysis Services (SSAS)** for SQL Server 2012, 2014, and 2016. Use SSAS for OLAP and data mining, while using Vertica as the source for cube creation.
- **SQL Server Integration Services (SSIS)** for SQL Server 2012, 2014, and 2016. SSIS provides SQL Server Type Mappings to map data types between Vertica and SQL Server. Use SSIS for data migration, data integration and workflow, and ETL.

The following figure displays the relationship between Microsoft components and Vertica dependencies.
BIDS and SSDT-BI

Business Intelligence Development Studio (BIDS) is available in Microsoft Visual Studio 2008 with additional project types that are specific to SQL Server business intelligence. BIDS is the primary environment that you use to develop business solutions that include Analysis Services, Integration Services, and Reporting Services projects.

Both BIDS and SSDT-BI are client-based applications that include additional project types specific to SQL Server Business Intelligence.

You can use the Visual Studio Shell Integration plug-in to browse a database from within the Visual Studio Server Explorer. This capability allows you to work outside of BIDS or SSDT-BI development to perform tasks, such as listing tables or inserting data. When you use Visual Studio in BIDS or SSDT-BI mode, you can develop business solutions using the data in your Vertica database. For example, you can create cubes or open tables.

Microsoft does not support the following configurations:

- You cannot use Microsoft Visual Studio 2008 with BIDS development to create a SQL Server 2012 Business Intelligence solution.
- You cannot use Microsoft Visual Studio 2010/2012/2013/2015 with SSDT-BI development to create a SQL Server 2008 Business Intelligence solution.
SQL Server Analysis Services (SSAS) Support

BIDS or SSDT-BI includes the Analysis Services project for developing online analytical processing (OLAP) for business intelligence applications. This project type includes templates for:

- Cubes
- Dimensions
- Data sources
- Data source views

It also provides the tools for working with these objects.

**Note:** OpenText recommends that you use the Vertica OLE DB driver when connecting to the Vertica server from SSAS due to improved performance.

You can find the OLE DB connection properties in [OLE DB Connection Properties](#).
SQL Server Integration Services (SSIS) Support

BIDS or SSDT-BI includes the Integration Services project for developing ETL solutions. This project type includes templates for:

- Packages
- Data sources
- Data source views

It also provides the tools for working with these objects.

You can find support for using Vertica as a data source and target from both SSIS and the import/export wizard. You must install mapping files specific to Vertica on the Integration Server and BIDS or SSDT-BI workstation to enable this capability. The Vertica Client Drivers and Tools for Windows installs these mapping files as the "SQL Server Type Mappings" component(s) in both 32-bit and 64-bit versions.

**Note:** Always use the Vertica ADO.NET driver when connecting to the Vertica server from SSIS.
**SQL Server Reporting Services (SSRS) Support**

BIDS or SSDT-BI includes Report projects for developing reporting solutions.

You can use Vertica as a data source for Reporting Services. The installer implements various configuration file modifications to enable this capability on both the BIDS or SSDT-BI workstation and the Reporting Services server.

**Compatibility Issues and Limitations**

This section lists compatibility issues and limitations for integrating the Microsoft Connectivity Pack with Microsoft Visual Studio and Microsoft SQL Server.
BIDS and SSDT-BI Limitations

BIDS and SSDT-BI are 32-bit development environments for Analysis Services, Integration Services, and Reporting Services projects. They are not designed to run on the Itanium 64-bit architecture and thus are not installed on Itanium servers.
SSAS Limitations

- The SSAS Tabular Model is not supported.
- If, after installing the Vertica OLE DB driver, an SSAS cube build fails, restart the SSAS service.
SSIS Data Type Limitations

The following sections cover data type limitations when using SQL Server Integration Services (SSIS).

Time Data Transfer

When transferring time data, SSIS uses the TimeSpan data type that supports precision greater than six digits. The Vertica ADO.NET driver translates TimeSpan as an Interval data type that supports up to six digits. The Interval type is not converted to the TimeSpan type during transfer. As a result, if the time value has a precision of more than six digits, the data is truncated, not rounded.

For information on ADO.NET data types, refer to ADO.NET Data Types.

DATE and DATETIME Precision

To function without errors, DATE and DATETIME have a range from 0001-01-01 00:00:00.0000000 to 9999-12-31 23:59:59.999999.

In SSIS, the DATETIME type (DT_TIMESTAMP) supports only a scale up to three decimal places for seconds. Any decimal places after that are automatically discarded. You can perform derived column transformations only on DATETIME values between January 1, 1753 through December 31, 9999.

Numeric Precision

The maximum and minimum decimal allowed is:

- Max: +79,228,162,514,264,337,593,543,950,335
- Min: -79,228,162,514,264,337,593,543,950,335

For example, if the scale is 16, the range of values is:

+/- 7,922,816,251,426.4337593543950335

The valid scale range is any number that is smaller than 29 and greater than 38. Using a scale between 29 and 38 does not generate an error.

Unsupported Floating Point Values

SQL Server does not support NaN, Infinity, or –Infinity values. These values are supported when you use SSIS to transfer between Vertica instances, but they are not supported with a SQL Server Destination.

String Conversion

The CHAR and VARCHAR data types used in SSIS are DTWSTR, with a maximum length of 4000 characters.

In SSIS, Vertica strings are converted to Unicode strings in SSIS to handle multi-lingual data. You can convert these strings to ASCII using a Data Conversion Task.

Scale

Whenever you use a scale greater than 38, SSIS replaces it with a value of 4.

Interval Conversion

SSIS does not support interval types. It converts them to TIME and strips off the day component. Any package that has interval types greater than a day returns incorrect results.

Data Mapping Issues with SQL Server Import and Export Wizard

When you create an Integrated Services package (SSIS) using the SQL Server Import and Export Wizard, certain data types do not automatically map correctly. A mapping issue can occur when you use the wizard with:

- SQL Server Native OLE DB Provider for SQL Server 2008 or 2012
- SQL Server Native Client 10.0/11.0 Provider for SQL Server 2010/2012

To avoid this issue, manually change the type mappings with BIDS or SSDT-BI.
Data Transfer Failures

When using an Integrated Services package (SSIS) with the SQL Server OLE DB Provider for SQL Server 2008 or 2012, certain data type transfers can fail when transferring from Vertica to SQL Server. To avoid this issue, use either BIDS or SSDT-BI when transferring data.

Batch Insert of VARBINARY/LONG VARBINARY Data Types

Sometimes, one row of a batch insert of VARBINARY or LONG VARBINARY data types exceeds the data type limit:

- VARBINARY: 65 KB
- LONG VARBINARY: 32 MB

In such cases, all rows are rejected, rather than just the one row whose length exceeds the type limit. The batch insert fails with the message "row(s) are rejected".

To avoid this issue, use a predicate to filter out rows from the source that do not fit into the receiving database.

Boolean Queries in SQL Server Query Designer

When issuing a Boolean query in SQL Server Query Designer, you must enclose Boolean column values in quotes. Otherwise, you receive a SQL execution error (for example, someboolean = 'true').
SSRS Limitations

Data Connection Wizard Workaround

The SSRS Report Wizard provides a data connection wizard. After you select the wizard and enter all the connection information, the OK button is disabled. You cannot save your work and continue. The workaround is to not use the wizard and to use the following panel instead:

![Report Wizard - Query Designer](image)

**Report Wizard - Query Designer**

Vertica uses the Report Wizard's Generic Query Designer. Other data sources use a Graphical Query Designer that supports building queries visually. The Graphical Query Designer is a part of a package called Visual Data Tools (VDT). The Graphical Query Designer works only with Generic OLE DB providers and the built-in providers. You cannot use it with the Vertica Data Provider.

**Report Builder**

Report Builder is a web-based report design tool. It does not support creating reports using custom data extensions, so you cannot use it with Vertica. When you create a report using Report Builder, existing Vertica data sources appear in the list of available data sources. However, choosing a Vertica data source causes an error.

**Schema Name Not Automatically Provided when Mapping Vertica Destination**

Currently, when you map a Vertica destination, the schema name is not automatically provided. You must enter it manually or pick it from the drop-down menu as follows:
The OLE DB Client Driver for Windows

The Vertica OLE DB driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the [Client Drivers downloads page](#).

The values for the OLE DB driver's settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver.

For information on how the OLE DB driver integrates with Microsoft components previously installed on your system, see [Microsoft Component Configuration](#).

OLE DB Connection Properties

Use the [Connection Manager](#) to set the OLE DB connection string properties, which define your connection. You access the Connection Manager from within Visual Studio.

These connection parameters appear on the Connection page.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provider</td>
<td>Select the native OLE DB provider for the</td>
<td>None</td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extended Properties</td>
<td>Not supported.</td>
<td>Leave blank. Do not set this field.</td>
</tr>
<tr>
<td>Locale Identifier</td>
<td>Indicates the Locale ID.</td>
<td>0</td>
</tr>
<tr>
<td>Mode</td>
<td>Specifies access permissions.</td>
<td>0</td>
</tr>
<tr>
<td>Connect Timeout</td>
<td>Not supported. The value can be</td>
<td>0</td>
</tr>
</tbody>
</table>

The All page from the Connection Manager dialog box includes all possible connection string properties for the provider.

The table that follows lists the connection parameters for the All page.

For OLE DB properties information specific to Microsoft, see the Microsoft documentation [OLE DB Properties](#).

### Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>OLE DB Provider</td>
<td>Indicates Vertica OLE DB Provider.</td>
<td>None</td>
</tr>
<tr>
<td>Server or file name</td>
<td>Enter the server or file name.</td>
<td>None</td>
</tr>
<tr>
<td>Location</td>
<td>Not supported.</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Use Windows NT Integrated Security</td>
<td>Not supported.</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Use a specific user name and password</td>
<td>Enter a user name and password. Connect with No Password:</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>Select the <strong>Blank password</strong> check box.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Save and Encrypt Password:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Select <strong>Allow saving password</strong>.</td>
<td></td>
</tr>
<tr>
<td>Initial Catalog</td>
<td>The name of the database running on the server.</td>
<td>None</td>
</tr>
</tbody>
</table>

The All page from the Connection Manager dialog box includes all possible connection string properties for the provider.
<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
<th>Default Value</th>

<td>Action</td>
<td>Default Value</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>configuration</td>
<td>configure the connection, such as setting a schema search path.</td>
<td></td>
</tr>
</tbody>
</table>
|fony symbol: ';' To set multiple parameters in this field use '%3B' for ','.
<p>| Spaces: Use '+'.                 |                                                                         |               |
| ConvertSquareBracketIdentifiers  | Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. | False         |
| DirectBatchInsert                | Controls where data inserted through the connection is stored.          | False         |
|                                 | Valid Values:                                                          |               |
|                                 | • True — Data inserted directly into ROS containers.                   |               |
|                                 | • False — Stores data using AUTO mode.                                 |               |
|                                 | When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS. For details about load options, see Choosing a Load Method. |               |
| KerberosHostName                 | Provides the instance or host name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM | None.         |
| KerberosServiceName              | Provides the service name portion of the Vertica Kerberos principal; for example: | None          |</p>
<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>vertica/host@EXAMPLE.COM</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Label</td>
<td>Sets a label for the connection on the server. This value appears in the session_id column of the <code>V_MONITOR.SESSIONS</code> system table.</td>
<td>None</td>
</tr>
<tr>
<td>LogLevel</td>
<td>Specifies the amount of information included in the log. Leave this field blank or set to 0 unless otherwise instructed by Vertica Customer Support.</td>
<td>None</td>
</tr>
<tr>
<td>LogPath</td>
<td>The path for the log file.</td>
<td>None</td>
</tr>
<tr>
<td>Port</td>
<td>The port number on which Vertica listens for OLE DB connections.</td>
<td>None</td>
</tr>
</tbody>
</table>
| PreferredAddressFamily | The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are:  
  - ipv4—Connect to the server using IPv4.  
  - ipv6—Connect to the server using IPv6.  
  - none—Use the IP address provided by the DNS server. | None          |
| SSLCertFile         | The absolute path of the client's public certificate file. This file can reside anywhere on the system. | None          |
| SSLKeyFile          | The absolute path to the client's private key file. This file can reside anywhere on the system. | None          |
| SSLMode             | Controls whether the connection to the database uses SSL                | Prefer        |
### Parameters, Action, Default Value

- **encryption.** Valid values follow.
  
  **Valid Values:**
  
  - **require**—Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails.
  - **prefer**—Prefers that the server use SSL. If the server does not offer an encrypted channel, the client requests one. The first attempt is made with SSL. If that attempt fails, the second attempt is over a clear channel.
  - **allow**—Makes a connection to the server whether or not the server uses SSL. The first attempt is made over a clear channel. If that attempt fails, a second attempt is over SSL.
  - **disable**—Never connects to the server using SSL. Typically, you use this setting for troubleshooting.

---

### Diverting OLE DB Log Entries to ETW

On Windows clients, you can direct Vertica to send OLE DB log entries to Event Tracing for Windows (ETW). Once set, OLE DB log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
Know where to find the logs within Event Viewer.
Understand the meaning of the Event IDs in your log entries.

Register the OLE DB Driver as a Windows Event Log Provider, and Enable the Logs

To use ETW logging, you must register the OLE DB driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

**Important:**
If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

**Important:**
You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.

   1. For the 64-bit OLE DB driver, run:

```
wevtutil im "c:\Program Files\Vertica Systems\OLEDB64\lib\VerticaOLEDB64.man"
/resourceFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_olddb.dll"
/messageFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_olddb.dll"
```

   2. For the 32-bit OLE DB driver, run:

```
wevtutil im "c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\VerticaOLEDB32.man"
/resourceFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_olddb.dll"
/messageFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_olddb.dll"
```

3. Run the command `wevtutil sl` to enable the logs.
1. For 64-bit OLE DB driver logs, run:

   `wevtutil sl VerticaOLEDB64/e:true`

2. For the 32-bit ODBC driver logs, run:

   `wevtutil sl VerticaOLEDB32/e:true`

**Note:** Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.

---

**Add the String Value LogType**

By default, Vertica does not send OLE DB log entries to ETW. To activate ETW, add the string LogType to your Windows registry, and set its value to ETW.

1. Start the registry editor by typing `regedit.exe` in the Windows Run command box.
2. Navigate to the correct location in the registry.

   `HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver`

3. Right-click in the right pane of the **Registry Editor** window. Select **New** and then select **String Value**.
4. Change the name of the string value from **New Value #1** to LogType.
5. Double-click the new LogType entry. When prompted for a new value, enter ETW.
6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

---

**Event Viewer Log Levels**

The LogLevel parameter setting is described in the section, Additional Parameter Settings. The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.
## Vertica LogLevel Setting

<table>
<thead>
<tr>
<th>Vertica LogLevel Setting</th>
<th>Vertica LogLevel Description</th>
<th>Entries are sent to Event Viewer as log level...</th>
<th>Event Viewer Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(No logging)</td>
<td>0</td>
<td>(No logging)</td>
</tr>
<tr>
<td>1</td>
<td>Fatal Errors</td>
<td>1</td>
<td>Critical</td>
</tr>
<tr>
<td>2</td>
<td>Errors</td>
<td>2</td>
<td>Error</td>
</tr>
<tr>
<td>3</td>
<td>Warnings</td>
<td>3</td>
<td>Warning</td>
</tr>
<tr>
<td>4</td>
<td>Info</td>
<td>4</td>
<td>Information</td>
</tr>
<tr>
<td>5</td>
<td>Debug</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Trace (all messages)</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

### Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

## Where to Find Logs in Event Viewer

1. Launch the **Windows Event Viewer**.
2. From **Event Viewer (Local)**, expand **Applications and Services Logs**.
3. Expand the folder that contains the log you want to review (for example, VericaOLEDB64).
4. Select the Vertica OLE DB log under the folder. Entries appear in the right pane.

## Event Log Entry: Event ID

Once you have chosen an OLE DB log in Event Viewer, note the value in the **Event ID** field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.
The **ADO.NET Driver for Windows**

The Vertica ADO.NET driver for Windows is installed as part of the Client Drivers and Tools for Windows.

The ADO.NET driver is installed in the ADO.NET folder of the installation folder. The driver is also installed into the Windows Global Assembly Cache (GAC).

For information on how the ADO.NET driver integrates with Microsoft components previously installed on your system, see [Microsoft Components](#).

The **Visual Studio Plug-in for Windows**

The Visual Studio plug-in for Windows is installed as part of the Client Drivers and Tools for Windows.

For information on how the Visual Studio plug-in integrates with Microsoft components previously installed on your system, see [Microsoft Components](#).

**Visual Studio Limitations**

**Visual Studio 2012 May Require Update 3**

You may need to install update 3 to Visual Studio 2012 if:

- You launch Server Explorer to view and work with your Vertica server, but the Vertica data source is not visible.
- You create a SSAS cube, connect to Vertica, and find either an empty list of tables or tables not functioning correctly.

This issue does not occur for other versions of Visual Studio supported by Vertica.

**Results Viewer Limited to 655 Columns**

The Visual Studio results viewer cannot execute a query that includes more than 655 columns. If a table includes more than 655 columns, select specific columns (up to 655 total) rather than selecting all columns.

**Manually Refresh Settings for Visual Studio**
If, after installing the Visual Studio plug-in, you do not see Vertica listed as a data provider, manually refresh.

To do so, run devenv.exe/setup, which you can find in the Visual Studio installation folder.

**SQL Pane Issues**

- **ALTER TABLE or CREATE TABLE**
  
  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and issue the ALTER TABLE or CREATE TABLE statement in the SQL pane. However, a message displays telling you that the statement is not supported. To resolve the error, click **Continue**, and the query executes.

- **Queries with Semicolons**
  
  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and execute a SQL query in the SQL pane. If you include a semicolon (;) with your query, the query executes, but the result returned cannot be edited. To avoid this issue, enter the same query in the SQL pane without the semicolon.

- **Quoting Boolean Values**
  
  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 to connect to the Vertica database and execute a SQL query in the SQL pane. When attempting to insert a value into a Boolean column without putting quotes around the value, subsequent execution of the SQL statement returns an error. To work around this issue, include quotes.

**Uninstalling Client Drivers and Tools for Windows Error**

There is a scenario where an uninstall of the Client Drivers and Tools for Windows package fails with a message that the .NET framework is required. What follows is the scenario that causes this issue.

1. You Install the Client Drivers and Tools for Windows.
2. You then install Visual Studio 2010 or 2012, which includes installation of the .NET framework 4.0 or 4.5.
3. You uninstall the .NET framework using the Windows Control Panel.
4. You then attempt to uninstall the Client Drivers and Tools for Windows. The uninstall fails with the message that .NET framework is required.

Perform the following to correct this issue:
1. Reinstall the .NET framework 4.0 or 4.5 manually, using the Windows Control Panel.
2. Uninstall the Client Drivers and Tools for Windows.

**Installing the Client Drivers on Mac OS X**

This section details how to install the client drivers on Mac OS X.

**Installing the JDBC Driver on Mac OS X**

To install the Vertica JDBC driver on your Mac OS X client system, download the cross-platform JDBC driver .jar file to your system and ensure OS X's Java installation can find it.

**Downloading the JDBC Driver**

To download the Vertica JDBC driver on Mac OS X:

1. On your Mac client system, open a browser and log into the myVertica portal.
2. Navigate to the Downloads page, scroll to the Client Software download section, and click the download link for the JDBC driver.
3. Accept the license agreement and wait for the download to complete.

**Ensuring Java Can Find the JDBC Driver**

In order for your Java client application to use the Vertica JDBC driver, the Java interpreter needs to be able to find its library file. Choose one of these methods to tell the Java interpreter where to look for the library:

- Copy the JDBC .jar file you downloaded to either the system-wide Java Extensions folder (/Library/Java/Extensions) or your user Java Extensions folder (/Users/username/Library/Java/Extensions).
- Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).
- Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java command line.
Installing the ODBC Driver on Mac OS X

You can download the Vertica ODBC driver for Mac OS X as a .pkg file from the Vertica driver downloads page. You can run the installer as a regular Mac OS X installer or silently.

The installer is designed to be used with the standard iODBC Driver Manager included in Mac OS X. While Mac OS X ships with the iODBC Driver Manager already installed, you may choose to download the most recent version of the driver at the iODBC.org website.

By default, the installer installs the driver in the following location: /Library/Vertica/ODBC/lib/libverticaodbc.dylib. The installer also automatically registers a driver named "Vertica" with the iODBC Driver Manager.

To use the unixODBC Driver Manager instead of Apple's iODBC Driver Manager, see the unixODBC.org website.

Before You Download the Driver

If you installed a previous version of the Vertica ODBC driver for Mac OS X, your system might already have a registered driver named "Vertica." In this case, you must remove or rename the older version of the driver before installing the Vertica ODBC driver .pkg file.

To have multiple versions of the driver installed on your system at the same time, you must rename the currently installed version of the driver to something other than "Vertica."

Download the Driver

Follow these steps to download the Vertica ODBC driver for Mac OS X:

1. On your Mac OS X client system, open a browser, and log in to the myVertica portal.
2. Install the Vertica ODBC driver for Mac OS X:
   1. Navigate to the Downloads tab, and scroll to the Client Software section.
   2. Click the download link for the Mac OS X ODBC installer.
3. Accept the license agreement, and wait for the download to complete.
Install the Mac OS X ODBC Driver

As a Mac OS X Administrator, double-click the installer to start the installation. Follow the prompts as the wizard guides you through each step of the process.

**Note:**
After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X Clients.

Silently Install the Mac OS X ODBC Driver

1. Log into the client Mac in one of two ways:
   - As an administrator account, if you are installing the driver for system-wide use
   - As the user who needs to use the Vertica ODBC driver
2. Open a terminal window. In the Finder, click **Applications > Utilities > Terminal**.
3. Install the .pkg file containing the ODBC driver using the command:

   ```bash
   sudo installer -pkg ~/Downloads/vertica-odbc9.3.pkg -target /
   ```

   In the preceding .pkg command, change the path to that of the downloaded file, *if*:
   - You downloaded the driver .pkg file to a directory other than your Downloads directory.
   - You downloaded the driver using another user account.

**Note:**
After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X Clients.

Uninstall the Mac OS X ODBC Driver

Uninstalling the Mac OS X ODBC Client-Driver does not remove any existing DSNs associated with the driver.

To uninstall:
1. Open a terminal window.
2. Enter the command:

```
sudo /Library/Vertica/ODBC/bin/Uninstall
```

**Upgrade or Downgrade the Mac OS X ODBC Driver**

All installations of the Vertica ODBC driver for Mac OS X are uniquely identified by a package ID and version number. The package ID does not change between versions, but the version number does. If you attempt multiple installations of the same version of the driver, a name collision error occurs. Therefore, multiple installations of the same version of the driver cannot coexist on a single operating system.

- **Upgrading**—Newly installed versions of the Vertica ODBC driver for Mac OS X automatically upgrade the relevant driver system settings. Any DSNs associated with a previous version of the driver are not affected, except that they begin using the newer version of the driver.
- **Downgrading**—Run the uninstall script to remove the current version of the Vertica ODBC driver for Mac OS X. Complete this step before installing an older driver version.

**ODBC Driver Settings on Mac OS X**

ODBC driver settings are automatically configured using the Vertica ODBC driver installer on Mac OS X. It is not necessary to configure additional ODBC driver settings on Mac OS X platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings by editing the VERTICAINI environment variable in each user's `~/.MacOSX/environment.plist` file. See the [Environment Variables](#) entry in the Apple Developer's Library for more information.

See [Additional Parameter Settings](#) for a list of the additional settings.
Creating an ODBC Data Source Name (DSN)

A Data Source Name (DSN) is the logical name that is used by Open Database Connectivity (ODBC) to refer to the driver and other information that is required to access data from a data source. Whether you are developing your own ODBC client code or you are using a third-party tool that needs to access Vertica using ODBC, you need to configure and test a DSN. The method you use depends upon the client operating system you are using.

Refer to the following sections for information specific to your client operating system.

- Creating an ODBC DSN for Linux
- Creating an ODBC DSN for Windows Clients
- Creating an ODBC DSN for Macintosh OS X Clients
- Data Source Name (DSN) Connection Properties
- Setting DSN Connection Properties

Creating an ODBC DSN for Linux

You define DSN on Linux and other UNIX-like platforms in a text file. Your client's driver manager reads this file to determine how to connect to your Vertica database. The driver manager usually looks for the DSN definitions in two places:

- /etc/odbc.ini
- ~/.odbc.ini (a file named .odbc.ini in the user's home directory)

Users must be able to read the odbc.ini file in order to use it to connect to the database. If you use a global odbc.ini file, consider creating a UNIX group with read access to the file. Then, add the users who need to use the DSN to this group.

The structure of these files is the same—only their location differs. If both files are present, the ~/.odbc.ini file usually overrides the system-wide /etc/odbc.ini file.

**Note:**
See your ODBC driver manager's documentation for details on where these files should be located and any other requirements.
**odbc.ini File Structure**

The odbc.ini is a text file that contains two types of lines:

- Section definitions, which are text strings enclosed in square brackets.
- Parameter definitions, which contain a parameter name, an equals sign (=), and then the parameter's value.

The first section of the file is always named [ODBC Data Sources], and contains a list of all the DSNs that the odbc.ini file defines. The parameters in this section are the names of the DSNs, which appear as section definitions later in the file. The value is a text description of the DSN and has no function. For example, an odbc.ini file that defines a single DSN named VerticaDSN could have this ODBC Data Sources section:

```
[ODBC Data Sources]
VerticaDSN = "vmartdb"
```

Appearing after the ODBC data sources section are sections that define each DSN. The name of a DSN section must match one of the names defined in the ODBC Data Sources section.

**Configuring the odbc.ini file:**

To create or edit the DSN definition file:

1. Using the text editor of your choice, open odbc.ini or ~/.odbc.ini.
2. Create an ODBC Data Sources section and define a parameter:
   - Whose name is the name of the DSN you want to create
   - Whose value is a description of the DSN
   
   For example, to create a DSN named VMart, you would enter:

   ```
   [ODBC Data Sources]
   VMart = "VMart database on Vertica"
   ```

3. Create a section whose name matches the DSN name you defined in step 2. In this section, you add parameters that define the DSN's settings. The most commonly-defined parameters are:
• **Description** – Additional information about the data source.
• **Driver** – The location and designation of the Vertica ODBC driver, or the name of a driver defined in the odbcinst.ini file (see below). For future compatibility, use the name of the symbolic link in the library directory, rather than the library file:
  - (/opt/vertica/lib, on 32-bit clients
  - /opt/vertica/lib64, on 64-bit clients
For example, the symbolic link for the 64-bit ODBC driver library is:

/opt/vertica/lib64/libverticaodbc.so

The symbolic link always points to the most up-to-date version of the Vertica client ODBC library. Use this link so that you do not need to update all of your DSNs when you update your client drivers.

• **Database** – The name of the database running on the server. This example uses vmartdb for the vmartdb.
• **ServerName** — The name of the server where Vertica is installed. Use localhost if Vertica is installed on the same machine.

You can provide an IPv4 address, IPv6 address, or host name.

In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.

• **UID** — Either the database superuser (same name as database administrator account) or a user that the superuser has created and granted privileges. This example uses the user name dbadmin.
• **PWD** — The password for the specified user name. This example leaves the password field blank.
• **Port** — The port number on which Vertica listens for ODBC connections. For example, 5433.
• **ConnSettings** — Can contain SQL commands separated by a semicolon. These commands can be run immediately after connecting to the server.
• **SSLKeyFile** — The file path and name of the client's private key. This file can reside anywhere on the system.
• **SSLCertFile** — The file path and name of the client's public certificate. This file can reside anywhere on the system.
• **Locale** — The default locale used for the session. By default, the locale for the database is: en_US@collation=binary (English as in the United States of America). Specify the locale as an ICU Locale. See the ICU User Guide
(http://userguide.icu-project.org/locale) for a complete list of parameters that can be used to specify a locale.

- PreferredAddressFamily:

  The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are:

  - ipv4—Connect to the server using IPv4.
  - ipv6—Connect to the server using IPv6.
  - none—Use the IP address provided by the DNS server.

For example:

```
[VMart]
Description = Vmart Database
Driver = /opt/vertica/lib64/libverticaodbc.so
Database = vmartdb
Servername = host01
UID = dbadmin
PWD =
Port = 5433
ConnSettings =
AutoCommit = 0
SSLKeyFile = /home/dbadmin/client.key
SSLCertFile = /home/dbadmin/client.crt
Locale = en_US@collation=binary
```

See Data Source Name (DSN) Connection Properties for a complete list of parameters including Vertica-specific ones.

**Using an odbcinst.ini File**

Instead of giving the path of the ODBC driver library in your DSN definitions, you can use the name of a driver defined in the odbcinst.ini file. This method is useful method if you have many DSNs and often need to update them to point to new driver libraries. It also allows you to set some additional ODBC parameters, such as the threading model.

Just as in the odbc.ini file, odbcinst.ini has sections. Each section defines an ODBC driver that can be referenced in the odbc.ini files.

In a section, you can define the following parameters:

- **Description** — Additional information about the data source.
- **Driver** — The location and designation of the Vertica ODBC driver, such as /opt/vertica/lib64/libverticaodbc.so

For example:
Vertica Documentation
Connecting to Vertica

[Vertica]
Description = Vertica ODBC Driver
Driver = /opt/vertica/lib64/libverticaodbc.so

Then, in your odbc.ini file, use the name of the section you created in the odbcinst.ini file that describes the driver you want to use. For example:

[VMart]
Description = Vertica Vmart database
Driver = Vertica

If you are using the unixODBC driver manager, you should also add an ODBC section to override its standard threading settings. By default, unixODBC serializes all SQL calls through ODBC, which prevents multiple parallel loads. To change this default behavior, add the following to your odbcinst.ini file:

[ODBC]
Threading = 1

**Configuring Additional ODBC Settings**

On Linux and UNIX systems, you need to configure some additional driver settings before you can use your DSN. See [Required ODBC Driver Configuration Settings for Linux and UNIX](#) for details.

**Testing an ODBC DSN Using Isql**

The unixODBC driver manager includes a utility named isql, which is a simple ODBC command-line client. It lets you to connect to a DSN to send commands and receive results, similarly to vsql.

To use isql to test a DSN connection:

1. Run the following command:

   ```
   $ isql -v DSNname
   ```

   Where **DSNname** is the name of the DSN you created.

   A connection message and a SQL prompt display. If they do not, you could have a configuration problem or you could be using the wrong user name or password.
2. Try a simple SQL statement. For example:

```
SQL> SELECT table_name FROM tables;
```

The isql tool returns the results of your SQL statement.

**Note:**
If you have not set the ErrorMessagesPath in the additional driver configuration settings, any errors during testing will trigger a missing error message file ("The error message NoSQLGetPrivateProfileString could not be found in the en-US locale"). See Required ODBC Driver Configuration Settings for Linux and UNIX for more information.

Creating an ODBC DSN for Windows Clients

To create a DSN for Microsoft Windows clients, you must perform the following tasks:

### Setting Up an ODBC DSN

A *Data Source Name (DSN)* is the ODBC logical name for the drive and other information the database needs to access data. The name is used by Internet Information Services (IIS) for a connection to an ODBC data source.

This section describes how to use the Vertica ODBC Driver to set up an ODBC DSN. This topic assumes that the driver is already installed, as described in Installing Client Drivers on Windows.

To set up a DSN

1. Open the ODBC Administrator. For example, you could navigate to Start > Control Panel > Administrative Tools > Data Sources (ODBC).

**Note:**
The method you use to open the ODBC Administrator depends on your version of Windows. Differences between Windows versions and Start Menu customizations could require you to take a different action to
open the ODBC Administrator.

2. Decide if you want all users on your client system to be able to access to the DSN for the Vertica database.
   - If you want all users to have access, then click the System DSN tab.
   - Otherwise, click the User DSN tab to create a DSN that is only usable by your Windows user account.

3. Click Add to create a new DSN to connect to the Vertica database.

4. Scroll through the list of drivers in the Create a New Data Source dialog box to locate the Vertica driver. Select the driver, and then click Finish.

Note: If you have installed more than one version of the Vertica client drivers on your Windows client system, you may see multiple versions of the driver in this list. Choose the version that you know is compatible with your client application and Vertica Analytic Database server. If you are unsure, use the latest version of the driver.

The Vertica ODBC DSN configuration dialog box appears.

5. Click the More >>> button to view a description of the field you are editing and the connection string defined by the DSN.

6. Enter the information for your DSN. The following fields are required:
   - **DSN Name** — The name for the DSN. Clients use this name to identify the DSN to which they want to connect. The DSN name must satisfy the following requirements:
     - Its maximum length is 32 characters.
     - It is composed of ASCII characters except for the following: [ ] { } ; ? * = ! @ \ 
     - It contains no spaces.
   - **Server** — The host name or IP address of the Vertica server to which you want to connect. Use localhost, if Vertica is installed on the same machine.

   You can provide an IPv4 address, IPv6 address, or host name.

   In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.

   The PreferredAddressFamily option is available on the Client Settings tab.
- **Backup Servers** — A comma-separated list of host names or IP addresses used to connect to if the server specified by the Server field is down. Optional.
- **Database** — The name of the Vertica database.
- **User Name** — The name of the user account to use when connecting to the database. If the application does not supply its own user name when connecting to the DSN, this account name is used to log into the database.

The rest of the fields are optional. See [DSN Parameters](#) for detailed information about the DSN parameters you can define.

7. If you want to test your connection:
   1. Enter at least a valid **DSN name**, **Server name**, **Database**, and either **User name** or select **Windows authentication**.
   2. If you have not selected **Windows authentication**, you can enter a password in the **Password** box. Alternately, you can select **Password prompt** to have the driver prompt you for a password when connecting.
   3. Click **Test Connection**.

8. When you have finished editing and testing the DSN, click **OK**. The Vertica ODBC DSN configuration window closes, and your new DSN is listed in the ODBC Data Source Administrator window.

9. Click **OK** to close the ODBC Data Source Administrator.

After creating the DSN, you can test it using [Microsoft Excel 2007](#).

### Setting up a 32-Bit DSN on 64-Bit Versions of Microsoft Windows

On 64-bit versions of Windows, the default ODBC Data Source Administrator creates and edits DSNs that are associated with the 64-bit Vertica ODBC library.

Attempting to use these 64-bit DSNs with a 32-bit client application results in an architecture mismatch error. Instead, you must create a specific 32-bit DSN for 32-bit clients by running the 32-bit ODBC Administrator usually located at:

```
c:\Windows\SysWOW64\odbcad32.exe
```

This administrator window edits a set of DSNs that are associated with the 32-bit ODBC library. You can then use your 32-bit client applications with the DSNs you create with this version of the ODBC administrator.
**Encrypting Passwords on ODBC DSN**

When you install an ODBC driver and create a Data Source Name (DSN) the DSN settings are stored in the registry, including the password. Encrypting passwords on ODBC DSN applies only to Windows systems.

Encrypting passwords on an ODBC data source name (DSN) provides security against unauthorized database access. The password is not encrypted by default and is stored in plain-text.

**Note:**
Password encryption applies only to new or modified ODBC DSNs. If you have a DSN created in Version 8.0 or earlier and upgrade to 8.1, the password does not get encrypted regardless of the encryption settings.

**Enable Password Encryption**

Use the EncryptPassword parameter to enable or disable password encryption for an ODBC DSN:

- `EncryptPassword = true` enables password encryption
- `EncryptPassword = false` (default) disabling password encryption

Set `EncryptPassword` in the Windows registry - `HKEY_LOCAL_MACHINE > Software > Vertica > ODBC > Driver EncryptPassword=<true/false>`.

**Note:**
For 32 bit driver running on 64 bit windows verify password encryption here:

```
HKEY_LOCAL_MACHINE > Software > Wow6432Node > Vertica > ODBC > Driver > EncryptPassword=<true/false>
```

Encrypted passwords get updated in the following registry locations:

**For a user DSN:**

```
HKEY_CURRENT_USER-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD
```

**For a system DSN:**
The path to the password encryption key is:

HKEY_LOCAL_MACHINE -> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD

**Verify Password Encryption**

Use Windows Registry editor to determine if password encryption is enabled based on the value of EncryptPassword. Depending on the type of DSN you installed, check the following:

For a user DSN: HKEY_CURRENT_USER > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For a system DSN: HKEY_LOCAL_MACHINE > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For each DSN, the value of the isPasswordEncrypted parameter indicates the status of the password encryption, where 1 indicates an encrypted password and 0 indicates an unencrypted password.

---

**Testing an ODBC DSN Using Excel**

You can use Microsoft Excel to verify that an application can connect to an ODBC data source or other ODBC application.

1. Open Microsoft Excel, and select Data > Get External Data > From Other Sources > From Microsoft Query.
2. When the Choose Data Source dialog box opens:
   1. Select **New Data Source**, and click **OK**.
   2. Enter the name of the data source.
   3. Select the Vertica driver.
   4. Click **Connect**.
3. When the Vertica Connection Dialog box opens, enter the connection information for the DSN, and click **OK**.
4. Click **OK** on the Create New Data Source dialog box to return to the Choose Data Source dialog box.
5. Select VMart_Schema*, and verify that the Use the Query Wizard check box is deselected. Click OK.

6. When the Add Tables dialog box opens, click Close.

7. When the Microsoft Query window opens, click the SQL button.

8. In the SQL window, write any simple query to test your connection. For example:

   ```sql
   SELECT DISTINCT calendar_year FROM date_dimension;
   ```

9. • If you see the caution, "SQL Query can't be represented graphically. Continue anyway?" click OK.  
   • The data values 2003, 2004, 2005, 2006, 2007 indicate that you successfully connected to and ran a query through ODBC.

10. Select File > Return Data to Microsoft Office Excel.

11. In the Import Data dialog box, click OK.

   The data is now available for use in an Excel worksheet.

### Creating an ODBC DSN for Macintosh OS X Clients

You can use the Vertica ODBC Driver to set up an ODBC DSN. This procedure assumes that the driver is already installed, as described in [Installing the ODBC Driver on Macintosh OS X](#).

### Setting Up a DSN

1. Using your web browser, download and install the Apple [ODBC Administrator Tool](#).

2. Locate and open the ODBC Administrator Tool after installation:
   1. Navigate to Finder > Applications > Utilities.
   2. Open the ODBC Administrator Tool.
   3. Click the Drivers tab, and verify that the Vertica driver is installed.
4. Specify if you want all users on your client system to be able to access the DSN for the Vertica database:
   • If you want all users to have access, then click the System DSN tab.
   • Otherwise, click the User DSN tab to create a DSN that is only usable by your Macintosh user account.

5. Click Add... to create a new DSN to connect to the Vertica database.

6. Scroll through the list of drivers in the Choose A Driver dialog box to locate the Vertica driver. Select the driver, and then click OK. A dialog box opens that requests DSN parameter information.

7. In the dialog box, enter the Data Source Name (DSN) and an optional Description. To do so, click Add to insert keywords (parameters) and values that define the settings needed to connect to your database, including database name, server host, database user name (such as dbadmin), database password, and port. Then, click OK.

8. In the ODBC Administrator dialog box, click Apply.

See Data Source Name (DSN) Connection Properties for a complete list of parameters including those specific to Vertica.
After configuring the ODBC Administrator Tool, you may need to configure additional driver settings before you can use your DSN, depending on your environment. See Additional ODBC Driver Configuration Settings for details.

Note:
If you want to test your connection, use the iodbctest utility. For the procedure, see Testing a DSN Using iodbctest.

Testing an ODBC DSN Using iodbctest

The standard iODBC Driver Manager on OS X includes a utility named iodbctest that lets you test a DSN to verify that it is correctly configured. You pass this command a connection string in the same format that you would use to open an ODBC database connection. After configuring your DSN connection, you can run a query to verify that the connection works.

For example:

```
# iodbctest "DSN=VerticaDSN;UID=dbadmin;PWD=password"
This program shows an interactive SQL processor
Driver Manager: 03.52.0607.1008
Driver: 07.01.0200 (verticaodbcw.so)
SQL> SELECT table_name FROM tables;
table_name
---------------------------------------------
customer_dimension
product_dimension
promotion_dimension
date_dimension
vendor_dimension
employee_dimension
shipping_dimension
warehouse_dimension
inventory_fact
store_dimension
store_sales_fact
store_orders_fact
online_page_dimension
call_center_dimension
online_sales_fact
numbers
result set 1 returned 16 rows.
```
Data Source Name (DSN) Connection Properties

The following tables list the connection properties you can set in the DSNs for use with Vertica's ODBC driver.

Required Connection Properties

These connection properties are the minimum required to create a functioning DSN.

**NOTE:** If you use a host name (Servername) whose DNS entry resolves to multiple IP addresses, the client attempts to connect to the first IP address returned by the DNS. If a connection cannot be made to the first address, the client attempts to connect to the second, then the third, continuing until it either connects successfully or runs out of addresses.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver</td>
<td>The file path and name of the driver used.</td>
<td>none</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database running on the server.</td>
<td>none</td>
</tr>
<tr>
<td>Servername</td>
<td>The host name or IP address of any active node in a Vertica cluster.</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>You can provide an IPv4 address, IPv6 address, or host name.</td>

## Optional Properties

These are basic properties that are optional.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The port number on which Vertica listens for ODBC connections.</td>
<td>5433</td>
</tr>
<tr>
<td>PWD</td>
<td>The password for the specified user name. You may insert an empty string to leave this property blank.</td>
<td>none (login only succeeds if the user does not have a password set)</td>
</tr>
</tbody>
</table>
| PreferredAddressFamily | The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are:  
  - ipv4—Connect to the server using IPv4.  
  - ipv6—Connect to the server using IPv6.  
  - none—Use the IP address provided by the DNS server. | none                                               |

## Advanced Settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoCommit</td>
<td>A Boolean value that controls whether the driver automatically commits transactions after executing a DML statement.</td>
<td>true</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>BackupServerNode</td>
<td>A string containing the host name or IP address that client libraries can try to connect to if the host specified in ServerName is unreachable. Connection attempts continue until successful or until the list of server nodes is exhausted. <strong>Valid values:</strong> Comma-separated list of servers optionally followed by a colon and port number.</td>
<td>none</td>
</tr>
<tr>
<td>ConnectionLoadBalance</td>
<td>A Boolean value that indicates whether the connection can be redirected to a host in the database other than the ServerNode. This affects the connection only if the load balancing is set to something other than &quot;none&quot;. When the node differs from the node the client is connected to, the client disconnects and reconnects to the targeted node. See About Native Connection Load Balancing in the Administration Guide.</td>
<td>false</td>

</tr>
</tbody>
</table>
**Encryption**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default</th>
<th>Standard/Vertica</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSLMode</td>
<td>Controls whether the connection to the database uses SSL encryption. Valid values follow. For descriptions of these values, refer to Configuring TLS for ODBC Clients.</td>
<td>prefer</td>
<td>Vertica</td>
</tr>
<tr>
<td></td>
<td>• require</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• prefer—Prefers that the server use SSL. If the server does not offer an encrypted channel, the client requests one. The first connection attempt to the database tries to use SSL. If that attempt fails, a second connection is attempted over a clear channel.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• allow—Makes a connection to the server whether the server uses SSL or not. The first connection attempt to the database is attempted over a clear channel. If that fails, a second connection is attempted over SSL.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• disable—Never connects to the server using SSL. Typically, you use this setting for troubleshooting.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SSLCertFile</td>
<td>The absolute path of the client’s public certificate file. This file can reside anywhere on the system.</td>
<td>none</td>
<td>Vertica</td>
</tr>
<tr>
<td>SSLKeyFile</td>
<td>The absolute path to the client’s private key file. This file can reside anywhere on the system.</td>
<td>none</td>
<td>Vertica</td>
</tr>
</tbody>
</table>
## Third-Party Compatibility

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default</th>
<th>Standard/Vertica</th>
</tr>
</thead>
<tbody>
<tr>
<td>ColumnsAsChar</td>
<td>Specifies how character column types are reported when the driver is in Unicode mode. When set to false, the ODBC driver reports the data type of character columns as WCHAR. If you set ColumnsAsChar to true, the driver identifies character column as CHAR. You typically use this setting for compatibility with some third-party clients, such as Informatica.</td>
<td>false</td>
<td>Vertica</td>
</tr>
<tr>
<td>ThreePartNaming</td>
<td>A Boolean value that controls how catalog names are interpreted by the driver. When this value is false, the driver reports that catalog names are not supported. When catalog names are not supported, they cannot be used as a filter in database metadata API calls. In this case, the</td>
<td>false (UNIX)</td>
<td>Vertica</td>
</tr>
<tr>
<td></td>
<td></td>
<td>true (Window)</td>
<td></td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Default</td>
<td>Standard/Vertica</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>---------</td>
<td>-----------------</td>
</tr>
<tr>
<td></td>
<td>driver returns NULL as the catalog name in all driver metadata results. When this value is true, catalog names can be used as a filter in database metadata API calls. In this case, the driver returns the database name as the catalog name in metadata results. Some third-party applications assume a certain catalog behavior and do not work properly with the default values. Enable this option if your client software expects to get the catalog name from the database metadata and use it as part of a three-part name reference.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>EnforceBatchInsertNullConstraints</td>
<td>Prevents NULL values from being loaded into columns with a NOT NULL constraint during batch inserts. When this value is set to true, batch inserts roll back when NULL values are inserted in to columns</td>
<td>false</td>
<td>Vertica</td>

- Required ODBC Driver Configuration Settings for Linux and UNIX

Setting DSN Connection Properties

The properties in the following tables are common for all user and system DSN entries. The examples provided are for Windows clients.

To edit DSN properties:

- On UNIX and Linux client platforms, you can edit the odbc.ini file. The location of this file is specific to the driver manager. See Creating an ODBC DSN for Linux.
- On Windows client platforms, you can edit some DSN properties using the Vertica ODBC client driver interface. See Creating an ODBC DSN for Windows Clients.

- You can also edit the DSN properties directly by opening the DSN entry in the Windows registry (for example, at HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI\DSNname). Directly editing the registry can be risky, so you should only use this method for properties that cannot be set through the ODBC driver's user interface, or via your client code.

- You can set properties in the connection string when opening a connection using the SQLDriverConnect() function:

```sql
sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=DSNName;Locale=en_GB@collation=binary", SQL_NTS, szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

**Note:**

In the connection string ';' is a reserved symbol. If you need to set multiple properties as part of the ConnSettings property use '%3B' in place of ';'. Also use '+' instead of spaces.

For example:

```sql
sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=VerticaSQL;ConnSettings=set+search_path+toa,b,c%3Bset+locale=ch;SSLMode=prefer", SQL_NTS, szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

- Your client code can retrieve DSN property values after a connection has been made to Vertica using the SQLGetConnectAttr() and SQLGetStmtAttr() API calls. Some properties can be set and using SQLSetConnectAttr() and
SQLSetStmtAttr().

For details of the list of properties specific to Vertica see ODBC Header Files specific to Vertica.
Programming ODBC Client Applications

Vertica provides an Open Database Connectivity (ODBC) driver that allows applications to connect to the Vertica database. This driver can be used by custom-written client applications that use the ODBC API to interact with Vertica. ODBC is also used by many third-party applications to connect to Vertica, including business intelligence applications and extract, transform, and load (ETL) applications.

This section details the process for configuring the Vertica ODBC driver. It also explains how to use the ODBC API to connect to Vertica in your own client applications.

This section assumes that you have already installed the ODBC libraries on your client system. If you have not, see Client Drivers.

ODBC Architecture

The ODBC architecture has four layers:

- **Client Application**
  
  Is an application that opens a data source through a Data Source Name (DSN). It then sends requests to the data source, and receives the results of those requests. Requests are made in the form of calls to ODBC functions.

- **Driver Manager**
  
  Is a library on the client system that acts as an intermediary between a client application and one or more drivers. The driver manager:

  - Resolves the DSN provided by the client application.
  - Loads the driver required to access the specific database defined within the DSN.
  - Processes ODBC function calls from the client or passing them to the driver.
  - Retrieves results from the driver.
  - Unloads drivers when they are no longer needed.

  On Windows and Mac client systems, the driver manager is provided by the operating system. On Linux and UNIX systems, you usually need to install a driver manager. See ODBC Prerequisites for a list of driver managers that can be used with Vertica on your client platform.
• **Driver**

A library on the client system that provides access to a specific database. It translates requests into the format expected by the database, and translates results back into the format required by the client application.

• **Database**

The database processes requests initiated at the client application and returns results.

### ODBC Feature Support

The ODBC driver for Vertica supports the most of the features defined in the Microsoft ODBC 3.5 specifications. The following features are *not* supported:

- Updatable result sets
- Backwards scrolling cursors
- Cursor attributes
- More than one open statement per connection. Simultaneously executing statements must each belong to a different connection. For example, you cannot execute a new statement while another statement has a result set open. To execute another statement with the same connection/session, wait for the current statement to finish executing and close its result set, then execute the new statement.
- Keysets
- Bookmarks

The Vertica ODBC driver accurately reports its capabilities. If you need to determine whether it complies with a specific feature, you should query the driver’s capabilities directly using the SQLGetInfo() function.

### Vertica and ODBC Data Type Translation

Most data types are transparently converted between Vertica and ODBC. This section explains several data types require special handling.

<table>

</tr>
</tbody>
</table>
Vertica Data Types | C Data Type | ODBC C Typedef | C Type Identifier |
---|---|---|---|
GEOGRAPHY | char[] | SQL_LONGVARBINARY | SQL_C_CHAR |
UUID | SQLGUID (see note below) | SQL_GUID | SQL_C_GUID |

**Notes**

- The GEOMETRY and GEOGRAPHY data types are treated as LONG VARCHAR data by the ODBC driver.
- Vertica supports the standard interval data types supported by ODBC. See [Interval Data Types](#) in Microsoft's ODBC reference.
- Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with the earlier client driver versions that do not support the UUID data type (see [Client Driver and Server Version Version Compatibility](#) for the versions of the client drivers that Vertica supports). When one of these older clients queries tables with UUID columns in them, Vertica automatically translates the native UUID values to CHAR values. Also, when an older client inserts data into a UUID column, Vertica automatically converts the CHAR value sent by the client into a native UUID value. Vertica also reports the data type of these columns as CHAR when an older client queries a UUID column’s metadata.

**See Also**

- SQL Data Types
- Using LONG VARCHAR and LONG VARBINARY Data Types with ODBC
- Using GEOMETRY and GEOGRAPHY Data Types in ODBC
- SQL Data Types in the Microsoft ODBC reference documentation

**Using LONG VARCHAR and LONG VARBINARY Data Types with ODBC**

The ODBC drivers support the LONG VARCHAR and LONG VARBINARY data types similarly to VARCHAR and VARBINARY data types. When binding input or output parameters to a LONG
VARCHAR or LONG VARBINARY column in a query, use the SQL_LONGVARCHAR and SQL_LONGVARBINARY constants to set the column's data type. For example, to bind an input parameter to a LONG VARCHAR column, you would use a statement that looks like this:

```c
rc = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR, 80000, 0, (SQLPOINTER)myLongString, sizeof(myLongString), NULL);
```

**Note:**
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

**ODBC Header File Specific to Vertica**

The Vertica ODBC driver provides a C header file named `verticaodbc.h` that defines several useful constants that you can use in your applications. These constants let you access and alter settings specific to Vertica.

This file's location depends on your client operating system:

- `/opt/vertica/include` on Linux and UNIX systems.
- `C:\Program Files (x86)\Vertica\ODBC\include` on Windows systems.

The constants defined in this file are listed below.

<table>
<thead>

</tr>
</tbody>
</table>

### Connecting to the Database

The first step in any ODBC application is to connect to the database. When you create the connection to a data source using ODBC, you use the name of the DSN that contains the details of the driver to use, the database host, and other basic information about connecting to the data source.

There are 4 steps your application needs to take to connect to a database:

1. Call SQLAllocHandle() to allocate a handle for the ODBC environment. This handle is used to create connection objects and to set application-wide settings.
2. Use the environment handle to set the version of ODBC that your application wants to use. This ensures that the data source knows which API your application will use to interact with it.
3. Allocate a database connection handle by calling `SQLAllocHandle()`. This handle represents a connection to a specific data source.

4. Use the `SQLConnect()` or `SQLDriverConnect()` functions to open the connection to the database.

**Note:** If you specify a locale either in the connection string or in the DSN, the call to the connection function returns `SQL_SUCCESS_WITH_INFO` on a successful connection, with messages about the state of the locale.

When creating the connection to the database, use `SQLConnect()` when the only options you need to set at connection time is the username and password. Use `SQLDriverConnect()` when you want to change connection options, such as the locale.

The following example demonstrates connecting to a database using a DSN named `ExampleDB`. After it creates the connection successfully, this example simply closes it.

```c
// Demonstrate connecting to Vertica using ODBC.
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
#include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC 3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application version to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    [...]
```
ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate database handle.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Allocated Database handle.\n");
}
// Connect to the database using
// SQL Connect
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char* userID = "ExampleUser";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}
// We're connected. You can do real
// work here

// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect( hd1Dbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_DBC, hd1Dbc);
SQLFreeHandle(SQL_HANDLE_ENV, hd1Env);
exit(EXIT_SUCCESS);
}

Running the above code prints the following:

Allocated an environment handle.
Set application version to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Disconnecting and freeing handles.

See Setting the Locale and Encoding for ODBC Sessions for an example of using
SQLDriverConnect to connect to the database.
Notes

- If you use the DataDirect® driver manager, you should always use the SQL_DRIVER_NOPROMPT value for the SQLDriverConnect function's DriverCompletion parameter (the final parameter in the function call) when connecting to Vertica. Vertica's ODBC driver on Linux and UNIX platforms does not contain a UI, and therefore cannot prompt users for a password.

- On Windows client platforms, the ODBC driver can prompt users for connection information. See Prompting Windows Users for Missing Connection Properties for more information.

- If your database does not comply with your Vertica license agreement, your application receives a warning message in the return value of the SQLConnect() function. Always have your application examine this return value to see if it is SQL_SUCCESS_WITH_INFO. If it is, have your application extract and display the message to the user.

Enabling Native Connection Load Balancing in ODBC

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the DSN entry or in the connection string. The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.
// Demonstrate enabling native load connection balancing.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <cassert>

// Only needed for Windows clients
#include <windows.h>

// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;

int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_VIDEO);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));

    // Connect four times. If load balancing is on, client should
    // connect to different nodes.
    for (int x=1; x <= 4; x++)
    {
        // Connect to the database using SQDriverConnect. Set
        // ConnectionLoadBalance to 1 (true) to enable load
        // balancing.
        cout << endl << "Connection attempt #" << x << ":...;"
        const char *connStr = "DSN=VMart;ConnectionLoadBalance=1;"
                             "UID=ExampleUser;PWD=password123"
                             
        ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
                                NULL, 0, NULL, SQL_DRIVER_NOPROMPT);
        if(!SQL_SUCCEEDED(ret)) {
            cout << "failed. Exiting." << endl;
            exit(EXIT_FAILURE);
        } else {
            cout << "succeeded" << endl;
        }
    // We're connected. Query the v_monitor.current_session table to
    // find the name of the node we've connected to.
        // Set up a statement handle
        SQLHSTMT hdlStmt;
        SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
        assert(SQL_SUCCEEDED(ret));
        // Use a statement to execute a query
        // Build a query string
        // Execute the query
    }
}
```c++
ret = SQLExecDirect( hd1stmt, (SQLCHAR*)"SELECT node_name FROM "
                "V_MONITOR.CURRENT_SESSION;", SQL_NTS );

if(SQL_SUCCEEDED(ret)) {
    // Bind variable to column in result set.
    SQLTCHAR node_name[256];
    ret = SQLBindCol(hd1stmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
                     sizeof(node_name), NULL);
    while(SQL_SUCCEEDED(ret = SQLFetchScroll(hd1stmt, SQL_FETCH_NEXT,1))) {
        // Print the bound variables, which now contain the values from the
        // fetched row.
        cout << "Connected to node " << node_name << endl;
    }
    // Free statement handle
    SQLFreeHandle(SQL_HANDLE_STMT,hd1stmt);
    cout << "Disconnecting." << endl;
    ret = SQLDisconnect( hd1Dbc );
    assert(SQL_SUCCEEDED(ret));
}
// When done, free all of the handles to close them
// in an orderly fashion.
cout << endl << "Freeing handles..." << endl;
SQLFreeHandle(SQL_HANDLE_DBC,hd1Dbc);
SQLFreeHandle(SQL_HANDLE_ENV, hd1Env);
cout << "Done!" << endl;
exit(EXIT_SUCCESS);
```

Running the above example produces output similar to the following:

```
Connection attempt #1... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Connection attempt #2... succeeded
Connected to node v_vmart_node0002
Disconnecting.

Connection attempt #3... succeeded
Connected to node v_vmart_node0003
Disconnecting.

Connection attempt #4... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Freeing handles...
Done!
```
ODBC Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.
If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

**Using DNS Failover**

To use DNS failover, you need to change your DNS server’s settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

**Using the Backup Host List**

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string
intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```cpp
// Demonstrate using connection failover.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <assert.h>

// Only needed for Windows clients
// #include <windows.hgt;

// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;

int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));

    /* DSN for this connection specifies a bad node, and good backup nodes:
       [VMartBadNode]
       Description=VMart Vertica Database
       Driver=/opt/vertica/lib64/libverticaodbc.so
       Database=VMart
       Servername=badnode.example.com
       BackupServerNode=v_vmart_node0002.example.com,v_vmart_node0003.example.com
       */

    // Connect to the database using SQLConnect
    cout << "Connecting to database." << endl;
    const char *dsnName = "VMartBadNode"; // Name of the DSN
    const char* userID = "ExampleUser"; // Username
    const char* passwd = "password123"; // password
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
                     SQL_NTS, (SQLCHAR*)userID, SQL_NTS,
                     (SQLCHAR*)passwd, SQL_NTS);
    if (!SQL_SUCCEEDED(ret)) {
        cout << "Could not connect to database." << endl;
        exit(EXIT_FAILURE);
    }
```
} else {
    cout << "Connected to database." << endl;
}

// We're connected. Query the v_monitor.current_session table to
// find the name of the node we've connected to.

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
assert(SQL_SUCCEEDED(ret));

ret = SQLExecDirect( hdlStmt, (SQLCHAR*)"SELECT node_name FROM "
                   "v_monitor.current_session;", SQL_NTS );

if(SQL_SUCCEEDED(ret)) {
    // Bind variable to column in result set.
    SQLTCHAR node_name[256];
    ret = SQLBindCol(hdlStmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
                     sizeof(node_name), NULL);
    while(SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT,1))) {
        // Print the bound variables, which now contain the values from the
        // fetched row.
        cout << "Connected to node " << node_name << endl;
    }
}

cout << "Disconnecting." << endl;
ret = SQLDisconnect( hdlDbc );
assert(SQL_SUCCEEDED(ret));

// When done, free all of the handles to close them
// in an orderly fashion.
cout << endl << "Freeing handles..." << endl;
SQLFreeHandle(SQL_HANDLE_STMT,hdlStmt);
SQLFreeHandle(SQL_HANDLEDBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
cout << "Done!" << endl;
exit(EXIT_SUCCESS);

} // end of function
}

When run, the example's output on the system console is similar to the following:

Connecting to database.
Connected to database.
Connected to node v_vmart_node0002
Disconnecting.

Freeing handles...
Done!

Notice that the connection was made to the first node in the backup list (node 2).

Note:
When native connection load balancing is enabled, the additional servers
specified in the BackupServerNode connection parameter are only used for
the initial connection to a Vertica host. If host redirects the client to another
host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in ODBC.

Prompting Windows Users for Missing Connection Properties

The Vertica Windows ODBC driver can prompt the user for connection information if required information is missing. The driver displays the Vertica Connection Dialog if the client application calls SQLDriverConnect to connect to Vertica and either of the following is true:

- the DriverCompletion property is set to SQL_DRIVER_PROMPT.
- the DriverCompletion property is set to SQL_DRIVER_COMPLETE or SQL_DRIVER_COMPLETE_REQUIRED and the connection string or DSN being used to connect is missing the server, database, or port information.

If either of the above conditions are true, the driver displays a Vertica Connection Dialog to the user to prompt for connection information.

![Vertica Connection Dialog](image)

The dialog has all of the property values supplied in the connection string or DSN filled in.

**Note:**
Your connection string at least needs to specify Vertica as the driver, otherwise Windows will not know to use the Vertica ODBC driver to try to open the connection.
The required fields on the connection dialog are Database, UID, Server, and Port. Once these are filled in, the form enables the OK button.

If the user clicks Cancel on the dialog, the SQLDriverConnect function call returns SQL_NO_DATA immediately, without attempting to connect to Vertica. If the user supplies incomplete or incorrect information for the connection, the connection function returns SQL_ERROR after the connection attempt fails.

**Note:**
If the DriverCompletion property of the SQLDriverConnect function call is SQL_DRIVER_NOPROMPT, the ODBC driver immediately returns a SQL_ERROR indicating that it cannot connect because not enough information has been supplied and the driver is not allowed to prompt the user for the missing information.

### Prompting Windows Users for Passwords

If the connection string or DSN supplied to the SQLDriverConnect function that client applications call to connect to Vertica lacks any of the required connection properties needed to connect, the Vertica's Windows ODBC driver opens a dialog box to prompt the user to enter the missing information (see Prompting Windows Users for Missing Connection Properties). The user’s password is not normally considered a required connection property, since Vertica user accounts may not have a password. If the password property is missing, the ODBC driver still tries to connect to Vertica without supplying a password.

You can use the PromptOnNoPassword DSN parameter to force ODBC driver to treat the password as a required connection property. This parameter is useful if you do not want to store passwords in DSN entries. Passwords saved in DSN entries are insecure, since they are stored as clear text in the Windows registry and therefore visible to other users on the same system.

There are two other factors which also decide whether the ODBC driver displays the Vertica Connection Dialog. These are (in order of priority):

- The SQLDriverConnect function call's DriverCompletion parameter.
- Whether the DSN or connection string contain a password

The following table shows how the PromptOnNoPassword DSN parameter, the DriverCompletion parameter of the SQLDriverConnect function, and whether the DSN or connection string contains a password interact to control whether the Vertica Connection dialog appears.
<table>
<thead>
<tr>
<th>PromptOnNoPassword Setting</th>
<th>DriverCompletion Value</th>
<th>DSN or Connection String Contains Password?</th>
<th>Vertica Connection Dialog Displays?</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>any value</td>
<td>SQL_DRIVER_PROMPT</td>
<td>any case</td>
<td>Yes</td>
<td>This DriverCompletion value forces the dialog to always appear, even if all required connection properties are supplied.</td>
</tr>
<tr>
<td>any value</td>
<td>SQL_DRIVER_NOPROMPT</td>
<td>any case</td>
<td>No</td>
<td>This DriverCompletion value always prevents the dialog from appearing.</td>
</tr>
<tr>
<td>any value</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>Yes</td>
<td>No</td>
<td>Connection dialog displays if another required connection property is missing.</td>
</tr>
<tr>
<td>true</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>No</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>false (default)</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>No</td>
<td>No</td>
<td>Connection dialog displays if another required connection property is missing.</td>
</tr>
</tbody>
</table>

The following example code demonstrates using the PromptOnNoPassword DSN parameter along with a system DSN.
### No Password Entry vs. Empty Passwords

There is a difference between not having a password property in the connection string or DSN and having an empty password. The PromptOnNoPassword DSN parameter only has an effect if the connection string or DSN does not have a PWD property (which holds the user's password). If it does, even if it is empty, PromptOnNoPassword will not prompt the Windows ODBC driver to display the Vertica Connection Dialog.

This difference can cause confusion if you are using a DSN to provide the properties for your connection. Once you enter a password for a DSN connection in the Windows ODBC Manager and save it, Windows adds a PWD property to the DSN definition in the registry. If you later delete the password, the PWD property remains in the DSN definition—value is just set to an empty string. The PWD property is created even if you just use the Test button on the ODBC Manager dialog to test the DSN and later clear it before saving the DSN.

Once the password has been set, the only way to remove the PWD property from the DSN definition is to delete it using the Windows Registry Editor:

1. On the Windows Start menu, click Run.
2. In the Run dialog, type regedit, then click OK.
3. In the Registry Editor window, click Edit > Find (or press Ctrl+F).
4. In the Find window, enter the name of the DSN whose PWD property you want to delete and click OK.
5. If find operation did not locate a folder under the ODBC.INI folder, click Edit > Find Next (or press F3) until the folder matching your DSN's name is highlighted.

6. Select the PWD entry and press Delete.

7. Click Yes to confirm deleting the value.

The DSN now does not have a PWD property and can trigger the connection dialog to appear when used along with PromptOnNoPassword=true and DriverConnect=SQL_DRIVER_COMPLETE.

### Setting the Locale and Encoding for ODBC Sessions

Vertica provides the following methods to set the locale and encoding for an ODBC session:

- Specify the locale for all connections made using the DSN:
  - On Linux and other UNIX-like platforms: [Creating an ODBC DSN for Linux](#)
  - On Windows platforms, set the locale in the ODBC DSN configuration editor's Locale field on the Server Settings tab. See [Creating an ODBC DSN for Windows Clients](#) for detailed information.
- Set the Locale connection parameter in the connection string in SQLDriverConnect() function. For example:

```sql
SQLDriverConnect(conn, NULL, (SQLCHAR*)"DSN=Vertica;Locale=en_GB@collation=binary", SQL_NTS, szConnOut, sizeof(szConnOut), &iAvailable, SQL_DRIVER_NOPROMPT)
```
Use SQLSetConnectAttr() to set the encoding and locale. In general, you should always set the encoding with this function as opposed to, for example, setting it in the DSN.

- Pass the SQL_ATTR_VERTICA_LOCALE constant and the ICU string as the attribute value. For example:

  ```c
  SQLSetConnectAttr(hdbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)newLocale, SQL_NTS);
  ```

- Pass the SQL_ATTR_AP_WCHAR_TYPE constant and the encoding as the attribute value. For example:

  ```c
  SQLSetConnectAttr(hdbc, SQL_ATTR_APP_WCHAR_TYPE, (void *)SQL_DD_CP_UTF16, SQL_IS_INTEGER);
  ```

## Notes

- Having the client system use a non-Unicode locale (such as setting LANG=C on Linux platforms) and using a Unicode locale for the connection to Vertica can result in errors such as "(10170) String data right truncation on data from data source." If data received from Vertica isn't in UTF-8 format. The driver allocates string memory based on the system's locale setting, and non-UTF-8 data can trigger an overrun. You can avoid these errors by always using a Unicode locale on the client system.

  If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.

- ODBC applications can be in either ANSI or Unicode mode:

  - If Unicode, the encoding used by ODBC is UCS-2.
  - If ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 on the database server.

  The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.

- If the end-user application is not already in UCS-2, the application is responsible for converting the input data to UCS-2, or unexpected results could occur. For example:

  - On non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
  - Or the symbol provided in the alternate encoding could be a valid UCS-2 symbol; in this case, incorrect data is inserted into the database.
ODBC applications should set the correct server session locale using `SQLSetConnectAttr` (if different from database-wide setting) in order to set the proper collation and string functions behavior on server.

The following example code demonstrates setting the locale using both the connection string and with the `SQLSetConnectAttr()` function.

```c
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
#include <windows.h>

#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

#include <verticaodbc.h>

int main() {
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }

    // Set the ODBC version we are going to use to 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION, (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC 3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application version to ODBC 3.\n");
    }

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.\n");
    }

    // Connect to the database using SQLDriverConnect
    printf("Connecting to database.\n");
    // Set the locale to English in Great Britain.
    const char *connStr = "DSN=ExampleDB;locale=en_GB;"
                        "UID=dbadmin;PWD=password123";
    ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS, 
                           NULL, 0, NULL, SQL_DRIVER_NOPROMPT);
}
if (!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Get the Locale
char locale[256];
SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale), 0);
printf("Locale is set to: %s\n", locale);
// Set the locale to a new value
const char* newLocale = "en_GB";
SQLSetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)newLocale, SQL_NTS);

// Get the Locale again
SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale), 0);
printf("Locale is now set to: %s\n", locale);

// Set the encoding
SQLSetConnectAttr(hdbc, SQL_ATTR_APP_WCHAR_TYPE, (void *)SQL_DD_CP_UTF16, SQL_IS_INTEGER);

// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect( hdlDbc );
if (!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

### AUTOCOMMIT and ODBC Transactions

The AUTOCOMMIT connection attribute controls whether INSERT, ALTER, COPY and other data-manipulation statements are automatically committed after they complete. By default, AUTOCOMMIT is enabled—all statements are committed after they execute. This is often not the best setting to use, since it is less efficient. Also, you often want to control whether a set of statements are committed as a whole, rather than have each individual statement committed. For example, you may only want to commit a series of inserts if all of the inserts succeed. With AUTOCOMMIT disabled, you can roll back the transaction if one of the statements fail.

If AUTOCOMMIT is on, the results of statements are committed immediately after they are executed. You cannot roll back a statement executed in AUTOCOMMIT mode.
For example, when AUTOCOMMIT is on, the following single INSERT statement is automatically committed:

```c
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
  "'Smith, Sam', '123-456-789');", SQL_NTS);
```

If AUTOCOMMIT is off, you need to manually commit the transaction after executing a statement. For example:

```c
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
  "'Smith, Sam', '123-456-789');", SQL_NTS);
// Other inserts and data manipulations
// Commit the statements(s)
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
```

The inserted row is only committed when you call SQLEndTran(). You can roll back the INSERT and other statements at any point before committing the transaction.

**Note:** Prepared statements cache the AUTOCOMMIT setting when you create them using SQLPrepare(). Later changing the connection's AUTOCOMMIT setting has no effect on the AUTOCOMMIT settings of previously created prepared statements. See Using Prepared Statements for details.

The following example demonstrates turning off AUTOCOMMIT, executing an insert, then manually committing the transaction.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
  // Set up the ODBC environment
  SQLRETURN ret;
  SQLHENV hdlEnv;
  ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
  if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate a handle.\n");
    exit(EXIT_FAILURE);
  } else {
    printf("Allocated an environment handle.\n");
  }
  // Tell ODBC that the application uses ODBC 3.
  ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
    (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
  if(!SQL_SUCCEEDED(ret)) {
```
printf("Could not set application version to ODBC3.
"); exit(EXIT_FAILURE);
} else {
  printf("Set application to ODBC 3.
");
}

// Allocate a database handle.

}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

Running the above code results in the following output:

Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Autocommit is set to: 1
Disabling autocommit.
Autocommit is set to: 0
Performed single insert.
Committing transaction.
Free handles.

Note:
You can also disable AUTOCOMMIT in the ODBC connection string. See
Setting DSN Connection Properties for more information.
Retrieving Data Through ODBC

To retrieve data through ODBC, you execute a query that returns a result set (SELECT, for example), then retrieve the results using one of two methods:

- Use the SQLFetch() function to retrieve a row of the result set, then access column values in the row by calling SQLGetData().
- Use the SQLBindColumn() function to bind a variable or array to a column in the result set, then call SQLExtendedFetch() or SQLFetchScroll() to read a row of the result set and insert its values into the variable or array.

In both methods you loop through the result set until you either reach the end (signaled by the SQL_NO_DATA return status) or encounter an error.

Note:
Vertica supports one cursor per connection. Attempting to use more than one cursor per connection will result in an error. For example, you receive an error if you execute a statement while another statement has a result set open.

The following code example demonstrates retrieving data from Vertica by:

1. Connecting to the database.
2. Executing a SELECT statement that returns the IDs and names of all tables.
3. Binds two variables to the two columns in the result set.
4. Loops through the result set, printing the ids and name values.

```c++
// Demonstrate running a query and getting results by querying the tables
// system table for a list of all tables in the current schema.
// Some standard headers
#include <stdlib.h>
#include <sstream>
#include <iostream>
#include <assert.h>

// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

// Use std namespace to make output easier
using namespace std;

// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
  // Get the status records.
```
typedef struct {
    SQLHENV hdlEnv;
    SQLHDBC hdlDbc;
} DBConnection;

void connect(DBConnection *pConnInfo) {
    // Set up the ODBC environment
    SQLRETURN ret;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &pConnInfo->hdlEnv);
    assert(SQL_SUCCEEDED(ret));
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(pConnInfo->hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER)SQL_OV_ODBC3, SQL_IS_UINTEGER);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    ret = SQLAllocHandle(SQL_HANDLE_DBC, pConnInfo->hdlEnv, &pConnInfo->hdlDbc);
    assert(SQL_SUCCEEDED(ret));

    // Connect to the database
    cout << "Connecting to database."
        << endl;
    const char* dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(pConnInfo->hdlDbc, (SQLCHAR*)dsnName,
        SQL_NTS, (SQLCHAR*)userID, SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if (!SQL_SUCCEEDED(ret)) {
        cout << "Could not connect to database" << endl;
        reportError<SQLHDBC>(SQL_HANDLE_DBC, pConnInfo->hdlDbc);
        exit(EXIT_FAILURE);
    } else {
        cout << "Connected to database."
            << endl;
    }
}

void disconnect(DBConnection *pConnInfo) {
    SQLRETURN ret;
    // Clean up by shutting down the connection
    cout << "Free handles."
        << endl;
    ret = SQLDisconnect(pConnInfo->hdlDbc);
    if (!SQL_SUCCEEDED(ret)) {
        cout << "Error disconnecting. Transaction still open?" << endl;
    }
}
void executeQuery(SQLHDBC hdlDbc, SQLCHAR* pQuery)
{
    SQLRETURN ret;
    // Set up a statement handle
    SQLHSTMT hdlStmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
    assert(SQL_SUCCEEDED(ret));

    // Execute a query to get the names and IDs of all tables in the schema
    // search p[ath (usually public).
    ret = SQLExecDirect(hdlStmt, pQuery, SQL_NTS);
    if (!SQL_SUCCEEDED(ret)) {
        // Report error an go no further if statement failed.
        cout << "Error executing statement."
             << endl;
        reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);
        exit(EXIT_FAILURE);
    } else {
        // Query succeeded, so bind two variables to the two columns in the
        // result set,
        cout << "Fetching results..." << endl;
        SQLBIGINT table_id;  // Holds the ID of the table.
        SQLTCHAR table_name[256]; // buffer to hold name of table
        ret = SQLBindCol(hdlStmt, 1, SQL_C_SBIGINT, (SQLPOINTER)&table_id,
                         sizeof(table_id), NULL);
        ret = SQLBindCol(hdlStmt, 2, SQL_C_TCHAR, (SQLPOINTER)table_name,
                         sizeof(table_name), NULL);

        // Loop through the results, while (SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT, 1))) {
            // Print the bound variables, which now contain the values from the
            // fetched row.
            cout << table_id << " | " << table_name << endl;
        }

        // See if loop exited for reasons other than running out of data
        if (ret != SQL_NO_DATA) {
            // Exit for a reason other than no more data... report the error.
            reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);
        }
    }
    SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
}

int main()
{
    DBConnection conn;
    connect(&conn);
    executeQuery(conn.hdlDbc,
                 (SQLCHAR*)"SELECT table_id, table_name FROM tables ORDER BY table_name");
    executeQuery(conn.hdlDbc,
                 (SQLCHAR*)"SELECT table_id, table_name FROM tables ORDER BY table_name");
}
(SQLCHAR*)"SELECT table_id, table_name FROM tables ORDER BY table_id");
disconnect(&conn);
exit(EXIT_SUCCESS);

Running the example code in the vmart database produces output similar to this:

Connecting to database.
Connected to database.

Loading Data Through ODBC

A primary task for many client applications is loading data into the Vertica database. There are several different ways to insert data using ODBC, which are covered by the topics in this section.
Using a Single Row Insert

The easiest way to load data into Vertica is to run an INSERT SQL statement using the SQLExecuteDirect function. However this method is limited to inserting a single row of data.

```
ret = SQLExecDirect(hstmt, (SQLTCHAR*)"INSERT into Customers values"
   "(1,'abcda','efgh','1')", SQL_NTS);
```

Using Prepared Statements

Vertica supports using server-side prepared statements with both ODBC and JDBC. Prepared statements let you define a statement once, and then run it many times with different parameters. The statement you want to execute contains placeholders instead of parameters. When you execute the statement, you supply values for each placeholder.

Placeholders are represented by question marks (?) as in the following example query:

```
SELECT * FROM public.inventory_fact WHERE product_key = ?
```

Server-side prepared statements are useful for:

- Optimizing queries. Vertica only needs to parse the statement once.
- Preventing SQL injection attacks. A SQL injection attack occurs when user input is either incorrectly filtered for string literal escape characters embedded in SQL statements or user input is not strongly typed and thereby unexpectedly run. Since a prepared statement is parsed separately from the input data, there is no chance the data can be accidentally executed by the database.
- Binding direct variables to return columns. By pointing to data structures, the code doesn't have to perform extra transformations.

The following example demonstrates a using a prepared statement for a single insert.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Some constants for the size of the data to be inserted.
```
#define CUST_NAME_LEN 50
#define PHONE_NUM_LEN 15
#define NUM_ENTRIES 4

int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION, (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName, SQL_NTS, (SQLCHAR*)userID, SQL_NTS,
                    (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }
    // Disable AUTOCOMMIT
    printf("Disabling autocommit.\n");
    ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not disable autocommit.\n");
        exit(EXIT_FAILURE);
    }
    // Set up a statement handle
    SQLHSTMT hdlStmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
    SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
                  SQL_NTS);
    SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers "
                  "(CustID int, CustName varchar(100), Phone_Number char(15))");
}
// Set up a bunch of variables to be bound to the statement
// parameters.

// Create the prepared statement. This will insert data into the
// table we created above.
printf("Creating prepared statement\n");

    SQLFreeHandle(SQL_HANDLE_STMT, hStmt);
    SQLFreeHandle(SQL_HANDLE_DBC, hDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hEnv);
    exit(EXIT_FAILURE);
} else {
    printf("Bound phoneNum to prepared statement\n");
}
Using Batch Inserts

You use batch inserts to insert chunks of data into the database. By breaking the data into batches, you can monitor the progress of the load by receiving information about any rejected rows after each batch is loaded. To perform a batch load through ODBC, you typically use a prepared statement with the parameters bound to arrays that contain the data to be loaded. For each batch, you load a new set of data into the arrays then execute the prepared statement.

When you perform a batch load, Vertica uses a COPY statement to load the data. Each additional batch you load uses the same COPY statement. The statement remains open until you end the transaction, close the cursor for the statement, or execute a non-INSERT statement.

Using a single COPY statement for multiple batches improves batch loading efficiency by:

- reducing the overhead of inserting individual batches
- combining individual batches into larger ROS containers
**Note:**
If the database connection has AUTOCOMMIT enabled, then the transaction is automatically committed after each batch insert statement which closes the COPY statement. Leaving AUTOCOMMIT enabled makes your batch load much less efficient, and can cause added overhead in your database as all of the smaller loads are consolidated.

Even though Vertica uses a single COPY statement to insert multiple batches within a transaction, you can locate which (if any) rows were rejected due to invalid row formats or data type issues after each batch is loaded. See [Finding the Number of Accepted Rows](#) for details.

**Note:**
While you can find rejected rows during the batch load transaction, other types of errors (such as running out of disk space or a node shutdown that makes the database unsafe) are only reported when the COPY statement ends.

Since the batch loads share a COPY statement, errors in one batch can cause earlier batches in the same transaction to be rolled back.

### Batch Insert Steps

The steps your application needs to take in order to perform an ODBC Batch Insert are:

1. Connect to the database.
2. Disable autocommit for the connection.
3. Create a prepared statement that inserts the data you want to load.
4. Bind the parameters of the prepared statement to arrays that will contain the data you want to load.
5. Populate the arrays with the data for your batches.
6. Execute the prepared statement.
7. Optionally, check the results of the batch load to find rejected rows.
8. Repeat the previous three steps until all of the data you want to load is loaded.
9. Commit the transaction.
10. Optionally, check the results of the entire batch transaction.

The following example code demonstrates a simplified version of the above steps.

```c
// Some standard headers
#include <stdio.h>
```
#include <stdlib.h>
// Only needed for Windows clients
#include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

int main()
{
    // Number of data rows to insert
    const int NUM_ENTRIES = 4;

    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }

    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }

    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.\n");
    }

    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hd1Dbc, (SQLCHAR*)dsnName,
                     SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
                     (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }

    // Disable AUTOCOMMIT
    printf("Disabling autocommit.\n");
    ret = SQLSetConnectAttr(hd1Dbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF,
                            SQL_NTS);
}
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not disable autocommit.
",
    exit(EXIT_FAILURE);
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create a table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
    SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers "
    "(CustID int, CustName varchar(100), Phone_Number char(15));",
    SQL_NTS);

// Create the prepared statement. This will insert data into the
// table we created above.
printf("Creating prepared statement\n");
ret = SQLPrepare(hdlStmt, (SQLTCHAR*)"INSERT INTO customers (CustID, "
    "CustName, Phone_Number) VALUES(?, ?, ?)", SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not create prepared statement\n");
    exit(EXIT_FAILURE);
} else {
    printf("Created prepared statement.\n");
}

// This is the data to be inserted into the database.
SQLCHAR custNames[][50] = { "Allen, Anna", "Brown, Bill", "Chu, Cindy",
    "Dodd, Don"};
SQLINTEGER custIDs[] = { 100, 101, 102, 103};
    "1-508-555-4321", "1-617-555-4444"};

// Bind the data arrays to the parameters in the prepared SQL
// statement. First is the custID.
ret = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_LONG, SQL_INTEGER,
    0, 0, (SQLPOINTER)custIDs, sizeof(SQLINTEGER), NULL);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind custID array\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound CustIDs array to prepared statement\n");
}

// Bind CustNames
ret = SQLBindParameter(hdlStmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_VARCHAR,
    50, 0, (SQLPOINTER)custNames, 50, NULL);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind custNames\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound CustNames array to prepared statement\n");
}

// Bind phoneNums
ret = SQLBindParameter(hdlStmt, 3, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_CHAR,
    15, 0, (SQLPOINTER)phoneNums, 15, NULL);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind phoneNums\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound phoneNums array to prepared statement\n");
}
Tell the ODBC driver how many rows we have in the array.

```c
ret = SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAMSET_SIZE, (SQLPOINTER)NUM_ENTRIES, 0);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind set parameter size\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound phoneNums array to prepared statement\n");
}
```

Add multiple batches to the database. This just adds the same batch of data four times for simplicity’s sake. Each call adds the 4 rows into the database.

```c
for (int batchLoop=1; batchLoop<=5; batchLoop++) {
    // Execute the prepared statement, loading all of the data in the arrays.
    printf("Adding Batch #%d...,\n", batchLoop);
    ret = SQLExecute(hdlStmt);
    if(!SQL_SUCCEEDED(ret)) {
        printf("not successful!\n");
    } else {
        printf("successful.\n");
    }
}
```

Done with batches, commit the transaction.

```c
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not commit transaction\n");
} else {
    printf("Committed transaction\n");
}
```

Clean up.

```c
printf("Free handles.\n");
ret = SQLDisconnect(hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
```

The result of running the above code is shown below.

Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Creating prepared statement
Created prepared statement.
Bound CustIDs array to prepared statement
Bound CustNames array to prepared statement
Bound phoneNums array to prepared statement
Adding Batch #1...successful.
Adding Batch #2...successful.
Adding Batch #3...successful.
Adding Batch #4...successful.
Adding Batch #5...successful.
Committing transaction
Committed transaction
Free handles.

The resulting table looks like this:

```sql
=> SELECT * FROM customers;
```

<table>
<thead>
<tr>
<th>CustID</th>
<th>CustName</th>
<th>Phone_Number</th>
</tr>
</thead>

</tbody>
</table>

(20 rows)

**Note:**
An input parameter bound with the SQL_C_NUMERIC data type uses the default numeric precision (37) and the default scale (0) instead of the precision and scale set by the SQL_NUMERIC_STRUCT input value. This behavior adheres to the ODBC standard. If you do not want to use the default precision and scale, use `SQLSetDescField()` or `SQLSetDescRec()` to change them in the statement's attributes.

**Tracking Load Status (ODBC)**

After loading a batch of data, your client application can get the number of rows that were processed and find out whether each row was accepted or rejected.
**Finding the Number of Accepted Rows**

To get the number of rows processed by a batch, you add an attribute named SQL_ATTR_PARAMS_PROCESSED_PTR to the statement object that points to a variable to receive the number rows:

```c
SQLULEN rowsProcessed;
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAMS_PROCESSED_PTR, &rowsProcessed, 0);
```

When your application calls SQLExecute() to insert the batch, the Vertica ODBC driver saves the number of rows that it processed (which is not necessarily the number of rows that were successfully inserted) in the variable you specified in the SQL_ATTR_PARAMS_PROCESSED_PTR statement attribute.

**Finding the Accepted and Rejected Rows**

Your application can also set a statement attribute named SQL_ATTR_PARAM_STATUS_PTR that points to an array where the ODBC driver can store the result of inserting each row:

```c
SQLUSMALLINT rowResults[NUM_ENTRIES];
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAM_STATUS_PTR, rowResults, 0);
```

This array must be at least as large as the number of rows being inserted in each batch.

When your application calls SQLExecute to insert a batch, the ODBC driver populates the array with values indicating whether each row was successfully inserted (SQL_PARAM_SUCCESS or SQL_PARAM_SUCCESS_WITH_INFO) or encountered an error (SQL_PARAM_ERROR).

The following example expands on the example shown in Using Batch Inserts to include reporting the number of rows processed and the status of each row inserted.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
#include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to print SQL error messages.
```

Error Handling During Batch Loads

When loading individual batches, you can find information on how many rows were accepted and what rows were rejected (see Finding the Number of Accepted Rows for details). Other errors, such as disk space errors, do not occur while inserting individual batches. This behavior is caused by having a single COPY statement perform the loading of multiple consecutive batches. Using the single COPY statement makes the batch load process perform much faster. It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Your bulk loading application should check for errors when the COPY statement closes. Normally, you force the COPY statement to close by calling the SQLEndTran() function to end the transaction. You can also force the COPY statement to close by closing the cursor using the SQLCloseCursor() function, or by setting the database connection's AutoCommit property to true before inserting the last batch in the load.

**Note:**
The COPY statement also closes if you execute any non-insert statement. However having to deal with errors from the COPY statement in what might be an otherwise-unrelated query is not intuitive, and can lead to confusion and a harder to maintain application. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

**Using the COPY Statement**

The COPY statement lets you bulk load data from a file on stored on a database node into the Vertica database. This method is the most efficient way to load data into Vertica because the file resides on the database server. One drawback is that only a database superuser can use COPY, since it requires privilege in order to access the file system of the database node.

One drawback of using COPY instead of performing batch loads is that you can only get results of the load (the number of accepted and rejected rows) when the COPY statement has finished. With batch loads, you can monitor the progress as batches are inserted. The ability to monitor the progress of a load can be a useful feature if you want to stop loading if a large portion of the data is being rejected.
**Note:**
For databases created in Vertica releases ≥ 9.3, Vertica ignores load options and hints and defaults to a load method of DIRECT. You can configure this behavior with configuration parameter DMLTargetDirect.

In databases created in a version of Vertica version earlier than 9.3, a primary concern when bulk loading data using COPY is deciding whether the data should be loaded directly into ROS using the DIRECT option, or by using the AUTO method (loading into WOS until it fills, then loading into ROS). You should load directly into the ROS when your transaction will load a large (more than 100MB of data or so) amount of data.

**Note:**
The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the COPY command. Specify a local path and filename for these modifiers when executing a COPY query from the driver.

The following example loads data into the **WOS (Write Optimized Store)** until it fills, then stores additional data directly in **ROS (Read Optimized Store)**.

```sql
ret=SQLExecDirect(hd1Stmt, (SQLCHAR*)"COPY customers 
"FROM '/data/customers.txt' AUTO",SQL_NTS);
```

The following example loads data into the **ROS (Read Optimized Store)**.

```sql
ret=SQLExecDirect(hd1Stmt, (SQLCHAR*)"COPY customers 
"FROM '/data/customers.txt' DIRECT",SQL_NTS);
```

See the [COPY](#) statement in the SQL Reference Manual for more information about its syntax and use.

The following example demonstrates using the COPY command.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
#include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to determine if an ODBC function call returned
// successfully.
bool notSuccess(SQLRETURN ret) {
    return (ret != SQL_SUCCESS && ret != SQL_SUCCESS_WITH_INFO);
}
```
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(notSuccess(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION, (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(notSuccess(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    // Note: User MUST be a database superuser to be able to access files on the
    // filesystem of the node.
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName, SQL_NTS, (SQLCHAR*)userID, SQL_NTS, (SQLCHAR*)passwd, SQL_NTS);
    if(notSuccess(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }
    // Disable AUTOCOMMIT
    printf("Disabling autocommit.\n");
    ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);
    if(notSuccess(ret)) {
        printf("Could not disable autocommit.\n");
        exit(EXIT_FAILURE);
    }
    // Set up a statement handle
    SQLHSTMT hdlStmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
    // Create table to hold the data
    SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers", SQL_NTS);
    SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers"
        "(Last_Name char(50) NOT NULL, First_Name char(50), Email char(50), "
        "Phone_Number char(15));",};
The example prints the following when run:

Allocated an environment handle.
Set application to ODBC 3.
Connecting to database.
Connected to database.
Disabling autocommit.
Successfully inserted 10001 rows.
Committing transaction
Committed transaction

**Streaming Data From the Client Using COPY LOCAL**

The LOCAL option of the SQL COPY statement lets you stream data from a file on a client system to your Vertica database. This statement works through the ODBC driver, making the task of transferring data files from the client to the server much easier.
The LOCAL option of COPY works transparently through the ODBC driver. Just have your client application execute a statement containing a COPY LOCAL statement, and the ODBC driver will read and stream the data file from the client to the server.

**Note:**
The COPY LOCAL statement must be the first statement within a query containing multiple statements. If you attempt to use COPY LOCAL as the second or later statement, you will receive the error "COPY LOCAL statement must be the first statement in a multiple statement query."

This example demonstrates loading data from the client system using the COPY LOCAL statement:

```c
#include <stdio.h>
#include <stdlib.h>
#include <windows.h>
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
            (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Connect to the database
    return 0;
}
```
printf("Connecting to database.\n");
const char* dsnName = "ExampleDB";
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",

    ret = SQLRowCount(hdlStmt, &numRows);
    printf("Successfully inserted %d rows.\n", numRows);
}

// COPY commits automatically, unless it is told not to, so
// there is no need to commit the transaction.

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect( hd1Dbc );
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hd1Dbc);
SQLFreeHandle(SQL_HANDLE_ENV, hd1Env);
exit(EXIT_SUCCESS);
This example is essentially the same as the example shown in Using the COPY Statement, except it uses the COPY statement's LOCAL option to load data from the client system rather than from the file system of the database node.

**Note:**
On Windows clients, the path you supply for the COPY LOCAL file is limited to 216 characters due to limitations in the Windows API.

**See Also**
- COPY LOCAL

**Programming JDBC Client Applications**

The Vertica JDBC driver provides you with a standard JDBC API. If you have accessed other databases using JDBC, you should find accessing Vertica familiar. This section explains how to use the JDBC to connect your Java application to Vertica.

You must first install the JDBC client driver on all client systems that will be accessing the Vertica database. For installation instructions, see Installing the Vertica Client Drivers.

For more information about JDBC:
- Vertica Analytic Database JDBC Documentation (Vertica extensions)
- An Introduction to JDBC, Part 1

**JDBC Feature Support**

The Vertica JDBC driver complies with the JDBC 4.0 standards (although it does not implement all of the optional features in them). Your application can use the DatabaseMetaData class to determine if the driver supports a particular feature it wants to use. In addition, the driver implements the Wrapper interface, which lets your client code discover Vertica-specific extensions to the JDBC standard classes, such as VerticaConnection and VerticaStatement classes.

Some important facts to keep in mind when using the Vertica JDBC driver:
• Cursors are forward only and are not scrollable. Result sets cannot be updated.
• A connection supports executing a single statement at any time. If you want to execute multiple statements simultaneously, you must open multiple connections.
• Because Vertica does not have stored procedures, CallableStatement is not supported. The DatabaseMetaData.getProcedures() and .getProcedureColumns() methods return information about SQL functions (including User Defined Functions) instead of stored procedures.

**Multiple SQL Statement Support**

The Vertica JDBC driver can execute strings containing multiple statements. For example:

```java
stmt.executeUpdate("CREATE TABLE t(a INT);INSERT INTO t VALUES(10);");
```

Only the Statement interface supports executing strings containing multiple SQL statements. You cannot use multiple statement strings with PreparedStatement. COPY statements that copy a file from a host file system work in a multiple statement string. However, client COPY statements (COPY FROM STDIN) do not work.

**Multiple Batch Conversion to COPY Statements**

The Vertica JDBC driver converts all batch inserts into Vertica COPY statements. If you turn off your JDBC connection's AutoCommit property, the JDBC driver uses a single COPY statement to load data from sequential batch inserts which can improve load performance by reducing overhead. See Batch Inserts Using JDBC Prepared Statements for details.

**Multiple JDBC Version Support**

The Vertica JDBC driver implements both JDBC 3.0 and JDBC 4.0 compliant interfaces. The interface that the driver returns to your application depends on the JVM version on which it is running. If your application is running on a 5.0 JVM, the driver supplies your application with JDBC 3.0 classes. If your application is running on a 6.0 or later JVM, the driver supplies it with JDBC 4.0 classes.
Multiple Active Result Sets (MARS)

The Vertica JDBC driver supports Multiple Active Result Sets (MARS). MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.
Creating and Configuring a Connection

Before your Java application can interact with Vertica, it must create a connection. Connecting to Vertica using JDBC is similar to connecting to most other databases.

**Importing SQL Packages**

Before creating a connection, you must import the Java SQL packages. A simple way to do so is to import the entire package using a wildcard:

```java
import java.sql.*;
```

You may also want to import the `Properties` class. You can use an instance of this class to pass connection properties when instantiating a connection, rather than encoding everything within the connection string:

```java
import java.util.Properties;
```

If your application needs to run in a Java 5 JVM, it uses the older JDBC 3.0-compliant driver. This driver requires that you to manually load the Vertica JDBC driver using the `Class.forName()` method:

```java
// Only required for old JDBC 3.0 driver
try {
    Class.forName("com.vertica.jdbc.Driver");
} catch (ClassNotFoundException e) {
    // Could not find the driver class. Likely an issue
    // with finding the .jar file.
    System.err.println("Could not find the JDBC driver class.");
    e.printStackTrace();
    return; // Exit. Cannot do anything further.
}
```

Your application may run in a Java 6 or later JVM. If so, then the JVM automatically loads the Vertica JDBC 4.0-compatible driver without requiring the call to `Class.forName`. However, making this call does not adversely affect the process. Thus, if you want your application to be compatible with both Java 5 and Java 6 (or later) JVMs, it can still call `Class.forName`.
Opening the Connection

With SQL packages imported, you are ready to create your connection by calling the `DriverManager.getConnection()` method. You supply this method with at least the following information:

- The IP address or host name of a node in the database cluster:
  
  You can provide an IPv4 address, IPv6 address, or host name.

  In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.

- Port number for the database
- Name of the database
- Username of a database user account
- Password of the user (if the user has a password)

The first three parameters are always supplied as part of the _connection string_, a URL that tells the JDBC driver where to find the database. The format of the connection string is:

```
"jdbc:vertica://VerticaHost:portNumber/databaseName"
```

The first portion of the connection string selects the Vertica JDBC driver, followed by the location of the database.

You can provide the last two parameters, username and password, to the JDBC driver, in one of three ways:

- **As part of the connection string.** The parameters are encoded similarly to URL parameters:

  ```
  "jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password"
  ```

- **As separate parameters** to `DriverManager.getConnection()`:

  ```java
  Connection conn = DriverManager.getConnection(
    "jdbc:vertica://VerticaHost:portNumber/databaseName",
    "username", "password";
  ```

- **In a `Properties` object**:

  ```java
  Properties myProp = new Properties();
  myProp.put("user", "username");
  ```
Of these three methods, the Properties object is the most flexible because it makes passing additional connection properties to the getConnection() method easy. See Connection Properties and Setting and Getting Connection Property Values for more information about the additional connection properties.

If there is any problem establishing a connection to the database, the getConnection() method throws a SQLException on one of its subclasses. To prevent an exception, enclose the method within a try-catch block, as shown in the following complete example of establishing a connection.

```java
import java.sql.*;
import java.util.Properties;

public class VerySimpleVerticaJDBCExample {
    public static void main(String[] args) {
        /*
         * If your client needs to run under a Java 5 JVM, It will use the older
         * JDBC 3.0-compliant driver, which requires you manually load the
         * driver using Class.forName
         */
        /*
         * try { Class.forName("com.vertica.jdbc.Driver"); } catch
         * (ClassNotFoundException e) { // Could not find the driver class.
         * Likely an issue // with finding the .jar file.
         * System.err.println("Could not find the JDBC driver class.");
         * e.printStackTrace(); return; // Bail out. We cannot do anything
         * further. }
         */
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        myProp.put("loginTimeout", "35");
        myProp.put("KeystorePath", "c:/keystore/keystore.jks");
        myProp.put("KeystorePassword", "keypwd");
        myProp.put("TrustStorePath", "c:/truststore/localstore.jks");
        myProp.put("TrustStorePassword", "trustpwd");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:portNumber/databaseName", myProp);
            System.out.println("Connected!");
            conn.close();
        } catch (SQLException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.println("Network connection issue: ");
            System.out.println(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        }
    }
}
```
Creating a Connection with a Kestore and Truststore

You can create secure connections with your JDBC client driver using a keystore and a truststore. For more information on security within Vertica, refer to Security and Authentication.

Note:

Openssl.cnf is configuration file automatically created by OpenSSL that handles certificate generation requests. Its default location varies between distributions:

- RedHat, CentOS: /etc/pki/tls/openssl.cnf
- Debian: /etc/ssl/openssl.cnf

To specify a custom configuration file, use the following option when generating your certificates and keys:

- config filename

1. Generate a certifying authority certificate. For information on this process, refer to the OpenSSL documentation. The following example shows a typical create command.

   openssl req -config openssl.cnf -new -x509 -days 3650 -sha256 -extensions v3_ca -nodes -out certs/ca.pem -keyout private/ca.key
   -subj "/C=US/ST=Colorado/L=Denver/O=ExampleCo/OU=Software/CN=Root CA"

2. Generate an intermediate certifying authority. The intermediate authority is not required, but can be useful for testing and debugging your connection. The following example shows a typical create command.
3. Generate and sign a certificate for your SSL certificate, as shown.

```bash
openssl req -config openssl.cnf -out csr/intermediate_ca.csr -newkey rsa:2048 -keyout private/intermediate_ca.key -nodes -subj "/C=US/ST=Colorado/L=Denver/O=ExampleCo/OU=Software/CN=Intermediate CA"
openssl ca -config openssl.cnf -in csr/intermediate_ca.csr -out certs/intermediate_ca.pem -extensions v3_intermediate_ca -notext -batch
```

4. Use the `ALTER DATABASE` statement to configure Vertica to use client/server TLS and to enable import and over SSL.

```bash
vsql -c "ALTER DATABASE DEFAULT SET EnableSSL = 1;"
vsql -c "$(printf "ALTER DATABASE DEFAULT SET SSLCertificate = '%s';" `cat certs/server.pem certs/intermediate_ca.pem`)
vsql -c "$(printf "ALTER DATABASE DEFAULT SET SSLPrivateKey = '%s';" `cat private/server.key`)"
```

5. To enable client certificate authentication, identify a certifying authority for the server.

```bash
vsql -c "$(printf "ALTER DATABASE DEFAULT SET SSLCA = '%s';" `cat certs/ca.pem`)"
```

6. Optionally, you can disable all non-SSL connections using the `CREATE AUTHENTICATION` statement.

```bash
vsql -c "CREATE AUTHENTICATION no_tls METHOD 'reject' HOST NO TLS '0.0.0.0/0';" 
CREATE AUTHENTICATION no_tls METHOD 'reject' HOST NO TLS '::/128';"
```

7. Generate and sign a certificate for your client using the same intermediate certifying authority as the server.

```bash
openssl req -config openssl.cnf -out csr/client.csr -newkey rsa:2048 -keyout private/client.key -nodes 
openssl ca -config openssl.cnf -in csr/client.csr -out certs/client.pem -extensions internode_cert -notext -cert certs/intermediate_ca.pem -keyfile private/intermediate_ca.key -batch
```

8. Convert your chain of pem certificates to a single pkcs 12 file

```bash
cat certs/client.pem certs/intermediate_ca.pem > certs/client_chain.pem 
openssl pkcs12 -export -in certs/client_chain.pem -inkey private/client.key -out certs/client.p12 -certfile certs/ca.pem -name my_alias -passout pass:my_password
```

9. Import the client key and chain into a keystore JKS file from your pkcs12 file. For information on using the keytool command interface, refer to the Java
Usage Considerations

- When you disconnect a user session, any uncommitted transactions are automatically rolled back.
- If your database is not compliant with your Vertica license terms, Vertica issues a SQLWarning when you establish the connection to the database. You can retrieve this warning using the Connection.getWarnings() method. See Managing Licenses in the Administrator's Guide for more information about complying with your license terms.

**JDBC Connection Properties**

You use connection properties to configure the connection between your JDBC client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number to use to connect to your database. They also let you tune the performance of your connection and enable logging.

You can set a connection property in any of three ways:

- Include the property name and value as part of the connection string you pass to the DriverManager.getConnection() method.
- Set the properties in a Properties object, and then pass it to the DriverManager.getConnection() method.
- Use the VerticaConnection.setProperty() method. With this approach, you can change only those connection properties that remain changeable after the connection has been established.

In addition, some of the standard JDBC connection properties have getters and setters on the Connection interface (such as Connection.setAutocommit()).
# Connection Properties

The properties in the following table can only be set before you open the connection to the database. Two of them are required for every connection.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnSettings</td>
<td>A string containing SQL statements that the JDBC driver automatically runs after it connects to the database. You can use this property to set the locale or schema search path, or perform other configuration that the connection requires.</td>
</tr>
<tr>
<td></td>
<td><strong>Required?</strong>: No</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value</strong>: none</td>
</tr>
<tr>
<td>DisableCopyLocal</td>
<td>When set to true, disables file-based COPY LOCAL operations, including copying data from local files and using local files to store data and exceptions. You can use this property to prevent users from writing to and copying from files on a Vertica host, including an MC host.</td>
</tr>
<tr>
<td></td>
<td><strong>Required?</strong>: No</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value</strong>: false</td>
</tr>
<tr>
<td>Label</td>
<td>Sets a label for the connection on the server. This value appears in the client_label column of the <code>V_MONITOR.SESSIONS</code> system table.</td>
</tr>
<tr>
<td></td>
<td><strong>Required?</strong>: No</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value</strong>: <code>jdbc-driver_version-random_number</code></td>
</tr>
<tr>
<td>LoginTimeout</td>
<td>The number of seconds Vertica waits for a connection to be established to the database before throwing a SQLException.</td>
</tr>
<tr>
<td></td>
<td><strong>Required?</strong>: No</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value</strong>: 0 (no TCP timeout)</td>
</tr>
<tr>
<td>SSL</td>
<td>When set to true, use SSL to encrypt the connection to the database.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| TLSmode         | Identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS/SSL connections before you can establish an encrypted connection to it. See TLS Protocol in the Administrator's Guide. Valid values are:   
  - disable - JDBC connects using plain text and implements no security measures.   
  - require - JDBC connects using TLS/SSL.   
  - verify-ca - JDBC connects using TLS/SSL and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated ssl=true property.   
  - verify-full - JDBC connects using TLS/SSL, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate.   
  If this property and the ssl property are set, this property takes precedence.  
  Required?: No  
  Default Value: false                                                                                                                                 |
| HostnameVerifier| If TLSmode is set to verify-full, this property the fully qualified domain name of the verifier that you want to confirm the host name.  
  Required?: No  
  Default Value: none                                                                                                                                 |
<p>| Password        | The password to use to log into the database.                                                                                                                                 |</p>
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Required?</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Default Value:</strong></td>
<td>none</td>
</tr>
<tr>
<td><strong>User</strong></td>
<td>The database user name to use to connect to the database.</td>
</tr>
<tr>
<td><strong>Required?</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Default Value:</strong></td>
<td>none</td>
</tr>
<tr>
<td><strong>ConnectionLoadBalance</strong></td>
<td>A Boolean value indicating whether the client is willing to have its connection redirected to another host in the Vertica database. This setting has an effect only if the server has also enabled connection load balancing. See About Native Connection Load Balancing in the Administrator's Guide for more information about native connection load balancing.</td>
</tr>
<tr>
<td><strong>Required?</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Default Value:</strong></td>
<td>false</td>
</tr>
<tr>
<td><strong>BackupServerNode</strong></td>
<td>A string containing the host name or IP address of one or more hosts in the database. If the connection to the host specified in the connection string times out, the client attempts to connect to any host named in this string. The host name or IP address can also include a colon followed by the port number for the database. If no port number is specified, the client uses the standard port number (5433). Separate multiple host name or IP address entries with commas.</td>
</tr>
<tr>
<td><strong>Required?</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Default Value:</strong></td>
<td>none</td>
</tr>
<tr>
<td><strong>PreferredAddressFamily</strong></td>
<td>The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>• ipv4—Connect to the server using IPv4.</td>
</tr>
<tr>
<td></td>
<td>• ipv6—Connect to the server using IPv6.</td>
</tr>
<tr>
<td></td>
<td>• none—Use the IP address provided by the DNS server.</td>
</tr>
<tr>
<td><strong>Required?</strong></td>
<td>No</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>KeyStorePath</td>
<td>The server path to a .JKS file containing your private keys and their corresponding certificate chains. For information on creating a keystore, refer to documentation for your development environment. For information on creating a keystore, <a href="#">refer to the Java documentation</a>.</td>
</tr>
<tr>
<td></td>
<td><strong>Required?</strong>: No</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value</strong>: none</td>
</tr>
<tr>
<td>KeyStorePassword</td>
<td>The password protecting the keystore file. If individual keys are also encrypted, the keystore file password must match the password for a key within the keystore.</td>
</tr>
<tr>
<td></td>
<td><strong>Required?</strong>: No</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value</strong>: none</td>
</tr>
<tr>
<td>TrustStorePath</td>
<td>The local path to a .JKS truststore file containing certificates from authorities you trust.</td>
</tr>
<tr>
<td></td>
<td><strong>Required?</strong>: No</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value</strong>: none</td>
</tr>
<tr>
<td>TrustStorePassword</td>
<td>The password protecting the truststore file.</td>
</tr>
<tr>
<td></td>
<td><strong>Required?</strong>: No</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value</strong>: none</td>
</tr>
</tbody>
</table>

### General Properties

The following properties can be set after the connection is established. None of these properties are required.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoCommit</td>
<td>Controls whether the connection automatically commits transactions. Set this parameter to false to prevent the</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>connection from automatically committing its transactions. You often want to do this when you are bulk loading multiple batches of data and you want the ability to roll back all of the loads if an error occurs. Previous Property NameNote: This property was called defaultAutoCommit in previous versions of the Vertica JDBC driver. Set After Connection: Connection.setAutoCommit() Default Value: true</td>
</tr>
<tr>
<td>DirectBatchInsert</td>
<td>Determines whether a batch insert stored data directly into ROS (true) or using AUTO mode (false). When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS. For details about load options, see Choosing a Load Method. Set After Connection: VerticaConnection.setProperty() Default Value: false</td>
</tr>
<tr>
<td>MultipleActiveResultSets</td>
<td>Allows more than one active result set on a single connection via MultipleActiveResultSets (MARS). If both MultipleActiveResultSets and ResultBufferSize are turned on, MultipleActiveResultSets takes precedence. The connection does not provide an error, however ResultBufferSize is ignored. Set After Connection: VerticaConnection.setProperty() Default Value: false</td>
</tr>
<tr>
<td>ReadOnly</td>
<td>When set to true, makes the data connection read-only. Any queries attempting to update the database using a read-only connection cause a SQLException. Set After Connection: Connection.setReadOnly()</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> false</td>
</tr>
<tr>
<td>ResultBufferSize</td>
<td>Sets the size of the buffer the Vertica JDBC driver uses to temporarily store result sets. A value of 0 means ResultBufferSize is turned off. <strong>Note:</strong> This property was named maxLRSMemory in previous versions of the Vertica JDBC driver. <strong>Set After Connection:</strong> VerticaConnection.setProperty() <strong>Default Value:</strong> 8912 (8KB)</td>
</tr>
<tr>
<td>SearchPath</td>
<td>Sets the schema search path for the connection. This value is a string containing a comma-separated list of schema names. See <a href="https://www.vertica.com/documentation/administrator-guide/v102x/v102x0000-frindex.html#content/1066-1108-Setting%20Search%20Paths">Setting Search Paths</a> in the Administrator's Guide for more information on the schema search path. <strong>Set After Connection:</strong> VerticaConnection.setProperty() <strong>Default Value:</strong> &quot;$user&quot;, public, v_catalog, v_monitor, v_internal</td>
</tr>
<tr>
<td>ThreePartNaming</td>
<td>A Boolean value that controls how DatabaseMetaData reports the catalog name. When set to true, the database name is returned as the catalog name in the database metadata. When set to false, NULL is returned as the catalog name. Enable this option if your client software is set up to get the catalog name from the database metadata for use in a three-part name reference. <strong>Set After Connection:</strong> VerticaConnection.setProperty() <strong>Default Value:</strong> true</td>
</tr>
<tr>
<td>TransactionIsolation</td>
<td>Sets the isolation level of the transactions that use the connection. See <a href="https://www.vertica.com/documentation/administrator-guide/v102x/v102x0000-frindex.html#content/1066-1118-Changing%20the%20Transaction%20Isolation%20Level">Changing the Transaction Isolation Level</a> for details.</td>
</tr>
</tbody>
</table>
### Property Description

**Note:** In previous versions of the Vertica JDBC driver, this property was only available using a getter and setter on the PGConnection object. You can now set it in the same way as other connection properties.

**Set After Connection:**
Connection.setTransactionIsolation()

**Default Value:** TRANSACTION_READ_COMMITTED

### Logging Properties

The properties that control client logging must be set before the connection is opened. None of these properties are required, and none can be changed after the Connection object has been instantiated.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LogLevel</td>
<td>Sets the type of information logged by the JDBC driver. The value is set to one of the following values:</td>
</tr>
<tr>
<td></td>
<td>• &quot;DEBUG&quot;</td>
</tr>
<tr>
<td></td>
<td>• &quot;ERROR&quot;</td>
</tr>
<tr>
<td></td>
<td>• &quot;TRACE&quot;</td>
</tr>
<tr>
<td></td>
<td>• &quot;WARNING&quot;</td>
</tr>
<tr>
<td></td>
<td>• &quot;INFO&quot;</td>
</tr>
<tr>
<td></td>
<td>• &quot;OFF&quot;</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> &quot;OFF&quot;</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>LogNameSpace</th>
<th>Restricts logging to just messages generated by a specific packages. Valid values are:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• com.vertica — All messages generated by the JDBC driver</td>
</tr>
<tr>
<td></td>
<td>• com.vertica.jdbc — All messages generated by the top-level JDBC API</td>
</tr>
<tr>
<td></td>
<td>• com.vertica.jdbc.kv — All messages generated by the JDBC KV API</td>
</tr>
<tr>
<td></td>
<td>• com.vertica.jdbc.core — Connection and statement settings</td>
</tr>
</tbody>
</table>
### Property | Description
---|---
| | - `com.vertica.jdbc.io` — Client/server protocol messages  
| | - `com.vertica.jdbc.util` — Miscellaneous utilities  
| | - `com.vertica.jdbc.dataengine` — Query execution and result set iteration  
| | - `com.vertica.dataengine` — Query execution and result set iteration  
| **Default Value:** | none  

| LogPath | Sets the path where the log file is written.  
| **Default Value:** | The current working directory  

### Kerberos Connection Parameters

Use the following parameters to set the service and host name principals for client authentication using Kerberos.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
</table>
| **JAASConfigName** | Provides the name of the JAAS configuration that contains the JAAS Krb5LoginModule and its settings  
| **Default Value:** | verticajdbc  
| **KerberosServiceName** | Provides the service name portion of the Vertica Kerberos principal, for example: `vertica/host@EXAMPLE.COM`  
| **Default Value:** | vertica  
| **KerberosHostname** | Provides the instance or host name portion of the Vertica Kerberos principal, for example: `vertica/host@EXAMPLE.COM`  
| **Default Value:** | Value specified in the servername connection string property  

Routable Connection API Connection Parameters

Use the following parameters to set properties to enable and configure the connection for Routable Connection lookups.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EnableRoutableQueries</td>
<td>Enables Routable Connection lookup. See Routing JDBC Queries Directly to a Single Node.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> false</td>
</tr>
<tr>
<td>FailOnMultiNodePlans</td>
<td>If the query plan requires more than one node, then the query fails. Only applicable when EnableRoutableQueries = true.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> true</td>
</tr>
<tr>
<td>MetadataCacheLifetime</td>
<td>The time in seconds to keep projection metadata. Only applicable when EnableRoutableQueries = true.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong></td>
</tr>
<tr>
<td>MaxPooledConnections</td>
<td>Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Only applicable when EnableRoutableQueries = true.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> 20</td>
</tr>
<tr>
<td>MaxPooledConnections PerNode</td>
<td>Per-node maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Only applicable when EnableRoutableQueries = true.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> 5</td>
</tr>
</tbody>
</table>

**Note:** You can also use VerticaConnection.setProperty() method to set properties that have standard JDBC Connection setters, such as AutoCommit.
For information about manipulating these attributes, see Setting and Getting Connection Property Values.

**Setting and Getting Connection Property Values**

You can set a connection property in any of three ways:

- Include the property name and value as part of the connection string you pass to the DriverManager.getConnection() method.
- Set the properties in a Properties object, and then pass it to the DriverManager.getConnection() method.
- Use the VerticaConnection.setProperty() method. With this approach, you can change only those connection properties that remain changeable after the connection has been established.

In addition, some of the standard JDBC connection properties have getters and setters on the Connection interface (such as Connection.setAutocommit()).

**Setting Properties When Connecting**

There are two ways you can set connection properties when creating a connection to Vertica:

- In the connection string, using the same URL parameter format that you can use to set the username and password. The following example enables a TLS/SSL connection:

  "jdbc:vertica://VerticaHost:5433/db?user=UserName&password=Password&TLSmode=require"

Setting a host name using the setProperty() method overrides the host name set in a connection string as seen above. If this occurs, Vertica may not be able to connect to a host. For example, using the connection string above, the following overrides the VerticaHost name:

```
Properties props = new Properties();
props.setProperty("dataSource", dataSourceURL);
props.setProperty("database", database);
props.setProperty("user", user);
props.setProperty("password", password);
ps.setProperty("jdbcDriver", jdbcDriver);
props.setProperty("hostName", "NonVertica_host");
```
However, if a new connection or override connection is needed, you may enter a valid host name in the hostname properties object.

The NonVertica_host hostname overrides VerticaHost name in the connection string. To avoid this issue comment out the props.setProperty("hostName", "NonVertica_host"); line:

```java
//props.setProperty("hostName", "NonVertica_host");
```

- In a Properties object that you pass to the getConnection() call. You will need to import the java.util.Properties class in order to instantiate a Properties object. Then you use the put() method to add the property name and value to the object:

```java
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
myProp.put("LoginTimeout", "35");
Connection conn;
try {
    conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:/ExampleDB", myProp);
} catch (SQLException e) {
    e.printStackTrace();
}
```

**Note:**
The data type of all of the values you set in the Properties object are strings, regardless of the property value's data type.

### Getting and Setting Properties After Connecting

The VerticaConnection.getProperty() method lets you get the value of some connection properties. You can use VerticaConnection.setProperty() method to change the value for properties that can be set after the database connection has been established. Since these methods are Vertica-specific, to use them you must cast your Connection object to the VerticaConnection interface. To cast to VerticaConnection, you must either import it into your client application or use a fully-qualified reference (com.vertica.jdbc.VerticaConnection). The following example demonstrates getting and setting the value of the DirectBatchInsert property.

```java
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;
```
public class SetConnectionProperties {
    public static void main(String[] args) {
        // Note: If your application needs to run under Java 5, you need to
        // load the JDBC driver using Class.forName() here.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        // Set DirectBatchInsert to true initially
        myProp.put("DirectBatchInsert", "true");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);
            // Show state of the DirectBatchInsert property. This was set at the
            // time the connection was created.
            System.out.println("DirectBatchInsert state: 
                + ((VerticaConnection) conn).getProperty("DirectBatchInsert");

            // Change it and show it again
            ((VerticaConnection) conn).setProperty("DirectBatchInsert", false);
            System.out.println("DirectBatchInsert state is now: 
                + ((VerticaConnection) conn).getProperty("DirectBatchInsert");

            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}

When run, the example prints the following on the standard output:

DirectBatchInsert state: true
DirectBatchInsert state is now: false

**Setting and Returning a Client Connection Label**

The JDBC Client has a method to set and return the client connection label: `getClientInfo()` and `setClientInfo()`. You can use these methods with the SQL Functions `GET_CLIENT_LABEL` and `SET_CLIENT_LABEL`.

When you use these two methods, make sure you pass the string value `APPLICATIONNAME` to both the setter and getter methods.

Use `setClientInfo()` to create a client label, and use `getClientInfo()` to return the client label:

```java
import java.sql.*;
import java.util.Properties;
```
public class ClientLabelJDBC {

    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        myProp.put("loginTimeout", "35");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://docc05.verticacorp.com:5433/docdb", myProp);
            System.out.println("Connected!");
            conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
            System.out.println("New Conn label: " + conn.getClientInfo("APPLICATIONNAME"));
            conn.close();
        } catch (SQLTransientConnectionException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.println("Network connection issue: ");
            System.out.println(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.println("Could not log into database: ");
            System.out.println(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        } }
    }
}

When you run this method, it prints the following result to the standard output:

   Connected!
   New Conn label: JDBC Client - Data Load

**Setting the Locale for JDBC Sessions**

You set the locale for a connection while opening it by including a SET LOCALE statement in the ConnSettings property, or by executing a SET LOCALE statement at any time after opening the connection. Changing the locale of a Connection object affects all of the Statement objects you instantiated using it.

You can get the locale by executing a SHOW LOCALE query. The following example demonstrates setting the locale using ConnSettings and executing a statement, as well as getting the locale:
import java.sql.*;
import java.util.Properties;

public class GetAndSetLocale {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, you need to load the JDBC driver 
        // using Class.forName here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        // Set Locale to true en_GB on connection. After the connection 
        // is established, the JDBC driver runs the statements in the 
        // ConnSettings property.
        myProp.put("ConnSettings", "SET LOCALE TO en_GB");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);

            // Execute a query to get the locale. The results should 
            // show "en_GB" as the locale, since it was set by the 
            // conn settings property.
            Statement stmt = conn.createStatement();
            ResultSet rs = null;
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }

            // Now execute a query to set locale.
            stmt.execute("SET LOCALE TO en_US");

            // Run query again to get locale.
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query now reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }

            // Clean up
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}

Running the above example displays the following on the system console:

Query reports that Locale is set to: en_GB (LEN)
Query now reports that Locale is set to: en_US (LEN)
Notes:

- JDBC applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. Failing to convert the data can result in errors or the data being stored incorrectly.
- The JDBC driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16.

**Changing the Transaction Isolation Level**

Changing the transaction isolation level lets you choose how transactions prevent interference from other transactions. By default, the JDBC driver matches the transaction isolation level of the Vertica server. The Vertica default transaction isolation level is READ_COMMITTED, which means any changes made by a transaction cannot be read by any other transaction until after they are committed. This prevents a transaction from reading data inserted by another transaction that is later rolled back.

Vertica also supports the SERIALIZABLE transaction isolation level. This level locks tables to prevent queries from having the results of their WHERE clauses changed by other transactions. Locking tables can have a performance impact, since only one transaction is able to access the table at a time.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

You can change the transaction isolation level connection property after the connection has been established using the Connection object's setter (setTransactionIsolation()) and getter (getTransactionIsolation()). The value for transaction isolation property is an integer. The Connection interface defines constants to help you set the value in a more intuitive manner:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection.TRANSACTION_READ_COMMITTED</td>
<td>2</td>
</tr>
<tr>
<td>Connection.TRANSACTION_SERIALIZABLE</td>
<td>8</td>
</tr>
</tbody>
</table>
Note:
The Connection interface also defines several other transaction isolation constants (READ_UNCOMMITTED and REPEATABLE_READ). Since Vertica does not support these isolation levels, they are converted to READ_COMMITTED and SERIALIZABLE, respectively.

The following example demonstrates setting the transaction isolation level to SERIALIZABLE.

```java
import java.sql.*;
import java.util.Properties;

public class SetTransactionIsolation {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Get default transaction isolation
            System.out.println("Transaction Isolation Level: ", conn.getTransactionIsolation());
            // Set transaction isolation to SERIALIZABLE
            conn.setTransactionIsolation(Connection.TRANSACTION_SERIALIZABLE);
            // Get the transaction isolation again
            System.out.println("Transaction Isolation Level: ", conn.getTransactionIsolation());
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Running the example results in the following being printed out to the console:

```
Transaction Isolation Level: 2
Transaction Isolation Level: 8
```

**Using a Pooling Data Source**

A pooling data source uses a collection of persistent connections in order to reduce the overhead of repeatedly opening network connections between the client and server. Opening a new connection for each request is more costly for both the server and the client than keeping a small pool of connections open constantly, ready to be used by new requests. When a request comes in, one of the pre-existing connections in the pool is assigned to it. Only if there are no free connections in the pool is a new connection created.
Once the request is complete, the connection returns to the pool and waits to service another request.

The Vertica JDBC driver supports connection pooling as defined in the JDBC 4.0 standard. If you are using a J2EE-based application server in conjunction with Vertica, it should already have a built-in data pooling feature. All that is required is that the application server work with the PooledConnection interface implemented by Vertica's JDBC driver. An application server's pooling feature is usually well-tuned for the works loads that the server is designed to handle. See your application server's documentation for details on how to work with pooled connections. Normally, using pooled connections should be transparent in your code—you will just open connections and the application server will worry about the details of pooling them.

If you are not using an application server, or your application server does not offer connection pooling that is compatible with Vertica, you can use a third-party pooling library, such as the open-source c3p0 or DBCP libraries, to implement connection pooling.

**Note:**
The Vertica Analytic Database client driver's native connection load balancing feature works with third-party connection pooling supplied by application servers and third-party pooling libraries. See Enabling Native Connection Load Balancing in JDBC for more information.

### Enabling Native Connection Load Balancing in JDBC

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true. The following example demonstrates connecting to the database several
times with native connection load balancing enabled and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```java
import java.sql.*;
import java.util.Properties;
import java.sql.*;
import java.util.Properties;
public class JDBCLoadingBalanceExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "example_password123");
        myProp.put("loginTimeout", "35");
        myProp.put("ConnectionLoadBalance", "1");
        Connection conn;
        for (int x=1; x <= 4; x++) {
            try {
                System.out.print("Connect attempt #" + x + "...");
                conn = DriverManager.getConnection(
                        "jdbc:vertica://node01.example.com:5433/vmart", myProp);
                Statement stmt = conn.createStatement();
                // Set the load balance policy to round robin before testing the database's load balancing.
                stmt.execute("SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');");
                // Query system to table to see what node we are connected to. Assume a single row
                // in response set.
                ResultSet rs = stmt.executeQuery("SELECT node_name FROM v_monitor.current_session;");
                rs.next();
                System.out.println("Connected to node " + rs.getString(1).trim());
                conn.close();
            } catch (SQLTransientConnectionException connException) {
                // There was a potentially temporary network error
                // Could automatically retry a number of times here, but
                // instead just report error and exit.
                System.out.print("Network connection issue: ");
                System.out.print(connException.getMessage());
                System.out.println(" Try again later!");
                return;
            } catch (SQLException e) {
                // Catch-all for other exceptions
                e.printStackTrace();
            }
        }
    }
}
```

Running the above example produces the following output:
Connect attempt #1...Connected to node v_vmart_node0002
Connect attempt #2...Connected to node v_vmart_node0003
Connect attempt #3...Connected to node v_vmart_node0001
Connect attempt #4...Connected to node v_vmart_node0002

**JDBC Connection Failover**

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

**Choosing a Failover Method**

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup...
hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

**Note:**

If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

### Using DNS Failover

To use DNS failover, you need to change your DNS server’s settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

### Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the BackupServerNode parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.
The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```java
import java.sql.*;
import java.util.Properties;

public class ConnectionFailoverExample {
    public static void main(String[] args) {
        // Assume using JDBC 4.0 driver on JVM 6+. No driver loading needed.
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        // Set two backup hosts to be used if connecting to the first host
        // fails. All of these hosts will be tried in order until the connection
        // succeeds or all of the connections fail.
        myProp.put("BackupServerNode", "VerticaHost02,VerticaHost03");
        Connection conn;
        try {
            // The connection string is set to try to connect to a known
            // bad host (in this case, a host that never existed).
            conn = DriverManager.getConnection(
                    "jdbc:vertica://BadVerticaHost:5433/vmart", myProp);
            System.out.println("Connected!");
            // Query system to table to see what node we are connected to.
            // Assume a single row in response set.
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("SELECT node_name FROM v_monitor.current_session;");
            rs.next();
            System.out.println("Connected to node " + rs.getString(1).trim());
            // Done with connection.
            conn.close();
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When run, the example outputs output similar to the following on the system console:

```
Connected!
Connected to node v_vmart_node0002
```

Notice that the connection was made to the first node in the backup list (node 2).

**Notes**

- When native connection load balancing is enabled, the additional servers specified in the `BackupServerNode` connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to
handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in JDBC for more information.
JDBC Data Types

The JDBC driver transparently converts most Vertica data types to the appropriate Java data type. In a few cases, a Vertica data type cannot be directly translated to a Java data type; these exceptions are explained in this section.

The VerticaTypes Class

JDBC does not support all of the data types that Vertica supports. The Vertica JDBC client driver contains an additional class named VerticaTypes that helps you handle identifying these Vertica-specific data types. It contains constants that you can use in your code to specify Vertica data types. This class defines two different categories of data types:

- Vertica's 13 types of interval values. This class contains constant properties for each of these types. You can use these constants to select a specific interval type when instantiating members of the VerticaDayTimeInterval and VerticaYearMonthInterval classes:

  ```java
  // Create a day to second interval.
  VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(      
      VerticaTypes.INTERVAL_DAY_TO_SECOND, 10, 0, 5, 40, 0, 0, false);
  // Create a year to month interval.
  VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(      
      VerticaTypes.INTERVAL_YEAR_TO_MONTH, 10, 6, false);
  ```

- Vertica UUID data type. One way you can use the VerticaTypes.UUID is to query a table's metadata to see if a column is a UUID. See UUID Values for an example.

See the JDBC Documentation for more information on this class.

Numeric Data Alias Conversion

The Vertica server supports data type aliases for integer, float and numeric types. The JDBC driver reports these as its basic data types (BIGINT, DOUBLE PRECISION, and NUMERIC), as follows:
<table>
<thead>
<tr>
<th>Vertica Server Types and Aliases</th>
<th>Vertica JDBC Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>BIGINT</td>
</tr>
<tr>
<td>INT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>INT8</td>
<td>BIGINT</td>
</tr>
<tr>
<td>BIGINT</td>
<td></td>
</tr>
<tr>
<td>SMALLINT</td>
<td></td>
</tr>
<tr>
<td>TINYINT</td>
<td></td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>DOUBLE PRECISION</td>
</tr>
<tr>
<td>FLOAT5</td>
<td></td>
</tr>
<tr>
<td>FLOAT8</td>
<td></td>
</tr>
<tr>
<td>REAL</td>
<td></td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>NUMERIC</td>
<td></td>
</tr>
<tr>
<td>NUMBER</td>
<td></td>
</tr>
<tr>
<td>MONEY</td>
<td></td>
</tr>
</tbody>
</table>

If a client application retrieves the values into smaller data types, Vertica JDBC driver does not check for overflows. The following example demonstrates the results of this overflow.

```java
import java.sql.*;
import java.util.Properties;

public class JDBCDataTypes {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        // using Class.forName here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/VMart",
                                               myProp);
            Statement statement = conn.createStatement();
            // Create a table that will hold a row of different types of
            // numeric data.
        }
    }
}
```
stmt.executeUpdate("DROP TABLE IF EXISTS test_all_types cascade");
stmt.executeUpdate("CREATE TABLE test_all_types (" + "c0 INTEGER, c1 TINYINT, c2 DECIMAL, " + "c3 MONEY, c4 DOUBLE PRECISION, c5 REAL")
// Add a row of values to it.
stmt.executeUpdate("INSERT INTO test_all_types VALUES(" + "111111111111, 444, 5555555555.5555, " + "77777777.77, 8888888888888888.88, " + "10101010.10101010101010")
// Query the new table to get the row back as a result set.
ResultSet rs = stmt.executeQuery("SELECT * FROM test_all_types");
// Get the metadata about the row, including its data type.
ResultSetMetaData md = rs.getMetaData();
// Loop should only run once...
while (rs.next()) {
    // Print out the data type used to defined the column, followed
    // by the values retrieved using several different retrieval
    // methods.
    String[] vertTypes = new String[] {"INTEGER", "TINYINT", "DECIMAL", "MONEY", "DOUBLE PRECISION", "REAL"};
    for (int x=1; x<7; x++) {
        System.out.println("Column " + x + " (" + vertTypes[x-1] + ")");
        System.out.println("getColumnType()		" + md.getColumnType(x));
        System.out.println("getColumnTypeName()	" + md.getColumnTypeName(x));
        System.out.println("getShort()		" + rs.getShort(x));
        System.out.println("getLong()		" + rs.getLong(x));
        System.out.println("getInt()		" + rs.getInt(x));
        System.out.println("getByte()		" + rs.getByte(x));
    }
}
rstmt.close();
stmt.executeUpdate("drop table test_all_types cascade");
stmt.close();
} catch (SQLException e) {
    e.printStackTrace();
}

The above example prints the following on the console when run:

<table>
<thead>
<tr>
<th>Column 1 (INTEGER)</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>getColumnType()</td>
<td>-5</td>
</tr>
<tr>
<td>getColumnTypeName()</td>
<td>BIGINT</td>
</tr>
<tr>
<td>getShort()</td>
<td>455</td>
</tr>
<tr>
<td>getLong()</td>
<td>111111111111</td>
</tr>
<tr>
<td>getInt()</td>
<td>555038585</td>
</tr>
<tr>
<td>getByte()</td>
<td>-57</td>
</tr>
<tr>
<td>Column 2 (TINYINT)</td>
<td></td>
</tr>
<tr>
<td>getColumnType()</td>
<td>-5</td>
</tr>
</tbody>
</table>
### Using Intervals with JDBC

The JDBC standard does not contain a data type for intervals (the duration between two points in time). To handle Vertica's `INTERVAL` data type, you must use JDBC's database-specific object type.

When reading an interval value from a result set, use the `ResultSet.getObject()` method to retrieve the value, and then cast it to one of the Vertica interval classes: `VerticaDayTimeInterval` (which represents all ten types of day/time intervals) or `VerticaYearMonthInterval` (which represents all three types of year/month intervals).

**Note:**
The units interval style is not supported. Do not use the `SET INTERVALSTYLE` statement to change the interval style in your client applications.
Using Intervals in Batch Inserts

When inserting batches into tables that contain interval data, you must create instances of the VerticaDayTimeInterval or VerticaYearMonthInterval classes to hold the data you want to insert. You set values either when calling the class's constructor, or afterwards using setters. You then insert your interval values using the PreparedStatement.setObject() method. You can also use the .setString() method, passing it a string in "DD HH:MM:SS" or "YY-MM" format.

The following example demonstrates inserting data into a table containing a day/time interval and a year/month interval:

```java
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class IntervalDemo {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/VMart", myProp);
            // Create table for interval values
            Statement stmt = conn.createStatement();
            stmt.execute("DROP TABLE IF EXISTS interval_demo");
            stmt.executeUpdate("CREATE TABLE interval_demo"
                            + "DayInt INTERVAL DAY TO SECOND,"
                            + "MonthInt INTERVAL YEAR TO MONTH");
            // Insert data into interval columns using
            // VerticaDayTimeInterval and VerticaYearMonthInterval
            // classes.
            PreparedStatement pstmt = conn.prepareStatement("INSERT INTO interval_demo VALUES(? , ?)");
            // Create instances of the Vertica classes that represent
            // intervals.
            VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(10, 0, 5, 40, 0, 0, false);
            VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(10, 6, false);
            // These objects can also be manipulated using setters.
            dayInt.setHour(7);
            // Add the interval values to the batch
            ((VerticaPreparedStatement) pstmt).setObject(1, dayInt);
            ((VerticaPreparedStatement) pstmt).setObject(2, monthInt);
            pstmt.addBatch();
        }
    }
}
```
// Set another row from strings.
// Set day interval in "days HH:MM:SS" format
pstmt.setString(1, "10 10:10:10");
// Set year to month value in "MM-YY" format
pstmt.setString(2, "12-09");
pstmt.addBatch();
// Execute the batch to insert the values.
try {
    pstmt.executeBatch();
} catch (SQLException e) {
    System.out.println("Error message: " + e.getMessage());
}

Reading Interval Values

You read an interval value from a result set using the ResultSet.getObject() method, and cast the object to the appropriate Vertica object class: VerticaDayTimeInterval for day/time intervals or VerticaYearMonthInterval for year/month intervals. This is easy to do if you know that the column contains an interval, and you know what type of interval it is. If your application cannot assume the structure of the data in the result set it reads in, you can test whether a column contains a database-specific object type, and if so, determine whether the object belongs to either the VerticaDayTimeInterval or VerticaYearMonthInterval classes.

// Retrieve the interval values inserted by previous demo.
// Query the table to get the row back as a result set.
ResultSet rs = stmt.executeQuery("SELECT * FROM interval_demo");
// If you do not know the types of data contained in the result set,
// you can read its metadata to determine the type, and use
// additional information to determine the interval type.
ResultSetMetaData md = rs.getMetaData();
while (rs.next()) {
    for (int x = 1; x <= md.getColumnCount(); x++) {
        // Get data type from metadata
        int colDataType = md.getColumnType(x);
        // You can get the type in a string:
        System.out.println("Column " + x + " is a "
                            + md.getColumnTypeName(x));
        // Normally, you'd have a switch statement here to
        // handle all sorts of column types, but this example is
        // simplified to just handle database-specific types
        if (colDataType == Types.OTHER) {
            // Column contains a database-specific type. Determine
            // what type of interval it is. Assuming it is an
            // interval...
            Object columnVal = rs.getObject(x);
            if (columnVal instanceof VerticaDayTimeInterval) {
                // We know it is a date time interval
                VerticaDayTimeInterval interval =
                    (VerticaDayTimeInterval) columnVal;
                // You can use the getters to access the interval's
// data
System.out.print("Column " + x + "'s value is ");
System.out.print(interval.getDay() + " Days ");
System.out.print(interval.getHour() + " Hours ");
System.out.println(interval.getMinute()
 + " Minutes");
} else if (columnVal instanceof VerticaYearMonthInterval) {
    VerticaYearMonthInterval interval =
        (VerticaYearMonthInterval) columnVal;
    System.out.print("Column " + x + "'s value is ");
    System.out.print(interval.getYear() + " Years ");
    System.out.println(interval.getMonth() + " Months");
} else {
    System.out.println("Not an interval.");
}

The example prints the following to the console:

Column 1 is a INTERVAL DAY TO SECOND
Column 1’s value is 10 Days 7 Hours 5 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2’s value is 10 Years 6 Months
Column 1 is a INTERVAL DAY TO SECOND
Column 1’s value is 10 Days 10 Hours 10 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2’s value is 12 Years 9 Months

Another option is to use database metadata to find columns that contain intervals.

// Determine the interval data types by examining the database
// metadata.
DatabaseMetaData dbmd = conn.getMetaData();
ResultSet dbMeta = dbmd.getColumns(null, null, "interval_demo", null);
int colcount = 0;
while (dbMeta.next()) {

    // Get the metadata type for a column.
    int javaType = dbMeta.getInt("DATA_TYPE");
    System.out.println("Column " + ++colcount + " Type name is " +
        dbMeta.getString("TYPE_NAME"));

    if(javaType == Types.OTHER) {
        // The SQL_DATETIME_SUB column in the metadata tells you
        // Specifically which subtype of interval you have.
        // The VerticaDayTimeInterval.isDayTimeInterval()
        // methods tells you if that value is a day time.
        //
        int intervalType = dbMeta.getInt("SQL_DATETIME_SUB");
    }
if(VerticaDayTimeInterval.isDayTimeInterval(intervalType)) {
    // Now you know it is one of the 10 day/time interval types.
    // When you select this column you can cast to
    // VerticaDayTimeInterval.
    // You can get more specific by checking intervalType
    // against each of the 10 constants directly, but
    // they all are represented by the same object.
    System.out.println("column " + colcount + " is a " +
    "VerticaDayTimeInterval intervalType = "
    + intervalType);
} else if(VerticaYearMonthInterval.isYearMonthInterval(intervalType)) {
    // now you know it is one of the 3 year/month intervals,
    // and you can select the column and cast to
    // VerticaYearMonthInterval
    System.out.println("column " + colcount + " is a " +
    "VerticaDayTimeInterval intervalType = "
    + intervalType);
} else {
    System.out.println("Not an interval type.");
}

UUID Values

UUID is a core data type in Vertica. However, it is not a core Java data type. You must use
the java.util.UUID class to represent UUID values in your Java code. The JDBC driver
does not translate values from Vertica to non-core Java data types. Therefore, you must
send UUID values to Vertica using generic object methods such as
PreparedStatement.setObject(). You also use generic object methods (such as
ResultSet.getObject()) to retrieve UUID values from Vertica. You then cast the
retrieved objects as a member of the java.util.UUID class.

The following example code demonstrates inserting UUID values into and retrieving
UUID values from Vertica.

package jdbc_uuid_example;
import java.sql.*;
import java.util.Properties;

public class VerticaUUIDExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        Connection conn;
try {
    conn = DriverManager.getConnection("jdbc:vertica://doch01:5433/VMart", myProp);
    Statement stmt = conn.createStatement();

    // Create a table with a UUID column and a VARCHAR column.
    stmt.execute("DROP TABLE IF EXISTS UUID_TEST CASCADE;");
    stmt.execute("CREATE TABLE UUID_TEST (id UUID, description VARCHAR(25));");

    // Prepare a statement to insert a UUID and a string into the table.
    PreparedStatement ps = conn.prepareStatement("INSERT INTO UUID_TEST VALUES(?,?)");
    java.util.UUID uuid; // Holds the UUID value.
    for (Integer x = 0; x < 10; x++) {
        // Generate a random uuid
        uuid = java.util.UUID.randomUUID();
        // Set the UUID value by calling setObject.
        ps.setObject(1, uuid);
        // Set the String value to indicate which UUID this is.
        ps.setString(2, "UUID #" + x);
        ps.execute();
    }

    // Query the uuid
    ResultSet rs = stmt.executeQuery("SELECT * FROM UUID_TEST ORDER BY description ASC");
    while (rs.next()) {
        // Cast the object from the result set as a UUID.
        uuid = (java.util.UUID) rs.getObject(1);
        System.out.println(rs.getString(2) + " : " + uuid.toString());
    }
} catch (SQLException e) {
    e.printStackTrace();
}

The previous example prints output similar to the following:

<table>
<thead>
<tr>
<th>UUID #0</th>
<th>67b6dbc6-c28c-4965-b9f7-5c830a04664d</th>
</tr>
</thead>
<tbody>
<tr>
<td>UUID #1</td>
<td>485d3835-2887-4233-b003-392254fa97e0</td>
</tr>
<tr>
<td>UUID #2</td>
<td>8142f51-cb03-473d-8cfc-2c184582a117</td>
</tr>
<tr>
<td>UUID #3</td>
<td>bec88b66a-b650-f7be-852c-8229153332d9</td>
</tr>
<tr>
<td>UUID #4</td>
<td>8ae5e3ec-d143-4ef7-8901-24f6d0483abf</td>
</tr>
<tr>
<td>UUID #5</td>
<td>669696ce-5e86-4e87-b8d0-a937f5fc18d7</td>
</tr>
<tr>
<td>UUID #6</td>

</tr>
<tr>
<td>UUID #7</td>
<td>971821ed-5c7e-3daa-9922-6f7e80dfe173</td>
</tr>
<tr>
<td>UUID #8</td>
<td>c763c3a2b-a9ef-4d65-b2f7-7c637f78723c</td>
</tr>
<tr>
<td>UUID #9</td>
<td>3cbcc2d6e-c177-4277-b3df-bf4d9389f69d</td>
</tr>
</tbody>
</table>

Determining Whether a Column has a UUID Data Type

JDBC does not support the UUID data type. This limitation means you cannot use the usual ResultSetMetaData.getColumnType() method to determine column's data type is
UUID. Calling this method on a UUID column returns Types.OTHER. This value is also to identify interval columns. You can use two ways to determine if a column contains UUIDs:

- Use ResultSetMetaData.getColumnTypeName() to get the name of the column's data type. For UUID columns, this method returns the value "Uuid" as a String.
- Query the table's metadata to get the SQL data type of the column. If this value is equal to VerticaTypes.UUID, the column's data type is UUID.

The following example demonstrates both of these techniques:

```java
// This example assumes you already have a database connection
// and result set from a query on a table that may contain a UUID.

// Get the metadata of the result set to get the column definitions
ResultSetMetaData meta = rs.getMetaData();
int colcount;
int maxcol = meta.getColumnCount();
System.out.println("Using column metadata:");
for (colcount = 1; colcount < maxcol; colcount++) {
    if (meta.getColumnType(colcount) == Types.OTHER) {
        // To determine that it is a UUID column, test the name of the column type.
        if (meta.getColumnTypeName(colcount).equalsIgnoreCase("uuid")) {
            // It's a UUID column
            System.out.println("Column "+colcount+" is UUID");
        }
    }
}

// You can also query the table's metadata to find its column types and compare
// it to the VerticaType.UUID constant to see if it is a UUID column.
System.out.println("Using table metadata:");
DatabaseMetaData dbmd = conn.getMetaData();
// Get the metadata for the previously-created test table.
ResultSet tableMeta = dbmd.getColumns(null, null, "UUID_TEST", null);
colcount = 0;
// Each row in the result set has metadata that describes a single column.
while (tableMeta.next()) {
colcount++;
    // The SQL_DATA_TYPE column holds the Vertica database data type. You compare
    // this value to the VerticaTypes.UUID constant to see if it is a UUID.
    if (tableMeta.getInt("SQL_DATA_TYPE") == VerticaTypes.UUID) {
        // Column is a UUID data type...
        System.out.println("Column "+colcount+" is a UUID column.");
    }
}
```

This example prints the following to the console if it is run after running the prior example:

```
Using column metadata:
Column 1 is UUID
Using table metadata:
Column 1 is a UUID column.
```
Executing Queries Through JDBC

To run a query through JDBC:

2. Run the query.

The method you use to run the query depends on the type of query you want to run:

- a DDL query that does not return a result set.
- a DDL query that returns a result set.
- a DML query

Executing DDL (Data Definition Language) Queries

To run DDL queries, such as CREATE TABLE and COPY, use the Statement.execute() method. You get an instance of this class by calling the createStatement method of your connection object.

The following example creates an instance of the Statement class and uses it to execute a CREATE TABLE and a COPY query:

```java
Statement stmt = conn.createStatement();
stmt.execute("CREATE TABLE address_book (Last_Name char(50) default ''", +
            "'First_Name char(50),Email char(50),Phone_Number char(50))");
stmt.execute("COPY address_book FROM 'address.dat' DELIMITER ',' NULL 'null'");
```

Executing Queries That Return Result Sets

Use the Statement class's executeQuery method to execute queries that return a result set, such as SELECT. To get the data from the result set, use methods such as getInt, getString, and getDouble to access column values depending upon the data types of columns in the result set. Use ResultSet.next to advance to the next row of the data set.

```java
ResultSet rs = null;
rs = stmt.executeQuery("SELECT First_Name, Last_Name FROM address_book");
int x = 1;
while(rs.next()){
    System.out.println(x + ". " + rs.getString(1).trim() + " "
```
Note:
The Vertica JDBC driver does not support scrollable cursors. You can only read forwards through the result set.

Executing DML (Data Manipulation Language) Queries Using `executeUpdate`

Use the `executeUpdate` method for DML SQL queries that change data in the database, such as `INSERT`, `UPDATE` and `DELETE` which do not return a result set.

```java
stmt.executeUpdate("INSERT INTO address_book " +
    "VALUES ('Ben-Shachar', 'Tamar', 'tarrow@example.com', " +
    "'555-380-6466')");
stmt.executeUpdate("INSERT INTO address_book (First_Name, Email) " +
    "VALUES ('Pete', 'pete@example.com')");
```

Note:
The Vertica JDBC driver's `Statement` class supports executing multiple statements in the SQL string you pass to the `execute` method. The `PreparedStatement` class does not support using multiple statements in a single execution.
Loading Data Through JDBC

You can use any of the following methods to load data via the JDBC interface:

- Executing a SQL INSERT statement to insert a single row directly.
- Batch loading data using a prepared statement.
- Bulk loading data from files or streams using COPY.

When loading data into Vertica, you need to decide whether to write data to the **Write Optimized Store (WOS)** or the Read Optimized Store (ROS). By default, most data loading methods insert data into the WOS until it fills up, then insert any additional data directly into ROS containers (called AUTO mode). This is the best method to use when frequently loading small amounts of data (often referred to as trickle-loading). When performing less frequent large data loads (any loads over 100MB of data at once), you should change this behavior to insert data directly into the ROS.

The following sections explain in detail how you load data using JDBC.

### Using a Single Row Insert

The simplest way to insert data into a table is to use the SQL **INSERT** statement. You can use this statement by instantiating a member of the Statement class, and use its `executeUpdate()` method to run your SQL statement.

The following code fragment demonstrates how you can create a Statement object and use it to insert data into a table named `address_book`:

```java
Statement stmt = conn.createStatement();
stmt.executeUpdate("INSERT INTO address_book " +
    "VALUES ('Smith', 'John', 'jsmith@example.com', " +
    "'555-123-4567')");
```

This method has a few drawbacks: you need to convert your data to string and escape any special characters in your data. A better way to insert data is to use prepared statements. See **Batch Inserts Using JDBC Prepared Statements**.
Using **LONG VARCHAR** and **LONG VARBINARY** Data Types with JDBC

Using LONG VARCHAR and LONG VARBINARY data types in a JDBC client application is similar to using VARCHAR and VARBINARY data types. The JDBC driver transparently handles the conversion (for example, between a Java String object and a LONG VARCHAR). The following example code demonstrates inserting and retrieving a LONG VARCHAR string. It uses the JDBC Types class to determine the data type of the string returned by Vertica, although it does not actually need to know whether the database column is a LONG VARCHAR or just a VARCHAR in order to retrieve the value.

```java
import java.sql.*;
import java.util.Properties;

public class LongVarcharExample {
    public static void main(String[] args) {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();

            // How long we want the example string to be. This is
            // larger than can fit into a traditional VARCHAR (which is limited
            // to 65000).
            int length = 100000;

            // Create a table with a LONG VARCHAR column that can store
            // the string we want to insert.
            stmt.execute("DROP TABLE IF EXISTS longtable CASCADE");
            stmt.execute("CREATE TABLE longtable (text LONG VARCHAR(" + length + "))");

            // Build a long string by appending an integer to a string builder
            // until we hit the size limit. Will result in a string
            // containing 01234567890123...-
            StringBuilder sb = new StringBuilder(length);
            for (int i = 0; i < length; i++) {
                sb.append(i % 10);
            }
```
String value = sb.toString();

System.out.println("String value is "+ value.length()+" characters long.");

// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO longtable (text) "+" VALUES(?)");
try {
// Insert LONG VARCHAR value
System.out.println("Inserting LONG VARCHAR value");
pstmt.setString(1, value);
pstmt.addBatch();
pstmt.executeBatch();

// Query the table we created to get the value back.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT * FROM longtable");

// Get metadata about the result set.
ResultSetMetaData rsmd = rs.getMetaData();
// Print the type of the first column. Should be
// LONG VARCHAR. Also check it against the Types class, to
// recognize it programmatically.
System.out.println("Column #1 data type is: "+
rsmd.getColumnTypeName(1));
if (rsmd.getColumnType(1) == Types.LONGVARCHAR) {
    System.out.println("It is a LONG VARCHAR");
} else {
    System.out.println("It is NOT a LONG VARCHAR");
}

// Print out the string length of the returned value.
while (rs.next()) {
    // Use the same getString method to get the value that you
    // use to get the value of a VARCHAR.
    System.out.println("Returned string length: "+
        rs.getString(1).length());
}
} catch (SQLException e) {
    System.out.println("Error message: "+ e.getMessage());
    return; // Exit if there was an error
}
// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}

Note:
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size.
For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).
**Batch Inserts Using JDBC Prepared Statements**

You can load batches of data into Vertica using prepared `INSERT` statements—server-side statements that you set up once, and then call repeatedly. You instantiate a member of the `PreparedStatement` class with a SQL statement that contains question mark placeholders for data. For example:

```java
PreparedStatement pstmt = conn.prepareStatement(
    "INSERT INTO customers(last, first, id) VALUES(?,?,?)");
```

You then set the parameters using data-type-specific methods on the `PreparedStatement` object, such as `setString()` and `setInt()`. Once your parameters are set, call the `addBatch()` method to add the row to the batch. When you have a complete batch of data ready, call the `executeBatch()` method to execute the insert batch.

Behind the scenes, the batch insert is converted into a `COPY` statement. When the connection's AutoCommit parameter is disabled, Vertica keeps the COPY statement open and uses it to load subsequent batches until the transaction is committed, the cursor is closed, or your application executes anything else (or executes any statement using another `Statement` or `PreparedStatement` object). Using a single `COPY` statement for multiple batch inserts makes loading data more efficient. If you are loading multiple batches, you should disable the AutoCommit property of the database to take advantage of this increased efficiency.

When performing batch inserts, experiment with various batch and row sizes to determine the settings that provide the best performance.

The following example demonstrates using a prepared statement to batch insert data.

```java
import java.sql.*;
import java.util.Properties;

public class BatchInsertExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        //Set streamingBatchInsert to True to enable streaming mode for batch inserts.
        //myProp.put("streamingBatchInsert", "True");

        Connection conn;
        try {
            conn = DriverManager.getConnection(
```

```java
```
"jdbc:vertica://VerticaHost:5433/ExampleDB",
myProp);
// establish connection and make a table for the data.
Statement stmt = conn.createStatement();

// Set AutoCommit to false to allow Vertica to reuse the same
// COPY statement
conn.setAutoCommit(false);

// Drop table and recreate.
stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
stmt.execute("CREATE TABLE customers (CustID int, Last_Name
  + " char(50), First_Name char(50),Email char(50),
  + "Phone_Number char(12))");
// Some dummy data to insert.
String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
  "Don", "Eric" };
String[] lastNames = new String[] { "Allen", "Brown", "Chu",
  "Dodd", "Estavez" };
String[] emails = new String[] { "aang@example.com",
  "b.brown@example.com", "cindy@example.com",
  "d.d@example.com", "e.estavez@example.com" };
String[] phoneNumbers = new String[] { "123-456-7890",
  "555-444-3333", "555-867-5309",
  "555-555-1212", "781-555-0000" };
// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement(
  "INSERT INTO customers (CustID, Last_Name, " +
  "First_Name, Email, Phone_Number) +
  " VALUES (?, ?, ?, ?))");
// Add rows to a batch in a loop. Each iteration adds a
// new row.
for (int i = 0; i < firstNames.length; i++) {
  // Add each parameter to the row.
pstmt.setInt(1, i + 1);
pstmt.setString(2, lastNames[i]);
pstmt.setString(3, firstNames[i]);
pstmt.setString(4, emails[i]);
pstmt.setString(5, phoneNumbers[i]);
  // Add row to the batch.
pstmt.addBatch();
}

try {
  // Batch is ready, execute it to insert the data
  pstmt.executeBatch();
} catch (SQLException e) {
  System.out.println("Error message: " + e.getMessage());
  return; // Exit if there was an error
}

// Commit the transaction to close the COPY command
conn.commit();

// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, "}
+ "Last_Name FROM customers ORDER BY CustID";
    while (rs.next()) {
        System.out.println(rs.getInt(1) + " - " + rs.getString(2).trim() + " " + rs.getString(3).trim());
    }
  // Cleanup
  conn.close();
} catch (SQLException e) {
  e.printStackTrace();
}
}

The result of running the example code is:

1 - Anna Allen
2 - Bill Brown
3 - Cindy Chu
4 - Don Dodd
5 - Eric Estavez

Streaming Batch Inserts

By default, Vertica performs batch inserts by caching each row and inserting the cache when the user calls the `executeBatch()` method. Vertica also supports streaming batch inserts. A streaming batch insert adds a row to the database each time the user calls `addBatch()`. Streaming batch inserts improve database performance by allowing parallel processing and reducing memory demands.

Note:

Once you begin a streaming batch insert, you cannot make other JDBC calls that require client-server communication until you have executed the batch or closed or rolled back the connection.

To enable streaming batch inserts, set the `streamingBatchInsert` property to True. The preceding code sample includes a line enabling `streamingBatchInsert` mode. Remove the `//` comment marks to enable this line and activate streaming batch inserts.

The following table explains the various batch insert methods and how their behavior differs between default batch insert mode and streaming batch insert mode.

<table>
<thead>
<tr>
<th>Method</th>
<th>Default Batch Insert Behavior</th>
<th>Streaming Batch Insert Behavior</th>
</tr>
</thead>
</table>
### addBatch()
Adds a row to the row cache.

### executeBatch()
Adds the contents of the row cache to the database in a single action.

### clearBatch()
Clears the row cache without inserting any rows.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>addBatch()</td>
<td>Adds a row to the row cache.</td>
<td>Inserts a row into the database.</td>
</tr>
<tr>
<td>executeBatch()</td>
<td>Adds the contents of the row cache to the database in a single action.</td>
<td>Sends an end-of-batch message to the server and returns an array of integers indicating the success or failure of each addBatch() attempt.</td>
</tr>
<tr>
<td>clearBatch()</td>
<td>Clears the row cache without inserting any rows.</td>
<td>Not supported. Triggers an exception if used when streaming batch inserts are enabled.</td>
</tr>
</tbody>
</table>

### Notes
- Using the PreparedStatement.setFloat() method can cause rounding errors. If precision is important, use the .setDouble() method instead.
- The PreparedStatement object caches the connection's AutoCommit property when the statement is prepared. Later changes to the AutoCommit property have no effect on the prepared statement.

### Loading Batches Directly into ROS
When loading large batches of data (more than 100MB or so), you should load the data directly into ROS containers. Inserting directly into ROS is more efficient for large loads than AUTO mode, since it avoids overflowing the WOS and spilling the remainder of the batch to ROS. Otherwise, the Tuple Mover has to perform a moveout on the data in the WOS, while subsequent data is directly written into ROS containers causing your data to be segmented across storage containers.

When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS. For details about load options, see Choosing a Load Method.

To directly load batches into ROS, set the directBatchInsert connection property to true. See Setting and Getting Connection Property Values for an explanation of how to set connection properties. When this property is set to true, all batch inserts bypass the WOS and load directly into a ROS container.
If all of batches being inserted using a connection should be inserted into the ROS, you should set the DirectBatchInsert connection property to true in the Properties object you use to create the connection:

```java
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
// Enable directBatchInsert for this connection
myProp.put("DirectBatchInsert", "true");
Connection conn;
try {
    conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
...}
```

If you will be using the connection for inserting both large and small batches (or you do not know the size batches you will be inserting when you create the Connection object), you can set the DirectBatchInsert property after the connection has been established using the VerticaConnection.setProperty method:

```
((VerticaConnection)conn).setProperty("DirectBatchInsert", true);
```

See Setting and Getting Connection Property Values for a full example of setting DirectBatchInsert.

### Error Handling During Batch Loads

When loading individual batches, you can find how many rows were accepted and what rows were rejected (see Identifying Accepted and Rejected Rows for details). If you have disabled the AutoCommit connection setting, other errors (such as disk space errors, for example) do not occur while inserting individual batches. This behavior is caused by having a single SQL COPY statement perform the loading of multiple consecutive batches (which makes the load process more efficient). It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Therefore, your bulk loading application should be prepared to check for errors when the COPY statement closes. You can trigger the COPY statement to close by:

- ending the batch load transaction by calling `Connection.commit()`
- closing the statement using `Statement.close()`
- setting the connection's AutoCommit property to true before inserting the last batch in the load

**Note:**
The COPY statement also closes if you execute any non-insert statement or
execute any statement using a different Statement or PreparedStatement object. Ending the COPY statement using either of these methods can lead to confusion and a harder-to-maintain application, since you would need to handle batch load errors in a non-batch load statement. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

### Identifying Accepted and Rejected Rows (JDBC)

The return value of PreparedStatement.executeUpdate is an integer array containing the success or failure status of inserting each row. A value 1 means the row was accepted and a value 0 means that the row was rejected. In the case where an exception occurred during the batch execution, you can also get the array using BatchUpdateException.getUpdateCounts().

The following example extends the example shown in Batch Inserts Using JDBC Prepared Statements to retrieve this array and display the results the batch load.

```java
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class BatchInsertErrorHandlingExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;

        // establish connection and make a table for the data.
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);

            // Disable auto commit
            conn.setAutoCommit(false);

            // Create a statement
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                + " char(50), First_Name char(50), Email char(50), "
                + "Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
```
"Don", "Eric";
String[] emails = new String[] { "aang@example.com", "b.brown@example.com", "cindy@example.com", "d.d@example.com", "e.estavez@example.com" };

// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement(  
    "INSERT INTO customers (CustID, Last_Name, " +  
    "First_Name, Email, Phone_Number)" +  
    " VALUES(?,?,?,?)";

    // Add rows to a batch in a loop. Each iteration adds a  
    // new row.
    for (int i = 0; i < firstNames.length; i++) {  
        // Add each parameter to the row.
        pstmt.setInt(1, i + 1);
        pstmt.setString(2, lastNames[i]);
        pstmt.setString(3, firstNames[i]);
        pstmt.setString(4, emails[i]);
        pstmt.setString(5, phoneNumbers[i]);
        // Add row to the batch.
        pstmt.addBatch();
    }

    // Integer array to hold the results of inserting  
    // the batch. Will contain an entry for each row,  
    // indicating success or failure.
    int[] batchResults = null;

    try {  
        // Batch is ready, execute it to insert the data
        batchResults = pstmt.executeBatch();
    } catch (BatchUpdateException e) {  
        // We expect an exception here, since one of the  
        // inserted phone numbers is too wide for its column. All of the  
        // rest of the rows will be inserted.
        System.out.println("Error message: " + e.getMessage());

        // Batch results isn't set due to exception, but you  
        // can get it from the exception object.
        //
        // In your own code, you shouldn't assume the a batch  
        // exception occurred, since exceptions can be thrown  
        // by the server for a variety of reasons.
        batchResults = e.getUpdateCounts();
    }

    // You should also be prepared to catch SQLExceptions in your own  
    // application code, to handle dropped connections and other general  
    // problems.

    // Commit the transaction
    conn.commit();

    // Print the array holding the results of the batch insertions.
```
System.out.println("Return value from inserting batch: "+ Arrays.toString(batchResults));
// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, "+ "Last_Name FROM customers ORDER BY CustID");
while (rs.next()) {
    System.out.println(rs.getInt(1) + " - " + rs.getString(2).trim() + " "+ rs.getString(3).trim());
}
// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
```

Running the above example produces the following output on the console:

```
Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.
Return value from inserting batch: [1, 1, -3, 1, 1]
1 - Anna Allen
2 - Bill Brown
4 - Don Dodd
5 - Eric Estavez
```

Notice that the third row failed to insert because its phone number is too long for the `Phone_Number` column. All of the rest of the rows in the batch (including those after the error) were correctly inserted.

**Note:**

It is more efficient for you to ensure that the data you are inserting is the correct data type and width for the table column you are inserting it into than to handle exceptions after the fact.

## Rolling Back Batch Loads on the Server

Batch loads always insert all of their data, even if one or more rows is rejected. Only the rows that caused errors in a batch are not loaded. When the database connection's AutoCommit property is true, batches automatically commit their transactions when they complete, so once the batch finishes loading, the data is committed.

In some cases, you may want all of the data in a batch to be successfully inserted—none of the data should be committed if an error occurs. The best way to accomplish this is to turn off the database connection's AutoCommit property to prevent batches from automatically...
committing themselves. Then, if a batch encounters an error, you can roll back the
transaction after catching the BatchUpdateException caused by the insertion error.

The following example demonstrates performing a rollback if any error occurs when loading
a batch.

```java
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class RollbackBatchOnError {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Disable auto-commit. This will allow you to roll back a
            // a batch load if there is an error.
            conn.setAutoCommit(false);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.executeUpdate("DROP TABLE IF EXISTS customers CASCADE");
            stmt.executeUpdate("CREATE TABLE customers (CustID int, Last_Name char(50), First_Name char(50), Email char(50), Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy", "Don", "Eric" };
            String[] emails = new String[] { "aang@example.com", "b.brown@example.com", "cindy@example.com", "d.d@example.com", "e.estavez@example.com" };

            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customers (CustID, Last_Name, " +
            "First_Name, Email, Phone_Number) " +
            "VALUES(?,?,?,?);");
            // Add rows to a batch in a loop. Each iteration adds a
            // new row.
            for (int i = 0; i < firstNames.length; i++) {
                // Add each parameter to the row.
                pstmt.setInt(1, i + 1);
                pstmt.setString(2, lastNames[i]);
                pstmt.setString(3, firstNames[i]);
                pstmt.setString(4, emails[i]);
                pstmt.setString(5, phoneNumbers[i]);
            }
            // Execute the batch.
            pstmt.executeBatch();
        }
    }
}
```
try {
    // Batch is ready, execute it to insert the data
    batchResults = pstmt.executeBatch();
    // If we reach here, we inserted the batch without errors.
    // Commit it.
    System.out.println("Batch insert successful. Committing.");
    conn.commit();
} catch (BatchUpdateException e) {
    System.out.println("Error message: " + e.getMessage());
    // Batch results isn’t set due to exception, but you
    // can get it from the exception object.
    batchResults = e.getUpdateCounts();
    // Roll back the batch transaction.
    System.out.println("Rolling back batch insertion");
    conn.rollback();
} catch (SQLException e) {
    // General SQL errors, such as connection issues, throw
    // SQLExceptions. Your application should do something more
    // than just print a stack trace,
    e.printStackTrace();
}
System.out.println("Return value from inserting batch: " + Arrays.toString(batchResults));
System.out.println("Customers table contains:");

// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, " + "Last_Name FROM customers ORDER BY CustID");
while (rs.next()) {
    System.out.println(rs.getInt(1) + " - " + rs.getString(2).trim() + " - " + rs.getString(3).trim());
}

// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}

Running the above example prints the following on the system console:

Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.Rolling back batch insertion
Return value from inserting batch: [1, 1, -3, 1, 1]
Customers table contains:
The return values indicate whether each row was successfully inserted. The value 1 means the row inserted without any issues, and a -3 indicates the row failed to insert.

The customers table is empty since the batch insert was rolled back due to the error caused by the third column.

**Bulk Loading Using the COPY Statement**

One of the fastest ways to load large amounts of data into Vertica at once (bulk loading) is to use the **COPY statement**. This statement loads data from a file stored on a Vertica host (or in a data stream) into a table in the database. You can pass the COPY statement parameters that define the format of the data in the file, how the data is to be transformed as it is loaded, how to handle errors, and how the data should be loaded. See the [COPY documentation in the SQL Reference Manual](https://manual.vertica.com/9.3.2/Vertica_SI manual.pdf) for details.

**Note:**

For databases created in Vertica releases ≥ 9.3, Vertica ignores load options and hints and defaults to a load method of DIRECT. You can configure this behavior with configuration parameter `DMLTargetDirect`.

In databases created in versions of Vertica prior to 9.3, one parameter that is particularly important is the DIRECT option, which tells COPY to load the data directly into ROS rather than going through the WOS. You should use this option when you are loading large files (over 100MB) into the database. Without this option, your load may fill the WOS and overflow into ROS, requiring the Tuple Mover to perform a Moveout on the data in the WOS. It is more efficient to directly load into ROS and avoid forcing a moveout. In databases created in Vertica version 9.3 and later, Vertica uses the DIRECT option for all DML operations.

Only a **superuser** can use the COPY statement to copy a file stored on a host, so you must connect to the database using a superuser account. If you want to have a non-superuser user bulk-load data, you can use COPY to load from a stream on the host (such as STDIN) rather than a file or stream data from the client (see Streaming Data Via JDBC). You can also perform a standard **batch insert using a prepared statement**, which uses the COPY statement in the background to load the data.

**Note:**

When using this COPY parameter on any node, confirm that the source file is identical on all nodes. Using different files can produce inconsistent results.
The following example demonstrates using the COPY statement through the JDBC to load a file name `customers.txt` into a new database table. This file must be stored on the database host to which your application connects (in this example, a host named `VerticaHost`). Since the `customers.txt` file used in the example is very large, this example uses the DIRECT option to bypass WOS and load directly into ROS.

```java
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

class COPYFromFile {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleAdmin"); // Must be superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Disable AutoCommit
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
            // Create a table to hold data.
            stmt.execute("DROP TABLE IF EXISTS customers;" );
            stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                             + " NOT NULL, First_Name char(50), Email char(50), "
                             + " Phone_Number char(15))");
            // Use the COPY command to load data. Load directly into ROS, since
            // this load could be over 100MB. Use ENFORCELENGTH to reject
            // strings too wide for their columns.
            boolean result = stmt.execute("COPY customers FROM "
                                          + " '/data/customers.txt' DIRECT ENFORCELENGTH") ;
            // Determine if execution returned a count value, or a full result
            // set.
            if (result) {
                System.out.println("Got result set");
            } else {
                // Count will usually return the count of rows inserted.
                System.out.println("Got count");
                int rowCount = stmt.getUpdateCount();
                System.out.println("Number of accepted rows = " + rowCount);
            }
            // Commit the data load
            conn.commit();
        } catch (SQLException e) {
            System.out.println("Error: ");
            System.out.println(e.toString());
        }
    }
}
```

The example prints the following out to the system console when run (assuming that the `customers.txt` file contained two million valid rows):
Streaming Data Via JDBC

There are two options to stream data from a file on the client to your Vertica database:

- Use the VerticaCopyStream class to stream data in an object-oriented manner - details on the class are available in the JDBC Documentation
- Execute a COPY LOCAL SQL statement to stream the data

The topics in this section explain how to use these options.

Using VerticaCopyStream

The VerticaCopyStream class (details on the class are available in the JDBC Documentation) lets you stream data from the client system to a Vertica database. It lets you use the SQL COPY statement directly without having to copy the data to a host in the database cluster first. Using the COPY command to load data from the host requires superuser privileges to be able to access the host's file system. The COPY statement used to load data from a stream does not require superuser privileges so your client can connect using any user account that has INSERT privileges on the table that will receive the data.

To copy streams into the database:

1. Disable the database connections AutoCommit connection parameter.
2. Instantiate a VerticaCopyStreamObject, passing it at least the database connection objects and a string containing a COPY statement to load the data. This statement must copy data from the STDIN into your table. You can use whatever parameters are appropriate for your data load.

   Note:
The VerticaCopyStreamObject constructor optionally takes a single InputStream object, or a List of InputStream objects. This option lets you pre-populate the list of streams to be copied into the database.

3. Call VerticaCopyStreamObject.start() to start the COPY statement and begin streaming the data in any streams you have already added to the VerticaCopyStreamObject.
4. Call `VerticaCopyStreamObject.addStream()` to add additional streams to the list of streams to send to the database. You can then call `VerticaCopyStreamObject.execute()` to stream them to the server.

5. Optionally, call `VerticaCopyStreamObject.getRejects()` to get a list of rejected rows from the last `.execute()` call. The list of rejects is reset by each call to `.execute()` or `.finish()`.

   **Note:**
   If you used either the REJECTED DATA or EXCEPTIONS options in the COPY statement you passed to `VerticaCopyStreamObject` the object in step 2, `.getRejects()` returns an empty list. You can only use one method of tracking the rejected rows at a time.

6. When you are finished adding streams, call `VerticaCopyStreamObject.finish()` to send any remaining streams to the database and close the COPY statement.

7. Call `Connection.commit()` to commit the loaded data.

### Getting Rejected Rows

The `VerticaCopyStreamObject.getRejects()` method returns a List containing the row numbers of rows that were rejected after the previous `.execute()` method call. Each call to `.execute()` clears the list of rejected rows, so you need to call `.getRejects()` after each call to `.execute()`. Since `.start()` and `.finish()` also call `.execute()` to send any pending streams to the server, you should also call `.getRejects()` after these methods as well.

The following example demonstrates loading the content of five text files stored on the client system into a table.

```java
import java.io.File;
import java.io.FileInputStream;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Iterator;
import java.util.List;
import java.util.Properties;
import com.vertica.jdbc.VerticaConnection;
import com.vertica.jdbc.VerticaCopyStream;

public class CopyMultipleStreamsExample {
    public static void main(String[] args) {
        // Note: If running on Java 5, you need to call Class.forName
        // to manually load the JDBC driver.
        // Set up the properties of the connection
        Properties myProp = new Properties();
```
myProp.put("user", "ExampleUser"); // Must be superuser
myProp.put("password", "password123");
// When performing bulk loads, you should always disable the
// connection's AutoCommit property to ensure the loads happen as
// efficiently as possible by reusing the same COPY command and
// transaction.
myProp.put("AutoCommit", "false");
Connection conn;
try {
  conn = DriverManager.getConnection(
    "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
  Statement stmt = conn.createStatement();

  // Create a table to receive the data
  stmt.execute("DROP TABLE IF EXISTS customers");
  stmt.execute("CREATE TABLE customers (Last_Name char(50), "
    + "First_Name char(50),Email char(50), "
    + "Phone_Number char(15))");

  // Prepare the query to insert from a stream. This query must use
  // the COPY statement to load data from STDIN. Unlike copying from
  // a file on the host, you do not need superuser privileges to
  // copy a stream. All your user account needs is INSERT privileges
  // on the target table.
  String copyQuery = "COPY customers FROM STDIN "
    + " DELIMITER ' |' DIRECT ENFORCELENGTH";

  // Create an instance of the stream class. Pass in the
  // connection and the query string.
  VerticaCopyStream stream = new VerticaCopyStream(
    (VerticaConnection) conn, copyQuery);

  // Keep running count of the number of rejects
  int totalRejects = 0;

  // start() starts the stream process, and opens the COPY command.
  stream.start();

  // If you added streams to VerticaCopyStream before calling start(),
  // You should check for rejects here (see below). The start() method
  // calls execute() to send any pre-queued streams to the server
  // once the COPY statement has been created.

  // Simple for loop to load 5 text files named customers-1.txt to
  // customers-5.txt
  for (int loadNum = 1; loadNum <= 5; loadNum++) {
    // Prepare the input file stream. Read from a local file.
    String filename = "C:\Data\customers-" + loadNum + ".txt";
    System.out.println("\n\nLoading file: " + filename);
    File inputFile = new File(filename);
    FileInputStream inputStream = new FileInputStream(inputFile);

    // Add stream to the VerticaCopyStream
    stream.addStream(inputStream);

    // call execute() to load the newly added stream. You could
    // add many streams and call execute once to load them all.
    // Which method you choose depends mainly on whether you want
    // the ability to check the number of rejections as the load
    // progresses so you can stop if the number of rejects gets too
// high. Also, high numbers of InputStreams could create a
// resource issue on your client system.
stream.execute();

// Show any rejects from this execution of the stream load
// getRejects() returns a List containing the
// row numbers of rejected rows.
List<Long> rejects = stream.getRejects();

// The size of the list gives you the number of rejected rows.
int numRejects = rejects.size();
totalRejects += numRejects;
System.out.println("Number of rows rejected in load "+
+ loadNum + ": " + numRejects);

// List all of the rows that were rejected.
Iterator<Long> rejIter = rejects.iterator();
long linecount = 0;
while (rejIter.hasNext()) {
    System.out.print("Rejected row "+ ++linecount);
    System.out.println(" is row " + rejIter.next());
}
// Finish closes the COPY command. It returns the number of
// rows inserted.
long results = stream.finish();
System.out.println("Finish returned "+ results);

// If you added any streams that hadn't been executed(),
// you should also check for rejects here, since finish() 
// calls execute() to
// You can also get the number of rows inserted using
// getRowCount().
System.out.println("Number of rows accepted: "+
+ stream.getRowCount());
System.out.println("Total number of rows rejected: "+ totalRejects);

// Commit the loaded data
conn.commit();
}
} catch (Exception e) {
    e.printStackTrace();
}
}

Running the above example on some sample data results in the following output:

Loading file: C:\Data\customers-1.txt
Number of rows rejected in load #1: 3
Rejected row #1 is row 3
Rejected row #2 is row 7
Rejected row #3 is row 51

Loading file: C:\Data\customers-2.txt
Number of rows rejected in load #2: 5
Rejected row #1 is row 4143
Rejected row #2 is row 6132
Rejected row #3 is row 9998
Rejected row #4 is row 10000
Rejected row #5 is row 10050
Loading file: C:\Data\customers-3.txt
Number of rows rejected in load #3: 9
Rejected row #1 is row 14142
Rejected row #2 is row 16131
Rejected row #3 is row 19999
Rejected row #4 is row 20001
Rejected row #5 is row 20005
Rejected row #6 is row 20049
Rejected row #7 is row 20056
Rejected row #8 is row 20144
Rejected row #9 is row 20236
Loading file: C:\Data\customers-4.txt
Number of rows rejected in load #4: 8
Rejected row #1 is row 23774
Rejected row #2 is row 24141
Rejected row #3 is row 25906
Rejected row #4 is row 26130
Rejected row #5 is row 27317
Rejected row #6 is row 28121
Rejected row #7 is row 29321
Rejected row #8 is row 29998
Loading file: C:\Data\customers-5.txt
Number of rows rejected in load #5: 1
Rejected row #1 is row 39997
Finish returned 39995
Number of rows accepted: 39995
Total number of rows rejected: 26

Note:
The above example shows a simple load process that targets one node in the Vertica cluster. It is more efficient to simultaneously load multiple streams to multiple database nodes. Doing so greatly improves performance because it spreads the processing for the load across the cluster.

Using COPY LOCAL with JDBC

To use COPY LOCAL with JDBC, just execute a COPY LOCAL statement with the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class (details on the class are available in the JDBC Documentation). However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a file (streamed over a network connection, for example).

You can use COPY LOCAL in a multiple-statement query. However, you should always make it the first statement in the query. You should not use it multiple times in the same query.

The following example code demonstrates using COPY LOCAL to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY...
Statement, except for the use of the LOCAL option in the COPY statement, and the path to the data file is on the client system, rather than on the server.

**Note:**
The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the copy local command. Specify a local path and filename for these modifiers when executing a COPY LOCAL query from the driver.

```java
import java.sql.*;
import java.util.Properties;

public class COPYLocal {
    public static void main(String[] args) {
        // Note: If using Java 5, you must call Class.forName to load the
        // JDBC driver.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser"); // Do not need to superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Disable AutoCommit
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
            // Create a table to hold data.
            stmt.execute("DROP TABLE IF EXISTS customers;");
            stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
            + "NOT NULL, First_Name char(50), Email char(50), "
            + "Phone_Number char(15))");

            // Use the COPY command to load data. Load directly into ROS, since
            // this load could be over 100MB. Use ENFORCELENGTH to reject
            // strings too wide for their columns.
            boolean result = stmt.execute("COPY customers FROM LOCAL "
            + "'C:\Data\customers.txt' DIRECT ENFORCELENGTH");

            // Determine if execution returned a count value, or a full result
            // set.
            if (result) {
                System.out.println("Got result set");
            } else {
                // Count will usually return the count of rows inserted.
                System.out.println("Got count");
                int rowCount = stmt.getUpdateCount();
                System.out.println("Number of accepted rows = " + rowCount);
            }
            conn.close();
        } catch (SQLException e) {
            System.out.print("Error: ");
            System.out.println(e.toString());
        }
    }
}
```
The result of running this code appears below. In this case, the customers.txt file contains 10000 rows, seven of which get rejected because they contain data too wide to fit into their database columns.

<table>
<thead>
<tr>
<th>Got countNumber of accepted rows = 9993</th>
</tr>
</thead>
</table>

Handling Errors

When the Vertica JDBC driver encounters an error, it throws a SQLException or one of its subclasses. The specific subclass it throws depends on the type of error that has occurred. Most of the JDBC method calls can result in several different types of errors, in response to which the JDBC driver throws a specific SQLException subclass. Your client application can choose how to react to the error based on the specific exception that the JDBC driver threw.

Note:
The specific SQLException subclasses were introduced in the JDBC 4.0 standard. If your client application runs in a Java 5 JVM, it will use the older JDBC 3.0-compliant driver which lacks these subclasses. In that case, all errors throw a SQLException.

The hierarchy of SQLException subclasses is arranged to help your client application determine what actions it can take in response to an error condition. For example:

- The JDBC driver throws SQLTransientException subclasses when the cause of the error may be a temporary condition, such as a timeout error (SQLException) or a connection issue (SQLException). Your client application can choose to retry the operation without making any sort of attempt to remedy the error, since it may not reoccur.
- The JDBC driver throws SQLNonTransientException subclasses when the client needs to take some action before it could retry the operation. For example, executing a statement with a SQL syntax error results in the JDBC driver throwing the a SQLException (a subclass of SQLNonTransientException). Often, your client application just has to report these errors back to the user and have him or her resolve them. For example, if the user supplied your application with a SQL statement that triggered a SQLException, it could prompt the user to fix the SQL error.

See Vertica Analytic Database SQLState Mapping to Java Exception Classes for a list Java exceptions thrown by the JDBC driver.

## Routing JDBC Queries Directly to a Single Node

The JDBC driver has the ability to route queries directly to a single node using a special connection called a Routable Connection. This feature is ideal for high-volume "short" requests that return a small number of results that all exist on a single node. The common

</tr>
</tbody>
</table>
scenario for using this feature is to do high-volume lookups on data that is identified with a unique key. Routable queries typically provide lower latency and use less system resources than distributed queries. However, the data being queried must be segmented in such a way that the JDBC client can determine on which node the data resides.

**Vertica Typical Analytic Query**

Typical analytic queries require dense computation on data across all nodes in the cluster and benefit from having all nodes involved in the planning and execution of the queries.

![Vertica Typical Analytic Query Diagram]

**Vertica Routable Query API Query**

For high-volume queries that return a single or a few rows of data, it is more efficient to execute the query on the single node that contains the data.

![Vertica Routable Query API Query Diagram]

To effectively route a request to a single node, the client must determine the specific node on which the data resides. For the client to be able to determine the correct node, the table
must be [segmented](#) by one or more columns. For example, if you segment a table on a Primary Key (PK) column, then the client can determine on which node the data resides based on the Primary Key and directly connect to that node to quickly fulfill the request.

The Routable Query API provides two classes for performing routable queries: VerticaRoutableExecutor and VGet. VerticaRoutableExecutor provides a more expressive SQL-based API while VGet provides a more structured API for programmatic access.

- The **VerticaRoutableExecutor** class allows you to use traditional SQL with a reduced feature set to query data on a single node. Note that the client and server must be at least Release 7.1 SP1 to use the VerticaRoutableExecutor.

  For joins, the table must be joined on a key column that exists in each table you are joining, and the tables must be segmented on that key. However, this is not true for unsegmented tables, which can always be joined (since all the data in an unsegmented table is available on all nodes).

- The **VGet** class does not use traditional SQL syntax. Instead, it uses a data structure that you build by defining predicates and predicate expressions and outputs and output expressions. This class is ideal for doing Key/Value type lookups on single tables.

  The data structure used for querying the table must provide a predicate for each segmented column defined in the projection for the table. You must provide, at a minimum, a predicate with a constant value for each segmented column. For example, an `id` with a value of 12234 if the table is segmented only on the `id` column. You can also specify additional predicates for the other, non-segmented, columns in the table. Predicates act like a SQL `WHERE` clause and multiple predicates/predicate expressions apply together with a SQL AND modifier. Predicates must be defined with a constant value. Predicate expressions can be used to refine the query and can contain any arbitrary SQL expressions (such as less than, greater than, and so on) for any of the non-segmented columns in the table.

Java documentation for all classes and methods in the JDBC Driver is available in the Vertica JDBC Documentation.

**Note:**
The JDBC Routable Query API is read-only and requires JDK 1.6 or greater.
Creating Tables and Projections for use with the Routable Query API

For routable queries, the client must determine the appropriate node to get the data. The client does this by comparing all projections available for the table, and determining the best projection to use to find the single node that contains data. You must create a projection segmented by the key column(s) on at least one table to take full advantage of the routable query API. Other tables that join to this table must either have an unsegmented projection, or a projection segmented as described below.

**Note:**
Tables must be segmented by hash for routable queries. See Hash Segmentation Clause. Other segmentation types are not supported.

Creating Tables for use with Routable Queries

To create a table that can be used with the routable query API, segment (by hash) the table on a uniformly distributed column. Typically, you segment on a primary key. For faster lookups, sort the projection on the same columns on which you segmented. For example, to create a table that is well suited to routable queries:

```sql
CREATE TABLE users (  
id INT NOT NULL PRIMARY KEY,  
username VARCHAR(32),  
email VARCHAR(64),  
business_unit VARCHAR(16))  
ORDER BY id  
SEGMENTED BY HASH(id)  
ALL NODES;
```

This table is segmented based on the id column (and ordered by id to make lookups faster). To build a query for this table using the routable query API, you only need to provide a single predicate for the id column which returns a single row when queried.

However, you might add multiple columns to the segmentation clause. For example:

```sql
CREATE TABLE users2 (  
id INT NOT NULL PRIMARY KEY,  
username VARCHAR(32),
```
In this case, you need to provide two predicates when querying the `users2` table, as it is segmented on two columns, `id` and `business_unit`. However, if you know both `id` and `business_unit` when you perform the queries, then it is beneficial to segment on both columns, as it makes it easier for the client to determine that this projection is the best projection to use to determine the correct node.

### Designing Tables for Single-node JOINs

If you plan to use the `VerticaRoutableExecutor` class and join tables during routable queries, then you must segment all tables being joined by the same segmentation key. Typically this key is a primary/foreign key on all the tables being joined. For example, the `customer_key` may be the primary key in a customers dimension table, and the same key is a foreign key in a sales fact table. Projections for a `VerticaRoutableExecutor` query using these tables must be segmented by hash on the customer key in each table.

If you want to join with small dimension tables, such as date dimensions, then it may be appropriate to make those tables unsegmented so that the `date_dimension` data exists on all nodes. It is important to note that when joining unsegmented tables, you still must specify a segmented table in the `createRoutableExecutor()` call.

### Verifying Existing Projections for Tables

If tables are already segmented by hash (for example, on an ID column), then you can determine what predicates are needed to query the table by using the Vertica function `GET_PROJECTIONS` to view that table's projections. For example:

```sql
=> SELECT GET_PROJECTIONS ('users');
...
Projection Name: [Segmented] [SegCols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
------------------------------------------------------------------------------------------------------------------
public.users_b1 [Segmented: Yes] [SegCols: "public.users.id"] [K: 1] [public.users_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
public.users_b0 [Segmented: Yes] [SegCols: "public.users.id"] [K: 1] [public.users_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
```

For each projection, only the `public.users.id` column is specified, indicating your query predicate should include this column.
If the table is segmented on multiple columns, for example id and business_unit, then you need to provide both columns as predicates to the routable query.

**Creating a Connection for Routable Queries**

The JDBC Routable Query API provides the VerticaRoutableConnection (details are available in the JDBC Documentation) interface to connect to a cluster and allow for Routable Queries. This interface provides advanced routing capabilities beyond those of a normal VerticaConnection. The VerticaRoutableConnection provides access to the VerticaRoutableExecutor and VGet classes. See Defining the Query for Routable Queries using the VerticaRoutableExecutor Class and Defining the Query for Routable Queries Using the VGet Class respectively.

You enable access to this class by setting the EnableRoutableQueries JDBC connection property to true.

The VerticaRoutableConnection maintains an internal pool of connections and a cache of table metadata that is shared by all VerticaRoutableExecutor/VGet objects that are produced by the connection's createRoutableExecutor() / prepareGet() method. It is also a fully-fledged JDBC connection on its own and supports all the functionality that a VerticaConnection supports. When this connection is closed, all pooled connections managed by this VerticaRoutableConnection and all child objects are closed too. The connection pool and metadata is only used by child Routable Query operations.

**Example:**

You can create the connection using a JDBC DataSource:

```java
com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
jdbcSettings.setDatabase("exampleDB");
jdbcSettings.setHost("v_vmart_node0001.example.com");
jdbcSettings.setUserID("dbadmin");
jdbcSettings.setPassword("password");
jdbcSettings.setEnableRoutableQueries(true);
jdbcSettings.setPort((short) 5433);

VerticaRoutableConnection conn;
conn = (VerticaRoutableConnection)jdbcSettings.getConnection();
```

You can also create the connection using a connection string and the DriverManager.getConnection() method:
String connectionString = "jdbc:vertica://v_vmart_node0001.example.com:5433/exampleDB?user=dbadmin&password=&EnableRoutableQueries=true";
VerticaRoutableConnection conn = (VerticaRoutableConnection) DriverManager.getConnection (connectionString);

Both methods result in a conn connection object that is identical.

**Note:**
Avoid opening many VerticaRoutableConnection connections because this connection maintains its own private pool of connections which are not shared with other connections. Instead, your application should use a single connection and issue multiple queries through that connection.

In addition to the setEnableRoutableQueries property that the Routable Query API adds to the Vertica JDBC connection class, the API also adds additional properties. The complete list is below.

- **EnableRoutableQueries**: Enables Routable Query lookup capability. Default is false.
- **FailOnMultiNodePlans**: If the plan requires more than one node, and FailOnMultiNodePlans is true, then the query fails. If it is set to false then a warning is generated and the query continues. However, latency is greatly increased as the Routable Query must first determine the data is on multiple nodes, then a normal query is run using traditional (all node) execution and execution. Defaults to true. Note that this failure cannot occur on simple calls using only predicates and constant values.
- **MetadataCacheLifetime**: The time in seconds to keep projection metadata. The API caches metadata about the projection used for the query (such as projections). The cache is used on subsequent queries to reduce response time. The default is 300 seconds.
- **MaxPooledConnections**: Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Default 20.
- **MaxPooledConnectionsPerNode**: Per-node maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Default 5.

**Defining the Query for Routable Queries using the VerticaRoutableExecutor Class**

The VerticaRoutableExecutor class is used to access table data directly from a single node. VerticaRoutableExecutor directly queries Vertica only on the node that has all the data needed for the query, avoiding the distributed planning and execution costs.
associated with a normal Vertica execution. You can use VerticaRoutableExecutor if you need to join tables or use a group by clause, as these operations are not possible using VGet.

When using the VerticaRoutableExecutor class, you must follow these rules:

- If joining tables, all tables being joined must be segmented (by hash) on the same set of columns referenced in the join predicate, unless the table being joined is unsegmented.
- When using multiple conditions in WHERE clauses, the WHERE clause must use AND between the conditions. Using OR in the WHERE clause causes the query to degenerate to a multi-node plan. OR, IN list, or range conditions on columns outside of the join condition are acceptable if the data exists on the same node.
- You can only execute a single statement per request. "Chained" SQL statements are not permitted.
- Your query may be used in a driver-generated subquery to help determine if the query can be executed on a single node. Therefore, you cannot include the semicolon at the end of the statement and you cannot include SQL comments (using double-dashes, like so: `--`), as these would cause the driver-generated query to fail.

You create a VerticaRoutableExecutor by calling `createRoutableExecutor(schema, table)`; on a connection object. If schema is set to null, then the search path is used to find the table.

**VerticaRoutableExecutor Methods**

VerticaRoutableExecutor has the following methods (more details on the class are available in the JDBC Documentation):

- `execute(query string, [ column, value | Map ])` - Runs the query. Accepts as input the query to be executed, and either:
  - The column and value when the lookup is being done on just a single value. For example:

    ```java
    String column = "customer_key";
    Integer value = 1;
    ResultSet rs = q.execute(query, column, value)
    ```

  - A Java map of the column names and corresponding values if the lookup is being done on one or more columns. For example: `ResultSet rs = q.execute(query, map);`. The table must have at least one projection segmented by a set of columns exactly matching the columns in the map. Note that each column defined in the map must have only one value. You cannot
include more than one value for the same column. For example:

```java
Map<String, Object> map = new HashMap<String, Object>();
    map.put("customer_key", 1);
    map.put("another_key", 42);
ResultSet rs = q.execute(query, map);
```

The query being executed uses regular SQL. The SQL used must meet the rules of the VerticaRoutableExecutor class. For example, you can add limits and sorts, or use aggregate functions, provided the data exists on a single node.

**Important:** The JDBC client uses the column/value or map arguments to determine on which node to execute the query. You must make sure that the content of the query uses the same values that you provide in the column/value or map arguments.

**Note:** The following data types cannot be used as column values. Additionally, if a table is segmented on any columns with the following data types then the table cannot be queried using the Routable Query API:

- `interval`
- `timetz`
- `timestamptz`

**Note:** The driver does not verify the syntax of the query before it sends the query to the server. If your expression is incorrect, then the query fails.

- `close()` - Closes this VerticaRoutableExecutor by releasing resources used by this VerticaRoutableExecutor. It does not close the parent JDBC connection to Vertica.
- `getWarnings()` - Retrieves the first warning reported by calls on this VerticaRoutableExecutor. Additional warnings are chained and can be accessed with the JDBC `getNextWarning()` method.
Example Query Using VerticaRoutableExecutor

The following example details how to use VerticaRoutableExecutor to execute a query using both a JOIN clause and an aggregate function with a GROUP BY clause. The example also details how to create both a customer and a sales table, and how to segment the tables so they can be joined using the VerticaRoutableExecutor class. This example also uses the date_dimension table from the VMart schema to illustrate how you can also join data on unsegmented tables.

1. Create a table for customer details, and then create the projections which segment on the customer_key.

```sql
CREATE TABLE customers (customer_key INT, customer_name VARCHAR(128), customer_email VARCHAR(128));
CREATE PROJECTION cust_proj_b0 AS
  (SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES;
CREATE PROJECTION cust_proj_b1 AS
  (SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 1;
CREATE PROJECTION cust_proj_b2 AS
  (SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 2;
SELECT start_refresh();
```

2. Create a sales table, then create the projections which segment on the customer_key. Since both the customer and sales tables are segmented on the same key, you can join them with the VerticaRoutableExecutor Routable Query lookup.

```sql
CREATE TABLE sales (sale_key INT, customer_key INT, date_key INT, sales_amount FLOAT);
CREATE PROJECTION sales_proj_b0 AS
  (SELECT *
   FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES;
CREATE PROJECTION sales_proj_b1 AS
  (SELECT *
   FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES OFFSET 1;
```
CREATE PROJECTION sales_proj_b2 AS
  (SELECT *
   FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 2;

SELECT start_refresh();

3. Add some sample data:

INSERT INTO customers VALUES (1, 'Fred', 'fred@example.com');
INSERT INTO customers VALUES (2, 'Sue', 'Sue@example.com');
INSERT INTO customers VALUES (3, 'Dave', 'Dave@example.com');
INSERT INTO customers VALUES (4, 'Ann', 'Ann@example.com');
INSERT INTO customers VALUES (5, 'Jamie', 'Jamie@example.com');
COMMIT;

INSERT INTO sales VALUES(1, 1, 1, '100.00');
INSERT INTO sales VALUES(2, 2, 2, '200.00');
INSERT INTO sales VALUES(3, 3, 3, '300.00');
INSERT INTO sales VALUES(4, 4, 4, '400.00');
INSERT INTO sales VALUES(5, 5, 5, '400.00');
INSERT INTO sales VALUES(6, 1, 15, '500.00');
INSERT INTO sales VALUES(7, 1, 15, '400.00');
INSERT INTO sales VALUES(8, 1, 35, '300.00');
INSERT INTO sales VALUES(9, 1, 35, '200.00');
COMMIT;

4. Create an unsegmented projection of the VMart date_dimension table for use in this example. Note you must run SELECT start_refresh(); to unsegment the existing data:

=> CREATE PROJECTION date_dim_unsegment AS
  (SELECT *
   FROM date_dimension) UNSEGMENTED ALL NODES;

=> SELECT start_refresh();

Using the customer, sales, and date_dimension data, you can now create a Routable Query lookup that uses joins and a group by to query the customers table and return the total number of purchases per day for a given customer:

```java
import java.sql.*;
import java.util.HashMap;
import java.util.Map;
import com.vertica.jdbc.kv.*;

public class verticaKV_doc {
    public static void main(String[] args) {
        com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
        jdbcSettings.setDatabase("VMart");
        jdbcSettings.setHost("vertica.example.com");
        jdbcSettings.setUserID("dbadmin");
```
jdbcSettings.setPassword("password");
jdbcSettings.setEnableRoutableQueries(true);
jdbcSettings.setFailOnMultiNodePlans(true);
jdbcSettings.setPort((short) 5433);
VerticaRoutableConnection conn =
    new VerticaRoutableConnection()
    .getConnection();
String table = "customers";
VerticaRoutableExecutor q = conn.createRoutableExecutor(null, table);
String query = "select d.date, SUM(s.sales_amount) as Total ";
query += " from customers as c";
query += " join sales as s ";
query += " on s.customer_key = c.customer_key ";
query += " join date_dimension as d ";
query += " on d.date_key = s.date_key ";
query += " where c.customer_key = " + map.get("customer_key");
query += " group by (d.date) order by Total DESC";
ResultSet rs = q.execute(query, map);
while (rs.next()) {
    System.out.print("Date: " + rs.getString("date") + ":");
    System.out.println("Amount: " + rs.getString("Total"));
}
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}

The example code outputs:

<table>
<thead>
<tr>
<th>Date</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-15</td>
<td>900.0</td>
</tr>
<tr>
<td>2012-02-04</td>
<td>500.0</td>
</tr>
<tr>
<td>2012-01-01</td>
<td>100.0</td>
</tr>
</tbody>
</table>

Note that your dates may be different, because the VMart schema randomly generates the dates in the date_dimension table.

**Defining the Query for Routable Queries Using the VGet Class**

The VGet class (details on the class are available in the JDBC Documentation) is used to access table data directly from a single node when you do not need to join the data or use a group by clause. Like VerticaRoutableExecutor, VGet directly queries Vertica nodes that have the data needed for the query, avoiding the distributed planning and execution costs associated with a normal Vertica execution. However, VGet does not use SQL. Instead, you define predicates and values to perform Key/Value type lookups on a single table. VGet is especially suited to doing key/value-type lookups on single tables.
You create a VGet by calling `prepareGet(schema, table/proj)` on a connection object. `prepareGet()` takes the name of the schema and the name of a table or projection as arguments.

**VGet Methods**

VGet has the following methods:

- `addPredicate(string, object)` - adds a predicate column and a constant value to the query. You must include a predicate for each column on which the table is segmented. The predicate acts as the "WHERE" clause to the query. Multiple `addPredicate()` method calls are joined by AND modifiers. Note that the VGet retains this value after each call to execute. To remove it, use `ClearPredicates()`.

  **Note:**
  The following data types cannot be used as predicates. Additionally, if a table is segmented on any columns with the following data types then the table cannot be queried using the Routable Query API:
  
  - interval
  - timetz
  - timestamptz

- `addPredicateExpression(string)` - Accepts arbitrary SQL expressions that operate on the table's columns as input to the query. Predicate expressions and predicates are joined by AND modifiers. You can use segmented columns in predicate expressions, but they must also be specified as a regular predicate with `addPredicate()`. Note that the VGet retains this value after each call to execute. To remove it, use `ClearPredicates()`.

  **Note:**
  The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

- `addOutputColumn(string)` - Adds a column to be included in the output. By default the query runs as `SELECT *` and you do not need to define any output columns to return the data. If you add output columns then you must add all the columns you want returned. Note that the VGet retains this value after each call to execute. To remove it, use `ClearOutputs()`.

- `addOutputExpression(string)` - Accepts arbitrary SQL expressions that operate on the table's columns as output. Note that the VGet retains this value after each call
to execute. To remove it, use `ClearOutputs()`.

**Note:**
The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

**Note:**
`addOutputExpression()` is not supported when querying Flex Tables. If you attempt to use `addOutputExpression()` on a Flex Table query, then a `SQLException` is thrown.

- `addSortColumn(string, sortOrder)` - Adds a sort order to an output column. The output column can be either the one returned by the default query (SELECT *) or one of the columns defined in `addOutputColumn` or `addOutputExpression`. You can defined multiple sort columns.
- `setLimit(int)` - Sets a limit on the number of results returned. A limit of 0 is unlimited.
- `clearPredicates()` - Removes predicates that were added by `addPredicate()` and `addPredicateExpression()`.
- `clearOutputs()` - Removes outputs added by `addOutput()` and `addOutputExpression()`.
- `clearSortColumns()` - Removes sort columns previously added by `addSortColumn()`.
- `execute()` - Runs the query. Care must be taken to ensure that the predicate columns exist on the table and projection used by VGet, and that the expressions do not require multiple nodes to execute. If an expression is sufficiently complex as to require more than one node to execute, `execute()` throws a `SQLException` if the `FailOnMultiNodePlans` connection property is true.
- `close()` - Closes this VGet by releasing resources used by this VGet. It does not close the parent JDBC connection to Vertica.
- `getWarnings()` - Retrieves the first warning reported by calls on this VGet. Additional warnings are chained and can be accessed with the JDBC `getNextWarning()` method.

You call the `execute()` method to run query. By default, the VGet fetches all the columns of all the rows that satisfy the logical AND of all the predicates passed via the `addPredicate()` method. To further customize the get operation use the `addOutputColumn()`, `addOutputExpression()`, `addPredicateExpression()`, `addSortColumn()` and `setLimit()` methods.
**Note:**
VGet operations span multiple JDBC connections (and multiple Vertica sessions) and do not honor the parent connection's transaction semantics. If consistency is required across multiple executions, the parent VerticaRoutableConnection's consistent read API can be used to guarantee all operations occur at the same epoch.

VGet is thread safe, but all methods are synchronized, so threads that share a VGet instance are never run in parallel. For better parallelism, each thread should have its own VGet instance. Different VGet instances that operate on the same table share pooled connections and metadata in a manner that enables a high degree of parallelism.

**Example**

You can query the table defined in Creating Tables and Projections for use with the Routable Query API with the following example code. The table defines an id column that is segmented by hash.

```java
import java.sql.*;
import com.vertica.jdbc.kv.*;

public class verticaKV2 {
    public static void main(String[] args) {
        com.vertica.jdbc.DataSource jdbcSettings
            = new com.vertica.jdbc.DataSource();
        jdbcSettings.setDatabase("exampleDB");
        jdbcSettings.setHost("v_vmart_node0001.example.com");
        jdbcSettings.setUserID("dbadmin");
        jdbcSettings.setPassword("password");
        jdbcSettings.setEnableRoutableQueries(true);
        jdbcSettings.setPort((short) 5433);

        VerticaRoutableConnection conn;
        try {
            conn = (VerticaRoutableConnection)
                jdbcSettings.getConnection();
            System.out.println("Connected.");
            VGet get = conn.prepareGet("public", "users");
            get.addPredicate("id", 5);
            ResultSet rs = get.execute();
            rs.next();
            System.out.println("ID: " +
                rs.getString("id"));
            System.out.println("Username: "
                + rs.getString("username"));
            System.out.println("Email: "
                + rs.getString("email"));
            System.out.println("Closing Connection.");
            conn.close();
        }
    }
}
```
```java
} catch (SQLException e) {
    System.out.println("Error! Stacktrace:");
    e.printStackTrace();
}
```

The output:

Connected.
ID: 5
Username: userE
Email: userE@example.com
Closing Connection.

**Routable Query Performance and Troubleshooting**

This topic details performance considerations and common issues you might encounter when using the routable query API.

**Using Resource Pools with Routable Queries**

Individual routable queries are serviced quickly since they directly access a single node and return only one or a few rows of data. However, by default, Vertica resource pools use an AUTO setting for the `execution parallelism` parameter. When set to AUTO, the setting is determined by the number of CPU cores available and generally results in multi-threaded execution of queries in the resource pool. It is not efficient to create parallel threads on the server because routable query operations return data so quickly and routable query operations only use a single thread to find a row. To prevent the server from opening unneeded processing threads, you should create a specific resource pool for routable query clients. Consider the following settings for the resource pool you use for routable queries:

- Set execution parallelism to 1 to force single-threaded queries. This setting improves routable query performance.
- Use CPU affinity to limit the resource pool to a specific CPU or CPU set. The setting ensures that the routable queries have resources available to them, but it also
prevents routable queries from significantly impacting performance on the system for other general queries.

- If you do not set a CPU affinity for the resource pool, consider setting the maximum concurrency value of the resource pool to a setting that ensures good performance for routable queries, but does not negatively impact the performance of general queries.

Performance Considerations for Routable Query Connections

Because a VerticaRouteableConnection opens an internal pool of connections, it is important to configure MaxPooledConnections and MaxPooledConnectionsPerNode appropriately for your cluster size and the amount of simultaneous client connections. It is possible to impact normal database connections if you are overloading the cluster with VerticaRouteableConnections.

The initial connection to the initiator node discovers all other nodes in the cluster. The internal-pool connections are not opened until a VerticaRouteableExecutor or VGet query is sent. All VerticaRouteableExecutors/VGets in a connection object use connections from the internal pool and are limited by the MaxPooledConnections settings. Connections remain open until they are closed so a new connection can be opened elsewhere if the connection limit has been reached.

Troubleshooting Routable Queries

Routable query issues generally fall into two categories:

- Not providing enough predicates.
- Queries having to span multiple nodes.

Predicate Requirements

You must provide the same number of predicates that correspond to the columns of the table segmented by hash. To determine the segmented columns, call the Vertica function GET_PROJECTIONS. You must provide a predicate for each column displayed in the SegCols field.

For VGet, this means you must use addPredicate() to add each of the columns. For VerticaRouteableExecutor, this means you must provide all of the predicates and values in the map sent to execute().
Multi-node Failures

It is possible to define the correct number of predicates, but still have a failure because multiple nodes contain the data. This failure occurs because the projection's data is not segmented in such a way that the data being queried is contained on a single node. Enable logging for the connection and view the logs to verify the projection being used. If the client is not picking the correct projection, then try to query the projection directly by specifying the projection instead of the table in the create/prepare statement, for example:

- Using VerticaRoutableExecutor:
  
  ```java
  conn.createRoutableExecutor(schema, table/projection);
  ```

- Using VGet:
  
  ```java
  conn.prepareGet('schema','table/projection')
  ```

Additionally, you can use the `EXPLAIN` command in vsql to help determine if your query can run in single node. EXPLAIN can help you understand why the query is being run as single or multi-node.

Pre-Segmenting Data Using VHash

The VHash class is an implementation of the Vertica hash function for use with JDBC client applications.

Hash segmentation in Vertica allows you to segment a projection based on a built-in hash function. The built-in hash function provides even data distribution across some or all nodes in a cluster, resulting in optimal query execution.

Suppose you have several million rows of values spread across thousands of CSV files. Assume that you already have a table segmented by hash. Before you load the values into your database, you probably want to know to which node a particular value loads. For this reason, using VHash can be particularly helpful, by allowing you to pre-segment your data before loading.

The following example shows the VHash class hashing the first column of a file named "testFile.csv". The name of the first column in this file is `meterId`.

Segment the Data Using VHash

This example demonstrates how you can read the testFile.csv file from the local file system and run a hash function on the meterId column. Using the database metadata from a
projection, you can then pre-segment the individual rows in the file based on the hash value of meterId.

```java
import java.io.BufferedReader;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;
import java.io.FileReader;
import java.io.UnsupportedEncodingException;
import java.util.*;
import java.io.IOException;
import java.sql.*;
import com.vertica.jdbc.kv.VHash;

public class VerticaKVDoc {
    final Map<String, FileOutputStream> files;
    final Map<String, List<Long>> nodeToHashList;
    String segmentationMetadata;
    List<String> lines;

    public static void main(String[] args) throws Exception {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }

        Properties myProp = new Properties();
        myProp.put("user", "username");
        myProp.put("password", "password");

        VerticaKVDoc ex = new VerticaKVDoc();

        // Read in the data from a CSV file.
        ex.readLinesFromFile("C:\testFile.csv");

        try (Connection conn = DriverManager.getConnection(  
                "jdbc:vertica://VerticaHost:portNumber/databaseName", myProp)) {

            // Compute the hashes and create FileOutputStreams.
            ex.prepareForHashing(conn);

            // Write to files.
            ex.writeLinesToFiles();
        }

    public VerticaKVDoc() {
        files = new HashMap<String, FileOutputStream>();
        nodeToHashList = new HashMap<String, List<Long>>();
    }

    public void prepareForHashing(Connection conn) throws SQLException,  
            FileNotFoundException {
```
// Send a query to Vertica to return the projection segments.
try (ResultSet rs = conn.createStatement().executeQuery("SELECT get_projection_segments('public.projectionName')")) {
    rs.next();
    segmentationMetadata = rs.getString(1);
}

// Initialize the data files.
try (ResultSet rs = conn.createStatement().executeQuery("SELECT node_name FROM nodes")) {
    while (rs.next()) {
        String node = rs.getString(1);
        files.put(node, new FileOutputStream(node + ".csv"));
    }
}

public void writeLinesToFile() throws UnsupportedEncodingException, IOException {
    for (String line : lines) {
        long hashedValue = VHash.hashLong(getMeterIdFromLine(line));
        // Write the row data to that node's data file.
        String node = VHash.getNodeFor(segmentationMetadata, hashedValue);
        FileOutputStream fos = files.get(node);
        fos.write(line.getBytes("UTF-8"));
    }
}

private long getMeterIdFromLine(String line) {
    // In our file, "meterId" is the name of the first column in the file.
    return Long.parseLong(line.split(",")[0]);
}

public void readLinesFromFile(String filename) throws IOException {
    lines = new ArrayList<String>();
    String line;
    try (BufferedReader reader = new BufferedReader(new FileReader(filename))) {
        while ((line = reader.readLine()) != null) {
            lines.add(line);
        }
    }
}
Programming ADO.NET Applications

The Vertica driver for ADO.NET allows applications written in C# to read data from, update, and load data into Vertica databases. It provides a data adapter (Vertica Data Adapter) that facilitates reading data from a database into a data set, and then writing changed data from the data set back to the database. It also provides a data reader (VerticaDataReader) for reading data. The driver requires the .NET framework version 3.5+.

For more information about ADO.NET, see:

- Overview of ADO.NET
- .NET Framework Developer Guide

**Note:**
All of the examples provided in this section are in C#.

ADO.NET Data Types

This table details the mapping between Vertica data types and .NET and ADO.NET data types.

<table>
<thead>
<tr>
<th>.NET Framework Type</th>

### UUID Backwards Compatibility

Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with the earlier client driver versions that do not support the UUID data type (see Client Driver and Server Version Compatibility for the versions of the client drivers that Vertica supports). When one of these older clients queries tables with UUID columns in them, Vertica automatically translates the native UUID values to CHAR values. Also, when an older client inserts data into a UUID column, Vertica automatically converts the CHAR value sent by the client into a native UUID value. Vertica also reports the data type of these columns as CHAR when an older client queries a UUID column's metadata.

### Setting the Locale for ADO.NET Sessions

- ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions as for ODBC apply if this encoding is violated.
- The ADO.NET driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16.
- ADO.NET applications should set the correct server session locale by executing the `SET LOCALE TO` command in order to get expected collation and string functions behavior on the server.
If there is no default session locale at the database level, ADO.NET applications need to set the correct server session locale by executing the `SET LOCALE TO` command in order to get expected collation and string functions behavior on the server. See the `SET LOCALE` command in the SQL Reference Manual.

## Connecting to the Database

This section describes:

- Using SSL: Installing SSL Certificates on Windows
- Opening and Closing the Database Connection (ADO.NET)
- ADO.NET Connection Properties
- Configuring Log Properties

### Using TLS: Installing Certificates on Windows

You can optionally secure communication between your ADO.NET application and Vertica using TLS. The Vertica ADO.NET driver uses the default Windows key store when looking for TLS certificates. This is the same key store that Internet Explorer uses.

Before you can use TLS on the client side, you must implement TLS on the server. See TLS Protocol in the Administrator's Guide, perform those steps, then return to this topic to install the TLS certificate on Windows.

To use TLS for ADO.NET connections to Vertica:

- Import the server and client certificates into the Windows Key Store.
- If required by your certificates, import the public certificate of your Certifying Authority.

### Import the Server and Client Certificates into the Windows Key Store:

1. Copy the server.crt file you generated when you enabled TLS on the server to your Windows Machine.
2. Double-click the certificate.
3. Let Windows determine the key type, and click Install.
Import the Public Certificate of Your CA:

You must establish a chain of trust for the certificates. You may need to import the public certificate for your Certifying Authority (CA) (especially if it is a self-signed certificate).

1. Using the same certificate as above, double-click the certificate.
2. Select Place all certificates in the following store.
3. Click Browse, select Trusted Root Certification Authorities and click Next.
4. Click Install.

Enable SSL in Your ADO.NET Applications

In your connection string, be sure to enable SSL by setting the SSL property in VerticaConnectionStringBuilder to true, for example:

```csharp
//configure connection properties
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
    builder.Host = "192.168.17.10";
    builder.Database = "VMart";
    builder.User = "dbadmin";
    builder.SSL = true;
//open the connection
VerticaConnection _conn = new VerticaConnection(builder.ToString());
    _conn.Open();
```

Opening and Closing the Database Connection (ADO.NET)

Before you can access data in Vertica through ADO.NET, you must create a connection to the database using the VerticaConnection class which is an implementation of System.Data.DbConnection. The VerticaConnection class takes a single argument that contains the connection properties as a string. You can manually create a string of property keywords to use as the argument, or you can use the VerticaConnectionStringBuilder class to build a connection string for you.

To download the ADO.NET driver, go to the Client Drivers Downloads page.

This topic details the following:
• Manually building a connection string and connecting to Vertica
• Using VerticaConnectionStringBuilder to create the connection string and connecting to Vertica
• Closing the connection

To Manually Create a Connection string:

See ADO.NET Connection Properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

1. For each property, provide a value and append the properties and values one after the other, separated by a semicolon. Assign this string to a variable. For example:

   ```csharp
   String connectionString = "DATABASE=VMart;HOST=v_vmart_node0001;USER=dbadmin";
   ```

2. Build a Vertica connection object that specifies your connection string.

   ```csharp
   VerticaConnection _conn = new VerticaConnection(connectionString);
   ```

3. Open the connection.

   ```csharp
   _conn.Open();
   ```

4. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.

   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```

To Use the VerticaConnectionStringBuilder Class to Create a Connection String and Open a connection:

1. Create a new object of the VerticaConnectionStringBuilder class.

   ```csharp
   VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
   ```

2. Update your VerticaConnectionStringBuilder object with property values. See ADO.NET Connection Properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.
3. Build a Vertica connection object that specifies your connection
VerticaConnectionStringBuilder object as a string.

```csharp
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "v_vmart_node0001";
builder.Database = "VMart";
builder.User = "dbadmin";

VerticaConnection _conn = new VerticaConnection(builder.ToString());
```

4. Open the connection.

```csharp
_conn.Open();
```

5. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.

```csharp
VerticaCommand command = _conn.CreateCommand;
```

**Note:**
If your database is not in compliance with your Vertica license, the call to VerticaConnection.open() returns a warning message to the console and the log. See Managing Licenses in the Administrator's Guide for more information.

### To Close the connection:

When you're finished with the database, close the connection. Failure to close the connection can deteriorate the performance and scalability of your application. It can also prevent other clients from obtaining locks.

```csharp
_conn.Close();
```

### Example Usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
```
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            //Perform some operations
            _conn.Close();
        }
    }
}

**ADO.NET Connection Properties**

To download the ADO.NET driver, go to the [Client Drivers Downloads page](#).

You use connection properties to configure the connection between your ADO.NET client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number, needed to connect to your database.

You can set a connection property in two ways:

- Include the property name and value as part of the connection string you pass to a `VerticaConnection`.
- Set the properties in a `VerticaConnectionStringBuilder` object, and then pass the object as a string to a `VerticaConnection`.

### Enabling Native Connection Load Balancing in ADO.NET

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen. If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the connection string or using the ConnectionStringBuilder(). The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```csharp
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
        // Code snippet
    }
}
```
```csharp
    static void Main(string[] args)
    {
        VerticaConnectionStringBuilder builder =
            new VerticaConnectionStringBuilder();
        builder.Host = "v_vmart_node0001.example.com";
        builder.Database = "VMart";
        builder.User = "dbadmin";
        // Enable native client load balancing in the client,
        // must also be enabled on the server!
        builder.ConnectionLoadBalance = true;
        // Connect 3 times to verify a new node is connected
        // for each connection.
        for (int i = 1; i <= 4; i++)
        {
            try
            {
                VerticaConnection _conn =
                    new VerticaConnection(builder.ToString());
                _conn.Open();
                if (i == 1)
                {
                    // On the first connection, check the server policy for load balance
                    VerticaCommand sqlcom = _conn.CreateCommand();
                    sqlcom.CommandText =
                        "SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES";
                    var returnvalue = sqlcom.ExecuteScalar();
                    Console.WriteLine("Status of load balancy policy on server: " + returnvalue.ToString() + "\n");
                }
                VerticaCommand command = _conn.CreateCommand();
                command.CommandText =
                    "SELECT node_name FROM V_MONITOR.CURRENT_SESSION";
                VerticaDataReader dr = command.ExecuteReader();
                while (dr.Read())
                {
                    Console.Write("Connect attempt #" + i + "]... ");
                    Console.WriteLine("Connected to node " + dr[0]);
                }
                dr.Close();
                _conn.Close();
                Console.WriteLine("Disconnecting.\n");
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
        }
    }
```

Running the above example produces the following output:

Status of load balancy policy on server: roundrobin

Connect attempt #1... Connected to node v_vmart_node0001
Disconnecting.
ADO.NET Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.
Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

**Note:**
If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS Failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.
Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```csharp
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
                new VerticaConnectionStringBuilder();
            builder.Host = "not.a.real.host:5433";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            builder.BackupServerNode =
                "another.broken.node:5433,v_vmart_node0002.example.com:5433";
            try
            {
                VerticaConnection _conn =
                    new VerticaConnection(builder.ToString());
                _conn.Open();
                VerticaCommand sqlcom = _conn.CreateCommand();
                sqlcom.CommandText = "SELECT node_name FROM current_session";
                var returnValue = sqlcom.ExecuteScalar();
                Console.WriteLine("Connected to node: " +
                    returnValue.ToString() + "\n");
                _conn.Close();
                Console.WriteLine("Disconnecting.\n");
            } catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
        }
    }
}
```
Notes

- When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in ADO.NET.
- Connections to a host taken from the BackupServerNode list are not pooled for ADO.NET connections.

Configuring Log Properties (ADO.Net)

Log properties for ADO.Net are configured differently than they are other client drivers. On the other client drivers, log properties can be configured as one of the connection properties. The ADO.Net driver user the VerticaLogProperties class to configure the properties.

VerticaLogProperties

VerticaLogProperties is a static class that allows you to set and get the log settings for the ADO.net driver. You can control the log level, log path, and log namespace using this class.

The log is created when the first connection is opened. Once the connection is opened, you cannot change the log path. It must be set prior to opening the connection. You can change the log level and log namespace at any time.

Setting Log Properties

Setting the log properties is done using the three methods in the VerticaLogProperties class. The three methods are:

- SetLogPath(String path, bool persist)
- SetLogNamespace(String lognamespace, bool persist)
- SetLogLevel(VerticaLogLevel loglevel, bool persist)
Each of the methods requires a boolean persist argument. When set to true, the persist argument causes the setting to be written to the client's Windows Registry, where it is used for all subsequent connections. If set to false, then the log property only applies to the current session.

**SetLogPath**

The SetLogPath method takes as its arguments a string containing the path to the log file and the persist argument. If the path string contains only a directory path, then the log file is created with the name vdp-driver-MM-dd_HH.mm.ss.log (where MM-dd_HH.mm.ss is the date and time the log was created). If the path ends in a filename, such as log.txt or log.log, then the log is created with that filename.

If SetLogPath is called with an empty string for the path argument, then the client executable's current directory is used as the log path.

If SetLogPath is not called and no registry entry exists for the log path, and you have called any of the other VerticaLogProperties methods, then the client executable's current directory is used as the log path.

When the persist argument is set to true, the path specified is copied to the registry verbatim. If no filename was specified, then the filename is not saved to the registry.

**Note:**

Note: The path must exist on the client system prior to calling this method. The method does not create directories.

Example Usage:

```csharp
// set the log path
string path = "C:\\log";
VerticaLogProperties.SetLogPath(path, false);
```

**SetLogNamespace**

The SetLogNamespace method takes as its arguments a string containing the namespace to log and the persist argument. The namespace string to log can be one of the following:

- Vertica
- Vertica.Data.VerticaClient
- Vertica.Data.Internal.IO
• Vertica.Data.Internal.DataEngine
• Vertica.Data.Internal.Core

Namespaces can be truncated to include multiple child namespaces. For example, you can specify "Vertica.Data.Internal" to log for all of the Vertica.Data.Internal namespaces.

If a log namespace is not set, and no value is stored in the registry, then the "Vertica" namespace is used for logging.

Example Usage:

```csharp
//set namespace to log
string lognamespace = "Vertica.Data.VerticaClient";
VerticaLogProperties.SetLogNamespace(lognamespace, false);
```

### SetLogLevel

The SetLogLevel method takes as its arguments a VerticaLogLevel type and the persist argument. The VerticaLogLevel argument can be one of:

• VerticaLogLevel.None
• VerticaLogLevel.Fatal
• VerticaLogLevel.Error
• VerticaLogLevel.Warning
• VerticaLogLevel.Info
• VerticaLogLevel.Debug
• VerticaLogLevel.Trace

If a log level is not set, and no value is stored in the registry, then VerticaLogLevel.None is used.

Example Usage:

```csharp
//set log level
VerticaLogLevel level = VerticaLogLevel.Debug;
VerticaLogProperties.SetLogLevel(level, false);
```

### Getting Log Properties

You can get the log property values using the getters included in the VerticaLogProperties class. The properties are:
• LogPath
• LogNamespace
• LogLevel

Example Usage:

```csharp
//get current log settings
string logpath = VerticaLogProperties.LogPath;
VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
string logns = VerticaLogProperties.LogNamespace;
Console.WriteLine("Current Log Settings:");
Console.WriteLine("Log Path: " + logpath);
Console.WriteLine("Log Level: " + loglevel);
Console.WriteLine("Log Namespace: " + logns);
```

## Setting and Getting Log Properties Example

This complete example shows how to set and get log properties:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {

            //configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            //get current log settings
            string logpath = VerticaLogProperties.LogPath;
            VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
            string logns = VerticaLogProperties.LogNamespace;
            Console.WriteLine("Old Log Settings:");
            Console.WriteLine("Log Path: " + logpath);
            Console.WriteLine("Log Level: " + loglevel);
            Console.WriteLine("Log Namespace: " + logns);

            //set the log path
        }
    }
}
```
string path = "C:\log"; 
VerticaLogProperties.SetLogPath(path, false);

//set log level

VerticaLogLevel level = VerticaLogLevel.Debug; 
VerticaLogProperties.SetLogLevel(level, false);

//set namespace to log

string lognamespace = "Vertica";
VerticaLogProperties.SetLogNamespace(lognamespace, false);

//open the connection

VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();

//get new log settings

logpath = VerticaLogProperties.LogPath; 
loglevel = VerticaLogProperties.LogLevel;
logns = VerticaLogProperties.LogNamespace;
Console.WriteLine("New Log Settings:");
Console.WriteLine("Log Path: " + logpath);
Console.WriteLine("Log Level: " + loglevel);
Console.WriteLine("Log Namespace: " + logns);

//close the connection

_conn.Close();
}
}

The example produces the following output:

Old Log Settings:
Log Path:
Log Level: None
Log Namespace:
New Log Settings:
Log Path: C:\log
Log Level: Debug
Log Namespace: Vertica

Querying the Database Using ADO.NET

This section describes how to create queries to do the following:
• **Inserting data into the database**
• **Read data from the database**
• **Load data into the database**

![Note:](image)

The `ExecuteNonQuery()` method used to query the database returns an `int32` with the number of rows affected by the query. The maximum size of an `int32` type is a constant and is defined to be 2,147,483,547. If your query returns more results than the `int32` max, then ADO.NET throws an exception because of the overflow of the `int32` type. However the query is still processed by Vertica even when the reporting of the return value fails. This is a limitation in .NET, as `ExecuteNonQuery()` is part of the standard ADO.NET interface.

**Inserting Data (ADO.NET)**

Inserting data can be done using the `VerticaCommand` class. `VerticaCommand` is an implementation of `DbCommand`. It allows you to create and send a SQL statement to the database. Use the `CommandText` method to assign a SQL statement to the command and then execute the SQL by calling the `ExecuteNonQuery` method. The `ExecuteNonQuery` method is used for executing statements that do not return result sets.

**To Insert a Single Row of data:**

1. Create a connection to the database.
2. Create a command object using the connection.

   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```

3. Insert data using an `INSERT` statement. The following is an example of a simple insert. Note that it does not contain a COMMIT statement because the Vertica ADO.NET driver operates in autocommit mode.

   ```csharp
   command.CommandText = "INSERT into test values(2, 'username', 'email', 'password');"
   ```

4. Execute the query. The `rowsAdded` variable contains the number of rows added by the insert statement.
Int32 rowsAdded = command.ExecuteNonQuery();

The `ExecuteNonQuery()` method returns the number of rows affected by the command for UPDATE, INSERT, and DELETE statements. For all other types of statements it returns -1. If a rollback occurs then it is also set to -1.

**Example Usage:**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "INSERT into test values(2, 'username', 'email', 'password')";
            Int32 rowsAdded = command.ExecuteNonQuery();
            Console.WriteLine( rowsAdded + " rows added!");
            _conn.Close();
        }
    }
}
```

**Using Parameters**

You can use parameters to execute similar SQL statements repeatedly and efficiently.

**Using Parameters**

VerticaParameters are an extension of the System.Data.DbParameter base class in ADO.NET and are used to set parameters in commands sent to the server. Use Parameters in all queries (SELECT/INSERT/UPDATE/DELETE) for which the values in the WHERE clause are not
static; that is for all queries that have a known set of columns, but whose filter criteria is set dynamically by an application or end user. Using parameters in this way greatly decreases the chances of a SQL injection issue that can occur when simply creating a SQL query from a number of variables.

Parameters require that a valid DbType, VerticaDbType, or System type be assigned to the parameter. See SQL Data Types and ADO.NET Data Types for a mapping of System, Vertica, and DbType.

To create a parameter placeholder, place either the at sign (@) or a colon (:) character in front of the parameter name in the actual query string. Do not insert any spaces between the placeholder indicator (@ or :) and the placeholder.

**Note:**
The @ character is the preferred way to identify parameters. The colon (:) character is supported for backward compatibility.

For example, the following typical query uses the string 'MA' as a filter.

```sql
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = 'MA';
```

Instead, the query can be written to use a parameter. In the following example, the string MA is replaced by the parameter placeholder @STATE.

```sql
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = @STATE;
```

For example, the ADO.net code for the prior example would be written as:

```csharp
VerticaCommand command = _conn.CreateCommand();
command.CommandText = "SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = @STATE";
command.Parameters.Add(new VerticaParameter("STATE", VerticaType.VarChar));
command.Parameters["STATE"].Value = "MA";
```

**Note:**
Although the VerticaCommand class supports a Prepare() method, you do not need to call the Prepare() method for parameterized statements because Vertica automatically prepares the statement for you.
Creating and Rolling Back Transactions

Creating Transactions

Transactions in Vertica are atomic, consistent, isolated, and durable. When you connect to a database using the Vertica ADO.NET Driver, the connection is in autocommit mode and each individual query is committed upon execution. You can collect multiple statements into a single transaction and commit them at the same time by using a transaction. You can also choose to rollback a transaction before it is committed if your code determines that a transaction should not commit.

Transactions use the VerticaTransaction object, which is an implementation of DbTransaction. You must associate the transaction with the VerticaCommand object.

The following code uses an explicit transaction to insert one row each into to tables of the VMart schema.

To Create a Transaction in Vertica Using the ADO.NET driver:

1. Create a connection to the database.
2. Create a command object using the connection.
   
   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```
3. Start an explicit transaction, and associate the command with it.
   
   ```csharp
   VerticaTransaction txn = _conn.BeginTransaction();
   command.Connection = _conn;
   command.Transaction = txn;
   ```
4. Execute the individual SQL statements to add rows.
   
   ```csharp
   command.CommandText = "insert into product_dimension values( ... )";
   command.ExecuteNonQuery();
   command.CommandText = "insert into store_orders_fact values( ... )";
   ```
5. Commit the transaction.

```csharp
txn.Commit();
```

# Rolling Back Transactions

If your code checks for errors, then you can catch the error and rollback the entire transaction.

```csharp
VerticaTransaction txn = _conn.BeginTransaction();
VerticaCommand command = new
    VerticaCommand("insert into product_dimension values( 838929, 5, 'New item 5' )", _conn);
// execute the insert
command.ExecuteNonQuery();
command.CommandText = "insert into product_dimension values( 838929, 6, 'New item 6' )";
// try insert and catch any errors
bool error = false;
try
{
    command.ExecuteNonQuery();
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
    error = true;
}
if (error)
{
    txn.Rollback();
    Console.WriteLine("Errors. Rolling Back.");
}
else
{
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
}
```

# Commit and Rollback Example

This example details how you can commit or rollback queries during a transaction.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
```
{ static void Main(string[] args) {
  VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
  builder.Host = "192.168.1.10";
  builder.Database = "VMart";
  builder.User = "dbadmin";
  VerticaConnection _conn = new VerticaConnection(builder.ToString());
  _conn.Open();
  bool error = false;
  VerticaCommand command = _conn.CreateCommand();
  VerticaCommand command2 = _conn.CreateCommand();
  VerticaTransaction txn = _conn.BeginTransaction();
  command.Connection = _conn;
  command.Transaction = txn;
  command.CommandText = "insert into test values(1, 'test', 'test', 'test')";
  Console.WriteLine(command.CommandText);
  try {
    command.ExecuteNonQuery();
  } catch (Exception e) {
    Console.WriteLine(e.Message);
    error = true;
  }
  command.CommandText = "insert into test values(2, 'ear', 'eye', 'nose', 'extra')";
  Console.WriteLine(command.CommandText);
  try {
    command.ExecuteNonQuery();
  } catch (Exception e) {
    Console.WriteLine(e.Message);
    error = true;
  }
  if (error) {
    txn.Rollback();
    Console.WriteLine("Errors. Rolling Back.");
  } else {
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
  }
  _conn.Close();
}
}

The example displays the following output on the console:

insert into test values(1, 'test', 'test', 'test')
insert into test values(2, 'ear', 'eye', 'nose', 'extra')
[42601]ERROR: INSERT has more expressions than target columns
Errors. Rolling Back.

See Also

- Setting the Transaction Isolation Level
Setting the Transaction Isolation Level

You can set the transaction isolation level on a per-connection and per-transaction basis. See Transaction for an overview of the transaction isolation levels supported in Vertica. To set the default transaction isolation level for a connection, use the IsolationLevel keyword in the VerticaConnectionStringBuilder string (see Connection String Keywords for details). To set the isolation level for an individual transaction, pass the isolation level to the VerticaConnection.BeginTransaction() method call to start the transaction.

To set the Isolation Level on a connection-basis:

1. Use the VerticaConnectionStringBuilder to build the connection string.
2. Provide a value for the IsolationLevel builder string. It can take one of two values: IsolationLevel.ReadCommitted (default) or IsolationLevel.Serializeable. For example:

```csharp
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.1.100";
builder.Database = "VMart";
builder.User = "dbadmin";
VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
_conn1.Open();
```

To set the Isolation Level on a Transaction basis:

1. Set the IsolationLevel on the BeginTransaction method, for example

```csharp
VerticaTransaction txn = _conn.BeginTransaction(IsolationLevel.Serializeable);
```

Example usage:

The following example demonstrates:
- getting the connection's transaction isolation level.
- setting the connection's isolation level using connection property.
- setting the transaction isolation level for a new transaction.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
            _conn1.Open();
            VerticaTransaction txn1 = _conn1.BeginTransaction();
            Console.WriteLine("Transaction 1 Transaction Isolation Level: " +
            txn1.IsolationLevel.ToString());
            txn1.Rollback();
            VerticaTransaction txn2 = _conn1.BeginTransaction(IsolationLevel.Serializable);
            Console.WriteLine("Transaction 2 Transaction Isolation Level: " +
            txn2.IsolationLevel.ToString());
            txn2.Rollback();
            VerticaTransaction txn3 = _conn1.BeginTransaction(IsolationLevel.ReadCommitted);
            Console.WriteLine("Transaction 3 Transaction Isolation Level: " +
            txn3.IsolationLevel.ToString());
            _conn1.Close();
        }
    }
}
```

When run, the example code prints the following to the system console:

```
Transaction 1 Transaction Isolation Level: ReadCommitted
Transaction 2 Transaction Isolation Level: Serializable
Transaction 3 Transaction Isolation Level: ReadCommitted
```

**Reading Data (ADO.Net)**

To read data from the database use VerticaDataReader, an implementation of DbDataReader. This implementation is useful for moving large volumes of data quickly off the server where it can be run through analytic applications.
To Read Data From the Database Using VerticaDataReader:

1. Create a connection to the database.
2. Create a command object using the connection.
   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```
3. Create a query. This query works with the example VMart database.
   ```csharp
   command.CommandText = "SELECT fat_content, product_description " + 
                        "FROM (SELECT DISTINCT fat_content, product_description" + 
                        " FROM product_dimension " + 
                        " WHERE department_description " + 
                        " IN ('Dairy') " + 
                        " ORDER BY fat_content) AS food " + 
                        "LIMIT 10;"
   ```
4. Execute the reader to return the results from the query. The following command calls the ExecuteReader method of the VerticaCommand object to obtain the VerticaDataReader object.
   ```csharp
   VerticaDataReader dr = command.ExecuteReader();
   ```
5. Read the data. The data reader returns results in a sequential stream. Therefore, you must read data from tables row-by-row. The following example uses a while loop to accomplish this:
   ```csharp
   Console.WriteLine("\n\n Fat Content\t Product Description\n" + 
                     "-----------\t ---------------\n" + 
                     " 0\nwhile (dr.Read())
{ 
   Console.WriteLine(" + dr[0] + " \t " + dr[1]);
   ++rows;
}
Console.WriteLine("-----------\n (" + rows + " rows)\n");
   ```
6. When you're finished, close the data reader to free up resources.
   ```csharp
   dr.Close();
   ```
Example Usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "SELECT fat_content, product_description FROM (SELECT DISTINCT fat_content, product_description FROM product_dimension WHERE department_description IN ('Dairy') ORDER BY fat_content) AS food LIMIT 10;"
            VerticaDataReader dr = command.ExecuteReader();
            Console.WriteLine("\n\nFat Content	Product Description\n-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\-\n" + dr[0] + "	" + dr[1]);
            ++rows;
        }
    }
}
```

Loading Data Through ADO.Net

This section details the different ways that you can load data in Vertica using the ADO.NET client driver:
Using the Vertica Data Adapter

The Vertica data adapter (VerticaDataAdapter) enables a client to exchange data between a data set and a Vertica database. It is an implementation of DbDataAdapter. You can use VerticaDataAdapter to simply read data, or, for example, read data from a database into a data set, and then write changed data from the data set back to the database.

Batching Updates

When using the Update() method to update a dataset, you can optionally use the UpdateBatchSize() method prior to calling Update() to reduce the number of times the client communicates with the server to perform the update. The default value of UpdateBatchSize is 1. If you have multiple rows.Add() commands for a data set, then you can change the batch size to an optimal size to speed up the operations your client must perform to complete the update.

Reading Data From Vertica Using the Data adapter:

The following example details how to perform a select query on the VMart schema and load the result into a DataTable, then output the contents of the DataTable to the console.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
        }
    }
}
Reading Data From Vertica into a DataSet and Changing data:

The following example shows how to use a data adapter to read from and insert into a dimension table of the VMart schema.
using System;
using System.Collections.Generic;

using Vertica.Data.VerticaClient
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            // Try/Catch any exceptions
            try
            {
                using (_conn)
                {
                    //Create a data adapter object using the connection
                    VerticaDataAdapter da = new VerticaDataAdapter();

                    //Create a select statement that retrieves data from the table
                    da.SelectCommand = new
                    VerticaCommand("select * from product_dimension where product_key < 10",
                    _conn);
                    //Set up the insert command for the data adapter, and bind variables for
                    //some of the columns
                    da.InsertCommand = new
                    VerticaCommand("insert into product_dimension values( :key, :version, :desc
                    )",
                    _conn);
                    da.InsertCommand.Parameters.Add(new VerticaParameter("key", VerticaType.BigInt));
                    VerticaType.BigInt));
                    VerticaType.VarChar));
                    da.InsertCommand.Parameters[0].SourceColumn = "product_key";
                    da.InsertCommand.Parameters[1].SourceColumn = "product_version";
                    da.TableMappings.Add("product_key", "product_key");
                    da.TableMappings.Add("product_version", "product_version");
                    da.TableMappings.Add("product_description", "product_description");

                    //Create and fill a data set for this dimension table, and get the
                    //resulting DataTable.
                    DataSet ds = new DataSet();
                    da.Fill(ds, 0, 0, "product_dimension");
                    DataTable dt = ds.Tables[0];

                    //Bind parameters and add two rows to the table.
                    DataRow dr = dt.NewRow();
                    dr["product_key"] = 838929;
                }
            }
        }
    }
}
dr["product_version"] = 5;
dr["product_description"] = "New item 5";
dt.Rows.Add(dr);

dr = dt.NewRow();

dr["product_key"] = 838929;

//Exctract the changes for the added rows.

//Send the modifications to the server.
int updateCount = da.Update(ds2, "product_dimension");

//Merge the changes into the original Data set, and mark it up to date.

ds.Merge(ds2);

ds.AcceptChanges();

Console.WriteLine(updateCount + " updates made!");

catch (Exception e)
{
   Console.WriteLine(e.Message);
   _conn.Close();
}

Using Batch Inserts and Prepared Statements

You can load data in batches using a prepared statement with parameters. You can also use transactions to rollback the batch load if any errors are encountered.

If you are loading large batches of data (more than 100MB), then consider using a direct batch insert.

The following example details using data contained in arrays, parameters, and a transaction to batch load data.

The test table used in the example is created with the command:

=> CREATE TABLE test (id INT, username VARCHAR(24), email VARCHAR(64), password VARCHAR(8));
Example Batch Insert Using Parameters and Transactions

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            // Create arrays for column data
            int[] ids = {1, 2, 3, 4};
            string[] usernames = {"user1", "user2", "user3", "user4"};
            string[] emails = {"user1@example.com", "user2@example.com", "user3@example.com", "user4@example.com"};
            string[] passwords = {"pass1", "pass2", "pass3", "pass4"};
            // create counters for accepted and rejected rows
            int rows = 0;
            int rejRows = 0;
            bool error = false;
            // Create the transaction
            VerticaTransaction txn = _conn.BeginTransaction();
            // Create the parameterized query and assign parameter types
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "insert into TEST values (@id, @username, @email, @password)";
            command.Parameters.Add(new VerticaParameter("id", VerticaType.BigInt));
            command.Parameters.Add(new VerticaParameter("username", VerticaType.VarChar));
            command.Parameters.Add(new VerticaParameter("email", VerticaType.VarChar));
            command.Parameters.Add(new VerticaParameter("password", VerticaType.VarChar));
            // Prepare the statement
            command.Prepare();
            // Loop through the column arrays and insert the data
            for (int i = 0; i < ids.Length; i++)
            {
                command.Parameters["id"].Value = ids[i];
                command.Parameters["username"].Value = usernames[i];
                command.Parameters["email"].Value = emails[i];
                command.Parameters["password"].Value = passwords[i];
                try
                {
                    rows += command.ExecuteNonQuery();
                }
                catch (Exception e)
                {
                }
            }
        }
    }
}
```
{  
    Console.WriteLine("\nInsert failed - \n  " + e.Message + "\n");
    ++rejRows;
    error = true;
}
if (error)
{
    // Roll back if errors
    Console.WriteLine("Errors. Rolling Back Transaction.");
    Console.WriteLine(rejRows + " rows rejected.");
    txn.Rollback();
}
else
{
    // Commit if no errors
    Console.WriteLine("No Errors. Committing Transaction.");
    txn.Commit();
    Console.WriteLine("Inserted " + rows + " rows.");
}
_conn.Close();
}
Loading Batches Directly into ROS

When loading large batches of data (more than 100MB or so), you should load the data directly into ROS containers. Inserting directly into ROS is more efficient for large loads than AUTO mode, since it avoids overflowing the WOS and spilling the remainder of the batch to ROS. Otherwise, the Tuple Mover has to perform a moveout on the data in the WOS, while subsequent data is directly written into ROS containers. This results in the data from your batch being segmented across containers.

When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS. For details about load options, see Choosing a Load Method.

To directly load batches into ROS, set the DirectBatchInsert connection property to true. See Opening and Closing the Database Connection for details on all of the connection properties. When the DirectBatchInsert property is set to true, all batch inserts bypass the WOS and load directly into a ROS container.

Example usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            builder.DirectBatchInsert = true;
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            //Perform some operations
            _conn.Close();
        }
    }
}
Streaming Data Via ADO.NET

There are two options to stream data from a file on the client to your Vertica database through ADO.NET:

- Use the VerticaCopyStream ADO.NET class to stream data in an object-oriented manner
- Execute a COPY LOCAL SQL statement to stream the data

The topics in this section explain how to use these options.
Streaming From the Client Via VerticaCopyStream

The VerticaCopyStream class lets you stream data from the client system to a Vertica database. It lets you use the SQL COPY statement directly without having to copy the data to a host in the database cluster first by substituting one or more data stream(s) for STDIN.

Notes:

- Use Transactions and disable auto commit on the copy command for better performance.
- Disable auto commit using the copy command with the 'no commit' modifier. You must explicitly disable commits. Enabling transactions does not disable autocommit when using VerticaCopyStream.
- The copy command used with VerticaCopyStream uses copy syntax.
- VerticaCopyStream.rejects is zeroed every time execute is called. If you want to capture the number of rejects, assign the value of VerticaCopyStream.rejects to another variable before calling execute again.
- You can add multiple streams using multiple AddStream() calls.

Example usage:

The following example demonstrates using VerticaCopyStream to copy a file stream into Vertica.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            // Configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
```
//open the connection
VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();
try{
    using (_conn)
    {
        // Start a transaction
        VerticaTransaction txn = _conn.BeginTransaction();
        // Create a table for this example
        VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS copy_table", _conn);
        command.ExecuteNonQuery();
        command.CommandText = "CREATE TABLE copy_table(Last_Name char(50), "
            + "First_Name char(50), Email char(50), "
            + "Phone_Number char(15))";
        command.ExecuteNonQuery();
        // Create a new filestream from the data file
        string filename = "C:/customers.txt";
        Console.WriteLine("Loading File: " + filename);
        FileStream inputfile = File.OpenRead(filename);
        // Define the copy command
        string copy = "copy copy_table from stdin record terminator E'\n' delimiter '|' + " enforcelength "
            + " no commit";
        // Create a new copy stream instance with the connection and copy statement
        VerticaCopyStream vcs = new VerticaCopyStream(_conn, copy);
        // Start the VerticaCopyStream process
        vcs.Start();
        // Add the file stream
        vcs.AddStream(inputfile, false);
        // Execute the copy
        vcs.Execute();
        // Finish stream and write out the list of inserted and rejected rows
        long rowsInserted = vcs.Finish();
        IList<long> rowsRejected = vcs.Rejects;
        // Does not work when rejected or exceptions defined
        Console.WriteLine("Number of Rows inserted: " + rowsInserted);
        Console.WriteLine("Number of Rows rejected: " + rowsRejected.Count);
        if (rowsRejected.Count > 0)
        {
            for (int i = 0; i < rowsRejected.Count; i++)
            {
                Console.WriteLine("Rejected row #{0} is row {1}", i, rowsRejected[i]);
            }
        }
        // Commit the changes
        txn.Commit();
    }
} catch (Exception e)
{
    Console.WriteLine(e.Message);
}
```csharp
    //close the connection
    _conn.Close();
```
Using Copy with ADO.NET

To use COPY with ADO.NET, just execute a COPY statement and the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class. However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a local file (streamed over a network connection, for example).

The following example code demonstrates using COPY to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement and the path to the data file is on the client system, rather than on the server.

To load data that is stored on a database node, use a VerticaCommand object to create a COPY command:

1. Create a connection to the database through the node on which the data file is stored.
2. Create a command object using the connection.

```csharp
VerticaCommand command = _conn.CreateCommand();
```

3. Copy data. The following is an example of using the COPY command to load data. It uses the LOCAL modifier to copy a file local to the client issuing the command.

```csharp
command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'
+ 'record terminator E'\n\delimiter '|'
+ 'enforce length ';

Int32 insertedRows = command.ExecuteNonQuery();
Console.WriteLine(insertedRows + " inserted.");
```

Example Usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
```
```csharp
// Configure connection properties
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.1.10";
builder.Database = "VMart";
builder.User = "dbadmin";

// Open the connection
VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();
try {
    using (_conn)
    {
        // Start a transaction
        VerticaTransaction txn = _conn.BeginTransaction();

        // Create a table for this example
        VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS lcopy_table");
        command.ExecuteNonQuery();
        command.CommandText = "CREATE TABLE IF NOT EXISTS lcopy_table (Last_Name char(50), "
                           + "First_Name char(50), Email char(50), "
                           + "Phone_Number char(15))";
        command.ExecuteNonQuery();
        // Define the copy command
        command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'";
                           + " record terminator E'\n' delimiter '|'";
        command.ExecuteNonQuery();
        // Execute the copy
        Int32 insertedRows = command.ExecuteNonQuery();
        Console.WriteLine(insertedRows + " inserted.");
        // Commit the changes
        txn.Commit();
    }
    catch (Exception e)
    {
        Console.WriteLine("Exception: " + e.Message); 
    }

    // Close the connection
    _conn.Close();
}
```

Handling Messages (ADO.NET)

You can capture info and warning messages that Vertica provides to the ADO.NET driver by using the InfoMessage event on the VerticaConnection delegate class. This class captures
messages that are not severe enough to force an exception to be triggered, but might still provide information that can benefit your application.

**To Use the `VerticalInfoMessageEventHandler` class:**

1. Create a method to handle the message sent from the even handler:

   ```csharp
   static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
   {
       Console.WriteLine(e.SqlState + "": " + e.Message);
   }
   ```

2. Create a `connection` and register a new `VerticaInfoMessageHandler` delegate for the `InfoMessage` event:

   ```csharp
   _conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);
   ```

3. Execute your queries. If a message is generated, then the event handle function is run.

4. You can unsubscribe from the event with the following command:

   ```csharp
   _conn.InfoMessage -= new VerticaInfoMessageEventHandler(conn_InfoMessage);
   ```

**Example usage:**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {

        // define message handler to deal with messages
        static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
        {
            Console.WriteLine(e.SqlState + ": " + e.Message);
        }

        static void Main(string[] args)
        {

            //configure connection properties
```
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.1.10";
builder.Database = "VMart";
builder.User = "dbadmin";

//open the connection

VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();

//create message handler instance by subscribing it to the InfoMessage event of the connection

_conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);

//create and execute the command

VerticaCommand cmd = _conn.CreateCommand();
cmd.CommandText = "drop table if exists fakeTable";
cmd.ExecuteNonQuery();

//close the connection

_conn.Close();
}
}

This examples displays the following when run:

00000: Nothing was dropped

### Getting Table Metadata (ADO.Net)

You can get the table metadata by using the GetSchema() method on a connection and loading the metadata into a DataTable:

```csharp
DataTable table = _conn.GetSchema("Tables", new string[] { database_name, schema_name, table_name, table_type });
```

For example:

```csharp
DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });
```
database_name, schema_name, table_name can be set to null, be a specific name, or use a LIKE pattern.

**table_type** can be one of:

- "SYSTEM TABLE"
- "TABLE"
- "GLOBAL TEMPORARY"
- "LOCAL TEMPORARY"
- "VIEW"
- null

If **table_type** is set to null, then the metadata for all metadata tables is returned.

**Example Usage:**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {

            //configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            //open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            //create a new data table containing the schema
            DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });

            //print out the schema
```
foreach (DataRow row in table.Rows) {
    foreach (DataColumn col in table.Columns) {
        Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
    }
    Console.WriteLine("================================");
}

//close the connection

_conn.Close();
Programming Python Client Applications

To use Python with Vertica, you must either install the Vertica Python Client (see Python Client Documentation) or install the pyodbc module and a Vertica ODBC driver on the machine where Python is installed. See Python Prerequisites.

Python on Linux

Most Linux distributions come with Python preinstalled. If you want a more recent version, you can download and build it from the source code, though sometimes RPMs are also available. See the Python Web site and click an individual release for details. See also Python documentation.

To determine the Python version on your Linux operating systems, type the following at a command prompt:

```
# python -V
```

The system returns the version; for example:

```
Python 3.3.4
```

Python on Windows

Windows operating systems do not include Python by default. There are several different distributions of Python for windows:

- The ActiveState Web site distributes a free Windows installer for Python called ActivePython.
- The official Python.org site has installer packages for several versions of Python.

If you need installation instructions for Windows, see Using Python on Windows at python.org.
Python and Unicode

When you are using Python, be sure that all of your components are using the same unicode text encoding. By default, the DSN Parameter [ColumnsAsChar](http://columnsAsChar) causes the ODBC driver to report CHAR and VARCHAR values as SQL_WCHAR. The driver returns these values to the driver manager in the encoding expected by the driver manager, as controlled by the DriverManagerEncoding parameter in vertica.ini. Similarly, your Python application must use the encoding expected by the driver manager. If any of these components use different encodings, your output can become garbled.

The Vertica Python Client

Vertica has a native Python client you can use to communicate with your Vertica database.

Before you can connect to Vertica using Python, you need to download the Python Client. See the Vertica Python Client Documentation, for download and installation instructions.

Using pyodbc and Vertica

Before you can connect to Vertica using pyodbc, you need to download the pyodbc module, which communicates with iODBC/unixODBC driver on UNIX operating systems and the ODBC Driver Manager for Windows operating systems.

The pyodbc module is an open source, MIT-licensed Python module, letting you use ODBC to connect to almost any database from Windows, Linux, Mac OS/X, and other operating systems.

Vertica supports multiple versions of pyodbc. See [Python Prerequisites](http://pythonPrerequisites) for additional details.

Download the source distribution from the [pyodbc Web site](http://pyodbcWebSite), unpack it and build it. Note that you need the unixODBC development package (in addition to the regular build tools) to build pyodbc. For example, on RedHat/CentOS run: `yum install unixODBC-devel`, and on Ubuntu run: `sudo apt-get install unixodbc-dev`. See the [pyodbc wiki](http://pyodbcWiki) for detailed instructions.
Python Clients and the UUID Data Type

Both the Vertica Python client and Vertica ODBC driver (that pyodbc interacts with) do not support Vertica's native UUID data type. Values retrieved using these drivers from a UUID column are converted to strings. When your client queries the metadata for a UUID column, the drivers report its data type as a string. Convert any UUID values that you want to insert into a UUID column to strings. Vertica automatically converts these values into the native UUID data type before inserting them into a table.

Configuring the ODBC Run-Time Environment on Linux

To configure the ODBC run-time environment on Linux:

1. Create the odbc.ini file if it does not already exist.
2. Add the ODBC driver directory to the LD_LIBRARY_PATH system environment variable:

```bash
export LD_LIBRARY_PATH=/path-to-vertica-odbc-driver:$LD_LIBRARY_PATH
```

**Important:**
If you skip Step 2, the ODBC manager cannot find the driver in order to load it.

These steps are relevant only for unixODBC and iODBC. See their respective documentation for details on odbc.ini.

Querying the Database Using Python and pyodbc

The example session below uses pyodbc with the Vertica ODBC driver to connect Python to the Vertica database.

**Note:**
SQLFetchScroll and SQLFetch functions cannot be mixed together in iODBC code. When using pyodbc with the iODBC driver manager, skip cannot be used with the fetchall, fetchone, and fetchmany functions.

**Example Script**

The following example script shows how to query Vertica using Python 3, pyodbc, and an ODBC DSN.

```python
import pyodbc
cnxn = pyodbc.connect("DSN=VerticaDSN", ansi=True)
cursor = cnxn.cursor()
# create table
cursor.execute("CREATE TABLE TEST (" "C_ID INT," "C_FP FLOAT," "C_VARCHAR VARCHAR(100)," "C_DATE DATE, C_TIME TIME," "C_TS TIMESTAMP," "C_BOOL BOOL")")
cursor.execute("INSERT INTO test VALUES(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 09:00:09','t')")
cursor.execute("INSERT INTO test VALUES(2,3.4,'zxcasdqwe09876543','1991-11-11','00:00:01','1981-12-31 19:19:19','f')")
cursor.execute("SELECT * FROM TEST")
rows = cursor.fetchall()
for row in rows:
    print(row, end='\n')
cursor.execute("DROP TABLE TEST CASCADE")
cursor.close()
cnxn.close()
```

The resulting output displays:

```
(2, 3.4, 'zxcasdqwe09876543', datetime.date(1991, 11, 11), datetime.time(0, 0, 1), datetime.datetime(1981, 12, 31, 19, 19, 19), False)
(1, 1.1, 'abcdefg1234567890', datetime.date(1901, 1, 1), datetime.time(23, 12, 34), datetime.datetime(1901, 1, 1, 9, 0, 9), True)
```
Notes

SQLPrimaryKeys returns the table name in the primary (pk_name) column for unnamed primary constraints. For example:

- Unnamed primary key:

  ```sql
  CREATE TABLE schema.test(c INT PRIMARY KEY);
  SQLPrimaryKeys
  "TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <null>,
  "SCHEMA", "TEST", "C", 1, "TEST"
  ```

- Named primary key:

  ```sql
  CREATE TABLE schema.test(c INT CONSTRAINT pk_1 PRIMARY KEY);
  SQLPrimaryKeys
  "TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <null>,
  "SCHEMA", "TEST", "C", 1, "PK_1"
  ```

OpenText recommends that you name your constraints.

Programming Perl Client Applications

The Perl programming language has a Database Interface module (DBI) that creates a standard interface for Perl scripts to interact with databases. The interface module relies on Database Driver modules (DBDs) to handle all of the database-specific communication tasks. The result is an interface that provides a consistent way for Perl scripts to interact with many different types of databases.

Your Perl script can interact with Vertica using the Perl DBI module along with the DBD::ODBC database driver to interface to Vertica's ODBC driver. See the CPAN pages for Perl's [DBI](https://metacpan.org/pod/DBI) and [DBD::ODBC](https://metacpan.org/pod/DBD::ODBC) modules for detailed documentation.
Important:
With Perl ODBC clients, Vertica allows a forked process (a child process) to drop the parent connection to the Vertica server when the child process completes and exits. Vertica allows this behavior regardless of the setting of the Perl DBI AutoInactiveDestroy attribute. To change the default setting so that Vertica honors the setting of the Perl DBI AutoInactiveDestroy attribute, add the parameter CleanupInForkChild to your vertica.ini file, and set its value to 1. When the Perl DBI AutoInactiveDestroy attribute is set to 1, and the Vertica parameter CleanupInForkChild is set to 1, Vertica does not drop the parent connection upon child process completion.

Perl Client Prerequisites

In order run a Perl client script that connects to Vertica, your client system must have:

- The Vertica ODBC drivers installed and configured. See Installing the Vertica Client Drivers for details.
- A Data Source Name (DSN) containing the connection parameters for your Vertica. See Creating an ODBC Data Source Name. (Optionally, your Perl script can connect to Vertica without using a DSN as described in Connecting From Perl Without a DSN).
- A supported version of Perl installed
- The DBI and DBD::ODBC Perl modules (see below)

Supported Perl Versions

Vertica supports Perl versions 5.8 and 5.10. Versions later than 5.10 may also work.
**Perl on Linux**

Most Linux distributions come with Perl preinstalled. See your Linux distribution’s documentation for details of installing and configuring its Perl package if it is not already installed.

To determine the Perl version on your Linux operating systems, type the following at a command prompt:

```
# perl -v
```

The system returns the version; for example:

```
This is perl, v5.10.0 built for x86_64-linux-thread-multi
```

**Perl on Windows**

Perl is not installed by default on Windows platforms. There are several different Perl packages you can download and install on your Windows system:

- [ActivePerl](https://www.activestate.com/products/activeperl/) by Activestate is a commercially-supported version of Perl for Windows platforms.
- [Strawberry Perl](https://strawberryperl.com/) is an open-source port of Perl for Windows.

**The Perl Driver Modules (DBI and DBD::ODBC)**

Before you can connect to Vertica using Perl, your Perl installation needs to have the Perl Database Interface module (DBI) and the Database Driver for ODBC (DBD::ODBC). These modules communicate with iODBC/unixODBC driver on UNIX operating systems or the ODBC Driver Manager for Windows operating systems.

Vertica supports the following Perl modules:

- DBI version 1.609 (DBI-1.609.tar.gz)
- DBD::ODBC version 1.22 (DBD-ODBC-1.22.tar.gz)

Later versions of DBI and DBD::ODBC may also work.
DBI is installed by default with many Perl installations. You can test whether it is installed by executing the following command on the Linux or Windows command line:

```bash
# perl -e "use DBI;"
```

If the command exits without printing anything, then DBI is installed. If it prints an error, such as:

```
BEGIN failed--compilation aborted at -e line 1.
```

then DBI is not installed.

Similarly, you can see if DBD::ODBC is installed by executing the command:

```bash
# perl -e "use DBD::ODBC;"
```

You can also run the following Perl script to determine if DBI and DBD::ODBC are installed. If they are, the script lists any available DSNs.

```perl
#!/usr/bin/perl
use strict;
# Attempt to load the DBI module in an eval using require. Prevents
# script from erroring out if DBI is not installed.
eval
{
    require DBI;
    DBI->import();
};
if ($@) {
    # The eval failed, so DBI must not be installed
    print "DBI module is not installed\n";
} else {
    # Eval was successful, so DBI is installed
    print "DBI Module is installed\n";
    # List the drivers that DBI knows about.
    my @drivers = DBI->available_drivers;
    print "Available Drivers: \n";
    foreach my $driver (@drivers) {
        print "$driver \n";
    }
    # See if DBD::ODBC is installed by searching driver array.
    if (grep {/ODBC/} @drivers) {
        print "nDBD::ODBC is installed.\n";
        # List the ODBC data sources (DSNs) defined on the system
        print "Defined ODBC Data Sources:\n";
        my @dsns = DBI->data_sources('ODBC');
        foreach my $dsn (@dsns) {
            print "$dsn\n";
        }
    } else {
        print "DBD::ODBC is not installed\n";
    }
}
```
The exact output of the above code will depend on the configuration of your system. The following is an example of running the code on a Windows computer:

DBI Module is installed
Available Drivers:
  ADO
  DBM
  ExampleP
  File
  Gofer
  ODBC
  Pg
  Proxy
  SQLite
  Sponge
  mysql
DBD::ODBC is installed.
Defined ODBC Data Sources:
  dbi:ODBC:dBASE Files
  dbi:ODBC:Excel Files
  dbi:ODBC:MS Access Database
  dbi:ODBC:VerticaDSN

**Installing Missing Perl Modules**

If Perl's DBI or DBD::ODBC modules are not installed on your client system, you must install them before your Perl scripts can connect to Vertica. How you install modules depends on your Perl configuration:

- For most Perl installations, you use the `cpan` command to install modules. If the `cpan` command alias isn't installed on your system, you can try to start CPAN by using the command:

  ```shell
  perl -MCcpan -e shell
  ```

- Some Linux distributions provide Perl modules as packages that can be installed with the system package manager (such as yum or apt). See your Linux distribution's documentation for details.
- On ActiveState Perl for Windows, you use the Perl Package Manager (PPM) program to install Perl modules. See the [Activestate's PPM documentation](https://activestate.com) for details.

**Note:**
Installing Perl modules usually requires administrator or root privileges. If
you do not have these permissions on your client system, you need to ask your system administrator to install these modules for you.

Connecting to Vertica Using Perl

You use the Perl DBI module's connect function to connect to Vertica. This function takes a required data source string argument and optional arguments for the username, password, and connection attributes.

The data source string must start with "dbi:ODBC:“, which tells the DBI module to use the DBD::ODBC driver to connect to Vertica. The remainder of the string is interpreted by the DBD::ODBC driver. It usually contains the name of a DSN that contains the connection information needed to connect to your Vertica database. For example, to tell the DBD::ODBC driver to use the DSN named VerticaDSN, you use the data source string:

"dbi:ODBC:VerticaDSN"

The username and password parameters are optional. However, if you do not supply them (or just the username for a passwordless account) and they are not set in the DSN, attempting to connect always fails.

The connect function returns a database handle if it connects to Vertica. If it does not, it returns undef. In that case, you can access the DBI module's error string property ($DBI::errstr) to get the error message.

Note:
By default, the DBI module prints an error message to STDERR whenever it encounters an error. If you prefer to display your own error messages or handle errors in some other manner, you may want to disable these automatic messages by setting DBI's PrintError connection attribute to false. See Setting Perl DBI Connection Attributes for details. Otherwise, users may see two error messages: the one that DBI prints automatically, and the one that your script prints on its own.

The following example demonstrates connecting to Vertica using a DSN named VerticaDSN. The call to connect supplies a username and password. After connecting, it calls the database handle's disconnect function, which closes the connection.

```perl
#!/usr/bin/perl -w
use strict;
use DBI;
```
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();

### Setting ODBC Connection Parameters in Perl

To set ODBC connection parameters, replace the DSN name with a semicolon delimited list of parameter name and value pairs in the source data string. Use the DSN parameter to tell DBD::ODBC which DSN to use, then add in other the other ODBC parameters you want to set. For example, the following code connects using a DSN named VerticaDSN and sets the connection's locale to en_GB.

```perl
#!/usr/bin/perl -w
use strict;
use DBI;

my $dbh = DBI->connect("dbi:ODBC:DSN=VerticaDSN;Locale=en_GB@collation=binary","ExampleUser","password123");
unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```

See [Data Source Name (DSN) Connection Properties](#) for a list of the connection parameters you can set in the source data string.

### Setting Perl DBI Connection Attributes

The Perl DBI module has attributes that you can use to control the behavior of its database connection. These attributes are similar to the ODBC connection parameters (in several cases, they duplicate each other's functionality). The DBI connection attributes are a cross-platform way of controlling the behavior of the database connection.

You can set the DBI connection attributes when establishing a connection by passing the DBI `connect` function a hash containing attribute and value pairs. For example, to set the DBI connection attribute AutoCommit to false, you would use:
# Create a hash that holds attributes for the connection
my $attr = {AutoCommit => 0};

# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);

See the DBI documentation's Database Handle Attributes section for a full description of the attributes you can set on the database connection.

After your script has connected, it can access and modify the connection attributes through the database handle by using it as a hash reference. For example:

```perl
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
```

The following example demonstrates setting two connection attributes:

- **RaiseError** controls whether the DBI driver generates a Perl error if it encounters a database error. Usually, you set this to true (1) if you want your Perl script to exit if there is a database error.
- **AutoCommit** controls whether statements automatically commit their transactions when they complete. DBI defaults to Vertica's default AutoCommit value of true. Always set AutoCommit to false (0) when bulk loading data to increase database efficiency.

```perl
#!/usr/bin/perl
use strict;
use DBI;

# Create a hash that holds attributes for the connection
my $attr = {
    RaiseError => 1, # Make database errors fatal to script
    AutoCommit => 0, # Prevent statements from committing
        # their transactions.
};

# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);

if (defined $dbh->err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}

print "Connected!\n";

# The database handle lets you access the connection attributes directly:
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
print "The RaiseError attribute is: " . $dbh->{RaiseError} . "\n";

# And you can change values, too...
$dbh->{AutoCommit} = 1;
print "The AutoCommit attribute is now: " . $dbh->{AutoCommit} . "\n";
$dbh->disconnect();
```

The example outputs the following when run:
Connected! The AutoCommit attribute is: 0
The RaiseError attribute is: 1
The AutoCommit attribute is now: 1

**Connecting From Perl Without a DSN**

If you do not want to set up a Data Source Name (DSN) for your database, you can supply all of the information Perl's DBD::ODBC driver requires to connect to your Vertica database in the data source string. This source string must the DRIVER= parameter that tells DBD::ODBC which driver library to use in order to connect. The value for this parameter is the name assigned to the driver by the client system's driver manager:

- On Windows, the name assigned to the Vertica ODBC driver by the driver manager is Vertica.
- On Linux and other UNIX-like operating systems, the Vertica ODBC driver's name is assigned in the system's odbcinst.ini file. For example, if your /etc/odbcint.ini contains the following:

```ini
[Vertica]
Description = Vertica ODBC Driver
Driver = /opt/vertica/lib64/libverticaodbc.so
```

you would use the name Vertica. See [Creating an ODBC DSN for Linux](#) for more information about the odbcinst.ini file.

You can take advantage of Perl's variable expansion within strings to use variables for most of the connection properties as the following example demonstrates.

```perl
#!/usr/bin/perl
use strict;
use DBI;
my $server = 'VerticaHost';
my $port = '5433';
my $database = 'VMart';
my $user = 'ExampleUser';
my $password = 'password123';
# Connect without a DSN by supplying all of the information for the connection.
# The DRIVER value on UNIX platforms depends on the entry in the odbcinst.ini file.
my $dbh = DBI->connect("dbi:ODBC:DRIVER={Vertica};Server=$server;"
    "Port=$port;Database=$database;UID=$user;PWD=$password")
  or die "Could not connect to database: " . DBI::errstr;
print "Connected!\n";
$dbh->disconnect();
```

**Note:**
Surrounding the driver name with braces ({} and }) in the source string is
Executing Statements Using Perl

Once your Perl script has connected to Vertica (see Connecting to Vertica Using Perl), it can execute simple statements that return a value rather than a result set by using the Perl DBI module's do function. You usually use this function to execute DDL statements or data loading statements such as COPY (see Using COPY LOCAL to Load Data in Perl).

```perl
#!/usr/bin/perl
use strict;
use DBI;

# Disable autocommit
my $attr = {AutoCommit => 0};

# Open a connection using a DSN.
my $dbh = DBI::connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);

unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}

# You can use the do function to perform DDL commands.
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");

# Create a table to hold data.
$dbh->do("CREATE TABLE TEST(
    C_ID INT,
    C_FP FLOAT,
    C_VARCHAR VARCHAR(100),
    C_DATE DATE, C_TIME TIME,
    C_TS TIMESTAMP,
    C_BOOL BOOL");

# Commit changes and exit.
$dbh->commit();
$dbh->disconnect();
```

**Note:**
The do function returns the number of rows that were affected by the statement (or -1 if the count of rows doesn't apply or is unavailable). Usually, the only time you need to consult this value is after you deleted a number of rows or if you used a bulk load command such as COPY. You use other DBI functions instead of do to perform batch inserts and selects (see Batch Loading Data Using Perl and Querying Using Perl for details).
Batch Loading Data Using Perl

To load large batches of data into Vertica using Perl:

1. Set DBI's AutoCommit connection attribute to false to improve the batch load speed. See Setting Perl DBI Connection Attributes for an example of disabling AutoCommit.
2. Call the database handle's prepare function to prepare a SQL INSERT statement that contains placeholders for the data values you want to insert. For example:

   ```
   # Prepare an INSERT statement for the test table
   $sth = $dbh->prepare("INSERT into test values(?,?,?,?,?,?,?)");
   ```

   The prepare function returns a statement handle that you will use to insert the data.
3. Assign data to the placeholders. There are several ways to do this. The easiest is to populate an array with a value for each placeholder in your INSERT statement.
4. Call the statement handle's execute function to insert a row of data into Vertica.
   The return value of this function call lets you know whether Vertica accepted or rejected the row.
5. Repeat steps 3 and 4 until you have loaded all of the data you need to load.
6. Call the database handle's commit function to commit the data you inserted.

The following example demonstrates inserting a small batch of data by populating an array of arrays with data, then looping through it and inserting each row.

```perl
#!/usr/bin/perl
use strict;
use DBI;

# Create a hash reference that holds a hash of parameters for the # connection.
my $attr = {AutoCommit => 0, # Turn off autocommit
            PrintError => 0 # Turn off automatic error printing.
            # This is handled manually.};

# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);
if (defined DBI::err) {
    # Conneion failed.
    die "Failed to connect: $DBI::errstr"
}

print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";
# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;") or die "Could not drop table";
$dbh->do("CREATE TABLE TEST( \
      C_ID INT, \n      C_FNP FLOAT,\n      C_VARCHAR VARCHAR(100),\n      ")
```
C_DATE DATE, C_TIME TIME, 
C_TST TIMESTAMP, 
C_BOOL BOOL") or die "Could not create table";

# Populate an array of arrays with values. One of these rows contains 
# data that will not be successfully inserted. Another contains an 
# undef value, which gets inserted into the database as a NULL.
my @data = (
    [1,1.111,'Hello World!','2001-01-01','01:01:01', '2001-01-01 01:01:01', 't'],
    [2,2.22222,'How are you?','2002-02-02','02:02:02', '2002-02-02 02:02:02', 'f'],
    ['bad value',2.22222,'How are you?','2002-02-02','02:02:02', '2002-02-02 02:02:02', 'f'],
    [4,4.22222,undef,'2002-02-02','02:02:02', '2002-02-02 02:02:02', 'f'],
);

# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT into test values (?,?,?,?,?,?,?)");

my $rowcount = 0;

# Loop through the arrays to insert values
foreach my $tuple (@data) {
    $rowcount ++;
    # Insert the row
    my $retval = $sth->execute(@$tuple);

    # See if the row was successfully inserted.
    if ($retval == 1) {
        # Value of 1 means the row was inserted (1 row was affected by insert)
        print "Row $rowcount successfully inserted\n";
    } else {
        print "Inserting row $rowcount failed"
        # Error message is not set on some platforms/versions of DBUI. Check to 
        # ensure a message exists to avoid getting an uninitialized var warning.
        if ($sth->err) {
            print ": " . $sth->errstr();
        }
        print "\n";
    }
}

# Commit changes. With AutoCommit off, you need to use commit for batched 
# data to actually be committed into the database. If your Perl script exits 
# without committing its data, Vertica rolls back the transaction and the 
# data is not committed.
$dbh->commit();
$dbh->disconnect();

The previous example displays the following when successfully run:

Connection AutoCommit state is: 0
Row 1 successfully inserted
Row 2 successfully inserted
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An error occurred during query execution: Row rejected by server; see server log for details (SQL-01000)
Row 4 successfully inserted
Note that one of the rows was not inserted because it contained a string value that could not be stored in an integer column. See Conversions Between Perl and Vertica Data Types for details of data type handling in Perl scripts that communicate with Vertica.

## Using COPY LOCAL to Load Data in Perl

If you have delimited files (for example, a file with comma-separated values) on your client system that you want to load into Vertica, you can use the COPY LOCAL statement to directly load the file's contents into Vertica instead of using Perl to read, parse, and then batch insert the data. You execute a COPY LOCAL statement to load the file from the local file system. The result of executing the statement is the number of rows that were successfully inserted.

Note:
The COPY LOCAL statement must be the first statement within a query containing multiple statements. If you attempt to use COPY LOCAL as the second or later statement, you will receive the error "COPY LOCAL statement must be the first statement in a multiple statement query."

The following example code demonstrates loading a file named data.txt and located in the same directory as the Perl file into Vertica using a COPY LOCAL statement.

```perl
#!/usr/bin/perl
use strict;
use DBI;
# Filesystem path handling module
use File::Spec;
# Create a hash reference that holds a hash of parameters for the # connection.
my $attr = {AutoCommit => 0}; # Turn off AutoCommit
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
  $attr) or die "Failed to connect: $DBI::errstr";
print "Connected!\n";
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS Customers CASCADE;");
# Create a table to hold data.
$dbh->do("CREATE TABLE Customers(
  ID INT,\n  FirstName VARCHAR(100),\n  LastName VARCHAR(100),\n  Email VARCHAR(100),\n  Birthday DATE"));
# Find the absolute path to the data file located in the current working # directory and named data.txt
my $currDir = File::Spec->rel2abs(File::Spec->curdir());
```
my $dataFile = File::Spec->catfile($currDir, 'data.txt');
print "Loading file $dataFile\n";
# Load local file using copy local. Return value is the # of rows affected
# which equates to the number of rows inserted.
my $rows = $dbh->do("COPY Customers FROM LOCAL '$dataFile' DIRECT")
or die $dbh->errstr;
print "Copied $rows rows into database.\n";
$dbh->commit();
# Prepare a query to get the first 15 rows of the results
my $sth = $dbh->prepare("SELECT * FROM Customers WHERE ID < 15 \
ORDER BY ID");

$sth->execute() or die "Error querying table: ". $dbh->errstr;
my @row;  
# Predeclare variable to hold result row used in format statement.
# Use Perl formats to pretty print the output. Declare the heading for the
# form.
format STDOUT_TOP =
ID  First       Last     EMail      Birthday
==  ========    ========  ========    ========

# The Perl write statement will output a formatted line with values from the
# @row array. See http://perldoc.perl.org/perlform.html for details.
format STDOUT =
	@<<<<<<<<<<<< @<<<<<<<<<<<< @<<<<<<<<<<<<<<<<<<<< @<<<<<<<<<
@row .

# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
    write; # Format command does the work of extracting the columns from
    # the @row array and writing them out to STDOUT.
}
# Call commit to prevent Perl from complaining about uncommitted transactions
# when disconnecting
$dbh->commit();
$dbh->disconnect();

The data.txt file is a text file containing a row of data on each line. The columns are
 delimited by pipe (|) characters. This is the default format that the COPY command accepts,
which makes the COPY LOCAL statement in the example code simple. See the COPY
statement entry in the SQL Reference Manual for handling data files that are in different
formats. Here is an example of the content in this file:

1|Georgia|Gomez|Rhiannon@magna.us|1937-10-03
2|Abdul|Alexander|Kathleen@ipsum.gov|1941-03-10

```

**Note:**

Loading a single, large data file into Vertica through a single data connection is less efficient than loading a number of smaller files onto multiple nodes in parallel. Loading onto multiple nodes prevents any one node from becoming a bottleneck.

### Querying Using Perl

To query Vertica using Perl:

1. Prepare a query statement using the Perl DBI module's `prepare` function. This function returns a statement handle that you use to execute the query and get the result set.
2. Execute the prepared statement by calling the `execute` function on the statement handle.
3. Retrieve the results of the query from the statement handle using one of several methods, such as calling the statement handle's `fetchrow_array` function to retrieve a row of data, or `fetchall_array` to get an array of arrays containing the entire result set (not a good idea if your result set may be very large!).

The following example demonstrates querying the table created by the example shown in Batch Loading Data Using Perl. It executes a query to retrieve all of the content of the table,
then repeatedly calls the statement handle's fetchrow_array function to get rows of data in an array. It repeats this process until fetchrow_array returns undef, which means that there are no more rows to be read.

```perl
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1};  # Make errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them, getting each row as an array
while (my @row = $sth->fetchrow_array()) {
    # The @row array contains the column values for this row of data
    # Loop through the column values
    foreach my $column (@row) {
        if (!defined $column) {
            # NULLs are signaled by undefs. Set to NULL for clarity
            $column = "NULL";
        }
        print "$column\t";  # Output the column separated by a tab
    }
    print "\n";
}
$dbh->disconnect();
```

The example prints the following when run:

```
1 1.111 Hello World! 2001-01-01 01:01:01 2001-01-01 01:01:01 1
2 2.22222 How are you? 2002-02-02 02:02:02 2002-02-02 02:02:02 0
4 4.22222 NULL 2002-02-02 02:02:02 2002-02-02 02:02:02 0
```

**Binding Variables to Column Values**

Another method of retrieving the query results is to bind variables to columns in the result set using the statement handle's bind_columns function. You may find this method convenient if you need to perform extensive processing on the returned data, since your code can use variables rather than array references to access the data. The following example demonstrates binding variables to the result set, rather than looping through the row and column values.

```perl
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1};  # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
```
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN32","ExampleUser","password123", $attr);  # Prepare a query to get the content of the table  my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");  $sth->execute();  # Create a set of variables to bind to the column values  my ($C_ID, $C_FP, $C_VARCHAR, $C_DATE, $C_TIME, $C_TS, $C_BOOL);  # Bind the variable references to the columns in the result set  $sth->bind_columns($C_ID, $C_FP, $C_VARCHAR, $C_DATE, $C_TIME, $C_TS, $C_BOOL);  # Now, calling fetch() to get a row of data updates the values of the bound  # variables. Continue calling fetch until it returns undefined  while ($sth->fetch) {  # Note, you should always check that values are defined before using them,  # since NULL values are translated into Perl as undefined. For this  # example, just check the VARCHAR column for undefined values.  if (!defined $C_VARCHAR) {  $C_VARCHAR = "NULL";  }  # Just print values separated by tabs.  print "$C_ID\t$C_FP\t$C_VARCHAR\t$C_DATE\t$C_TIME\t$C_TS\t$C_BOOL\n";  }  $dbh->disconnect();

The output of this example is identical to the output of the previous example.

**Preparing, Querying, and Returning a Single Row**

If you expect a single row as the result of a query (for example, when you execute a `COUNT (*)` query), you can use the DBI module's `selectrow_array` function to combine executing a statement and retrieving an array as a result.

The following example shows using `selectrow_array` to execute and get the results of the `SHOW LOCALE` statement. It also demonstrates changing the locale using the `do` function.

```perl  #!/usr/bin/perl  use strict;  use DBI;  my $attr = {RaiseError => 1};  # Make SQL errors fatal to the Perl script.  # Open a connection using a DSN. Supply the username and password.  my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);  # Demonstrate setting/getting locale.  # Use selectrow_array to combine preparing a statement, executing it, and  # getting an array as a result.  my @localerv = $dbh->selectrow_array("SHOW LOCALE;"');  # The locale name is the 2nd column (array index 1) in the result set.  print "Locale: @localerv[1]\n";  # Use do() to execute a SQL statement to set the locale.  $dbh->do("SET LOCALE TO en_GB");```
The result of running the example is:

```
Locale: en_US@collation=binary (LEN_KBINARY)
Locale is now: en_GB (LEN)
```

### Executing Queries and ResultBufferSize Settings

When you call the `execute()` function on a prepared statement, the client library retrieves results up to the size of the result buffer. The result buffer size is set using ODBC's `ResultBufferSize` setting.

Vertica does not allow multiple active queries per connection. However, you can simulate multiple active queries by setting the result buffer to be large enough to accommodate the entire results from the first query. To ensure that the ODBC client driver's buffer is large enough to store result set for first query you can set `ResultBufferSize` to 0. Setting this parameter to 0 makes the result buffer size unlimited. The ODBC driver allocates enough memory to read the entire result set. With the entire result set from the first query stored in the result set buffer, the database connection is free to perform another query. Your client can execute this second query even though it has not processed the entire result set from the first query.

However, if you set the `ResultBufferSize` to 0, you may find that your calls to `execute()` result in the operating system killing your Perl client script. The operating system may terminate your script if the ODBC driver allocates too much memory to store a large result set.

A workaround for this behavior is limit the number of rows returned by your query. Then you can set the `ResultBufferSize` to a value that accommodates this limited result set. For example, you can estimate the amount of memory needed to store a single row of your query result. Then use the `LIMIT` and `OFFSET` clauses to get a specific number of rows that will fit into the space you allocated using `ResultBufferSize`. If the results of your query is able to fit within the limited result set buffer, you can then perform additional queries with the same database connection. This solution makes your code more complex as you will need to perform multiple queries to get the entire result set. Also, it is not appropriate in cases where you need to operate on an entire result set at once, rather than just a portion of it at a time.
A better solution is to use separate database connections for each query you want to perform. The overhead of the additional database connection is small compared to the resources needed to process large data sets.

## Conversions Between Perl and Vertica Data Types

Perl is a loosely-typed programming language that does not assign specific data types to values. It converts between string and numeric values based on the operations being performed on the values. For this reason, Perl has little problem extracting most string and numeric data types from Vertica. All interval data types (DATE, TIMESTAMP, etc.) are converted to strings. You can use several different date and time handling Perl modules to manipulate these values in your scripts.

Vertica NULL values translate to Perl's undefined (undef) value. When reading data from columns that can contain NULL values, you should always test whether a value is defined before using it.

When inserting data into Vertica, Perl's DBI module attempts to coerce the data into the correct format. By default, it assumes column values are VARCHAR unless it can determine that they are some other data type. If given a string value to insert into a column that has an integer or numeric data type, DBI attempts to convert the string's contents to the correct data type. If the entire string can be converted to a value of the appropriate data type, it inserts the value into the column. If not, inserting the row of data fails.

DBI transparently converts integer values into numeric or float values when inserting into column of FLOAT, NUMERIC, or similar data types. It converts numeric or floating values to integers only when there would be no loss of precision (the value to the right of the decimal point is 0). For example, it can insert the value 3.0 into an INTEGER column since there is no loss of precision when converting the value to an integer. It cannot insert 3.1 into an INTEGER column, since that would result in a loss of precision. It returns an error instead of truncating the value to 3.

The following example demonstrates some of the conversions that the DBI module performs when inserting data into Vertica.

```perl
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash reference that holds a hash of parameters for the # connection.
my $attr = {AutoCommit => 0, # Turn off autocommit
            PrintError => 0, # Turn off print error. Manually handled
};
# Open a connection using a DSN. Supply the username and password.
```
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123", $attr);
if (defined DBI::err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";
# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;\n$dbh->do("CREATE TABLE TEST ( \n   _C_ID INT, \n   _C_FP FLOAT,\n   _C_VARCHAR VARCHAR(100),\n   _C_DATE DATE, _C_TIME TIME,\n   _C_TS TIMESTAMP,\n   _C_BOOL BOOL)\n");
# Populate an array of arrays with values.
my @data = (  # Start with matching data types
    [1,1.111,'Matching datatypes','2001-01-01','01:01:01' ,  
     '2001-01-01 01:01:01','t'],
    # Force floats -> int and int -> float.
    [2.0,2,'Ints <- floats','2002-02-02','02:02:02'  
     , '2002-02-02 02:02:02',1],
    # Float -> int "only" works when there is no loss of precision.
    [3.1,3,'float -> int with trunc?','2003-03-03','03:03:03'  
     , '2003-03-03 03:03:03'],1],
    # String values are converted into numbers
    ["4","4.4","Strings -> numbers","2004-04-04","04:04:04",  
     '2004-04-04 04:04:04'],0],
    # String -> numbers only works if the entire string can be
    # converted into a number
    ['5 and a half","5.5","Strings -> numbers","2005-05-05",  
     '05:05:05', '2005-05-05 05:05:05'],0],
    # Number are converted into string values automatically,
    # assuming they fit into the column width.
    [6,6.6,3.14159, '2006-06-06', '06:06:06',  
     '2006-06-06 06:06:06'],0],
    # There are some variations in the accepted date strings
    [7,7.7,'Date/time formats','07/07/2007','07:07:07',  
     '07-07-2007 07:07:07'],1],
);
# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT into test values(?,?,?,?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {  
    $rowcount++;
    # Insert the row
    my $retval = $sth->execute(@$tuple);
    # See if the row was successfully inserted.
    if ($retval == 1) {
        # Value of 1 means the row was inserted (1 row was affected by insert)
        print "Row $rowcount successfully inserted\n";
    } else {
        print "Inserting row $rowcount failed with error ".  
        $sth->state . " . $sth->errstr . "\n";
    }
}
commit the data
$dbh->commit();
# Prepare a query to get the content of the table
$sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
$sth->execute() or die "Error: ". $dbh->errstr;
my @row; # Need to pre-declare to use in the format statement.
# Use Perl formats to pretty print the output.
format STDOUT_TOP = Int Float VarChar Date Time Timestamp Bool
=== ===== =============== =============== =============== ===============

format STDOUT = @>> @<<<<< @<<<<<<<<<<<<<<<<<<< @<<<<<<<<@<<<<<<<<<<<<<<<<<<< @<<<<

# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
    write; # Format command does the work of extracting the columns from
    # the array.
}
# Commit to stop Perl complaining about in-progress transactions.
$dbh->commit();
$dbh->disconnect();

The example produces the following output when run:

Connection AutoCommit state is: 0
Row 1 successfully inserted
Row 2 successfully inserted
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An error occurred during query execution: Row rejected by server; see server log for details (SQL-01000)
Row 4 successfully inserted
Inserting row 5 failed with error 01000 [Vertica][VerticaDSII] (20) An error occurred during query execution: Row rejected by server; see server log for details (SQL-01000)
Row 6 successfully inserted
Row 7 successfully inserted

Perl Unicode Support

Perl supports Unicode data with some caveats. See the perlunicode and the perlunitut (Perl Unicode tutorial) manual pages for details. (Be sure to see the copies of these manual pages included with the version of Perl installed on your client system, as the support for Unicode has changed in recent versions of Perl.) Perl DBI and DBD::ODBC also support
Unicode, however DBD::ODBC must be compiled with Unicode support. See the DBD::ODBC documentation for details. You can check the DBD::ODBC-specific connection attribute named odbc_has_unicode to see if Unicode support is enabled in the driver.

The following example Perl script demonstrates directly inserting UTF-8 strings into Vertica and then reading them back. The example writes a text file with the output, since there are may problems displaying Unicode characters in terminal windows or consoles.

```perl
#!/usr/bin/perl
use strict;
use DBI;
#
# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr"
}
#
# Output to a file. Displaying Unicode characters to a console or terminal
# window has many problems. This outputs a UTF-8 text file that can
# be handled by many Unicode-aware text editors:
open OUTFILE, ':utf8', "unicodeout.txt";
#
# See if the DBD::ODBC driver was compiled with Unicode support. If this returns
# 1, your Perl script will get get strings from the driver with the UTF-8
# flag set on them, ensuring that Perl handles them correctly.
print OUTFILE "Was DBD::ODBC compiled with Unicode support? ".
   $dbh->{odbc_has_unicode} . "\n";
#
# Create a table to hold VARCHARS
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;" );
#
# Create a table to hold data. Remember that the width of the VARCHAR column
# is the number of bytes set aside to store strings, which often does not equal
# the number of characters it can hold when it comes to Unicode!
$dbh->do("CREATE TABLE test( C VARCHAR VARCHAR(100) )");
print OUTFILE "Inserting data...\n";
#
# Use Do to perform simple inserts
$dbh->do("INSERT INTO test VALUES('Hello')");
#
# This string contains several non-latin accented characters and symbols, encoded
# with Unicode escape notation. They are converted by Perl into UTF-8 characters
$dbh->do("INSERT INTO test VALUES('My favorite band is "
   "\N{U+00BC}\N{U+00E1}\N{U+00F0}t \N{U+00C7}\N{U+00C1}\N{U+00B6}\N{U+00EF}\N{U+00C9}r\N{U+00C4}\N{U+00C3}"").
#
# Some Chinese (Simplified) characters. This again uses escape sequence
# that Perl translates into UTF-8 characters.
$dbh->do("INSERT INTO test VALUES('\x4F60\x597D')");
print OUTFILE "Getting data...\n";
#
# Prepare a query to get the content of the table
my $sth = $dbh->prepare_cached("SELECT * FROM test");
#
# Execute the query by calling execute on the statement handle
$sth->execute();
#
# Loop through result rows while we have them
while (my @row = $sth->fetchrow_array()) {
    # Loop through the column values
    foreach my $column (@row) {
        print OUTFILE "$column\n";
    }
    print OUTFILE "\n"
}
```
close OUTFILE;
$dbh->disconnect();

Viewing the unicodeout.txt file in a UTF-8-capable text editor or viewer displays:

```
Was DBD::ODBC compiled with Unicode support? 1
Inserting data...
Getting data...
My favorite band is Ümläüt Övërkïll ☺
你好
Hello
```

**Note:**
Terminal windows and consoles often have problems properly displaying Unicode characters. That is why the example writes the output to a text file. With some text editors, you may need to manually set the encoding of the text file to UTF-8 in order for the characters to properly appear (and the font used to display text must have a full Unicode character set). If the character still do not show up, it may be that your version of DBD::ODBC was not compiled with UTF-8 support.

**See Also**

- Unicode Character Encoding
- Required ODBC Driver Configuration Settings for Linux and UNIX
Programming PHP Client Applications

You can connect to Vertica through PHP-ODBC using the Unix ODBC or iODBC library.

In order to use PHP with Vertica, you must install the following packages (and their dependencies):

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbc (if you are using the iODBC driver)

PHP on Linux

PHP is available with most Linux operating systems as a module for the Apache web server. Check your particular Linux repository for PHP RPMs or Debian packages. You can also build PHP from source. See the PHP web site for documentation and source downloads.

PHP on Windows

PHP is available for windows for both the Apache and IIS web servers. You can download PHP for Windows and view installation instructions at the PHP web site.

The PHP ODBC Drivers

PHP supports both the UnixODBC drivers and iODBC drivers. Both drivers use PHP's ODBC database abstraction layer.

Setup

You must read Programming ODBC Client Applications before connecting to Vertica through PHP. The following example ODBC configuration entries detail the typical settings required...
for PHP ODBC connections. The driver location assumes you have copied the Vertica drivers to /usr/lib64.

**Example odbc.ini**

```ini
[ODBC Data Sources]
VerticaDSUnixodbc = exampledb
VerticaDNSiodbc = exampledb2

[VerticaDSUnixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
UserName = dbadmin
Password =
Port = 5433

[VerticaDNSiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
UserName = dbadmin
Password =
Port = 5433
```

**Example odbcinst.ini**

```ini
# Vertica
[VerticaDSUnixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so

[VerticaDNSiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so

[ODBC]
Threading = 1
```

**Verify the Vertica UnixODBC or iODBC Library**

Verify the Vertica UnixODBC library can load all dependant libraries with the following command (assuming you have copies the libraries to /usr/lib64):

For example:

```
ldd /usr/lib64/libverticaodbc.so
```
You must resolve any "not found" libraries before continuing.

**Test Your ODBC Connection**

Test your ODBC connection with the following.

```
isql -v VerticaDSN
```

**PHP Unicode Support**

PHP does not offer native Unicode support. PHP only supports a 256-character set. However, PHP provides the UTF-8 functions `utf8_encode()` and `utf8_decode()` to provide some basic Unicode functionality.

See the PHP manual for `strings` for more details about PHP and Unicode.

**Querying the Database Using PHP**

The example script below details the use of PHP ODBC functions to connect to the Vertica Analytics Platform.

```php
<?php

# Turn on error reporting
error_reporting(E_ERROR | E_WARNING | E_PARSE | E_NOTICE);

# A simple function to trap errors from queries
function errortrap_odbc($conn, $sql) {
    if (!$rs = odbc_exec($conn,$sql)) {
        echo "<br/>Failed to execute SQL: $sql<br/>", odbc_errormsg($conn);
    } else {
        echo "<br/>Success: " . $sql;
    }
    return $rs;
}

# Connect to the Database
$dsn = "VerticaDSNunixodbc";
$conn = odbc_connect($dsn, '' , ''); or die("<br/>CONNECTION ERROR");
echo "<p>Connected with DSN: $dsn</p>";

# Create a table
$sql = "CREATE TABLE TEST(
    C_ID INT,
    C_FP FLOAT,
    CVARCHAR VARCHAR(100),
    C_DATE DATE, C_TIME TIME,
    C_TS TIMESTAMP,";
C_BOOL BOOL);  $result = errortrap_odbc($conn, $sql);  # Insert data into the table with a standard SQL statement  $sql = "INSERT into test values(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34 ','1901-01-01 09:00:09','t');";  $result = errortrap_odbc($conn, $sql);  # Insert data into the table with odbc_prepare and odbc_execute  $values = array(2,2.28,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 09:00:09','t');  $statement = odbc_prepare($conn,"INSERT into test values(?,?,?,?,?,?,?)");  if(!$result = odbc_execute($statement, $values)) {    echo "<br/>odbc_execute Failed!";  } else {    echo "<br/>Success: odbc_execute.";  }  # Get the data from the table and display it  $sql = "SELECT * FROM TEST";  if($result = errortrap_odbc($conn, $sql)) {    echo "<pre>";    while($row = odbc_fetch_array($result) ) {      print_r($row);    }    echo "</pre>";  }  # Drop the table and projection  $sql = "DROP TABLE TEST CASCADE";  $result = errortrap_odbc($conn, $sql);  # Close the ODBC connection  odbc_close($conn);

Example Output

The following is the example output from the script.

Managing Query Execution Between the Client and Vertica

The following topics describe techniques that help you manage query execution between your client and your Vertica database.

**ResultBufferSize**

By default, Vertica uses the ResultBufferSize parameter to determine the maximum size (in bytes) of a result set that a client can retrieve from a server. When ResultBufferSize is enabled, Vertica sends rows of data directly to the client making the query. The number of rows returned to the client at each fetch of data depends on the size (in bytes) of the ResultBufferSize parameter.

Sometimes, the size of the result set requested by the client is greater than what the ResultBufferSize parameter allows. In such cases, Vertica retrieves only a portion of the result set at a time. Each fetch of data returns the amount of data equal to the size set by the ResultBufferSize parameter. Ultimately, as the client iterates over the individual fetches of data, the entire result set is returned.

**Benefits of ResultBufferSize**

If you are concerned with the effect of your queries on network latency, ResultBufferSize may provide an advantage over MARS. MARS requires that the client wait until all rows of data are written to the server before the client can retrieve the data. This delay may cause latency issues for your network while waiting for the results to be stored.

In addition, MARS requires that you send two separate requests to return rows of data. The first request performs the query execution which stores the result set on the server. The second request retrieves the data rows that are stored on the server. With
ResultBufferSize, you only need to send one request. This request both executes and retrieves the data rows of interest.

Query Execution with ResultBufferSize

The following graphic shows how Vertica returns rows of data from a database to the client with ResultBufferSize enabled:
The query execution performs the following steps:

1. The client sends a query, such as a `SELECT` statement, to the server. In the preceding graphic, the first query is named Query 1.
2. The server receives the client's request and begins to send both a description of the result set and the requested rows of data back to the client.
3. After all possible rows are returned to the client, the execution is complete. The size of the data set returned equals either that of the data that was requested or the maximum amount of data that ResultBufferSize parameter can retrieve. If the ResultBufferSize maximum size is not yet reached, Vertica can execute Query 2.

The server can accept Query 2 and perform the same steps that it did for Query 1. If the results for Query 1 had reached the maximum ResultBufferSize allowable, Vertica could not execute Query 2 until the client freed the results from Query 1.

After Query 2 runs, you cannot view the results you retrieved for Query 1, unless you execute Query 1 again.

Setting an Unlimited Buffer Size

Setting ResultBufferSize to 0 tells the client driver to use an unlimited result set buffer. With this setting, the client library allocates as much memory as it needs to read the entire result set of a query. You may choose to set ResultBufferSize to 0 if you want to simulate having multiple active queries over a single database connection at the same time. With an unlimited buffer size, your client can run a query and have its entire result set stored in memory. This ends the first query, so your client can execute a second query before it fully processes the results of the first query.

A drawback of this method is that your query may consume too much memory if your queries return large result sets. This over-allocation of memory can result in the operating system terminating your client. Due to this risk, consider using multiple database connections instead of trying to reuse a single connection for multiple queries. The overhead of multiple database connections is small compared to the overall amount of resources required to process a large data set.

Multiple Active Result Sets (MARS)

You can only enable MARS when you connect to Vertica using a JDBC client connection. MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.
MARS is set at the session level and must be enabled for every new session. When MARS is enabled, ResultBufferSize is disabled. No error is returned, however the ResultBufferSize parameter is ignored.

**Benefits of MARS**

In comparison with ResultBufferSize, MARS enables you to store multiple result sets from different queries at the same time. You can also send new queries before all of the results of a previous result set have been returned to the client. This allows applications to decouple query execution from result retrieval so that, on a single connection, you can process different results at the same time.

When you enable ResultBufferSize, you must wait until all result sets have been returned to the client before a new query can be executed.

Another benefit of MARS is that it allows you to free up query resources faster than ResultBufferSize allows. While a query is running, resources are held by that query session. When ResultBufferSize is enabled, a client that is performing slowly might read a single row of a result set and then have to stop to retrieve the next row. This prevents the query from finishing quickly and, therefore, prevents the resources used from being freed up for other applications. With MARS, the speed of the client is irrelevant to the reading of rows. As soon as the results are written to the MARS storage, the resources are freed and the speed at which the client retrieves rows no longer matters.

**Query Execution with MARS**

The following graphic demonstrates how multiple queries to the server are handled when MARS is enabled:
Query 1:

1. Query 1 is sent to the server.
2. Query 1's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.
3. Query 1 completes and its results are saved on the server.
   1. You can now send commands to retrieve the rows of Query 1's result set. These rows are stored on the server. Retrieved rows are sent to the client along with the status of the result set. By keeping track of the status of the result set,
Vertica is able to keep track of which rows have been retrieved from the server.

4. Now that Query 1 has successfully completed, and its result sets are being stored on the server, Query 2 can be executed.

**Query 2:**

1. Query 2 is sent to the server.
2. Query 2's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.
3. Query 2 completes and its results are stored on the server. Both Query 1 and Query 2 now have result sets stored on the server.
4. You can now send retrieval requests to both Query 1 and Query 2's result sets that are stored on the server. Whenever a retrieval request is made for rows from Query 1, the request is sent and rows and the result set status are sent to the client. The same occurs for Query 2.

Once all rows have been read by the client, the MARS storage on the server closes the active results session. The MARS storage on the server is then freed to store more data. The MARS storage also closes and frees once your session is finished.

**Enabling and Disabling MARS**

You can enable and disable MARS in two different ways:

1. To enable MARS using the JDBC client connection properties, see [JDBC Connection Properties](#).
2. To enable MARS using the SET SESSION command, see [SET SESSION MULTIPLEACTIVERESULTSETS](#).

**Management API**

The Management API is a REST API that you can use to view and manage Vertica databases with scripts or applications that accept REST and JSON. The response format for all requests is JSON.
**cURL**

cURL is a command-line tool and application library used to transfer data to or from a server. It uses URL syntax, such as HTTP and HTTPS. All API requests sent to a Vertica server must be made using HTTPS. A request made using HTTP will fail.

There are four HTTP requests that can be passed using cURL to call API methods:

<table>
<thead>
<tr>
<th>Request</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>Retrieves data.</td>
</tr>
<tr>
<td>PUT</td>
<td>Updates data.</td>
</tr>
<tr>
<td>POST</td>
<td>Creates new data.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Deletes data.</td>
</tr>
</tbody>
</table>

**Syntax**

curl https://<NODE>:5444/

**Options**

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h --help</td>
<td>Lists all available command-line options.</td>
</tr>
<tr>
<td>-H --header</td>
<td>Allows you to use custom headers in your command. This is useful for sending a request that requires a VerticaAPIKEY.</td>
</tr>
<tr>
<td></td>
<td>curl -H &quot;VerticaApiKey: ValidAPIKey&quot; https://&lt;NODE&gt;:5444/</td>
</tr>
<tr>
<td>-k --insecure</td>
<td>Allows SSL connections without certificate validation.</td>
</tr>
<tr>
<td></td>
<td>curl -k https://&lt;NODE&gt;:5444/</td>
</tr>
<tr>
<td>-X --request</td>
<td>Specifies the custom request used when communicating with a server.</td>
</tr>
</tbody>
</table>

curl -X REQUEST https://<NODE>:5444/

Can be one of the following values:

- GET
- PUT
- POST
- DELETE

**Note:**
If no request is specified, cURL automatically defaults to the GET request.

There are many more options available to add to your cURL query. For a comprehensive list with descriptions, visit the cURL Documentation Website.

## General API Information

These API calls can interact with either standard Vertica nodes or Management Console nodes.

<table>
<thead>
<tr>
<th>GET /</th>
<th>Returns the agent-specific information useful for version checking and service discovery.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET api</td>
<td>Returns a list of api objects and properties.</td>
</tr>
</tbody>
</table>
GET /

Returns API version information and a list of links to child resources for the Management API.

Resource URL

https://<NODE>:5444/

Authentication

Not required.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/ |

Response:

```json
{
  "body": {
    "mime-types": [
      "default",
      "application/vertica.database.configuration.json-v2",
      "application/json",
      "application/vertica.nodes.json-v2",
      "default",
      "application/json",
      "default",
      "application/vertica.hosts.json-v2",
      "application/vertica.jobs.json-v2",
      "default",
      "application/vertica.hosts.json-v2",
    ]
  }
}
```
GET api

Displays a list of all Management API commands and a brief description for each command. You can also access an HTML version of this information at https://<NODE>:5444/api.html. Replace <NODE> with the URL of a cluster node.

Resource URL

https://<NODE>:5444/api

Authentication

Not required.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/api |

Response:

## Rest APIs for the Agent

These API calls interact with standard Vertica nodes.

### Backup and Restore

<table>
<thead>
<tr>
<th>Method</th>
<th>Endpoint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>backups</td>
<td>Returns all the backups that have been created for all vbr configuration files ( *.ini ) that are located in the /opt/vertica/config directory.</td>
</tr>
<tr>
<td>POST</td>
<td>backups/:config_script_base</td>
<td>Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).</td>
</tr>
<tr>
<td>GET</td>
<td>backups/:config_script_base/:archive_id</td>
<td>Returns details for a specific backup archive.</td>
</tr>
<tr>
<td>POST</td>
<td>restore/:archive_id</td>
<td>Restores a backup.</td>
</tr>
</tbody>
</table>

### Databases

<table>
<thead>
<tr>
<th>Method</th>
<th>Endpoint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>databases</td>
<td>Returns a list of databases, their properties, and current status.</td>
</tr>
<tr>
<td>POST</td>
<td>databases</td>
<td>Creates a new database by supplying a valid set of parameters.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name</td>
<td>Returns details about a specific database.</td>
</tr>
<tr>
<td>PUT</td>
<td>databases/:database_name</td>
<td>Starts, stops, rebalances, or runs Workload Analyzer on a database.</td>
</tr>
<tr>
<td>DELETE</td>
<td>databases/:database_name</td>
<td>Deletes an existing database.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/configuration</td>
<td>Returns the current configuration parameters from the database.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>PUT databases/:database_name/configuration</td>
<td>Sets one or more configuration parameters in the database.</td>
<td></td>
</tr>
<tr>
<td>GET databases/:database_name/hosts</td>
<td>Returns hosts details for a specific database.</td>
<td></td>
</tr>
<tr>
<td>POST databases/:database_name/hosts</td>
<td>Adds a new host to the database.</td>
<td></td>
</tr>
<tr>
<td>DELETE databases/:database_name/hosts/:host_id</td>
<td>Removes a host from the database.</td>
<td></td>
</tr>
<tr>
<td>POST databases/:database_name/hosts/:host_id/process</td>
<td>Starts the database process on a specific host.</td>
<td></td>
</tr>
<tr>
<td>DELETE databases/:database_name/hosts/:host_id/process</td>
<td>Stops the database on a specific host.</td>
<td></td>
</tr>
<tr>
<td>POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new</td>
<td>Replaces a host with a standby host in the database.</td>
<td></td>
</tr>
<tr>
<td>GET databases/:database_name/license</td>
<td>Returns the Vertica license that the specified database is using.</td>
<td></td>
</tr>
<tr>
<td>PUT databases/:database_name/license</td>
<td>Upgrades the license in the database.</td>
<td></td>
</tr>
<tr>
<td>GET databases/:database_name/licenses</td>
<td>Returns all the feature licenses that the specified database is using.</td>
<td></td>
</tr>
<tr>
<td>GET databases/:database_name/nodes</td>
<td>Returns a list of nodes for the specified database.</td>
<td></td>
</tr>
<tr>
<td>GET databases/:database_name/nodes/:node_id</td>
<td>Returns details on a specific node for the specified database.</td>
<td></td>
</tr>
<tr>
<td>POST databases/:database_name/process</td>
<td>Starts the specified database.</td>
<td></td>
</tr>
<tr>
<td>GET databases/:database_name/process</td>
<td>Returns the state of the database as either UP or DOWN.</td>
<td></td>
</tr>
<tr>
<td>DELETE databases/:database_name/process</td>
<td>Stops the specified database on all hosts.</td>
<td></td>
</tr>
<tr>
<td>POST databases/:database_name/rebalance/process</td>
<td>Rebalances the specified database. This option can have a long run time.</td>
<td></td>
</tr>
<tr>
<td>POST databases/:database_name/Workload Analyzer/process</td>
<td>Runs the analyze workload action against the specified database. This option can have a long run time.</td>
<td></td>
</tr>
</tbody>
</table>

**Hosts**

| GET hosts | Returns a list of hosts in this cluster. |
| GET hosts/:hostid | Returns details for a specific host in this cluster. |

**Jobs**

| GET jobs | Returns a list of jobs the agent is tracking, along with their current status and exit codes. |
| GET jobs/:id | Returns the details (the saved output) for a specific job. |

**Licenses**

| POST licenses | Uploads and applies a new license to this cluster. |
| GET licenses | Returns the license field that databases created on this cluster use. |

**Nodes**

| GET nodes | Returns a list of nodes in this cluster. |
| GET nodes/:nodeid | Returns details for a specific node in this cluster. |
## Webhooks

<table>
<thead>
<tr>
<th>Method</th>
<th>Endpoint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>webhooks</td>
<td>Returns a list of active webhooks.</td>
</tr>
<tr>
<td>POST</td>
<td>webhooks/subscribe</td>
<td>Creates a new webhook.</td>
</tr>
<tr>
<td>DELETE</td>
<td>webhooks/:subscriber_id</td>
<td>Deletes an existing webhook.</td>
</tr>
</tbody>
</table>
VerticaAPIKey

The Management API requires an authentication key, named VerticaAPIKEY, to access some API resources. You can manage API keys by using the apikeymgr command-line tool.

API key management tool

optional arguments:
  -h, --help          show this help message and exit
  --user REQUESTOR    The name of the person requesting the key
  --app APPLICATION   The name of the application that will use the key
  --delete            Delete the key for the given R & A
  --create            Create a key for the given R & A
  --update            Update a key for the given R & A
  --migrate           migrate the keyset to the latest format
  --secure {restricted,normal,admin} Set the keys security level
  --list              List all the keys known

Example Request

To create a new VerticaAPIKEY for the dbadmin user with admin access, enter the following:

$ apikeymgr --user dbadmin --app vertica --create --secure admin

Response:

Requestor : dbadmin
Application: vertica
API Key    : ValidAPIKey
Synchronizing cluster...

Backup and Restore

You can use these API calls to perform backup and restore tasks for your database.

| GET backups | Returns all the backups that have been created for all vbr configuration files ( *.ini ) that are located in the |
/opt/vertica/config directory.

<table>
<thead>
<tr>
<th>Request Method</th>
<th>URI Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST</td>
<td>backups/:config_script_base</td>
<td>Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).</td>
</tr>
<tr>
<td>GET</td>
<td>backups/:config_script_base/:archive_id</td>
<td>Returns details for a specific backup archive.</td>
</tr>
<tr>
<td>POST</td>
<td>restore/:archive_id</td>
<td>Restores a backup.</td>
</tr>
</tbody>
</table>
GET backups

Returns a list of all backups created for vbr configuration (*.ini) files that reside in /opt/vertica/config and provides details about each backup.

Resource URL

https://<NODE>:5444/backups

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

```
GET https://<NODE>:5444/backups
```

Response:

```
[{
   "backups": [
      {
         "backup": "backup3_20140707_114852",
         "epoch": "61",
         "hosts": "v_vmart_node0001(10.20.100.247)",
         "objects": ""
      },
      "config_file": "/opt/vertica/config/backup3.ini",
      "num_backups": 1
   }
}
```
{  
  "backup": "backup_20140707_113737",
  "epoch": "61",
  "hosts": "v_vmart_node0001(10.20.100.247)",
  "objects": ""
},
{  
  "backup": "backup_archive20140707_113645",
  "epoch": "60",
  "hosts": "v_vmart_node0001(10.20.100.247)",
  "objects": ""
}
"config_file": "/opt/vertica/config/backup.ini",
"num_backups": 2
}
**POST backups/:config_script_base**

Creates a new backup job for the backup defined in the vbr configuration script `:config_script_base`. The vbr configuration script must reside in `/opt/vertica/configuration`. The `:config_script_base` value does not include the `.ini` filename extension.

To determine valid `:config_script_base` values, see [GET backups](#).

Returns a job ID that you can use to determine the status of the job.

### Resource URL

https://<NODE>:5444/backups/:config_script_base

### Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

### Parameters

None.

### Example Request

| POST          | https://<NODE>:5444/backups/backup3 |

**Response:**

```
{
   "id": "CreateBackup-VMart-1404750602.03",
   "url": "/jobs/CreateBackup-VMart-1404750602.03"
}
```
GET backups/:config_script_base/:archive_id

Returns details on a specific backup. You must provide the :config_script_base. This value is the name of a vbr config file (without the .ini filename extension) that resides in /opt/vertica/config. The :archive_id is the value of the backup field that the GET backups command returns.

Resource URL

https://<NODE>:5444/backups/:config_script_base/:archive_id

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/backups/backup3/backup3_20140707_123254 |

Response:

```
{
    "backup": "backup3_20140707_123254",
    "config_file": "/opt/vertica/config/backup3.ini",
    "epoch": "62",
    "hosts": "v_vmart_node0001(10.20.100.247)",
    "objects": ""
}
```
**POST restore/:archive_id**

Creates a new restore job to restore the database from the backup archive identified by :archive_id. The :archive_id is the value of a `backup` field that the `GET backups` command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

**Resource URL**

`https://<NODE>:5444/restore/:archive_id`

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| POST  | `https://<NODE>:5444/restore/backup3_20140707_132904` |

**Response:**

```json
{
  "id": "RestoreBackup-VMart-1404760113.71",
  "url": "/jobs/RestoreBackup-VMart-1404760113.71"
}
```

**Databases**

You can use these API calls to interact with your database.
<table>
<thead>
<tr>
<th>HTTP Method</th>
<th>Path</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>databases</td>
<td>Returns a list of databases, their properties, and current status.</td>
</tr>
<tr>
<td>POST</td>
<td>databases</td>
<td>Creates a new database by supplying a valid set of parameters.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name</td>
<td>Returns details about a specific database.</td>

<td>databases/:database_name/nodes</td>
<td>Returns a list of nodes for the specified database.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/nodes/:node_id</td>
<td>Returns details on a specific node for the specified database.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/process</td>
<td>Starts the specified database.</td>
</tr>
<tr>
<td>GET</td>
<td>databases/:database_name/process</td>
<td>Returns the state of the database as either UP or DOWN.</td>
</tr>
<tr>
<td>DELETE</td>
<td>databases/:database_name/process</td>
<td>Stops the specified database on all hosts.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/rebalance/process</td>
<td>Rebalances the specified database. This option can have a long run time.</td>
</tr>
<tr>
<td>POST</td>
<td>databases/:database_name/Workload Analyzer/process</td>
<td>Runs the analyze workload action against the specified database. This option can have a long run time.</td>
</tr>
</tbody>
</table>
**GET databases**

Returns a list of databases, their current status, and database properties.

**Resource URL**

https://<NODE>:5444/databases

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| GET | https://<NODE>:5444/databases |

An example of the full request using cURL:

```bash
curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/databases
```

**Response:**

```json
{
    "body": [
        {
            "href": "/databases/VMart",
            "mime-type": [
                "application/vertica.database.json-v2"
            ],
            "name": "VMart",
            "port": "5433",
            "status": "UP"
        }
    ]
}
```
{  "href": "/databases/testDB",
  "mime-type": [
    "application/vertica.database.json-v2"
  ],
  "name": "testDB",
  "port": "5433",
  "status": "DOWN"
}

,

"href": "/databases",
"links": [
  "/:database_name"
],
"mime-type": "application/vertica.databases.json-v2"
}
**POST databases**

Creates a job to create a new database with the provided parameters.

```
Important:
You must stop any running databases on the nodes on which you want to create the new database. If you do not, database creation fails.
```

Returns a job ID that can be used to determine the status of the job. See [GET jobs](#).

**Resource URL**

```
https://<NODE>:5444/database
```

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the database to create.</td>
</tr>
<tr>
<td>passwd</td>
<td>Password for the new database.</td>
</tr>
<tr>
<td>only</td>
<td>Optional list of hostnames to include in the database. By default, all nodes in the cluster are added to the database.</td>
</tr>
<tr>
<td>exclude</td>
<td>Optional list of hostnames to exclude from the database.</td>
</tr>
<tr>
<td>catalog</td>
<td>Path of the catalog directory.</td>
</tr>
<tr>
<td>data</td>
<td>Path of the data directory.</td>
</tr>
<tr>
<td>port</td>
<td>Port where the database listens for client connections. Default is 5433.</td>
</tr>
</tbody>
</table>
Example Request

<table>
<thead>
<tr>
<th>POST</th>
</tr>
</thead>
</table>

Response:

```json
{
    "userid": "dbadmin"
}
```
**GET databases/:database_name**

Returns details about a specific database. The :database_name is the value of the name field that the GET databases command returns.

**Resource URL**

https://<NODE>:5444/databases/:database_name

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| GET | https://<NODE>:5444/databases/VMart |

Response:

```json
{
    "body": {
        "database_id": "VMart",
        "id": "VMart",
        "nodes": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003",
        "nodes_new": [
            {
                "catalog_base": "/home/dbadmin",
                "data_base": "/home/dbadmin",
                "host": "10.20.100.247",
                "id": "v_vmart_node0001"
            },
            {
                "catalog_base": "/home/dbadmin",
                "data_base": "/home/dbadmin",
```
"host": "10.20.100.248",
"id": "v_vmart_node0002"
},
{
  "catalog_base": "/home/dbadmin",
  "data_base": "/home/dbadmin",
  "host": "10.20.100.249",
  "id": "v_vmart_node0003"
}
],
"path": "/home/dbadmin/VMart",
"port": "5433",
"restartpolicy": "kSafe",
"status": "UP"
}
"href": "/databases/VMart",
"links": [
  "/configuration",
  "/hosts",
  "/license",
  "/nodes",
  "/process",
  "/rebalance/process",
  "/status",
  "/Workload Analyzer/process"
],
"mime-type": "application/vertica.database.json-v2"}
**PUT** databases/:database_name

Creates a job to run the action specified by the `action` parameter against the database identified by `:database_name`. The `:database_name` is the value of the `name` field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

**Resource URL**

https://<NODE>:5444/databases/:database_name

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have normal level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>user_id</th>
<th>A database username.</th>
</tr>
</thead>
<tbody>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
<tr>
<td>action</td>
<td>Can be one of the following values:</td>
</tr>
<tr>
<td></td>
<td>start — Start the database.</td>
</tr>
<tr>
<td></td>
<td>stop — Stop the database.</td>
</tr>
<tr>
<td></td>
<td>rebalance — Rebalance the database.</td>
</tr>
<tr>
<td></td>
<td>Workload Analyzer — Run Work Load Analyzer against the database.</td>
</tr>
</tbody>
</table>

**Example Request**

```plaintext
PUT https://<NODE>:5444/databases/testDB?user_id=dbadmin"&"passwd=vertica"&"action=stop
```

**Response:**
Vertica Documentation
Connecting to Vertica

```json
{
    "id": "StopDatabase-testDB-2014-07-20 13:28:49.321744",
    "url": "/jobs/StopDatabase-testDB-2014-07-20 13:28:49.321744"
}
```
**DELETE databases/:database_name**

Creates a job to delete (drop) an existing database on the cluster. To perform this operation, you must first stop the database. The :database_name is the value of the name field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](#).

**Resource URL**

https://<NODE>:5444/databases/:database_name

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

**Parameters**

None.

**Example Request**

```
DELETE
https://<NODE>:5444/databases/TestDB
```

**Response:**

```
{
   "id": "DropDatabase-TestDB-2014-07-18 12:50:33.332383",
   "url": "/jobs/DropDatabase-TestDB-2014-07-18 12:50:33.332383"
}
```
**GET databases/:database_name/configuration**

Returns a list of configuration parameters for the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

**Resource URL**

https://<NODE>:5444/databases/:database_name/configuration

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
</tbody>
</table>

**Example Request**

| GET       | https://<NODE>:5444/databases/testDB/configuration |

**Response:**

This API call returns over 100 configuration parameters. The following response is a small subset of the total amount returned.

```json
[
  {
    "catalog_value": "1",
    "changeRequiresRestart": "f",

**PUT databases/:database_name/configuration**

Sets one or more configuration parameters for the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

Returns the parameter name, the requested value, and the result of the attempted change (Success or Failed).

**Resource URL**

https://<NODE>:5444/databases/:database_name/configuration

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
<tr>
<td>parameter_name</td>
<td>A parameter name and value combination for the parameter to be changed. Values must be URL encoded. You can include multiple name/value pairs to set multiple parameters with a single API call.</td>
</tr>
</tbody>
</table>

**Example Request**

```
PUT https://<NODE>:5444/databases/testDB/configuration?user_id=dbadmin"&"passwd=vertica"&"JavaBinaryForUDx=%2Fusr%2Fbin%2Fjava"&"TransactionIsolationLevel=SERIALIZABLE
```

**Response:**
[ 
  {
    "key": "JavaBinaryForUDx",
    "result": "Success",
    "value": "/usr/bin/java"
  },

  {
    "key": "TransactionIsolationLevel",
    "result": "Success",
    "value": "SERIALIZABLE"
  }
]
**GET databases/:database_name/hosts**

Returns the hostname/IP address, node name, and UP/DOWN status of each host associated with the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

**Resource URL**

https://<NODE>:5444/databases/:database_name/hosts

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| GET                         | https://<NODE>:5444/databases/VMart/hosts |

**Response:**

```json
{
  "body": [
    {
      "hostname": "10.20.100.247",
      "nodename": "v_vmart_node0001",
      "status": "UP",
    },
    {
      "hostname": "10.20.100.248",
      "nodename": "v_vmart_node0002",
      "status": "UP",
      "ts": "2014-07-18T13:12:31.904209"
    }
  ]
}
```

```json
{
   "hostname": "10.20.100.249",
   "nodename": "v_vmart_node0003",
   "status": "UP",
}
```

**POST databases/:database_name/hosts**

Creates a job to add a host to the database identified by :database_name. This host must already be part of the cluster. The :database_name is the value of the name field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

**Resource URL**

https://<NODE>:5444//:database_name/hosts

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
<tr>
<td>hostname</td>
<td>The hostname to add to the database. This host must already be part of the cluster.</td>
</tr>
</tbody>
</table>

**Example Request**

<table>
<thead>
<tr>
<th>Method</th>
<th>URL</th>
</tr>
</thead>
</table>

**Response:**

```json
{
    "id": "AddHostToDatabase-testDB-2014-07-20 12:24:04.088812",
```
DELETE databases/:database_name/hosts/:host_id

Creates a job to remove the host identified by :host_id from the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns. The :host_id is the value of the host field returned by GET databases:/database_name.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

https://<NODE>:5444/databases/:database_name/hosts/:host_id

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have admin level security.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
</tbody>
</table>

Example Request

<table>
<thead>
<tr>
<th>Method</th>
<th>URL</th>
<th>Request</th>
</tr>
</thead>
</table>

Response:

```json
{
    "id": "RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235",
    "url": "jobs/RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235"
}
```
**POST databases/:database_name/hosts/:host_id/process**

Creates a job to start the vertica process for the database identified by :database_name on the host identified by :host_id. The :database_name is the value of the name field that the GET databases command returns. The :host_id is the value of the host field returned by GET databases/:database_name.

Returns a job ID that you can use to determine the status of the job. See [GET jobs](https://<NODE>:5444/)

**Resource URL**

https://<NODE>:5444/:database_name/hosts/:host_id/process

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

**Response:**

```json
{
    "id": "StartDatabase-testDB-2014-07-20 13:14:03.968340",
    "url": "jobs/StartDatabase-testDB-2014-07-20 13:14:03.968340"
}
```
**GET databases/:database_name/license**

Returns details about the database license being used by the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

**Resource URL**

```
https://<NODE>:5444/:database_name/license
```

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
</tbody>
</table>

**Example Request**

```
GET https://<NODE>:5444/VMart/license
```

**Response:**

```json
{
   "body": {
      "details": {
         "assigned_to": "Vertica Systems, Inc.",
         "grace_period": 0,

}
},
"href": "/databases/VMart/license",
"links": [],
"mime-type": "application/vertica.license.json-v2"}
**GET databases/:database_name/licenses**

Returns details about all license being used by the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

**Resource URL**

https://<NODE>:5444/:database_name/licenses

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>The password for the username.</td>

"mime-type": "application/vertica.features.json-v2"}
**DELETE databases/:database_name/hosts/:host_id/process**

Creates a job to stop the vertica process for the database identified by :database_name on the host identified by :host_id. The :database_name is the value of the name field that the GET databases command returns. The :host_id is the value of the host field returned by GET databases/:database_name.

Returns a job ID that can be used to determine the status of the job. See [GET jobs](https://<NODE>:5444/databases/:database_name/hosts/:host_id/process).

**Note:**
If stopping the database on the hosts causes the database to no longer be k-safe, then the all database nodes may shut down.

**Resource URL**

https://<NODE>:5444/databases/:database_name/hosts/:host_id/process

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

DELETE

<table>
<thead>
<tr>
<th>DELETE</th>
</tr>
</thead>
</table>

Response:

```
{
  "id": "StopDatabase-testDB-2014-07-20 13:02:08.453547",
  "url": "/jobs/StopDatabase-testDB-2014-07-20 13:02:08.453547"
}
```
**POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new**

Creates a job to replace the host identified by `hosts/:host_id` with the host identified by `replace_with/:host_id`. Vertica performs these operations for the database identified by `:database_name`. The `:database_name` is the value of the `name` field that the `GET databases` command returns. The `:host_id` is the value of the `host` field as returned by `GET databases/:database_name`. You can find valid replacement hosts using `GET hosts`. The replacement host cannot already be part of the database. You must stop the vertica process on the host being replaced.

**Resource URL**

```
https://<NODE>:5444/databases/:database_name/hosts/:host_id/replace_with/:host_id_new
```

**Authentication**

The API key must have `admin` level security.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
</tbody>
</table>

**Example Request**

```
```

**Response:**
**GET databases/:database_name/nodes**

Returns a comma-separated list of node IDs for the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

**Resource URL**

https://<NODE>:5444/:database_name/nodes

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

**Parameters**

None.

**Example Request**

| GET  | https://<NODE>:5444/VMart/nodes |

**Response:**

```
[
  {
    "database_id": "VMart",
    "node_id": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003",
    "status": "Unknown"
  }
]
```
**GET databases/:database_name/nodes/:node_id**

Returns details about the node identified by :node_id. The :node_id is one of the node IDs returned by [GET databases/:database_name/nodes](#).

### Resource URL

```
https://<NODE>:5444/:database_name/nodes/:node_id
```

### Authentication

Requires a [VerticaAPIKey](#) in the request header.

The API key must have **restricted** level security or higher.

### Parameters

None.

### Example Request

| GET | https://<NODE>:5444/databases/VMart/nodes/v_vmart_node0001 |

### Response:

```
{
  "db": "VMart",
  "host": "10.20.100.247",
  "name": "v_vmart_node0001",
  "state": "up"
}
```
**POST databases/:database_name/process**

Creates a job to start the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

Returns a job ID that can be used to determine the status of the job. See GET jobs.

**Resource URL**

https://<NODE>:5444/databases/:database_name/process

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>epoch</td>
<td>Start the database from this epoch.</td>
</tr>
<tr>
<td>include</td>
<td>Include only these hosts when starting the database. Use a comma-separated list of hostnames.</td>
</tr>
</tbody>
</table>

**Example Request**

<table>
<thead>
<tr>
<th>Method</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST</td>
<td>https://&lt;NODE&gt;:5444/databases/:testDB/process</td>
</tr>
</tbody>
</table>

An example of the full request using cURL:

```
curl -X POST -H "VerticaApikey: ValidAPIKey" https://<NODE>:5444/:testDB/process
```

**Response:**

```
{
  "id": "StartDatabase-testDB-2014-07-20 12:41:46.061408",
```

Vertica Analytic Database (9.3.x)
## GET databases/:database_name/process

Returns a state of UP or DOWN for the database identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

### Resource URL

https://<NODE>:5444/databases/:database_name/process

### Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

### Parameters

None.

### Example Request

| GET | https://<NODE>:5444/databases/VMart/process |

Response:

```json
{
  "state": "UP"
}
```
**DELETE databases/:database_name/process**

Creates a job to stop the database identified by :database_name. The :database_name is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

**Resource URL**

https://<NODE>:5444/databases/:database_name/process

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have *restricted* level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>user_id</th>
<th>A database username.</th>
</tr>
</thead>
<tbody>
<tr>
<td>passwd</td>
<td>The password for the username.</td>
</tr>
</tbody>
</table>

**Example Request**

An example of the full request using cURL:

```bash
```

**Response:**

```
{
"id": "StopDatabase-testDB-2014-07-20 12:46:04.406637",
```
"url": "/jobs/StopDatabase-testDB-2014-07-20 12:46:04.406637"
**POST databases/:database_name/rebalance/process**

Creates a job to run a rebalance on the database identified by host identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

**Resource URL**

https://<NODE>:5444/databases/:database_name/rebalance/process

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
</tbody>
</table>

**Example Request**

<table>
<thead>
<tr>
<th>Request Method</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST</td>
<td>https://&lt;NODE&gt;:5444/databases/testDB/rebalance/process</td>
</tr>
</tbody>
</table>

**Response:**

```
{
    "id": "RebalanceData-testDB-2014-07-20 21:42:45.731038",
    "url": "/jobs/RebalanceData-testDB-2014-07-20 21:42:45.731038"
}
```
**POST databases/:database_name/Workload Analyzer/process**

Creates a job to run Workload Analyzer on the database identified by host identified by :database_name. The :database_name is the value of the name field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

**Resource URL**

https://<NODE>:5444/databases/:database_name/Workload Analyzer/process

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>A database username.</td>
</tr>
<tr>
<td>passwd</td>
<td>A password for the username.</td>
</tr>
</tbody>
</table>

**Example Request**

```
POST https://<NODE>:5444/databases/testDB/Workload Analyzer/process
```

**Response:**

```json
{
}
```
Hosts

You can use these API calls to get information on the hosts in your cluster.

<table>
<thead>
<tr>
<th>API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET hosts</td>
<td>Returns a list of hosts in this cluster.</td>
</tr>
<tr>
<td>GET hosts/:hostid</td>
<td>Returns details for a specific host in this cluster.</td>
</tr>
</tbody>
</table>
**GET hosts**

Returns a list of the hosts in the cluster and the hardware, software, and network details about each host.

**Resource URL**

https://<NODE>:5444/hosts

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| GET | https://<NODE>:5444/hosts |

**Response:**

```json

Vertica Analytic Database (9.3.x)  Page 5187 of 6246
**GET hosts/:hostid**

Returns hardware, software, and network details about the host identified by :host_id. You can find :host_id for each host using GET hosts.

**Resource URL**

https://<NODE>:5444/hosts/:hostid

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| GET               | https://<NODE>:5444/hosts/:10.20.100.247 |

**Response:**

```json
{
    "body": {
        "cpu_info": {
            "cpu_type": "Intel(R) Xeon(R) CPU E5-2695 v2 @ 2.40GHz",

                "name": "eth0",
                "netmask": "255.255.255.0",
                "speed": "unknown"
            }
        ]
    }
}
```
Jobs

You can use these API calls to get information on your database's jobs.

<table>
<thead>
<tr>
<th>GET jobs</th>
<th>Returns a list of jobs the agent is tracking, along with their current status and exit codes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET jobs/:id</td>
<td>Returns the details (the saved output) for a specific job.</td>
</tr>
</tbody>
</table>
**GET jobs**

Returns a list of jobs being tracked by the agent and job details.

Jobs always start immediately. The `is_running` field is a Boolean value. If `is_running` is false, then the job is complete.

The `exit_code` details the status of the job. The `exit_code` is different for certain types of jobs:

- For Backup jobs:
  - 0 indicates success.
  - Any other number indicates a failure.
- For all other jobs:
  - -9 indicates success.
  - Any other number indicates a failure.

You can see details about failures in `/opt/vertica/log/agentStdMsg.log`.

**Resource URL**

https://<NODE>:5444/jobs

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| GET   | https://<NODE>:5444/jobs |
Response:

```json
{
    "body": [
        {
            "exit_code": 0,
            "id": "CreateBackup-VMart-1405012447.75",
            "is_running": false,
            "status": "unused",
            "ts": "1405012461.18"
        },
        {
            "exit_code": 1,
            "id": "CreateBackup-VMart-1405012454.88",
            "is_running": false,
            "status": "unused",
            "ts": "1405012455.18"
        }
    ],
    "href": "/jobs",
    "links": [
        "/:jobid"
    ],
    "mime-type": "application/vertica.jobs.json-v2"
}
```
**GET jobs/:id**

Gets the details for a specific job with the provided :id. You can determine the list of job :ids using **GET jobs**.

Details for a specific job are the same as the details provided for all jobs by **GET jobs**.

**Note:**
You must URL encode the :id as some IDs may contain spaces or other special characters.

**Resource URL**

https://<NODE>:5444/jobs/:id

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| GET | https://<NODE>:5444/jobs/CreateBackup-VMart-1405012454.88 |

**Licenses**

You can use these API calls to manage licenses for your database.
<table>
<thead>
<tr>
<th><strong>POST licenses</strong></th>
<th>Uploads and applies a new license to this cluster.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>GET licenses</strong></td>
<td>Returns the license field that databases created on this cluster use.</td>
</tr>
</tbody>
</table>
**POST licenses**

Uploads and applies a license file to this cluster.

You must provide the license file as an HTTP POST form upload, identified by the name `license`. For example, you can use cURL:

```
curl -k --request POST -H "VerticaApiKey:ValidAPIKey" \\ https://v_vmart_node0001:5444/licenses --form "license=@vlicense.dat"
```

**Resource URL**

https://<NODE>:5444/licenses

**Authentication**

Requires a `VerticaApiKey` in the request header.

The API key must have `admin` level security.

**Parameters**

None.

**Example Request**

| POST   | https://<NODE>:5444/licenses |

**Response:**

There is no HTTP body response for successful uploads. A successful upload returns an HTTP 200/OK header.
GET licenses

Returns any license files that are used by this cluster when creating databases. License files must reside in /opt/vertica/config/share.

Resource URL

https://<NODE>:5444/licenses

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

| GET | https://<NODE>:5444/licenses |

Response:

```json
{
    "body": [
        {
            "comment": "Vertica license is valid",
            "end": "Perpetual",
            "grace": "0",
            "size": "1TB CE Nodes 3",
            "start": "2011-11-22",
            "status": true,
            "vendor": "Vertica Community Edition"
        }
    ],
    "href": "/license",
    "links": [],
    "mime-type": "application/vertica.license.json-v2"
}
```
Nodes

You can use these API calls to retrieve information on the nodes in your cluster.

<table>
<thead>
<tr>
<th>GET nodes</th>
<th>Returns a list of nodes in this cluster.</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET nodes/:nodeid</td>
<td>Returns details for a specific node in this cluster.</td>
</tr>
</tbody>
</table>
**GET nodes**

Returns a list of nodes associated with this cluster.

**Resource URL**

https://<NODE>:5444/nodes

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have *restricted* level security or higher.

**Parameters**

None.

**Example Request**

| GET    | https://<NODE>:5444/nodes |

**Response:**

```json
{
  "body": [
    "node0001",
    "node0002",
    "node0003",
    "v_testdb_node0001",
    "v_testdb_node0002",
    "v_testdb_node0003",
    "v_vmart_node0001",
    "v_vmart_node0002",
    "v_vmart_node0003"
  ],
  "href": "/nodes",
  "links": [
    "/:nodeid"
  ]
}
```
"mime-type": "application/vertica.nodes.json-v2"
**GET nodes/:nodeid**

Returns details about the node identified by :node_id. You can find the :node_id for each node using **GET nodes**.

In the body field, the following information is detailed in comma-separated format:

- Node Name
- Host Address
- Catalog Directory
- Data Directory

**Resource URL**

https://<NODE>:5444/nodes/:node_id

**Authentication**

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

**Parameters**

None.

**Example Request**

| GET | https://<NODE>:5444/nodes/v_smart_node0001 |

**Response:**

```json
{
    "body": [
        "v_smart_node0001",
        "10.20.100.247,/home/dbadmin,/home/dbadmin"
    ],
    "href": "/nodes/v_smart_node0001",
```
Webhooks

You can use these API calls to obtain information on, create, or delete webhooks.

<table>
<thead>
<tr>
<th>Method</th>
<th>Endpoint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>webhooks</td>
<td>Returns a list of active webhooks.</td>
</tr>
<tr>
<td>POST</td>
<td>webhooks/subscribe</td>
<td>Creates a new webhook.</td>
</tr>
<tr>
<td>DELETE</td>
<td>webhooks/:subscriber_id</td>
<td>Deletes an existing webhook.</td>
</tr>
</tbody>
</table>
**GET webhooks**

Returns a list of active webhooks for this cluster.

**Resource URL**

https://<NODE>:5444/webhooks

**Authentication**

Requires a [VerticaAPIKey](https://<NODE>:5444) in the request header.

The API key must have **restricted** level security or higher.

**Parameters**

None.

**Example Request**

| GET | https://<NODE>:5444/webhooks |

**Response:**

```json
{
   "body": [
      {
         "host": "192.168.232.1",
         "id": "79c1c8a18be02804b3d2f48ea6462909",
         "port": 80,
         "timestamp": "2014-07-20 22:54:09.829642",
         "url": "/gettest.htm"
      },
      {
         "host": "192.168.232.1",
         "id": "9c32cb0f3d2f9a7cb10835f1732fd4a7",
         "port": 80,
         "timestamp": "2014-07-20 22:54:09.829707",
         "url": "/getwebhook.php"
      }
   ]
}```
{"href": "/webhooks",
"links": [
    "/subscribe",
    ":subscriber_id"
],
"mime-type": "application/vertica.webhooks.json-v2"}
**POST webhooks/subscribe**

Creates a subscription for a webhook.

**Resource URL**

```
https://<NODE>:5444/webhooks/subscribe
```

**Authentication**

Requires a **VerticaAPIKey** in the request header.

The API key must have **restricted** level security or higher.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>A URL to an application that accepts JSON messages from this cluster.</td>
</tr>
</tbody>
</table>

**Example Request**

```
```

**Response:**

The response is not JSON encoded. The only text response is the ID of the webhook subscription. Additionally, an HTTP 200/OK header indicates success.

```
79c1c8a18be02804b3d2f48ea6462909
```
DELETE webhooks/:subscriber_id

Deletes the webhook identified by :subscriber_id. The :subscriber_id is the value of the id field that the GET webhooks command returns.

Resource URL

https://<NODE>:5444/webhooks/:subscriber_id

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have restricted level security or higher.

Parameters

None.

Example Request

| DELETE | https://<NODE>:5444/webhooks/79c1c8a18be02804b3d2f48ea6462909 |

Response:

There is no HTTP body response for successful deletes. A successful delete returns an HTTP 200/OK header.
Rest APIs for the Management Console

These API calls interact with Management Console nodes.

**Alerts**

| GET alerts | Returns alerts for the current user. |

**Time Information**

| GET mcTimeInfo | Returns the current time for the MC server and the timezone of the location where the MC server is located. |

**MC-User-ApIKey**

The `MC-User-ApIKey` is a user-specific key used with Management Console. Users must have an `MC-User-ApIKey` to interact with MC using the Rest API. All users with roles other than None automatically receive an `MC-User-ApIKey`.

This key grants users the same rights through the API that they have available through their MC roles. To interact with the MC, users pass the key in the request header for the API.

**View the MC-User-ApIKey**

If you are the database administrator, you can view the `MC-User-ApIKey` for all users. Individual users can view their own keys.

1. Connect to MC and go to MC Settings > User Management.
2. Select the user to view and click Edit. The user's key appears in the User API Key field.
GET alerts

Returns a list of MC alerts, their current status, and database properties.

Resource URL

https://<MC_NODE>:5450/webui/api/alerts

Authentication

Requires an MC-User-Apikey in the request header.

Filter Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>types</td>
<td>The type of alert to retrieve. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>• info</td>
</tr>
<tr>
<td></td>
<td>• notice</td>
</tr>
<tr>
<td></td>
<td>• warning</td>
</tr>
<tr>
<td></td>
<td>• error</td>
</tr>
<tr>
<td></td>
<td>• critical</td>
</tr>
<tr>
<td></td>
<td>• alert</td>
</tr>
<tr>
<td></td>
<td>• emergency</td>
</tr>
<tr>
<td>category</td>
<td>For information, see Thresholds Category Filter.</td>
</tr>
<tr>
<td>db_name</td>
<td>For information, see Database Name Category Filter.</td>
</tr>
<tr>
<td>limit</td>
<td>The maximum number of alerts to retrieve. If the limit is lower than the number of existing alerts, Vertica retrieves the most recent alerts. Used with the type parameter, Vertica retrieves up to the limit for each type. For example, for a limit of five and types of critical and emergency, you could receive up to ten total alerts.</td>
</tr>
<tr>
<td>time_from</td>
<td>The timestamp start point from which to retrieve alerts. You can use this parameter in combination with the time_to parameter to retrieve alerts for a specific time range. Values must be passed in the following</td>
</tr>
</tbody>
</table>
format: yyyy-MM-ddTHH:mm.

If you provide only the time_from parameter, and omit the time_to parameter, the response contains all alerts generated from the time_from parameter to the current time.

time_to

The timestamp end point from which to retrieve alerts. You can use this parameter in combination with the time_from parameter to retrieve alerts for a specific time range. Values must be passed in the following format: yyyy-MM-ddTHH:mm.

If you provide only the time_to parameter, and omit the time_from parameter, the response contains all alerts generated from the earliest possible time to the time passed in time_to.

Example Request

GET https://<MC_NODE>:5450/webui/api/alerts

Request Alerts Using cURL

This example shows how you can request alerts using cURL. In this example, the limit parameter is set to '2' and the types parameters is set to info and notice:

Response:

```json
[
  {
    "alerts": [ 
      {
        "id": 5502,
        "markedRead": false,
        "eventTypeCode": 0,
        "create_time": "2016-02-02 05:12:10.0",
        "updated_time": "2016-02-02 15:50:20.511",
        "severity": "warning",
        "status": 1,
        "nodeName": "v_vmart_node0001",
        "databaseName": "VMart",
        "databaseId": 1
      }
    ]
  }
]```
Request Alerts Within a Time Range

These examples show various ways in which you can request the same alert as in the preceding example, but within specified time ranges.

Request the alert within a specific time range, using the time_from and time_to parameters:

```
```

Request the alert from a specific start time to the present using the time_from parameter:

```
```

Request the alert to a specific end point using the time_to parameter. When you use the time_to parameter without the time_from parameter, the time_from parameter defaults to the oldest alerts your MC contains:
GET mcTimeInfo

Returns the current time for the MC server and the timezone where the MC server is located.

Resource URL

https://<MC_NODE>:5450/webui/api/mcTimeInfo

Authentication

Requires an MC-User-Apkey in the request header.

Parameters

None.

Example Request

<table>
<thead>
<tr>
<th>GET</th>
<th>https://&lt;MC_NODE&gt;:5450/webui/api/mcTimeInfo</th>
</tr>
</thead>
</table>

This example shows how you can request MC time information using cURL:

```
```

Response:

```
{"mc_current_time":"Tue, 2000-01-01 01:02:03 -0500","mc_timezone":"US/Eastern"}
```

Thresholds Category Filter

Returns a list of alerts related to threshold settings in MC.
Resource URL

https://<MC_NODE>:5450/webui/api/alerts?category=thresholds

Authentication

Requires an MC-User-Apkey in the request header.

Example Request

GET

```
GET https://<MC_NODE>:5450/webui/api/alerts?category=thresholds
```

This example shows how you can request alerts on thresholds using cURL:

```
```

Response:
[{
  "alerts": [
    {
      "id": 33,
      "markedRead": false,

- Combining Sub-Category Filters with Category Filters

Database Name Category Filter

Returns a list of MC alerts for a specific database.

Resource URL

https://<MC_NODE>:5450/webui/api/alerts?db_name=<database_name>

Authentication

Requires an MC-User-Apikey in the request header.

Example Request

| GET | http |
This example shows how you can view alerts on a specific database using cURL:

curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?db_name="mydb"

Response:

```json
[
	{
		"alerts": [ 
			{

"internal":false,
"count":1
}
Combining Sub-Category Filters with Category Filters

You can combine category filters with sub-category filters, to obtain alert messages for specific thresholds you set in MC. You can also use sub-category filters to obtain information about alerts on specific resource pools in your database.

Sub-Category Filters

You can use the following sub-category filters with the category filters. Sub-category filters are case sensitive and must be lowercase.

<table>
<thead>
<tr>
<th>Sub-Category Filter</th>
<th>Alerts Related to Threshold Value Set For:</th>
</tr>
</thead>
<tbody>
<tr>
<td>threshold_node_cpu</td>
<td>Node CPU</td>
</tr>
<tr>
<td>threshold_node_memory</td>
<td>Node Memory</td>
</tr>
<tr>
<td>threshold_node_disk_usage</td>
<td>Node Disk Usage</td>
</tr>
<tr>
<td>threshold_node_diskio</td>
<td>Node Disk I/O</td>
</tr>
<tr>
<td>threshold_node_cpuio</td>
<td>Node CPU I/O Wait</td>
</tr>
<tr>
<td>threshold_node_rebootrate</td>
<td>Node Reboot Rate</td>
</tr>
<tr>
<td>threshold_netio</td>
<td>Network I/O Error</td>
</tr>
<tr>
<td>threshold_query_queued</td>
<td>Queued Query Number</td>
</tr>
</tbody>
</table>
Resource Pool-Specific Sub-Category Filters

To retrieve alerts for a specific resource pool, you can use sub-category filters in combination with the following category filters:

- thresholds
- rp_name

If you use these sub-category filters without the rp_name filter, the query retrieves alerts for all resource pools in your database.

<table>
<thead>
<tr>
<th>Sub-Category Filter</th>
<th>Alerts Related to Threshold Value Set For:</th>
</tr>
</thead>
<tbody>
<tr>
<td>threshold_rp_query_max_time</td>
<td>Queries reaching the maximum allowed execution time.</td>
</tr>
<tr>
<td>threshold_rp_query_resource_reject</td>
<td>The number of queries with resource rejections.</td>
</tr>
<tr>
<td>threshold_rp_query_queue_time</td>
<td>The number of queries that ended because of queue time exceeding a limit.</td>
</tr>
<tr>
<td>threshold_rp_query_run_time</td>
<td>The number of queries that ended because of run time exceeding a limit.</td>
</tr>
<tr>
<td>threshold_rp_memory</td>
<td>The minimum allowed resource pool size.</td>
</tr>
<tr>
<td>threshold_rp_max_memory</td>
<td>The maximum allowed resource pool size.</td>
</tr>
</tbody>
</table>

Authentication

Requires an MC-User-Apikey in the request header.
## Example Request

<table>
<thead>
<tr>
<th>Get</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>http://&lt;MC_NO_DE&gt;:5450/webui/api/alerts?category=things_holds&amp;subject=category_filter&gt;</code></td>
</tr>
</tbody>
</table>
Combine the Thresholds Category Filter with a Sub-Category Filter

This example shows how you can request alerts using cURL with the thresholds category filter and a sub-category filter. You apply the following filters:

- thresholds
- threshold_node_cpu

```
```

Response:

```
[
  {
    "alerts": [
      {
        "id": 11749,
        "markedRead": false,
        "eventTypeCode": 2,
        "createTime": "2015-11-05 11:04:43.997",
        "updatedTime": "2015-11-05 11:04:43.997",
        "severity": "warning",
        "status": 1,
        "databaseName": "mydb",
        "databaseId": 105,
        "clusterName": "1443122180317_cluster",
        "description": "Database: mydb Lower than threshold Node CPU 10% \ "mydb_node0002
1;1.03\%
mydb_node0003;0.9\% mydb_node0001;1.36\%",
        "summary": "Threshold: Node CPU < 10\%",
        "internal": false,
        "count": 1
      },
      {
        "id": 11744,
        "markedRead": false,
        "eventTypeCode": 2,
        "createTime": "2015-11-05 10:59:46.107",
        "updatedTime": "2015-11-05 10:59:46.107",
        "severity": "warning",
        "status": 1,
        "databaseName": "mydb2",
        "databaseId": 106,
        "clusterName": "1443552354071_cluster",
        "description": "Database: mydb2 Lower than threshold Node CPU 10% \ "mydb2_node0002
0.83\% mydb2_node0001;1.14\%",
        "summary": "Threshold: Node CPU < 10\%",
        "internal": false,
        "count": 1
```
Request an Alert On a Specific Resource Pool

This example shows how you can request alerts using cURL on a specific resource pool. The name of the resource pool is resourcepool1. You apply the following filters:

- thresholds
- rp_name
- threshold_rp_query_run_time

```
```

Response:

```
[ {
   "alerts": [
   { "id":6525, "markedRead":false, "eventTypeCode":2, "create_time":"2015-11-05 14:25:36.797", "updated_time":"2015-11-05 14:25:36.797", "severity":"warning", "status":1, "databaseName":"mydb", "databaseId":106, "clusterName": "1443552354071_cluster", "description": "Resource Pool: resourcepool1 Threshold Name: Ended Query with Run Time Exceeding Limit Time Interval: 14:20:36 to 14:25:36 Threshold Value: 0 min(s) Actual Value: 2186 query(s)", "summary": "Resource Pool: resourcepool1; Threshold : Ended Query with Run Time Exceeding Limit > 0 min(s)", "internal":false, "count":1 }],
```
```
   { "id":6517, "markedRead":false, "eventTypeCode":2, "create_time":"2015-11-05 14:20:39.541", ```
"updated_time":"2015-11-05 14:20:39.541",
"severity":"warning",
"status":1,
"databaseName":"mydb",
"databaseId":106,
"clusterName":"1443552354071_cluster",

"request_time":"2015-11-05 11:07:43.988"
Using Eon Mode

You can operate your Vertica database in Eon Mode instead of in Enterprise Mode. In Enterprise Mode, the original Vertica "share nothing" configuration, each database node stores a portion of the data and performs a portion of the computation. In Eon Mode, computational processes are separated from a communal (shared) storage layer, which enables rapid scaling of computational resources as demand changes.

An Eon Mode database must be deployed on Amazon Web Services. You can use the Management Console to provision an Eon Mode database. (Enterprise Mode also supports deployment on AWS and also supports on-premise hardware and other cloud platforms.)

Vertica does not support upgrading or reviving a database running on any previous beta version to the current version. New databases created in Eon Mode in Vertica version 9.1 and later can be upgraded and revived.

Creating a Database in Eon Mode

Creating a Database on Eon Mode for Cloud Storage

If you deployed MC on Amazon Web Services (AWS) resources using a CloudFormation Template, MC provides a step-by-step wizard allowing you create a Vertica cluster and database.

You will provision new Vertica clusters in the same VPC and subnet as the Vertica Management Console instance. Using the wizard, you can create an initial cluster of up to 60 hosts.

**Note:** To provision a new database and cluster on-premise, see Creating a Cluster Using MC in the Installation Guide. Go to the steps in the Installation Guide if you installed MC using an RPM.

1. On the MC home page, click Create a New Vertica Database Cluster. The creation wizard appears in a new dialog.

2. Choose a mode for your database: Eon Mode or Enterprise Mode. Note that you cannot switch the mode on your database after creation.

3. Follow the cluster creation wizard and enter the parameters for your new cluster and database. You will use the authentication method you selected in the Cloudformation Console when launching MC with Provisioning.

If you choose Enterprise Mode, the wizard offers two paths:
- Quick Create provides default values during cluster creation.
- Custom Create allows you to specify EC2 instance types and other AWS resources for your Vertica cluster instances.

4. After confirming the details you have provided for your new cluster, click Create. The dialog shows you the progress of the creation process, which takes a few minutes. (You can leave or close the browser during this process; to return to this progress window, select Create a New Vertica Database Cluster on the home page.)

   Note:
   During Eon Mode database creation, use an existing Amazon S3 bucket in the same region as your instances for your communal storage location. You must also specify a new, nonexisting subfolder name, which Vertica will then dynamically create within the existing S3 bucket. Use a format beginning with s3://. For example, s3://existingbucket/newsubfolder1.

5. The dialog displays a success message when the creation process completes. Click Get Started to view the Fast Tasks page.

View your new database any time under the Available Databases section of the Management Console home page. See Managing Database Clusters for more about further managing your cluster, instances, and database using MC.

### Creating a Database on Eon Mode for On-Premise Storage

See Step 5: Create the Eon on Premise Database.
Sizing your Vertica Cluster for Eon Mode

Running Vertica in Eon Mode decouples the cluster size from the data volume and lets you configure for your compute needs independently from your storage needs.

Before You Begin

Vertica in Eon Mode works on Amazon Web Services (AWS). As a Vertica administrator setting up your production cluster running in Eon Mode, you must make important decisions about choosing the correct EC2 instances and cluster size to meet your needs. This topic provides guidelines and best practices for selecting instance types and cluster sizes for a Vertica database running in Eon Mode. It assumes that you have a basic understanding of the Eon Mode architecture and Eon mode concepts like communal storage, depot, and shards. If you need to refresh your understanding, see Eon Mode Architecture.

Cluster Sizing Guidelines

As a starting point, consider how Enterprise Mode clusters are sized. In Enterprise Mode, sizing your cluster depends a lot on the total compressed data size. Most Vertica implementations have a 2:1 compression or better on disk. For the number of nodes in your cluster, divide the total compressed data size by the storage capacity of each node. Vertica recommends that you store no more than 10 TB of compressed data per node.

Depending on the complexity of your workload and expected concurrency, choose instance types that have sufficient CPU and memory. For production clusters, Vertica recommends a minimum of 16 cores, 128 GB RAM, and a minimum of 3 nodes for high availability.

In Eon Mode, communal storage on AWS S3 is like a data lake that can store unlimited data. Communal storage holds the durable copy of the database. Unfortunately, AWS S3 is not always fast. To compensate for S3’s lack of performance, a Vertica node in Eon Mode must have local storage for managing depot (data cache), catalog, and temp data. Sizing for Eon Mode depends on the following factors:
• **Working Data Size**: The amount of data on which most of your queries will operate, often called "hot" data.

• **Depot Location**: To get the fastest response time for frequently executed queries, provision a depot large enough to hold your working data set. When loading data, Vertica writes uncommitted ROS files into the depot before uploading the files to communal storage by default. If the free space in the depot is not sufficient, Vertica evicts files from the depot to make space for new files. Alternatively, data can be loaded directly into S3. The amount of data concurrently loaded into Vertica cannot be larger than the sum of depot location sizes across all nodes.

**Note:**
In addition to storing the depot's files, Vertica uses the filesystem that stores the depot for temporary storage. By default, 60% of the filesystem is set aside for depot use, leaving the rest for temporary files. You can change the disk space allocated to the depot (see `ALTER_LOCATION_SIZE`). However, Vertica prevents you from allocating more than 80% of the filesystem for the depot to make sure it has room for temporary files.

• **Data Location**: Data location is used for data files that belong to temporary tables and temporary data from sort operators that spill to disk. When loading data into Vertica, the sort operator may spill to disk, and depending on the size of the load, Vertica may perform the sort in multiple merge phases. The amount of data concurrently loaded into Vertica cannot be larger than the sum of temp location sizes across all nodes divided by 2.

• **Catalog Location**: The catalog size depends on the number of database objects per shard and the number of shard subscriptions per node.

• **Local disk sizing recommendation**: Vertica recommends a minimum local storage capacity of 2 TB per node, out of which 60% must be reserved for the depot and the other 40% can be shared between the catalog and data location.

• **Concurrency and throughput scaling**: You can choose the instance type based on the complexity of queries in your workload and the expected concurrency. In Eon Mode, you can increase throughput by adding more nodes to your cluster. Then, remove the nodes to save money when demand goes down. We refer to adding and removing nodes according to workload demand as "elastic throughput scaling." Should the increase in demand involve different kinds of workload, for example different queries accessing different data, you will want to consider creating a subcluster for the new nodes. To create a subcluster, you need to define a fault group. For best results, the number of nodes in a subcluster should be a multiple of the number of shards or should be modulus=0 of the number of shards. That is, every node should be responsible for the same number of shards.
To choose an instance type and the number of nodes for the Vertica cluster running in Eon mode, you must know what your working data set is. For general operation, the number of shards that you choose at database creation determines the maximum number of compute nodes that execute your queries in parallel. For this reason, shard count should be determined by considering how many nodes are needed to process the most complex queries in the target timeframe.

The number of shards cannot be changed in a Vertica database running in Eon Mode. Vertica recommends that you select your shard count based on the following table. It recommends the number of initial nodes and shards based on the working data size:

<table>
<thead>
<tr>
<th>Cluster Type</th>
<th>Working Data Size</th>
<th>Number of Shards</th>
<th>Initial Node Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Small</td>
<td>Up to 24 TB</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>Medium</td>
<td>Up to 48 TB</td>
<td>12</td>
<td>6</td>
</tr>
<tr>
<td>Large</td>
<td>Up to 96 TB</td>
<td>24</td>
<td>12</td>
</tr>
<tr>
<td>Extra large</td>
<td>Up to 192 TB</td>
<td>48</td>
<td>24</td>
</tr>
</tbody>
</table>

**Important:**
A 2:1 ratio for shards:nodes is a performance recommendation, rather than a hard limit. If you attempt to go higher than 3:1, MC offers a warning to make sure you have taken all aspects of shard count into consideration because, once set, the shard count cannot be changed.

### Planning for Scaling Your Cluster

The number of shards you choose for your database can impact your ability to scale your database in the future. You have two options when growing your cluster above the initial cluster size shown in the previous table. Which you choose depends on the types of queries you run:

- To increase the performance of complex (analytic) queries, add nodes in addition to the initial node count shown in the previous table. These additional nodes usually improve the overall performance of these complex queries by splitting the load across more compute nodes.
- To increase the throughput of multiple short-term queries (often called "dashboard queries"), improve your cluster’s parallelism by adding nodes and assigning them to a
**Subcluster.** Subclusters can work independently and in parallel on these shorter queries.

These two approaches have an impact on the number of shards you choose to start your database with. Complex analytic queries perform better on clusters with more nodes, which means that 6 nodes with 6 shards perform better than 3 nodes and 6 shards. Dashboard-type queries operating on smaller data sets may not see much difference between 3 nodes with 6 shards and 6 nodes with 6 shards.

In general, choose a shard count that matches your expected working data size 6–12 months in the future.

However, as your shard count increases, inter-node communication and catalog complexity also increase. The user should be conservative when deciding.

**Choosing Instance Types**

Choose instance types that support ephemeral instance storage or EBS volumes for your depot, depending on cost and availability. It is not mandatory to have an EBS-backed depot, because in Eon Mode, a copy of the data is safely stored in communal storage. Vertica recommends either r4 or i3 instances for production clusters.

The following table provides information to help you make a decision on how to pick instances with ephemeral instance storage or EBS only storage. Check with [AWS](https://aws.amazon.com) for the latest cost per hour.

<table>
<thead>
<tr>
<th>Storage Type</th>
<th>Instance Type</th>
<th>Pros/Cons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance storage</td>
<td>i3.8xlarge</td>
<td>Instance storage offers better performance than EBS attached storage through multiple EBS volumes. Instance storage can be striped (RAIDed) together to increase throughput and load balance I/O. Data stored in instance-store volumes is not persistent through instance steps,</td>
</tr>
<tr>
<td>Storage Type</td>
<td>Instance Type</td>
<td>Pros/Cons</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------------------------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EBS-only storage</td>
<td>r4.8xlarge with 600 GB EBS volume attached</td>
<td>Newer instance types from AWS have only the EBS option. In most AWS regions, it's easier to provision a large number of instances. You can terminate an instance but leave the EBS volume around for faster revive. Take advantage of full-volume encryption.</td>
</tr>
</tbody>
</table>

**Important:**
If you select instances that use instance store, if you then terminate those instances there is the potential for data loss. For Eon mode, MC displays an alert to inform the user of the potential data loss when terminating instances that support instance store.

**Use Cases**

Let’s look at some use cases to learn how to size your Eon Mode cluster to meet your own particular requirements.

**Use Case 1: Save compute by provisioning close to need, rather than peak times**

This use case highlights the elastic throughput scaling (ETS) feature of Eon Mode to scale a cluster from 6 to 18 nodes with 3 subclusters of 6 nodes each. In this use case, you need to support a high concurrent, short query workload on a 24 TB or less working data set. You
create an initial cluster with 6 nodes and 6 shards. You scale out throughput on demand by adding one or more subclusters during certain days of the week or for specific date ranges when you are expecting a peak load. The cluster can then be shrunk back to its initial size by dropping nodes or subclusters to meet the requirements of normal workloads. With Vertica in Eon Mode, you save compute by provisioning close to the need, rather than provisioning for the peak times.

With Eon Mode, it's easy and quick to add and remove nodes from the cluster because it does not require reshuffling data via rebalancing, as you must do in Vertica Enterprise Mode.

**Use Case 2: Complex analytic workload requires more compute nodes**

This use case showcases the idea that complex analytic workloads on large working data sets benefit from high shard count and node count. You create an initial cluster of type large with 24 nodes and 24 shards. As needed, you can add and remove nodes to improve throughput scaling.

**Use Case 3: Workload isolation**

This use case showcases the idea of having separate subclusters to isolate ETL and report workloads. You create an initial cluster with 6 nodes and 6 shards for servicing queries, and add another 6-node subcluster for supporting ETL workloads. You may need to configure the network load balancer from AWS to separate the ETL workload from SELECT queries. Workload isolation can also be useful for isolating different users with varying Vertica skills.

**Use Case 4: Shrink your cluster to save costs**

This example showcases the idea that you can shrink your cluster by half during off-peak hours to save costs. To shrink the cluster size, drop nodes from the cluster. Vertica automatically rebalances the shards among the remaining nodes. When you shrink the cluster to a size smaller than the initial cluster (number of nodes = number of shards), the nodes may subscribe to more than two shards and have the following impact:
The catalog size is larger because nodes are subscribing to more shards.

The depot is shared by more shard subscriptions, which may lead to the evictions of files.

Each node processes more data, which may have performance impact on queries.

For more information, see Using Eon Mode.

### Managing Subclusters

Subclusters help you organize the nodes in your clusters to isolate workloads and make elastic scaling easier. See Subclusters for more information.

### See Also

### Creating Subclusters

By default, new Eon Mode databases contain a single primary subcluster named default_subcluster. This subcluster contains all of the nodes that are part of your database when you create it. To create a new subcluster, use the admintools db_add_subcluster tool:

```
$ admintools -t db_add_subcluster -h
Usage: db_add_subcluster [options]

Options:
  -h, --help          show this help message and exit
  -d DB, --database=DB Name of database to be modified
  -s HOSTS, --hosts=HOSTS
                      Comma separated list of hosts to add to the subcluster
  -p DBPASSWORD, --password=DBPASSWORD
                      Database password in single quotes
  -c SCNAME, --subcluster=SCNAME
                      Name of the new subcluster for the new node
  --is-secondary
                      Create secondary subcluster
  --timeout=NONINTERACTIVE_TIMEOUT
                      set a timeout (in seconds) to wait for actions to
                      complete (‘never’) will wait forever (implicitly sets
                      -i)
  -i, --noprompts     do not stop and wait for user input(default false).
                      Setting this implies a timeout of 20 min.
```

The simplest command adds an empty subcluster. It requires the database name, password, and name for the new subcluster. This example adds a subcluster named analytics_cluster to the database named verticadb:
By default, Vertica makes a new subclusters a `primary subcluster`. You can have it create a `secondary subcluster` by supplying the `--is-secondary` argument.

### Adding Nodes While Creating a Subcluster

You can also specify one or more nodes for Vertica to add to the subcluster while creating it. These nodes must be part of the cluster but not already part of the database. For example, nodes that you have added to the cluster using the MC or admintools, or nodes you have dropped from the database. This example creates `analytics_cluster` as a secondary subcluster and adds three nodes to it.

```
$ adminTools -t db_add_subcluster -d verticadb -p 'password' -c analytics_cluster \
   -s 10.11.12.117,10.11.12.251,10.11.12.193 \
   --is-secondary

Nodes added to subcluster analytics_cluster successfully.
Subcluster added to verticadb successfully.
```

Your newly-added nodes do not have any subscriptions to shards. See [Updating Shard Subscriptions After Adding Nodes](#) for more information.
Adding and Removing Nodes From Subclusters

You will often want to add new nodes to and remove existing nodes from a subcluster. This ability lets you scale your database to respond to changing analytic needs.

Adding New Nodes to a Subcluster

You can add nodes to a subcluster to meet additional workloads. The nodes that you add to the subcluster must already be part of your cluster. These can be:

- Nodes that you removed from other subclusters.
- Nodes you added following the steps in Add Nodes to a Running AWS Cluster.
- Nodes you created using your cloud provider's interface, such as the AWS EC2 "Launch more like this" feature.

**Note:**

Do not add more nodes to a subcluster than you have shards in your database. Instead, create a new subcluster to hold the new nodes. Having more nodes in a subcluster than you have shards in the database is less efficient than having those nodes in a separate subcluster.

To add new nodes to a subcluster, use the `db_add_node` command of admintools:

```
$ adminTools -t db_add_node -h
Usage: db_add_node [options]

Options:
  -h, --help        show this help message and exit
  -d DB, --database=DB Name of the database
  -s HOSTS, --hosts=HOSTS
                    Comma separated list of hosts to add to database
  -p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
  -a AHOSTS, --add=AHOSTS
                    Comma separated list of hosts to add to database
  -c SCNAME, --subcluster=SCNAME
                    Name of subcluster for the new node
  --timeout=NONINTERACTIVE_TIMEOUT
                    set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)
```
If you do not use the `-c` option, Vertica adds new nodes to the **default subcluster** (set to `default_subcluster` in new databases). This example adds a new node without specifying the subcluster:

```
$ adminTools -t db_add_node -p 'password' -d verticadb -s 10.11.12.117
Subcluster not specified, validating default subcluster
Nodes will be added to subcluster 'default_subcluster'
    Verifying database connectivity...10.11.12.10

Node Status: v_verticadb_node0007: (UP)
```
Communal storage detected: syncing catalog
Multi-node DB add completed
Nodes added to verticadb successfully.
You will need to redesign your schema to take advantage of the new nodes.

**Updating Shard Subscriptions After Adding Nodes**

After you add nodes to a subcluster they do not yet subscribe to shards. You can view the subscription status of all nodes in your database using the following query that joins the `V_CATALOG.NODES` and `V_CATALOG.NODE_SUBSCRIPTIONS` system tables:

```sql
=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name = ns.node_name) ORDER BY 1,2,3;
```

<table>
<thead>
<tr>
<th>subcluster_name</th>
<th>node_name</th>
<th>shard_name</th>
<th>subscription_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>analytics_subcluster</td>
<td>v_verticadb_node0004</td>
<td></td>
<td></td>
</tr>
<tr>
<td>analytics_subcluster</td>
<td>v_verticadb_node0005</td>
<td></td>
<td></td>
</tr>
<tr>
<td>analytics_subcluster</td>
<td>v_verticadb_node0006</td>
<td></td>
<td></td>
</tr>
<tr>
<td>default_subcluster</td>
<td>v_verticadb_node0001</td>
<td>replica</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>default_subcluster</td>
<td>v_verticadb_node0001</td>
<td>segment0001</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>default_subcluster</td>
<td>v_verticadb_node0001</td>
<td>segment0003</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>default_subcluster</td>
<td>v_verticadb_node0002</td>
<td>replica</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>default_subcluster</td>
<td>v_verticadb_node0002</td>
<td>segment0001</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>default_subcluster</td>
<td>v_verticadb_node0003</td>
<td>segment0002</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>default_subcluster</td>
<td>v_verticadb_node0003</td>
<td>segment0003</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

You can see that none of the nodes in the newly-added analytics_subcluster have subscriptions.

To update the subscriptions for new nodes, call the `REBALANCE_SHARDS` function. You can limit the rebalance to the subcluster containing the new nodes by passing its name to the `REBALANCE_SHARDS` function call. The following example runs rebalance shards to update the analytics_subcluster’s subscriptions:

```sql
=> SELECT REBALANCE_SHARDS('analytics_subcluster');
REBALANCE_SHARDS
--------------------
REBALANCED SHARDS
(1 row)
```

```sql
=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name = ns.node_name) ORDER BY 1,2,3;
```
In the previous example, the state of the subscription for the new nodes is PASSIVE. This state means they are warming their depots to prepare for queries. This state eventually becomes ACTIVE, when the nodes have filled their depot with recently-used data. The amount of time this process takes depends on the size of the depot and how frequently data is being evicted from the depot.

Removing Nodes

To remove one or more nodes, use admintools's db_remove_node tool:

```
$ adminTools -t db_remove_node -p 'password' -d verticadb -s 10.11.12.117
connecting to 10.11.12.10
Waiting for rebalance shards. We will wait for at most 36000 seconds.
Rebalance shards polling iteration number [0], started at [14:56:41], time out at [00:56:41]
Attempting to drop node v_verticadb_node0004 (10.11.12.117)
   Shutting down node v_verticadb_node0004
   Sending node shutdown command to
['v_verticadb_node0004', '10.11.12.117', '/vertica/data',
'/vertica/data']
   Deleting catalog and data directories
   Update admintools metadata for v_verticadb_node0004
   Eon mode detected. The node v_verticadb_node0004 has been removed from host 10.11.12.117.
   To remove the node metadata completely, please clean up the files corresponding to this node, at the communal
location: s3://eonbucket/metadata/verticadb/nodes/v_verticadb_node0004
   Reload spread configuration
   Replicating configuration to all nodes
```
Checking database state
Node Status: v_verticadb_node0001: (UP) v_verticadb_node0002: (UP) v_verticadb_node0003: (UP)
Communal storage detected: syncing catalog

When you remove one or more nodes from a subcluster, Vertica automatically rebalances shards in the subcluster. You do not need to manually rebalance shards after removing nodes.

Moving Nodes Between Subclusters

To move a node from one subcluster to another:

1. Remove the node or nodes from the subcluster it is currently a part of.
2. Add the node to the subcluster you want to move it to.

Managing Workloads with Subclusters

By default, queries are limited to executing on the nodes in the subcluster that contains the initiator node (the node the client is connected to). This example demonstrates executing an explain plan for a query when connected to node 4 of a cluster. Node 4 is part of a subcluster containing nodes 4 through 6. You can see that only the nodes in the subcluster will participate in a query:

```sql
=> EXPLAIN SELECT customer_name, customer_state FROM customer_dimension LIMIT 10;

QUERY PLAN

QUERY PLAN DESCRIPTION:

EXPLAIN SELECT customer_name, customer_state FROM customer_dimension LIMIT 10;

Access Path:
+-SELECT LIMIT 10 [Cost: 442, Rows: 10 (NO STATISTICS)] (PATH ID: 0)
  | Output Only: 10 tuples
  | Execute on: Query Initiator
  | +----> STORAGE ACCESS for customer_dimension [Cost: 442, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
  |      | Projection: public.customer_dimension.b0
  |      | Materialize: customer_dimension.customer_name,
  |      |   customer_dimension.customer_state
  |      | Output Only: 10 tuples
  |      | Execute on: v_verticadb_node0004, v_verticadb_node0005, v_verticadb_node0006
```
What Happens When a Subcluster Cannot Run a Query

In order to process queries, each subcluster’s nodes must have full coverage of all shards in the database. If the nodes do not have full coverage (which can happen if nodes are down), the subcluster can no longer process queries. This state does not cause the subcluster to shut down. Instead, if you attempt to run a query on a subcluster in this state, you receive error messages telling you that not enough nodes are available to complete the query.

```
=> SELECT node_name, node_state FROM nodes
    WHERE subcluster_name = 'analytics_cluster';

<table>
<thead>
<tr>
<th>node_name</th>
<th>node_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vertical_node0004</td>
<td>DOWN</td>
</tr>
<tr>
<td>v_vertical_node0005</td>
<td>UP</td>
</tr>
<tr>
<td>v_vertical_node0006</td>
<td>DOWN</td>
</tr>
</tbody>
</table>

(3 rows)
```

```
=> SELECT * FROM online_sales.online_sales_fact;
ERROR 9099: Cannot find participating nodes to run the query
```

Once the down nodes have recovered and the subcluster has full shard coverage, it will be able to process queries.

Controlling Where a Query Runs

You can control where specific types of queries run by controlling which subcluster the clients connect to. The best way to enforce restrictions is to create a set of connection load balancing policies to steer clients from specific IP address ranges to clients in the correct subcluster.

For example, suppose you have the following database with two subclusters: one for performing data loading, and one for performing analytics.
The data load tasks come from a set of ETL systems in the IP 10.20.0.0/16 address range. Analytics tasks can come from any other IP address. In this case, you can create set of connection load balance policies that ensure that the ETL systems connect to the data load subcluster, and all other connections go to the analytics subcluster.

```
=> SELECT node_name, node_address, node_address_family, subcluster_name
    FROM v_catalog.nodes;
node_name                  | node_address | node_address_family | subcluster_name
----------------------------+--------------+---------------------+-------------------
v_verticadb_node0001       | 10.11.12.10  | ipv4                | load_subcluster    
v_verticadb_node0002       | 10.11.12.20  | ipv4                | load_subcluster    
v_verticadb_node0003       | 10.11.12.30  | ipv4                | load_subcluster    
v_verticadb_node0004       | 10.11.12.40  | ipv4                | analytics_subcluster
v_verticadb_node0005       | 10.11.12.50  | ipv4                | analytics_subcluster
v_verticadb_node0006       | 10.11.12.60  | ipv4                | analytics_subcluster
(6 rows)

=> CREATE NETWORK ADDRESS node01 ON v_verticadb_node0001 WITH '10.11.12.10';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_verticadb_node0002 WITH '10.11.12.20';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 ON v_verticadb_node0003 WITH '10.11.12.30';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node04 ON v_verticadb_node0004 WITH '10.11.12.40';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node05 ON v_verticadb_node0005 WITH '10.11.12.50';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node06 ON v_verticadb_node0006 WITH '10.11.12.60';
CREATE NETWORK ADDRESS

=> CREATE LOAD BALANCE GROUP load_subcluster WITH SUBCLUSTER load_subcluster
    FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
=> CREATE LOAD BALANCE GROUP analytics_subcluster WITH SUBCLUSTER
```
Once you have created the load balance policies, you can test them using the `DESCRIBE_LOAD_BALANCE_DECISION` function.

```sql
=> SELECT describe_load_balance_decision('192.168.1.1');
```

```
  describe_load_balance_decision
  -----------------------------
  Describing load balance decision for address [192.168.1.1]
  Load balance cache internal version id (node-local): [1]
  Considered rule [etl_systems] source ip filter [10.20.0.0/16]...
     input address does not match source ip filter for this rule.
  Considered rule [analytic_clients] source ip filter [0.0.0.0/0]...
     input address matches this rule
  Matched to load balance group [analytics_cluster] the group has
     policy [ROUNDROBIN] number of addresses [3]
     (0) LB Address: [10.11.12.181]:5433
     (1) LB Address: [10.11.12.205]:5433
     (2) LB Address: [10.11.12.192]:5433
  Chose address at position [1]
  Routing table decision: Success. Load balance redirect to: [10.11.12.205]
     port [5433]

(1 row)
```

```sql
=> SELECT describe_load_balance_decision('10.20.1.1');
```

```
  describe_load_balance_decision
  -----------------------------
  Describing load balance decision for address [10.20.1.1]
  Load balance cache internal version id (node-local): [1]
  Considered rule [etl_systems] source ip filter [10.20.0.0/16]...
     input address matches this rule
  Matched to load balance group [default_cluster] the group has policy
     [ROUNDROBIN] number of addresses [3]
     (0) LB Address: [10.11.12.10]:5433
     (1) LB Address: [10.11.12.20]:5433
     (2) LB Address: [10.11.12.30]:5433
  Chose address at position [1]
  Routing table decision: Success. Load balance redirect to: [10.11.12.20]
     port [5433]

(1 row)
```

Normally, with these policies, all queries run by the ETL system will run on the load subcluster. All other queries will run on the analytics subcluster. There are some cases (especially if a subcluster is down) where a client may connect to a node in another subcluster. For this reason, clients should always verify they are connected to the correct
subcluster. See About Connection Load Balancing Policies for more information about load balancing policies.

**Starting and Stopping Subclusters**

Subclusters make it convenient to start and stop a group of nodes as needed. You start and stop them using the admintools command line.

**Starting a Subcluster**

To start a subcluster, use the `restart_subcluster` tool:

```
$ adminTools -t restart_subcluster -h
Usage: restart_subcluster [options]

Options:
-h, -help                              show this help message and exit
-d DB, --database=DB                  Name of database whose subcluster is to be restarted
-c SCNAME, --subcluster=SCNAME        Name of subcluster to be restarted
-p DBPASSWORD, --password=DBPASSWORD  Database password in single quotes
--timeout=NONINTERACTIVE_TIMEOUT      set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)
-i, --noprompts                        do not stop and wait for user input(default false).
-F, --force                            Force the nodes in the subcluster to start and auto recover if necessary
```

This example starts the subcluster named analytics_cluster:

```
$ adminTools -t restart_subcluster -c analytics_cluster \
-d verticadb -p password
*** Restarting subcluster for database verticadb ***
  Restarting host [10.11.12.192] with catalog [v_verticadb_node0006_catalog]
  Restarting host [10.11.12.181] with catalog [v_verticadb_node0004_catalog]
  Restarting host [10.11.12.205] with catalog [v_verticadb_node0005_catalog]
  Issuing multi-node restart
  Starting nodes:
    v_verticadb_node0004 (10.11.12.181)
    v_verticadb_node0005 (10.11.12.205)
    v_verticadb_node0006 (10.11.12.192)
  Starting Vertica on all nodes. Please wait, databases with a large catalog may take a while to initialize.
  Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (DOWN)
               v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN)
```
Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (DOWN) v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN) 

Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (DOWN) v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN) 

Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (UP) v_verticadb_node0005: (UP) v_verticadb_node0006: (UP) 

Communal storage detected: syncing catalog

Restart Subcluster result: 1

## Stopping a Subcluster

### Important:

Stopping a subcluster does not warn you if there are active user sessions connected to the subcluster. This behavior is same as the stopping an individual node. Before stopping a subcluster, verify that no users are connected to it.

To stop a subcluster, use the `stop_subcluster` tool:

```
$ adminTools -t stop_subcluster -h
Usage: stop_subcluster [options]

Options:
- `h, --help` show this help message and exit
- `d DB, --database=DB` Name of database whose subcluster is to be stopped
- `c SCNAME, --subcluster=SCNAME` Name of subcluster to be stopped
- `p DBPASSWORD, --password=DBPASSWORD` Database password in single quotes
- `--timeout=NONINTERACTIVE_TIMEOUT` set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)
- `i, --noprompts` do not stop and wait for user input (default false). Setting this implies a timeout of 20 min.
```

This example stops the subcluster named `analytics_cluster`:

```
$ adminTools -t stop_subcluster -c analytics_cluster -d verticadb -p password
*** Forcing subcluster shutdown ***
Verifying subcluster 'analytics_cluster'
Node 'v_verticadb_node0004' will shutdown
Node 'v_verticadb_node0005' will shutdown
Node 'v_verticadb_node0006' will shutdown
Shutdown subcluster command sent to the database
```
You can also use the SHUTDOWN_SUBCLUSTER function to stop a subcluster. See `SHUTDOWN_SUBCLUSTER` for details.

**Altering Subcluster Settings**

There are several settings you can alter on a subcluster using the `ALTER SUBCLUSTER` statement. You can also switch a subcluster from a primary to a secondary subcluster, or from a secondary to a primary.

**Renaming a Subcluster**

To rename an existing subcluster, use the `ALTER SUBCLUSTER` statement's `RENAME TO` clause:

```sql
=> ALTER SUBCLUSTER default_subcluster RENAME TO load_subcluster;
ALTER SUBCLUSTER

=> SELECT DISTINCT subcluster_name FROM subclusters;
  subcluster_name
---------------------
  load_subcluster
  analytics_cluster
(2 rows)
```

**Changing the Default Subcluster**

The default subcluster designates which subcluster Vertica adds nodes to if you do not explicitly specify a subcluster when adding nodes to the database. When you create a new database (or when a database is upgraded from a version prior to 9.3.0) the default_subcluster is the default. You can find the current default subcluster by querying the is_default column of the `SUBCLUSTERS` system table.

The following example demonstrates finding the default subcluster, and then changing it to the subcluster named analytics_cluster:

```sql
=> SELECT DISTINCT subcluster_name FROM SUBCLUSTERS WHERE is_default = true;
  subcluster_name
---------------------
  default_subcluster
(1 row)
```
ALTER SUBCLUSTER analytics_cluster SET DEFAULT;
ALTER SUBCLUSTER =>
=> SELECT DISTINCT subcluster_name FROM SUBCLUSTERS WHERE is_default = true;
subcluster_name
----------------------
analytics_cluster
(1 row)

Converting a Subcluster from Primary to Secondary, or Secondary to Primary

You usually choose whether a subcluster is primary or secondary when creating it (see Creating Subclusters for more information). However, you can switch a subcluster between the two settings after you have created it. You may want to change whether a subcluster is primary or secondary to impact the K-Safety of your database. For example, if you have a single primary subcluster that has down nodes that you cannot easily replace, you can promote a secondary subcluster to primary to ensure losing another primary node will not cause your database to shut down. On the other hand, you may choose to convert a primary subcluster to a secondary before eventually shutting it down. This conversion can prevent the database from losing K-Safety if the subcluster you are shutting down contains half or more of the total number of primary nodes in the database.

Note:
You cannot promote or demote a subcluster containing the initiator node. You must be connected to a node in a subcluster other than the one you want to promote or demote.

To make a secondary subcluster into a primary subcluster, use the PROMOTE_SUBCLUSTER_TO_PRIMARY function:

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
subcluster_name | is_primary
-------------------+----------
analytics_cluster | f
load_subcluster   | t
(2 rows)

=> SELECT PROMOTE_SUBCLUSTER_TO_PRIMARY('analytics_cluster');
PROMOTE_SUBCLUSTER_TO_PRIMARY
--------------------------
PROMOTE_SUBCLUSTER TO PRIMARY
(1 row)
Making a primary subcluster into a secondary subcluster is similar. Unlike converting a secondary subcluster to a primary, there are several issues that may prevent you from making a primary into a secondary. Vertica prevents you from making a primary into a secondary if any of the following is true:

- The subcluster contains a **critical node**.
- The subcluster is the only primary subcluster in the database. You must have at least one primary subcluster.
- The **initiator node** is a member of the subcluster you are trying to demote. You must call the `DEMOTE_SUBCLUSTER` function from another subcluster.

To convert a primary subcluster to secondary, use the `DEMOTE_SUBCLUSTER_TO_SECONDARY` function:

```sql
=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
 subcluster_name | is_primary
-----------------+---------------------
analytics_cluster | t
load_subcluster   | t
(2 rows)

=> SELECT DEMOTE_SUBCLUSTER_TO_SECONDARY('analytics_cluster');
DEMOTE_SUBCLUSTER_TO_SECONDARY
-----------------------------
DEMOTE_SUBCLUSTER_TO_SECONDARY
(1 row)

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
 subcluster_name | is_primary
-----------------+---------------------
analytics_cluster | f
load_subcluster   | t
(2 rows)
```

## Removing Subclusters

Removing a subcluster from the database deletes the subcluster from the Vertica catalog. During the removal, Vertica removes any nodes in the subcluster from the database. These nodes are still part of the database cluster, but are no longer part of the database. If you view your cluster in the MC, you will see these nodes with the status STANDBY. They can be
Vertica places several restrictions on removing a subcluster:

- You cannot remove the **default subcluster**. If you want to remove the subcluster that is set as the default, you must make another subcluster the default. See [Changing the Default Subcluster](#) for details.
- You cannot remove the last **primary subcluster** in the database. Your database must always have at least one primary subcluster.

**Note:**
Removing a subcluster can fail if the database is repartitioning. If this happens, you will see the error message "Transaction commit aborted because session subscriptions do not match catalog." Wait until the repartitioning is done before removing a subcluster.

To remove a subcluster, use the admintools command line `db_remove_subcluster` tool:

```
$ adminTools -t db_remove_subcluster -h
Usage: db_remove_subcluster [options]

Options:
  -h, --help                show this help message and exit
  -d DB, --database=DB     Name of database to be modified
  -c SCNAME, --subcluster=SCNAME
                           Name of subcluster to be removed
  -p DBPASSWORD, --password=DBPASSWORD
                           Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                           set a timeout (in seconds) to wait for actions to complete ('never') will wait forever (implicitly sets -i)
  -i, --noplusprompts      do not stop and wait for user input(default false). Setting this implies a timeout of 20 min.
  --skip-directory-cleanup
                           Caution: this option will force you to do a manual cleanup. This option skips directory deletion during remove subcluster. This is best used in a cloud environment where the hosts being removed will be subsequently discarded.
```

This example removes the subcluster named `analytics_cluster`:

```
$ adminTools -t db_remove_subcluster -d verticadb -c analytics_cluster -p 'password'
Found node v_verticadb_node0004 in subcluster analytics_cluster
Found node v_verticadb_node0005 in subcluster analytics_cluster
Found node v_verticadb_node0006 in subcluster analytics_cluster
Found node v_verticadb_node0007 in subcluster analytics_cluster
Waiting for rebalance shards. We will wait for at most 3600 seconds.
Rebalance shards polling iteration number [0], started at [17:09:35], time out at [03:09:35]
```
Managing The Depot

The depot is where nodes in an Eon Mode database cache data locally on disk. The node first looks in its depot for the data it needs to process a query. See The Depot for more information.

The topics in this section explain how you can configure the depot.
Canceling or Backgrounding Depot Warming

When a node joins an Eon Mode database, it prepares to take part in processing queries by loading data into its depot. This process is called "depot warming." Depot warming helps ensure that newly-added nodes do not negatively impact query performance. While it is warming its depot, the node does not take part in processing queries. If a node did not warm its depot, the results of the queries it takes part in processing would be delayed while it fetches all of the data it needs from communal storage.

During the warming process, the node contacts other nodes in its subcluster to determine what data they have in their depots. Based on his information, the newly-started node retrieves the corresponding data for the shards it subscribes to. It loads this data from communal storage unless the UseCommunalStorageForBatchDepotWarming parameter is set to 0 (see Eon Mode Parameters for more information). While the node warms its depot, it does not take part in queries.

A node that is warming its depot has a subscription state of PASSIVE in the NODE_SUBSCRIPTIONS system table. The following example shows that nodes 4 through 6 are warming their depots:

```sql
=> SELECT node_name, shard_name, subscription_state FROM v_catalog.node_subscriptions
   ORDER BY node_name, shard_name;
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>shard_name</th>
<th>subscription_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_veritacdb_node0001</td>
<td>replica</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0001</td>
<td>segment0001</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0001</td>
<td>segment0003</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0002</td>
<td>replica</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0002</td>
<td>segment0001</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0002</td>
<td>segment0002</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0003</td>
<td>replica</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0003</td>
<td>segment0002</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0003</td>
<td>segment0003</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0004</td>
<td>replica</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0004</td>
<td>segment0001</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0004</td>
<td>segment0003</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0005</td>
<td>replica</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0005</td>
<td>segment0001</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0005</td>
<td>segment0002</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0006</td>
<td>replica</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0006</td>
<td>segment0002</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_veritacdb_node0006</td>
<td>segment0003</td>
<td>PASSIVE</td>
</tr>
</tbody>
</table>

(18 rows)

In some cases, you may want to have the a node that is warming its depot to start processing queries immediately. You have two options to have the node start processing queries:
• Cancel the node's depot warming. The node immediately marks its subscriptions as active and begins taking part in queries.
• Tell the node to continue warming its depot in the background while it begins to process queries.

## Canceling Depot Warming

To cancel a node's depot warming, call the `CANCEL_DEPOT_WARMING` function. You pass this function the name of the node whose warming you want to cancel. You can optionally specify the name of a shard subscription to cancel warming a specific subscription.

When you call `CANCEL_DEPOT_WARMING`:

1. The node finishes transferring whatever data it is currently retrieving to warm its depot.
2. It marks its subscriptions as ACTIVE. If you canceled a specific subscription, only that shard's subscription becomes ACTIVE.
3. It begins processing queries if all of its subscriptions are now ACTIVE. If you chose to cancel warming a single subscription, the node continues to warm its depot if its other subscriptions are not yet warmed.

The node does not remove any data it has in its depot in response to the cancel request. It just stops loading new data to warm the depot.

The following demonstrates canceling the depot warming taking place on node 7:

```sql
=> SELECT node_name, shard_name, subscription_state FROM node_subscriptions
    WHERE subscription_state = 'PASSIVE' ORDER BY node_name, shard_name;
```

```plaintext
node_name               | shard_name | subscription_state
------------------------|------------|---------------------
verticadb_node0004     | replica    | PASSIVE
verticadb_node0004     | segment001 | PASSIVE
verticadb_node0004     | segment003 | PASSIVE
verticadb_node0005     | replica    | PASSIVE
verticadb_node0005     | segment001 | PASSIVE
verticadb_node0005     | segment002 | PASSIVE
verticadb_node0006     | replica    | PASSIVE
verticadb_node0006     | segment002 | PASSIVE
verticadb_node0006     | segment003 | PASSIVE
verticadb_node0007     | replica    | PASSIVE
verticadb_node0007     | segment001 | PASSIVE
verticadb_node0007     | segment003 | PASSIVE
(12 rows)
```

```sql
=> SELECT CANCEL_DEPOT_WARMING('v_verticadb_node0007');
```

```plaintext
CANCEL_DEPOT_WARMING
----------------------------------------
Depot warming cancelled.
```
Warming the Depot in the Background

Instead of canceling depot warming outright, you can choose to have a node start processing queries while it continues to warm its depot (also known as background depot warming). You may want to choose this option if you want the node to aid in processing queries immediately, but you believe that upcoming queries will benefit from having a warmed depot.

You tell the node to warm its depot in the background by calling the `BACKGROUND_DEPOT_WARMING` function. You pass this function the name of the node. You can choose to limit the background warming to a single shard subscription by passing the name of the shard as the second argument. Setting specific shards to warm in the background only has an effect if the node's other shard subscriptions are already warm (or canceled or sent to the background separately). Otherwise, the node continues to warm its depot for its other subscriptions.

You can only use this option when the node is warming its depot from the communal storage. If it is warming its depot from peers (which happens when the `UseCommunalStorageForBatchDepotWarming` configuration parameter is set to 0) it cannot warm its depot in the background. See Eon Mode Parameters for more information about this parameter.

When you tell a node to put its depot warming in the background, it sets all of its subscription states to ACTIVE if you did not pass in a specific shard to warm in the background. If you called `BACKGROUND_DEPOT_WARMING` with a specific shard name, the node makes just the that subscription ACTIVE. If its other subscriptions are not already warmed, the node continues to warm those subscriptions.

The following example demonstrates having node 6 of the verticadb database warm its depot in the background:

```sql
=> SELECT node_name, shard_name, subscription_state FROM node_subscriptions
    WHERE node_name = 'v_verticadb_node0007' ORDER BY shard_name;

<table>
<thead>
<tr>
<th>node_name</th>
<th>shard_name</th>
<th>subscription_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_verticadb_node0007</td>
<td>replica</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_verticadb_node0007</td>
<td>segment0001</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_verticadb_node0007</td>
<td>segment0003</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
```
=> SELECT node_name, shard_name, subscription_state FROM node_subscriptions
    WHERE node_name = 'v_verticadb_node0006';

<table>
<thead>
<tr>
<th>node_name</th>
<th>shard_name</th>
<th>subscription_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_verticadb_node0006</td>
<td>segment0003</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_verticadb_node0006</td>
<td>segment0002</td>
<td>PASSIVE</td>
</tr>
<tr>
<td>v_verticadb_node0006</td>
<td>replica</td>
<td>PASSIVE</td>
</tr>
</tbody>
</table>

(3 rows)

=> SELECT BACKGROUND_DEPOT_WARMING('v_verticadb_node0006');

BACKGROUND_DEPOT_WARMING

Depot warming running in background. Check monitoring tables for progress.

(1 row)

=> SELECT node_name, shard_name, subscription_state FROM node_subscriptions
    WHERE node_name = 'v_verticadb_node0006';

<table>
<thead>
<tr>
<th>node_name</th>
<th>shard_name</th>
<th>subscription_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_verticadb_node0006</td>
<td>segment0003</td>
<td>ACTIVE</td>
</tr>
<tr>
<td>v_verticadb_node0006</td>

Loading Data from an S3 Bucket

You can load data from an S3 bucket using COPY FROM. Before you can load data from S3, you must set certain configuration parameters.

**Important:**

When loading data from S3, the maximum key length is 1K (1024 bytes). The input url argument for the S3 source (which can contain multiple delimited URLs) can be no larger than 1MB.

Setting Parameters

To read from S3 you need to provide Vertica with certain information, such as the S3 region and a credential to use for authentication. There are two different ways of setting these parameters:
• COPY from S3 depends on the configuration parameters described in S3 Parameters. You can set parameters globally and for the current session with 
ALTER DATABASE...SET PARAMETER and ALTER SESSION...SET PARAMETER, respectively.

• The deprecated UDSource depends on the session parameters described in AWS Library S3-Compatible User-Defined Session Parameters, which you can set only at the session level using ALTER SESSION SET UDPARAMETER.

If you use ALTER SESSION SET to set AWS parameters, Vertica also sets the corresponding UDSource parameters as if you had also used ALTER SESSION SET UDPARAMETER. Therefore, a best practice when making session-level changes is to use ALTER SESSION SET with the AWS parameters instead of using ALTER SESSION SET UDPARAMETER with the AWS Library parameters, even if you are using the UDSource.

The following example shows how to set parameters using these methods.

```sql
--- set global default region
=> ALTER DATABASE DEFAULT SET PARAMETER AWSRegion = 'us-west-1';

--- set credentials in the session only (also applies to UDSource)
=> ALTER SESSION SET AWSAuth='ID:secret';

--- alternate way to set credentials, for UDSource only (not copy from S3)
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='aws-id';
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='aws-key';
```

Vertica can read from buckets in only one AWS region at a time. To load from more than one region, change the region value for the session between loads.

### Using COPY

Before you can read data from S3, you must create an IAM role for your EC2 instances to use, and grant that role permission to access your S3 resources. For more information about IAM roles, see Amazon Web Services documentation.

You must set the AWSRegion configuration parameter to your S3 bucket's region. If you do not set the correct region, you might experience a delay before the load fails because Vertica retries several times before giving up.

The following example shows how to load data from buckets in different regions.

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER AWSRegion = 'us-west-1';
=> COPY sales FROM 's3://AWS_Data_1/sales.parquet' PARQUET;
```
ALTER SESSION SET AWSRegion='us-east-1');
=> COPY sales FROM 's3://AWS_Data_2/sales.orc', 's3://AWS_Data_3/sales.orc' ORC;

For more information, see Specifying COPY FROM Options.

Verifying the Load

You can verify that ROS files were created in the communal storage location using the AWS CLI:

$ aws s3 ls S3://testdb/
PRE 024/
PRE 028/
PRE 030/
PRE 034/
PRE 036/
...

You can also use the AWS web interface by navigating to the bucket and viewing its contents.

Granting Permissions for Non-priviledged Users

By default, S3 locations are only available to database superusers. To enable other users to load data from S3 create a USER storage location based on the S3 URL, and then grant read permissions to a user or group. The following example demonstrates creating a storage location for the S3 bucket named datalake and granting it to a role named ExtUsers.

=> CREATE LOCATION 's3://datalake' SHARED USAGE 'USER' LABEL 's3user';
=> CREATE ROLE ExtUsers;
    --- Assign users to this role using GRANT (Role).
=> GRANT READ ON LOCATION 's3://datalake' TO ExtUsers;

See Loading from an S3 Bucket for more information.
Local Caching of Storage Containers

Vertica's Execution Engine uses the StorageMerge operator to read data from storage containers in cases where it is important to read container data in its projection-specified sort order. This is particularly useful for operations that must preserve the sort order of the data that is read from multiple storage containers, before merging it into a single storage container. Common operations that enforce sort order include mergeout, and some queries with ORDER BY clauses—for example CREATE TABLE...AS query, where query includes an ORDER BY clause.

The Execution Engine typically allocates multiple threads to the StorageMerge operator. Each thread is assigned a single Scan operator to open and read container contents. If the number of containers to read is greater than the number of available threads, the Execution Engine is likely to assign individual Scan operators to multiple containers. In this case, Scan operators might need to switch among different containers and reopen them multiple times before all required data is fetched and assembled. Doing so is especially problematic when reading storage containers on remote filesystems such as S3. The extra overhead incurred by reopening and reading remote storage containers can significantly impact performance and usage costs.

You can configure your database so the Execution Engine caches on local disk the data of S3 storage containers that require multiple opens. The size of temp space allocated per query to the StorageMerge operator for caching is set by configuration parameter StorageMergeMaxTempCacheMB. By default, this configuration parameter is set to -1 (unlimited). If caching requests exceed temp space limits or available disk space, Vertica caches as much container data as it can, and then reads from S3.

**Note:**
The actual temp space that is allocated is the lesser of two settings:

- StorageMergeMaxTempCacheMB
- A user's TEMPSPACECAP setting
- The session tempspacecap setting

To turn off caching, set StorageMergeMaxTempCacheMB to 0.

Browsing S3 Data Using External Tables

You might want to browse the data in a large data lake that is already stored on S3. Instead of loading data into Vertica, you can read it in place at query time using external tables.
You can create external tables to query Parquet, ORC, text, and delimited data stored in S3 buckets. External tables work the same way in Eon Mode as they do in Enterprise Mode, with one exception: users who are not superusers must have read access to an S3 storage location to run queries. You can create a USER storage location on S3 for this purpose.

S3 Authentication for External Tables

AWS supports two authentication modes for S3: IAM roles and legacy id and secret authentication. Which method you use for your external table depends on whether the IAM role you assigned to your Vertica instance has access to the S3 bucket you want to access:

- If the IAM role has access (or you can grant it access) to the S3 bucket, then you do not have to take additional steps to configure authentication. Vertica uses the IAM role to authenticate with S3 by default. Whenever possible, use IAM roles, as it centralizes and simplifies authentication.
- If the IAM role does not have access to the S3 bucket and you cannot grant it access, then you must use an id and secret for authentication. You set the credentials in the AWSAuth session parameter.

**Important:**
The alternate credentials you use to access the S3 bucket must also have access read and write to the S3 storage locations that Vertica uses for communal and catalog storage. When you set the AWSAuth session parameter, Vertica uses the credentials it contains for all S3 access for your session.

Example

The following example illustrates the steps to create a USER storage location, give a user access to it, and create an external table (as that user).

1. If the Vertica IAM role does not have access to the S3 bucket you want to browse, you must use alternate credentials. Define the AWS credentials associated with the S3 bucket where you will create the storage location:

   ```sql
   => ALTER SESSION SET AWSAuth='ID:secret';
   ```
2. As a superuser, create a USER storage location on the same bucket that holds the data.

```sql
=> CREATE LOCATION 's3://datalake' SHARED USAGE 'USER' LABEL 's3user';
```

The only storage locations you can create on S3 are USER locations. You must create it as a shared location.

3. As a superuser, give access to the roles or users who will run queries against external tables.

```sql
--- If you have not already created a role:
=> CREATE ROLE ExtUsers;
--- Assign users to this role using GRANT (Role).
=> GRANT READ ON LOCATION 's3://datalake' TO ExtUsers;
```

4. As a user who has that role, create the external table in the usual way.

```sql
=> CREATE EXTERNAL TABLE sales (itemID INT, date DATE, price FLOAT)
   AS COPY FROM 's3://datalake/sales/*.parquet' PARQUET;
```

See Creating External Tables for more information about creating and using external tables. If your data is in ORC or Parquet format, you can take advantage of partitioning to limit the data that Vertica reads during query execution. See Using Partition Columns.

## Managing an Eon Mode Database in MC

Vertica Management Console (MC), a database health and activity monitoring tool, provides in-browser wizards you can follow to deploy Vertica cluster instances and create an Eon Mode database on them.

You can use MC to manage and monitor your database and its resources. See Using Management Console Using Management Console for the full guide on how to use MC to manage your database. See Monitoring Using MC for all the ways you can monitor your database.

MC provides you with some tasks and monitoring tools that are specific to Eon Mode. For example:
Monitor Storage Usage and Subscription Status

To view storage usage and subscription charts for any Eon Mode database you monitor, click View Your Infrastructure on the MC Home page. Then click the Storage View tab.

Use the Storage View tab in MC to monitor the size and storage capacity of your databases. You can use this page to determine if you should downsize databases that are taking up more of your storage capacity and costs, or if you need to increase storage resources for a database that has been growing.

The Storage View tab also gives insight into Eon Mode database node-shard subscriptions. Subscriptions verify that your database is K-safe, and control your nodes' readiness to serve queries.

To see bar chart visualizations for subscriptions, click the Details link for any Eon Mode database listed on the Storage View tab.

To learn more about monitoring storage in MC, see Monitoring Database Storage. To understand how to read the subscription charts in MC, go to Monitoring Subscription Status in Eon Mode.

Monitor Depot Activity

The depot (see Eon Mode Architecture) improves query performance by preventing your queries from having to go to communal storage every time you run a query. Instead, the queries access the depot, which contains local copies of your data.

Use the Depot Activity page to monitor query activity, churn, and settings for your database's depot. To view this page, click the Activity tab at the bottom of your database's Overview page, then select Depot Activity Monitoring from the chart list.

See Monitoring Depot Activity in MC for more on monitoring using this page.

Shutting Down and Reviving An Eon Mode Database

An Eon Mode database keeps an up-to-date version of its data and metadata in its communal storage location. After you shut down the database, it continues to reside in communal storage, so you can terminate compute nodes. When you are ready to use the database again, you can revive the database and provision new compute nodes.

You can also drop a database and then revive it and start your Vertica database.

Vertica uses the existing data to restore the database in the same state it was in before you shut it down. You do not need to wait for data to be copied; queries initially fetch data from communal storage as the compute nodes begin to fill their depots.

With the Vertica Management Console on AWS, you can use a wizard to provision a new cluster and revive a database onto it from a browser. See Reviving an Eon Mode Database on AWS in MC for the Management Console revive process.

Databases can be revived using admintools (described below) or through Management Console.

### Important:
If you need to revive your database on a previously existing cluster, you must revive it using admintools, not MC. For example, use admintools if you stopped a cluster whose hosts use instance storage where data is not persistently stored, and plan to bring back the database on the same cluster.

Vertica persists catalog data in communal storage, updating it every few minutes. Nonetheless, before shutting down your database you should make sure your metadata is up to date on communal storage. To do so, see Synchronizing Metadata.

## Revive the Database Using Admintools

Use the following process to revive your Eon Mode database on an existing cluster using admintools.
Caution:
Using the same communal storage location for multiple running databases causes data corruption. To avoid corruption, never use the revive functionality to simultaneously run the same Eon Mode database on different clusters.

Prerequisites:

- In addition to the following, for Eon Mode in an on-premise storage option like Pure Storage, create an auth_params.conf file and set the awsauth and awsendpoint parameters with your credentials and the IP address and port of your on-premise S3 server.

```
awsauth = key:secret
awsendpoint = IP:port
```

- In addition to the following, for Eon Mode in a cloud storage option, such as AWS:
  - A cluster whose hosts are in the same region as your communal storage location's bucket (To use a cluster in a new region, you must first clone the previous communal storage location to a bucket in the new region)
  - Amazon key pair for SSH access to an instance in the cluster
  - Communal storage location of the stopped Eon Mode database you plan to revive
  - Username and password of the Eon Mode database you plan to revive
  - A cluster with no other running databases
  - IP addresses of all hosts on the cluster

To revive the database:

1. Use SSH to access a cluster host as an administrator.
2. For Eon Mode on a cloud storage option such as AWS, run the following:

```
$ admintools -t revive_db --communal-storage-location=s3://<directory> -s $HOSTLIST --force -d $DATABASENAME
```

3. For Eon Mode on an on-premise storage option such as Pure Storage, run the following:

```
$ admintools -t revive_db -x auth_params.conf --communal-storage-location=s3://<directory> -s $HOSTLIST --force -d $DATABASENAME
```
Initial queries after revive will read from communal storage, which may take longer. As the database begins to fetch data to depot storage, queries will run faster.

**Synchronizing Metadata**

If you revive a database, it will use the synced catalog maintained in communal storage. The catalog contains your database's metadata.

When an Eon Mode database is running, Vertica automatically syncs the catalog every five minutes by default. Thus, it is not usually necessary to intervene in the synchronization process. However, before shutting down it is a good idea to make sure that the persistent copy of the catalog contains all recent changes. You can use the following processes to make sure the database's catalog is up to date when you revive.

- Check when the catalog was last synchronized.
- Manually sync the catalog.
- Customize the catalog sync interval.

**Check When the Catalog Was Last Synchronized**

**While the database is running:**

The following system tables are only available when the database is up.

Use system table `CATALOG_SYNC_STATE` to see how recently each node synced its catalog to communal storage. Checking this requires the database to still be running.

```sql
=> SELECT * FROM catalog_sync_state;
```

The system table `CATALOG_TRUNCATION_STATUS` also indicates how up to date the catalog is on communal storage. It is completely up to date when the current catalog version is the same as the catalog truncation version. Checking this requires the database to still be running.

```sql
=> SELECT * FROM catalog_truncation_status;
```

**When the database is not running:**

If your database is not currently running, a JSON file containing additional cluster information is located in communal storage. This file indicates the catalog truncation version and timestamp of the last sync to communal storage:
/metadata/database-name/cluster_config.json

**Manually Sync the Catalog**

The `sync_catalog` function immediately synchronizes the catalog on all nodes or a specific node.

```
=> SELECT sync_catalog();
```

**Customize Catalog Sync Interval**

Use the `CatalogSyncInterval` parameter to set a time interval for which the metadata is pushed to communal storage:

```
=> ALTER DATABASE DEFAULT SET CatalogSyncInterval = 10 minutes
```
Welcome to the Vertica on the Cloud guide. This section explains how you can create Vertica clusters on different cloud platforms.

This document assumes that you are familiar with the cloud environment on which you will create your Vertica cluster.

Vertica on Amazon Web Services

Welcome to the Vertica on Amazon Web Services (AWS) guide. This section explains how to create and manage Vertica clusters on AWS.

When you launch a cluster on AWS resources and are ready to create your database, consider whether to run it in Eon Mode or Enterprise Mode. The differences in these two modes lay in their architecture, deployment, and scalability:

- The Enterprise Mode database architecture distributes data across local nodes, and works on-premise or in the cloud. Create an Enterprise Mode database on a cluster of predetermined size, which is good for running large queries quickly. Because it persistently stores its data locally, you do not need access to shared storage on Amazon S3 to use an Enterprise Mode database.
The **Eon Mode** database architecture leverages the flexibility of EC2 instances and the persistence of Amazon S3. Eon Mode databases are ideal when you want to frequently scale up your cluster in order to run many short, concurrent queries. Because an Eon Mode database stores its data in a persistent location outside of its local nodes, you can rapidly adjust the size of your cluster without interrupting ongoing workloads.
Eon Mode separates the computational processes from the communal storage layer of your database. This separation gives you the ability to store your data in a single location (on AWS) and elastically vary the number of compute nodes connected to that location according to your computational needs.

Vertica provides CloudFormation Templates (CFTs) through the AWS Marketplace. These CFTs also deploy Management Console.

**Note:**
For detailed information about which CFT to use, see [Creating a Database in Eon Mode](#).

After you provide parameters to the template, you create a stack to provision the AWS resources for your Vertica system. Now use Management Console (MC) to create and manage clusters and databases.

You can install an Eon Mode database using in-browser wizards provided by Management Console, available through the AWS Marketplace or using admintools. You can only create Eon Mode databases on clusters that reside on AWS resources.

See [Using Eon Mode](#) for more about Eon Mode database concepts.
Overview of Vertica on Amazon Web Services (AWS)

Vertica clusters on AWS can operate on EC2 instances automatically provisioned using a CloudFormation Template, or manually deployed from Amazon Machine Images (AMIs).

You can create a database in either Eon Mode or Enterprise Mode in a Vertica cluster in AWS.

For more information about Amazon cluster instances and their limitations, see the Amazon documentation.

CloudFormation Templates

Vertica provides Cloud Formation Templates (CFTs) through the AWS Marketplace. After you provide a few parameters to the template, create a stack to automatically provision the AWS resources for your Vertica system.

After creating the stack, in the Management Console (MC) you can create and manage your clusters and databases. See Provisioning a New Vertica Cluster and Database on AWS in MC.

Vertica Offerings on AWS

Using the license models and CFTs described in CloudFormation Template (CFT) Overview, you can install the following Vertica products:
Vertica BYOL, Amazon Linux 2.0
Vertica by the Hour, Amazon Linux 2.0
Vertica BYOL, Red Hat
Vertica by the Hour, Red Hat

See Launch MC and AWS Resources with a CloudFormation Template for information on installing these products

Vertica AMI Operating Systems for AWS

Vertica provides Vertica and Management Console AMIs in the following operating systems.

- Red Hat 7.4 and later
- Amazon Linux 2.0 and later

You can use the AMI to deploy MC hosts or cluster hosts.

**Important:**
When using Amazon Linux 2.0, you must compile C++ UDX libraries with a gcc version 4.8. For more information see Setting Up a Development Environment.

Supported AWS Instance Types

Vertica supports a range of Amazon Web Services instance types, each optimized for different purposes. Choose the instance type that best matches your requirements. The two tables below list the AWS instance types that Vertica supports for Vertica cluster hosts, and for use in MC. For more information, see the Amazon Web Services documentation on instance types and volumes.

**Instance Types for Vertica Cluster Hosts**

Each Amazon EC2 Instance type natively provides one of the following storage options:

- Elastic Block Store (EBS) provides durable storage: Data files stored on instance persist after instance is stopped.
• Instance Store provides temporary storage: Data files stored on instance are lost when instance is stopped.

**Important:**
Instance types that support EBS volumes support encrypting.

More Information

For more information about Amazon cluster instances and their limitations, see Manage Clusters in the Amazon Web Services documentation.

Vertica AMI Sleep C-States

By default, the following instances have their processor C-states set to a value of 1 in the Vertica AMI:

- c4.8xlarge
- d2.8xlarge
- m4.10xlarge

This measure is meant to improve performance by limiting the sleep states that an instance running Vertica uses.

For more information about sleep states, visit the AWS Documentation.

AWS Features Supported by Vertica

Vertica supports the following AWS features:

- **Enhanced Networking**: Vertica recommends that you use the AWS enhanced networking for optimal performance. For more information, see Enabling Enhanced Networking on Linux Instances in a VPC in the AWS documentation.
- **Command Line Interface**: Use the Amazon command-line Interface (CLI) with your Vertica AMIs. For more information, see What Is the AWS Command Line Interface?.
- **Elastic Load Balancing**: Use elastic load balancing (ELB) for queries up to one hour. When enabling ELB, configure the timer to 3600 seconds. For more information see Elastic Load Balancing in the AWS documentation.

AWS Authentication

Amazon defines two ways to control access to AWS resources such as S3: IAM roles and the combination of id, secrets, and (optionally) session tokens. For long-term access to non-
communal storage buckets, you should use IAM roles for access control centralization. You do not need to change your application's configuration if you want to change its access settings. You just alter the IAM role applied to your EC2 instances.

However, for one-time tasks like backing up and restoring the database or loading data to and from non-communal storage buckets, you should use an AWS access key.

Vertica uses both of these authentication methods to support different features and use cases:

- An Eon Mode database's access to S3 for communal and catalog storage must always use IAM role authentication. IAM roles are the default access control method for AWS resources. Vertica uses this method if you do not configure the legacy access control session parameters.
- Individual users can read data from S3 storage locations other than the ones Vertica uses for communal storage. For example, users can use COPY to load data into Vertica from an S3 bucket or query an external table stored on S3. If the IAM role assigned to the Vertica nodes does not have access to this external S3 data, the user must set an id, secret, and optionally an access token in session variables to authorize access to it. These session variables override the IAM role set on the server. See S3 Parameters for a list of these session parameters.
- Individual users can export data to S3 using the Vertica Library for AWS. This library cannot use IAM authorization. Users who want to export data to S3 using this library must set id, secret, and optionally access token values in session variables. See Configure the Vertica Library for Amazon Web Services for details.

**Important:**
If the database is running in Eon Mode, using id and secret authentication is more complex. In addition to having access to the external S3 data, any id that a user sets must be authorized to read from and write to the S3 storage locations that Vertica uses to store communal and catalog data. The queries that the user executes uses this id for all storage requests, not just those for accessing external S3 data. If the id does not have access to the catalog and communal storage, the user cannot execute queries.

**Configuring an IAM Role**

To configure an IAM role to grant Vertica to access AWS resources you must:

1. Create an IAM role to allow EC2 instances to access the specific resources.
2. Grant that role permission to access your resources.
3. Attach this IAM role to each EC2 instance in the Vertica cluster.

To see an example of IAM roles for a Vertica cluster, look at the roles defined in one of the Cloud Formation Templates provided by Vertica. You can download these templates from any of the Vertica entries in the Amazon Marketplace. Under each entry's Usage Information section, click the View CloudFormation Template link, then click Download CloudFormation Template.

For more information about IAM roles, see IAM Roles for Amazon EC2 in the AWS documentation.

## Installing Vertica with CloudFormation Templates

Vertica provides CloudFormation Templates (CFTs) on the AWS Marketplace that allow you to get a cluster up and running quickly. Using the template allows you to automatically provision your AWS resources and launch a Vertica cluster and Management Console, with minimal configuration required.

If you prefer to deploy a VPC, instances, and related resources manually, see Install Vertica with Manually Deployed AWS Resources.

## CloudFormation Template (CFT) Overview

With Vertica on AWS, use CloudFormation Templates (CFTs) to easily manage provisioning the AWS resources with a running Vertica system.

To access Vertica CFTs, go to the AWS Marketplace. Licensing models for CFTs are:

- **Bring Your Own License (BYOL):** By default, free CE license is installed with 3 nodes and 1 TB. To extend nodes or size, you can purchase the Vertica BYOL license. Outside of the BYOL license on CFTs, you can also access the Community Edition without a license file:
  - If you are using Management Console, simply leave the license field blank.
  - If you are using a command line (see Installing Vertica with the Installation Script), specify CE in the --license parameter during installation.
- **By the Hour:** A pay-as-you-go model where you pay for only the number of hours you use for each node. One advantage of using the Paid Listing is that all charges appear
on your Amazon AWS bill. This offers an alternative to purchasing a full Vertica license. This eliminates the need to compute potential storage needs in advance.

Available Vertica CFTs are:

- **Management Console with 3 Vertica nodes**: The easiest way to deploy Vertica. This CFT deploys an Eon Mode database by default. However, this environment can also be used to create an Enterprise Mode database. For more information, see Creating a Database.

- **Deploy Management Console into new VPC**: This CFT deploys all required AWS resources and installs the Vertica Management Console (MC). After stack creation completes, log in to the MC to provision a Vertica database cluster.

- **Deploy Management Console into existing VPC**: This CFT deploys the Vertica Management Console (MC) in an already-existing VPC and subnet. After stack creation completes, the MC is available. Log in to MC to provision either a Vertica database cluster or an Eon Mode database cluster.

For this CFT, you must first set up the VPC, subnet, and related network resources. For more information about the correct configuration of these resources for Vertica, see the following topics in the AWS documentation:

- Creating a Virtual Private Cloud
- Configuring the Network

**For More Information**

For supported operating systems for these CFTs, see Vertica AMI Operating Systems for AWS.

For Vertica products available on AWS, see Vertica Offerings on AWS.

**Prerequisites for Using CFTs**

Before you can install Vertica on AWS using CloudFormation Templates (CFTs), verify that you have:

- AWS account with permissions to create a VPC, subnet, security group, EC2 instances, and IAM roles (For more information about AWS accounts, see the AWS documentation)
Launch MC and AWS Resources with a CloudFormation Template

Launch Management Console (MC) and its associated AWS resources using CloudFormation templates (CFTs) that are available through the AWS Marketplace. For a list of available CFTs, see CloudFormation Template (CFT) Overview.

Starting in the AWS Marketplace, launch the provisioning instance from which you can install Vertica:

1. Log in to the AWS Marketplace with an AWS account (see the Prerequisites section above).
2. Search for "Vertica" in the AWS Marketplace.
3. Select a Vertica CFT. Each CFT leads you to a product overview page, with pricing estimates. (Also see CloudFormation Template (CFT) Overview for an overview of available templates and products).
4. Click Continue to Subscribe.
5. On the next page, select your launch settings based on your requirements for deployment.
6. If you have not agreed to Vertica EULA terms on the AWS Marketplace before, click Accept Software Terms to subscribe.
7. Click Launch with CloudFormation Console. The CloudFormation Console opens.
8. The CloudFormation Console automatically supplies the URL in the Specify an Amazon S3 template URL field. Click Next.
9. Follow the CloudFormation workflow and enter the parameters (collectively called a stack).

Important: Take note of the username and password you set for Management Console during this step. You cannot recover or reset these credentials after you create the stack.

10. After confirming the details you have provided for your new stack, click Create. The AWS console brings you to the Stacks page, where you can view the progress of the creation process. The process takes several minutes.

11. The Outputs tab displays information about accessing your environment after the process completes.
Next, access the Management Console (MC) to deploy your cluster instances and create a database, as described in Access Management Console.

**Access Management Console**

You use MC to deploy Vertica cluster instances and create a database. You can also use MC to manage and monitor your databases. You will use Management Console to provision a Vertica cluster and database on the AWS resources you just launched.

1. On the AWS CloudFormation Stacks page, select your new stack and view the Outputs tab. This tab provides information about accessing your environment, as well as documentation and licensing resources.
2. Click the Access Management Console URL. This link takes you to the MC login page.
3. To log in, enter the MC username and password that you created using the CloudFormation Console.

   After login, MC displays the home page, with options to provision a new cluster or database or import existing ones. If you chose a CFT that also creates a database, your new database is also displayed on the home page.

   This page also provides a Resources section with links to online training, blogs, community, and help resources.

You have successfully launched Management Console on AWS resources.

If you have not yet provisioned a Vertica cluster and database, follow the steps in Provisioning a New Vertica Cluster and Database on AWS in MC

**Provisioning a New Vertica Cluster and Database on AWS in MC**

If you deployed Management Console on Amazon Web Services (AWS) resources using a CloudFormation Template, MC provides a step-by-step wizard that allows you to create a
Vertica cluster and database.

You provision new Vertica clusters in the same VPC and subnet as the Vertica MC instance. Using the wizard, you can create an initial cluster of up to 60 hosts.

**Note:** To provision a new database and cluster on-premise, see Creating a Cluster Using MC in the Installation Guide. If you installed MC using an RPM, follow the steps in the Installation Guide.

1. On the MC home page, click **Create a New Vertica Database Cluster**.
2. Choose a mode for your database: Eon Mode or Enterprise Mode. You cannot switch the database mode after creation.
3. Follow the cluster creation wizard and enter the parameters for your new cluster and database.
   - By default, Vertica creates your cluster in the same subnet as your MC instance. If you want to manage all Vertica clusters in the same VPC (virtual private cloud), you can provision your Vertica database in a different subnet than the MC instance. To do so, on the **AWS Credentials** page, select **Show Advanced Options** and enter a value in the **Subnet** field.

   **Important:**
   If you specify a different subnet for your database, make sure to secure the subnet.

   - When launching MC with provisioning, use the authentication method you selected in the CloudFormation Console.
4. If you choose Enterprise Mode, complete the wizard by following one of these two paths:
   - **Quick Create** provides default values during cluster creation.
   - **Custom Create** allows you to specify EC2 instance types and other AWS resources for your Vertica cluster instances.
5. If you choose Eon Mode, in the **Vertica Version** field, select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can select RedHat, CentOS, or Amazon Linux for the operating system.

   **Vertica Version**
   ![Vertica Version](image)

6. Complete the rest of your login credentials and select Next.
7. In the **EC2 Instance Type** field, select the cloud instance type to use for your database cluster. Accept the defaults for the depot, catalog, and temp volumes. The wizard automatically configures separate volumes for the depot, catalog, and temp directories, based on the instance type you select. The last step displays a confirmation page showing the configured volumes. For details on the volume configurations that MC provides, see [Eon Mode Volume Configuration Defaults for AWS](#) and [Enterprise Mode Volume Configuration Defaults for AWS](#).

8. Also in Eon Mode, but only in the **Custom Create** path, for each EBS volume you can select whether the volume should be encrypted. With AWS, only 4th and 5th generation instance types (c4, r4, and m4; c5, r5, and m5) support encrypting EBS volumes.

9. Optionally, you can tag the EC2 instances. In the **Tag EC2 instances** field, if another cluster is already running, MC fills those fields with the tag values for the first instance in the cluster. You can accept the defaults, or enter new tag values.

10. On the summary page, review the details you entered for your new cluster.

11. Click **Create**. The dialog shows you the progress of the creation process, which takes a few minutes. (You can leave or close the browser during this process. To return to this progress window, select **Create a New Vertica Database Cluster** on the home page.)

    **Note:**
    During Eon Mode database creation, use an existing S3 bucket in the same region as the instances for your communal storage location. You must also specify a new, nonexisting subfolder name that Vertica then dynamically creates within the existing S3 bucket. Use a format beginning with s3://. For example, s3://existingbucket/newsubfolder1.

12. The dialog displays a success message when the creation process completes. Click **Get Started** to view the **Fast Tasks** page.

To view your new database, go to the **Available Databases** section of the MC home page.

For more information about further managing your cluster, instances, and database using MC, see [Managing Database Clusters](#).
Install Vertica with Manually Deployed AWS Resources

Vertica provides an AMI that you can install on AWS resources that you manually deploy. This section will guide you through configuring your network settings on AWS, launching and preparing EC2 instances using the Vertica AMI, and creating a Vertica cluster on those EC2 instances.

Choose this method of installation if you are familiar with configuring AWS and have many specific AWS configuration needs. (To automatically deploy AWS resources and a Vertica cluster instead, see Installing Vertica with CloudFormation Templates.

Configure Your Network

Before you create your cluster, you must configure the network on which Vertica will run. Vertica requires a number of specific network configurations to operate on AWS. You may also have specific network configuration needs beyond the default Vertica settings.

The following sections explain which Amazon EC2 features you need to configure for instance creation.

Create a Placement Group, Key Pair, and VPC

Part of configuring your network for AWS is to create the following:

- Placement Group
- Key Pair
- Virtual Private Cloud (VPC)

Create a Placement Group

A placement group is a logical grouping of instances in a single Availability Zone. Placement Groups are required for clusters and all Vertica nodes must be in the same Placement
Vertica recommends placement groups for applications that benefit from low network latency, high network throughput, or both. To provide the lowest latency, and the highest packet-per-second network performance for your Placement Group, choose an instance type that supports enhanced networking.

For information on creating placement groups, see Placement Groups in the AWS documentation.

**Create a Key Pair**

You need a key pair to access your instances using SSH. Create the key pair using the AWS interface and store a copy of your key (*.pem) file on your local machine. When you access an instance, you need to know the local path of your key.

Use a key pair to:

- Authenticate your connection as dbadmin to your instances from outside your cluster.
- Install and configure Vertica on your AWS instances.

For information on creating a key pair, see Amazon EC2 Key Pairs in the AWS documentation.

**Create a Virtual Private Cloud (VPC)**

You create a Virtual Private Cloud (VPC) on Amazon so that you can create a network of your EC2 instances. Your instances in the VPC all share the same network and security settings.

A Vertica cluster on AWS must be logically located in the same network. Create a VPC to ensure the nodes in your cluster can communicate with each other in AWS.

Create a single public subnet VPC with the following configurations:

- Assign a Network Access Control List (ACL) that is appropriate to your situation.
- Enable DNS resolution and enable DNS hostname support for instances launched in this VPC.
- Add the required network inbound and outbound rules to the Network ACL associated to the VPC.
Note:
A Vertica cluster must be operated in a single availability zone.

For information on creating a VPC, see Create a Virtual Private Cloud (VPC) in the AWS documentation.

**Network ACL Settings**

Vertica requires the following basic network access control list (ACL) settings on an AWS instance running the Vertica AMI. Vertica recommends that you secure your network with additional ACL settings that are appropriate to your situation.

**Inbound Rules**

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port Range</th>
<th>Use</th>
<th>Source</th>
<th>Allow/Deny</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSH</td>
<td>TCP (6)</td>
<td>22</td>
<td>SSH (Optional—for access to your cluster from outside your VPC)</td>
<td>User Specific</td>
<td>Allow</td>
</tr>
<tr>
<td>Custom TCP Rule</td>
<td>TCP (6)</td>
<td>5450</td>
<td>MC (Optional—for MC running outside of your VPC)</td>
<td>User Specific</td>
<td>Allow</td>
</tr>
<tr>
<td>Custom TCP Rule</td>
<td>TCP (6)</td>
<td>5433</td>
<td>SQL Clients (Optional—for access to your cluster from SQL clients)</td>
<td>User Specific</td>
<td>Allow</td>
</tr>
<tr>
<td>Custom TCP Rule</td>
<td>TCP (6)</td>
<td>50000</td>
<td>Rsync (Optional—for backup outside of your VPC)</td>
<td>User Specific</td>
<td>Allow</td>
</tr>
<tr>
<td>Custom TCP Rule</td>
<td>TCP (6)</td>
<td>1024-65535</td>
<td>Ephemeral Ports (Needed if you use any of the above)</td>
<td>User Specific</td>
<td>Allow</td>
</tr>
<tr>
<td>ALL Traffic</td>
<td>ALL</td>
<td>ALL</td>
<td>N/A</td>
<td>0.0.0.0/0</td>
<td>Deny</td>
</tr>
</tbody>
</table>

**Outbound Rules**
<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port Range</th>
<th>Use</th>
<th>Source</th>
<th>Allow/Deny</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom TCP Rule</td>
<td>TCP (6)</td>
<td>0–65535</td>
<td>Ephemeral Ports</td>
<td>0.0.0.0/0</td>
<td>Allow</td>
</tr>
</tbody>
</table>

You can use the entire port range specified in the previous table, or find your specific ephemeral ports by entering the following command:

$ cat /proc/sys/net/ipv4/ip_local_port_range

**More Information**

For detailed information on network ACLs within AWS, refer to Network ACLs in the Amazon documentation.

For detailed information on ephemeral ports within AWS, refer to Ephemeral Ports in the Amazon documentation.

**Configure TCP keepalive with AWS Network Load Balancer**

AWS supports three types of elastic load balancers (ELBs):

- Classic Load Balancers
- Application Load Balancers
- Network Load Balancers

Vertica strongly recommends the AWS Network Load Balancer (NLB), which provides the best performance with your Vertica database. The Network Load Balancer acts as a proxy between clients (such as JDBC) and Vertica servers. The Classic and Application Load Balancers do not work with Vertica, in Enterprise Mode or Eon Mode.

To avoid timeouts and hangs when connecting to Vertica through the NLB, it is important to understand how AWS NLB handles idle timeouts for connections. For the NLB, AWS sets the idle timeout value to 350 seconds and you cannot change this value. The timeout applies to both connection points.

For a long-running query, if either the client or the server fails to send a timely keepalive, that side of the connection is terminated. This can lead to situations where a JDBC client hangs waiting for results that would never be returned because the server fails to send a keepalive within 350 seconds.
To identify an idle timeout/keepalive issue, run a query like this via a client such as JDBC:

```sql
=> SELECT SLEEP(355);
```

If there’s a problem, one of the following situations occurs:

- The client connection terminates before 355 seconds. In this case, lower the JDBC keepalive setting so that keepalives are sent less than 350 seconds apart.
- The client connection doesn’t return a result after 355 seconds. In this case, you need to adjust the server keepalive settings (tcp_keepalive_time and tcp_keepalive_intvl) so that keepalives are sent less than 350 seconds apart.

For detailed information about AWS Network Load Balancers, see [What is a Network Load Balancer?](#) in the AWS documentation.

### Create and Assign an Internet Gateway

When you create a VPC, an Internet gateway is automatically assigned to it. You can use that gateway, or you can assign your own. If you are using the default Internet gateway, continue with the procedure described in [Create a Security Group](#).

Otherwise, create an Internet gateway specific to your needs. Associate that internet gateway with your VPC and subnet.

For information about how to create an Internet Gateway, see [Internet Gateways](#) in the AWS documentation.

### Assign an Elastic IP Address

An elastic IP address is an unchanging IP address that you can use to connect to your cluster externally. Vertica recommends you assign a single elastic IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using their internal IP addresses dictated by your VPC settings.

Create an elastic IP address. For information, see [Elastic IP Addresses](#) in the AWS documentation.
Create a Security Group

The Vertica AMI has specific security group requirements. When you create a Virtual Private Cloud (VPC), AWS automatically creates a default security group and assigns it to the VPC. You can use the default security group, or you can name and assign your own.

Create and name your own security group using the following basic security group settings. You may make additional modifications based on your specific needs.

Inbound

<table>
<thead>
<tr>
<th>Type</th>
<th>Use</th>
<th>Protocol</th>
<th>Port Range</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSH</td>
<td>TCP</td>
<td>22</td>
<td></td>
<td>The CIDR address range of administrative systems that require SSH access to the Vertica nodes. Make this range as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.</td>
</tr>
<tr>
<td>DNS (UDP)</td>
<td>UDP</td>
<td>53</td>
<td></td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
<tr>
<td>Custom UDP</td>
<td>Spread</td>
<td>UDP</td>
<td>4803 and 4804</td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
<tr>
<td>Custom TCP</td>
<td>Spread</td>
<td>TCP</td>
<td>4803</td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
<tr>
<td>Custom TCP</td>
<td>VSQL/SQL</td>
<td>TCP</td>
<td>5433</td>
<td>The CIDR address range of client systems that require access to the Vertica nodes. This range should be as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.</td>
</tr>
</tbody>
</table>
### Custom TCP Communication

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>5434</td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
<tr>
<td>TCP</td>
<td>5444</td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
<tr>
<td>TCP</td>
<td>5450</td>
<td>The CIDR address of client systems that require access to the management console. This range should be as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.</td>
</tr>
<tr>
<td>TCP</td>
<td>48073</td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
<tr>
<td>TCP</td>
<td>50000</td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
</tbody>
</table>

### ICMP

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>N/A</td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
<tr>
<td>ICMP</td>
<td>N/A</td>
<td>Your private subnet address range (for example, 10.0.0.0/24).</td>
</tr>
</tbody>
</table>

### Outbound

#### Note:

In Management Console (MC), the Java IANA discovery process uses port 7 once to detect if an IP address is reachable before the database import operation. Vertica tries port 7 first. If port 7 is blocked, Vertica switches to port 22.

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port Range</th>
<th>Destination</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>All TCP</td>
<td>TCP</td>
<td>0-65535</td>
<td>Anywhere</td>
<td>0.0.0.0/0</td>
</tr>
<tr>
<td>All ICMP</td>
<td>ICMP</td>
<td>0-65535</td>
<td>Anywhere</td>
<td>0.0.0.0/0</td>
</tr>
<tr>
<td>All UDP</td>
<td>UDP</td>
<td>0-65535</td>
<td>Anywhere</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>
For information about what a security group is, as well as how to create one, see Amazon EC2 Security Groups for Linux Instances in the AWS documentation.

**Deploy AWS Instances for your Vertica Database Cluster**

Once you have configured your network, you are ready to create your AWS instances and install Vertica. Follow these procedures to install and run Vertica on AWS.

**Configure and Launch an Instance**

After you configure your network settings on AWS, configure and launch the instances onto which you will install Vertica. An Elastic Compute Cloud (EC2) instance without a Vertica AMI is similar to a traditional host. Just like with an on-premises cluster, you must prepare and configure your cluster and network at the hardware level before you can install Vertica.

When you create an EC2 instance on AWS using a Vertica AMI, the instance includes the Vertica software and the recommended configuration. The Vertica AMI acts as a template, requiring fewer configuration steps. Vertica recommends that you use the Vertica AMI as is—without modification.

**Configure EC2 Instances in AWS**

1. Select the Vertica AMI from the AWS marketplace.
2. Select the desired fulfillment method.
3. Configure the following:
   - A supported instance type
   - The number of instances you want to launch. A Vertica cluster usually uses identically configured instances of the same type.
   - A VPC
   - Placement Group

**Add Storage to Your Instances**

Consider the following issues when you add storage to your instances:
• Add a number of drives equal to the number of physical cores in your instance. For example, for a c3.8xlarge instance, 16 drives. For an r3.4xlarge, add 8 drives.
• Do not store your information on the root volume.
• Amazon EBS provides durable, block-level storage volumes that you can attach to running instances. For guidance on selecting and configuring an Amazon EBS volume type, see Amazon EBS Volume Types in the Amazon Web Services documentation.

Decide Whether to Configure EBS Volumes as a RAID Array

You can choose to configure your EBS volumes into a RAID 0 array to improve disk performance. Before doing so, use the vioperf utility to determine whether the performance of the EBS volumes is fast enough without using them in a RAID array. Pass vioperf the path to a mount point for an EBS volume. In this example, an EBS volume is mounted on a directory named /vertica/data:

```
[dbadmin@ip-10-11-12-13 ~]$ /opt/vertica/bin/vioperf /vertica/data
```

The minimum required I/O is 20 MB/s read and write per physical processor core on each node, in full duplex i.e. reading and writing at this rate simultaneously, concurrently on all nodes of the cluster. The recommended I/O is 40 MB/s per physical core on each node. For example, the I/O rate for a server node with 2 hyper-threaded six-core CPUs is 240 MB/s required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/vertica/data"

<table>
<thead>
<tr>
<th>test</th>
<th>directory</th>
<th>counter name</th>
<th>counter</th>
<th>counter</th>
<th>counter</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

| Write | /vertica/data | MB/s | 259 | 259 | 32.375 | 32.375 |
| Write | /vertica/data | MB/s | 248 | 232 | 31 | 29 |
| Write | /vertica/data | MB/s | 240 | 234 | 30 | 29.25 |
| Write | /vertica/data | MB/s | 240 | 233 | 30 | 29.125 |
| Write | /vertica/data | MB/s | 240 | 232 | 30 | 29.125 |
| Write | /vertica/data | MB/s | 240 | 233 | 30 | 29.125 |
| Write | /vertica/data | MB/s | 240 | 232 | 30 | 29 |
| Write | /vertica/data | MB/s | 240 | 233 | 30 | 29.75 |
| Write | /vertica/data | MB/s | 240 | 232 | 30 | 29.75 |
| Write | /vertica/data | MB/s | 240 | 235 | 30 | 29.375 |
| Write | /vertica/data | MB/s | 240 | 237 | 30 | 29.625 |
| Write | /vertica/data | MB/s | 240 | 237 | 30 | 29.625 |
| Write | /vertica/data | MB/s | 237+237 | 237+237 | 29.625+29.625 | 29.625+29.625 |

Use vioperf to measure disk access in MB/s and calculate time (s) to write.
If the EBS volume read and write performance (the entries with Read and Write in column 1 of the output) is greater than 20MB/s per physical processor core (columns 6 and 7), you do not need to configure the EBS volumes as a RAID array to meet the minimum requirements to run Vertica. You may still consider configuring your EBS volumes as a RAID array if the performance is less than the optimal 40MB/s per physical core (as is the case in this example).

### Note:
If your EC2 instance has hyper-threading enabled, vioperf may incorrectly
count the number of cores in your system. The 20MB/s throughput per core requirement only applies to physical cores, rather than virtual cores. If your EC2 instance has hyper-threading enabled, divide the counter value (column 4 in the output) by the number of physical cores. See CPU Cores and Threads Per CPU Core Per Instance Type section in the AWS documentation topic Optimizing CPU Options for a list of physical cores in each instance type.

If you determine you need to configure your EBS volumes as a RAID 0 array, see the AWS documentation topic RAID Configuration on Linux the steps you need to take.

Security Group and Access

1. Choose between your previously configured security group or the default security group.
2. Configure S3 access for your nodes by creating and assigning an IAM role to your EC2 instance. See AWS Authentication for more information.

Launch Instances

Verify that your instances are running.

Connect to an Instance

Using your private key, take these steps to connect to your cluster through the instance to which you attached an elastic IP address:

1. As the dbadmin user, type the following command, substituting your ssh key:

   ```
   $ ssh --ssh-identity <ssh key> dbadmin@elasticipaddress
   ```

2. Select Instances from the Navigation panel.
3. Select the instance that is attached to the Elastic IP.
4. Click Connect.
5. On Connect to Your Instance, choose one of the following options:

   - A Java SSH Client directly from my browser—Add the path to your private key in the field Private key path, and click Launch SSH Client.
Connect with a standalone SSH client—Follow the steps required by your standalone SSH client.

Connect to an Instance from Windows Using Putty

If you connect to the instance from the Windows operating system, and plan to use Putty:

1. Convert your key file using PuTTYgen.
2. Connect with Putty or WinSCP (connect via the elastic IP), using your converted key (i.e., the *.ppk file).
3. Move your key file (the *.pem file) to the root dir using Putty or WinSCP.

Prepare Instances for Cluster Formation

After you create your instances, you need to prepare them for cluster formation. Prepare your instances by adding your AWS .pem key and your Vertica license.

By default, each AMI includes a Community Edition license. Once Vertica is installed, you can find the license at this location:

```
/opt/vertica/config/licensing/vertica_community_edition.license.key
```

1. As the dbadmin user, copy your *.pem file (from where you saved it locally) onto your primary instance.

   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the `install_vertica` script fails with a message similar to the following:

   ```
   FATAL (19): Failed Login Validation 10.0.3.158, cannot resolve or connect to host as root.
   ```

   If you receive a failure message, enter the following command to correct permissions on your *.pem file:

   ```
   $ chmod 600 /<name-of-pem>.pem
   ```

2. Copy your Vertica license over to your primary instance, placing it in your home directory or other known location.
**Change Instances on AWS**

You can change instance types on AWS. For example, you can downgrade a c3.8xlarge instance to c3.4xlarge. See [Supported AWS Instance Types](#) for a list of valid AWS instances.

When you change AWS instances you may need to:

- Reconfigure memory settings
- Reset memory size in a resource pool
- Reset number of CPUs in a resource pool

**Reconfigure memory settings**

If you change to an AWS instance type that requires a different amount of memory, you may need to recompute the following and then reset the values:

- **All Systems**
- **max_map_count**

**Note:**

You may need root user permissions to reset these values.

**Reset memory size in a resource pool**

If you used absolute memory in a resource pool, you may need to reconfigure the memory using the MEMORYSIZE parameter in `ALTER RESOURCE POOL`.

**Note:**

If you set memory size as a percentage when you created the original resource pool, you do not need to change it here.

**Reset number of CPUs in a resource pool**

If your new instance requires a different number of CPUs, you may need to reset the CPUAFFINITYSET parameter in `ALTER RESOURCE POOL`. 
Configure Storage

Vertica recommends that you do not store your information on the root volume, especially your data and catalog directories. Instead, use dedicated EBS volumes for node storage. When configuring your storage, make sure to use a supported file system.

**Note:**
When customizing an Eon mode cluster on AWS, note that Eon has been performance tested with a per-node EBS volume of up to 2TB. See Using Eon Mode.

For best performance, combine multiple EBS volumes into RAID-0. Vertica provides a shell script, which automates the storage configuration process. For more information about EBS volume types, see Amazon EBS Volume Types in the Amazon Web Services documentation.

Determining Volume Names

Before you combine volumes for storage, make note of your volume names so that you can alter the configure_aws_software_raid.sh shell script. You can find your volumes with the following commands:

```bash
$ cd /dev
$ ls
```

Your volumes start with xvd.

**Important:** Ignore your root volume. Do not include any of your root volumes in the RAID creation process.

Combining Volumes for Storage

Follow these sample steps to combine your EBS volumes into RAID 0 using the configure_aws_software_raid.sh shell script.

1. Edit the /opt/vertica/sbin/configure_aws_software_raid.sh shell file as follows:
a. Comment out the safety exit command at the beginning.
b. Change the sample volume names to your own volume names, which you noted previously. Add more volumes, if necessary.

2. Run the /opt/vertica/sbin/configure_aws_software_raid.sh shell file. Running this file creates a RAID 0 volume and mounts it to /vertica/data.

3. Change the owner of the newly created volume to dbadmin with chown.

4. Repeat steps 1-3 for each node on your cluster.

More Information

For more information about EBS storage, refer to the RAID Configuration on Linux in the Amazon documentation.

Create a Cluster

On AWS, use the install_vertica script to combine instances and create a cluster. Check your My Instances page on AWS for a list of current instances and their associated IP addresses. You need these IP addresses when you run install_vertica.

Create a cluster as follows:

1. While connected to your primary instance, enter the following command to combine your instances into a cluster. Substitute the IP addresses for your instances and include your root *pem file name.

   $ sudo /opt/vertica/sbin/install_vertica --hosts 10.0.11.164,10.0.11.165,10.0.11.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-pem>.pem --license <license.file>

   Note:
   If you are using Vertica Community Edition, which limits you to three instances, you can specify -L CE with no license file.

   When you issue install_vertica or update_vertica on a Vertica AMI script, --point-to-point is the default. This parameter configures Spread to use direct point-to-point communication between all Vertica nodes, which is a requirement for clusters on AWS.

2. After combining your instances, Vertica recommends deleting your *pem key from your cluster to reduce security risks. The example below uses the shred command to
delete the file:

```
$ shred examplekey.pem
```

3. After creating one or more clusters, create your database.

For complete information on the `install_vertica` script and its parameters, see Installing Vertica with the Installation Script.

**Important:**
Stopping or rebooting an instance or cluster without first shutting down the database down, may result in disk or database corruption. To safely shut down and restart your cluster, see Operating the Database.

### Check Open Ports Manually Using the Netcat Utility

Once your cluster is up and running, you can check ports manually through the command line using the `netcat (nc)` utility. What follows is an example using the utility to check ports.

Before performing the procedure, choose the private IP addresses of two nodes in your cluster.

The examples given below use nodes with the private IPs:

```
10.0.11.60 10.0.11.61
```

Install the `nc` utility on your nodes. Once installed, you can issue commands to check the ports on one node from another node.

1. To check a TCP port:

   a. Put one node in listen mode and specify the port. The following sample shows how to put IP 10.0.11.60 into listen mode for port 4804.

   ```
   [root@ip-10-0-11-60 ~]# nc -l 4804
   ```

   b. From the other node, run `nc` specifying the IP address of the node you just put in listen mode, and the same port number.

   ```
   [root@ip-10-0-11-61 ~]# nc 10.0.11.60 4804
   ```

   c. Enter sample text from either node and it should show up on the other node. To cancel after you have checked a port, enter `Ctrl+C`. 
Note: To check a UDP port, use the same `nc` commands with the `-u` option.

```
[root@ip-10-0-11-60 ~]# nc -u -l 4804
[root@ip-10-0-11-61 ~]# nc -u 10.0.11.60 4804
```

Use Management Console (MC) on AWS

Management Console (MC) is a database management tool that allows you to view and manage aspects of your cluster. Vertica provides an MC AMI, which you can use with AWS. The MC AMI allows you to create an instance, dedicated to running MC, that you can attach to a new or existing Vertica cluster on AWS. You can create and attach an MC instance to your Vertica on AWS cluster at any time.

For information on requirements and installing MC, see Installing and Configuring Management Console.

See Also

- Network ACL Settings

Log in to MC and Managing Your Cluster

After you launch your MC instance and configure your security group settings, log in to your database. To do so, use the elastic IP you specified during instance creation.

From this elastic IP, you can manage your Vertica database on AWS using standard MC procedures.

Considerations When Using MC on AWS

- Because MC is already installed on the MC AMI, the MC installation process does not apply.
To uninstall MC on AWS, follow the procedures provided in Uninstalling Management Console before terminating the MC Instance.

**Export Data From Amazon S3 Using the AWS Library**

The Vertica library for Amazon Web Services (AWS) is a set of functions and configurable session parameters. These parameters allow you to export data from Vertica to Amazon S3 storage without any third-party scripts or programs.

To use the AWS library, you must have access to an Amazon S3 storage account.

**In This Section**

**Configure the Vertica Library for Amazon Web Services**

You use the Vertica library for Amazon Web Services (AWS) to export data from Vertica to S3. This library does not support IAM authentication. You must configure it to authenticate with S3 by using session parameters containing your AWS access key credentials. You can set your session parameters directly, or you can store your credentials in a table and set them with the AWS_SET_CONFIG function.

Because the AWS library uses session parameters, you must reconfigure the library with each new session.

**Important:** Your AWS access key ID and secret access key are different from your account access credentials. For more information about AWS access keys, visit the Managing Access Keys for IAM Users in the AWS documentation.
Set AWS Authentication Parameters

The following AWS authentication parameters allow you to access AWS and work with the data in your Vertica database:

- **aws_id**: The 20-character AWS access key used to authenticate your account.
- **aws_secret**: The 40-character AWS secret access key used to authenticate your account.
- **aws_session_token**: The AWS temporary security token generated by running the AWS STS command `get-session-token`. This AWS STS command generates temporary credentials you can use to implement multi-factor authentication for security purposes. See Implement Multi-factor Authentication.

Implement Multi-factor Authentication

Implement multi-factor authentication as follows:

1. Run the AWS STS command `get-session-token`, this returns the following:

   ```bash
   $ Credentials": { 
   "SecretAccessKey": "bQid6jNuSwRqUzkIJCGF7c71gDHZY3h7aDSw2DU6", 
   "SessionToken": 
"FQoDYXdzEBcaDM1mWpeu88nDTTFICKSaBAi1DTW4e8BTH336tnUv09F/8mZickKLLy7W1cpT4F1flr6ltI0m242/U2C196/
XdC6e0ysU13UGH7cxhjXwa4fjgCKKYuNL764N2x8n0issmU03ku3GTdyc4U4iN1WyEng3S1shdiqV1k1It2Mk0isE 
QXKtx
F9VgfncDQ8xjZUCkY1zseZw5pUa9YqcJ0z1+Q23rdUcWu81FspSUJP0guH+wTqiM2XdHL5hscUomqm41gU=",
  "Expiration": "2018-04-12T01:58:50Z",
  "AccessKeyId": "ASIAJ4ZYGTOSVSLU1N7Q"
  }
```

   For more information on `get-session-token`, see the [AWS documentation](https://aws.amazon.com/documentation)

1. Using the SecretAccessKey returned from `get-session-token`, set your temporary `aws_secret`:

   ```sql
   => ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='bQid6jNuSwRqUzkIJCGF7c71gDHZY3h7aDSw2DU6';
   ```

2. Using the SessionToken returned from `get-session-token`, set your temporary `aws_session_token`:
ALTER SESSION SET UDPARAMETER FOR awslib aws_session_token='FQoDYXdzEBcaDKM1mKpeuUB6nDTTF1CksAbalIDTWe48
Th33tnUvo9F/8mZicKKLLy7WIcpT4FLfr61ItIm242/U2CI9G/XdC6eosyiU3UGH7cxdhjxAW4fjgCKKYuNL764N2xn0issmiU0ku3GTdy
c4U4iN1WyEng3S1shdiqV1k1It2Mk0i5eQXKtxx9VgfncDQ8xjZUCkyIzseZwSpULa9YQcJOzL+Q2JrdUCWu0FspSUJPh0guH+wTq
jM2XdHL5hcUComqm41gU=';

3. Using the AccessKeyId returned from get-session-token, set your temporary aws_id:

ALTER SESSION SET UDPARAMETER FOR awslib aws_id='ASIAJ4ZYGTOSVSLUIN7Q';

The Expiration value returned indicates when the temporary credentials expire. In this example expiration occurs April 12, 2018 at 01:58:50.

These examples show how to implement multifactor authentication using session parameters. You can use either of the following methods to securely set and store your AWS account credentials:

- Configure Session Parameters Directly
- Configure Session Parameters Using Credentials Stored in a Table

**Note:** To increase security, avoid directly setting the plain text value of your key directly in the aws_set_config parameter. Instead, store the value in a table protected with a access policy as described in Configure Session Parameters Using Credentials Stored in a Table.

**AWS Access Key Requirements**

To communicate with AWS, your access key must have the following permissions:

- s3:GetObject
- s3:PutObject
- s3:ListBucket

For security purposes, Vertica recommends that you create a separate access key with limited permissions specifically for use with the Vertica Library for AWS.
**Configure Session Parameters Directly**

These examples show how to set the session parameters for AWS using your own credentials. Parameter values are case sensitive:

- **aws_id**: This value is your AWS access key ID.
  
  ```sql
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_id='AKABCOEXAMPLEPKPXYZQ';
  ```

- **aws_secret**: This value is your AWS secret access key.
  
  ```sql
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='CEXAMPLE3tEXAMPLE1wEXAMPLEFrFEXAMPLE6+Yz';
  ```

- **aws_region**: This value is the AWS region associated with the S3 bucket you intend to access. Left unconfigured, aws_region will default to us-east-1. It identifies the default server used by Amazon S3.
  
  ```sql
  => ALTER SESSION SET UDPARAMETER FOR awslib aws_region='us-east-1';
  ```

When using **ALTER SESSION**:

- Using **ALTER SESSION** to change the values of **S3 Parameters** also changes the values of corresponding UDParameters.
- Setting a UDParameter changes only the UDParameter.
- Setting a configuration parameter changes both the AWS parameter and UDParameter.

**Configure Session Parameters Using Credentials Stored in a Table**

You can place your credentials in a table and secure them with a **row-level access policy**. You can then call your credentials with the AWS_SET_CONFIG scalar meta-function. This approach allows you to store your credentials on your cluster for future session parameter configuration. You must have dbadmin access to create access policies.

1. Create a table with rows or columns corresponding with your credentials:

  ```sql
  => CREATE TABLE keychain(accesskey varchar, secretaccesskey varchar);
  ```
2. Store your credentials in the corresponding columns:

```
=> COPY keychain FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> AEXAMPLEI5EXAMPLEYXQ|CCEXAMPLEtFjTEXAMPLEiEXAMPLE6+Yz
>> \
```

3. Set a row-level access policy appropriate to your security situation.

4. With each new session, configure your session parameters by calling the AWS_SET_CONFIG parameter in a SELECT statement:

```
=> SELECT AWS_SET_CONFIG('aws_id', accesskey), AWS_SET_CONFIG('aws_secret', secretaccesskey)
FROM keychain;
aws_set_config | aws_set_config
-----------------+-----------------+--------------------
aws_id | aws_secret
(1 row)
```

5. After you have configured your session parameters, verify them:

```
=> SHOW SESSION UDPARAMETER ALL;
```

**Related Topics**

- AWS_SET_CONFIG
- AWS_GET_CONFIG

**Export Data to Amazon S3 From Vertica**

After you configure the library for Amazon Web Services (AWS), you can export Vertica data to Amazon S3 by calling the S3EXPORT() transform function. S3EXPORT() writes data to files, based on the URL you provide. Vertica performs all communication over HTTPS, regardless of the URL type you use. Vertica does not support virtual host style URLs. If you use HTTPS URL constructions, you must use path style URLs.

**Note:**
If your S3 bucket contains a period in its path, set the prepend_hash parameter to True.

You can control the output of S3EXPORT() in the following ways:
• Adjust the base query provided to S3EXPORT
• Adjust the partition of your result set with the OVER() clause

**Adjust the Query Provided to S3EXPORT**

By adjusting the query given to S3EXPORT(), you can export anything from tables to reporting queries.

This example exports a whole table:

=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object') OVER(PARTITION BEST)
     FROM exampleTable;
rows | url
-----+---------------------
 606 | https://exampleBucket/object
(1 row)

This example exports the results of a query:

=> SELECT S3EXPORT(customer_name, annual_income USING PARAMETERS url='s3://exampleBucket/object')
     OVER()
     FROM public.customer_dimension
     WHERE (customer_gender, annual_income) IN
     (SELECT customer_gender, MAX(annual_income)
      FROM public.customer_dimension
      GROUP BY customer_gender);
rows | url
-----+---------------------
  25 | https://exampleBucket/object
(1 row)

**Adjust the Partition of Your Result Set with the OVER Clause**

Use the OVER clause to control your export partitions. Using the OVER() clause without qualification results in a single partition processed by the initiator for all of the query data. This example shows how to call the function with an unqualified OVER() clause:

=> SELECT S3EXPORT(name, company USING PARAMETERS url='s3://exampleBucket/object',
     delimiter=',') OVER()
     FROM exampleTable WHERE company='Vertica';
rows | url
-----+---------------------
  10 | https://exampleBucket/object
(1 row)
You can also use window clauses, such as window partition clauses and window order clauses, to manage exported objects.

This example shows how you can use a window partition clause to partition S3 objects based on company values:

```sql
=> SELECT S3EXPORT(name, company
   USING PARAMETERS url='s3://exampleBucket/object',
   delimiter=',' ) OVER(PARTITION BY company) AS MEDIAN
FROM exampleTable;
```

## Adjusting the Export Chunk Size for Wide Tables

You may encounter the following error when exporting extremely wide tables or tables with long data types such as LONG VARCHAR or LONG VARBINARY:

```sql
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object' ) OVER(PARTITION BEST)
FROM veryWideTable;
ERROR 5861: Error calling setup() in User Function s3export
at [/data/.../S3.cpp:787],
error code: 0, message: The specified buffer of 10485760 bytesRead is too small,
it should be at least 11279701 bytesRead.
```

Vertica returns this error if the data for a single row overflows the buffer storing the data before export. By default, this buffer is 10MB. You can increase the size of this buffer using the chunksize parameter, which sets the size of the buffer in bytes. This example sets it to around 60MB:

```sql
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object', chunksize=60485760)
   OVER(PARTITION BEST) FROM veryWideTable;
```

<table>
<thead>
<tr>
<th>rows</th>
<th>url</th>
</tr>
</thead>
<tbody>
<tr>
<td>606</td>
<td><a href="https://exampleBucket/object">https://exampleBucket/object</a></td>
</tr>
</tbody>
</table>

(1 row)

## Add Nodes to a Running AWS Cluster

There are three main steps to adding a node to a database cluster:
1. Provision the host in AWS. Hosts are also known as instances.
2. Add the host to the cluster
3. Add the node to the database

In the Vertica Management Console, the Add Instance wizard performs all three steps. See the instructions in the Managing AWS Instances section of Viewing and Managing Your Cluster and then perform the tasks listed below.

**Before You Start**

Before you add nodes to a cluster, verify that you have an AWS cluster up and running and that you have:

- Created a database.
- Defined a database schema.
- Loaded data.
- Run the Database Designer.
- Connected to your database.

**Launch New Instances to Add to an Existing Cluster**

Perform the procedure in Configure and Launch an Instance to create new instances that you then will add to your existing cluster. Be sure to choose the same details you chose when you created the original instances (VPC, placement group, subnet, and security group).

**Include New Instances as Cluster Nodes**

The Management Console Instances page lists the instances and their associated IP addresses. You need those IP addresses when you run the install_vertica script.

If you are configuring EBS volumes, be sure to configure the volumes on the node before you add the node to your cluster.

To add the new instances as nodes to your existing cluster:

1. Configure and launch your new instances.
2. Connect to the instance that is assigned to the Elastic IP. See Connect to an Instance if you need more information.
3. Run the Vertica installation script to add the new instances as nodes to your cluster. Specify the internal IP addresses for your instances and your *pem file name.

   $ sudo /opt/vertica/sbin/install_vertica --add-hosts <instance-ip> --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<nameof-pem>.pem

Add the Nodes

After you have added the new instances to your existing cluster, add them as nodes to your cluster, as described in Adding Nodes to a Database.

Rebalance the Database

After you add nodes to a database, always rebalance the database.

Remove Nodes From a Running AWS Cluster

Use the following procedures to remove instances/nodes from an AWS cluster.

To avoid data loss, Vertica strongly recommends that you back up your database before removing a node. For details, see Backing Up and Restoring the Database.

In This Section

Remove Hosts From the Database

Before you remove hosts from the database. Verify that you have:

- Backed up the database.
- Lowered the K-safety of the database.
Note: Do not stop the database.

To remove a host from the database:

1. While logged on as dbadmin, launch Administration Tools.
   ```
   $ /opt/vertica/bin/admintools
   ```

   Note: Do not remove the host that is attached to your elastic IP address.

2. From the Main Menu, select Advanced Menu.
3. From Advanced Menu, select Cluster Management. Click OK.
4. From Cluster Management, select Remove Host(s). Click OK.
5. From Select Database, choose the database from which you plan to remove hosts. Click OK.
6. Select the host(s) to remove. Click OK.
7. Click Yes to confirm removal of the hosts.

   Note: Enter a password if necessary. Leave blank if there is no password.

8. Click OK. The system displays a message telling you that the hosts have been removed. Automatic rebalancing also occurs.
9. Click OK to confirm. Administration Tools brings you back to the Cluster Management menu.

Remove Nodes From the Cluster

To remove nodes from a cluster, run the `install_vertica` script and specify:

- The option `--remove-hosts`, followed by the IP addresses of the nodes you are removing.
- The option `--ssh-identity`, followed by the location and name of your *pem file.
- The option `--dba-user-password-disabled`.

The following example removes one node from the cluster:

```bash
sudo /opt/vertica/sbin/install_vertica --remove-hosts 10.0.11.165 --point-to-point --ssh-identity ~/<name-of-pem>.pem --dba-user-password-disabled
```
Stop the AWS Instances (Optional)

After you have removed one or more nodes from your cluster, to save costs associated with running instances, you can choose to stop the AWS instances that were previously part of your cluster.

To stop an instance in AWS:

1. On AWS, navigate to your Instances page.
2. Right-click the instance, and choose Stop.

This step is optional because, after you have removed the node from your Vertica cluster, Vertica no longer sees the node as part of the cluster, even though it is still running within AWS.

Upgrade Vertica on AWS

Before you upgrade to the latest Vertica version, do the following:

1. Back up your existing database.
2. Download the Vertica install package as described in Download and Install the Vertica Install Package.

Upgrade to the Latest Version of Vertica on AWS

To upgrade to the latest version of Vertica on AWS, follow the instructions in Upgrading Vertica.

If you are setting up a Vertica cluster on AWS for the first time, follow the procedure for installing and running on AWS.

These procedures assume that you have a 7.1 or later cluster successfully configured and running on AWS.
Upgrade Vertica Running on AWS

Vertica supports upgrades of Vertica server running on AWS instances created from the Vertica AMI. To upgrade Vertica, follow the instructions provided in Upgrading Vertica.

Make sure to add the following arguments to the upgrade script:

- `--dba-user-password-disabled`
- `--point-to-point`

Copying and Exporting Data on AWS: What You Need to Know

There are common issues that occur when exporting or copying on AWS clusters, as described below. Except for these specific issues as they relate to AWS, copying and exporting data works as documented in Importing and Exporting Data Across Databases.

To copy or export data on AWS:

1. **Verify that all nodes in source and destination clusters have their own elastic IPs (or public IPs) assigned.**
   
   If your destination cluster is located within the same VPC as your source cluster, proceed to step 3. Each node in one cluster must be able to communicate with each node in the other cluster. Thus, each source and destination node needs an elastic IP (or public IP) assigned.

2. **(For non-CloudFormation Template installs) Create an S3 gateway endpoint.**
   
   If you aren’t using a CloudFormation Template (CFT) to install Vertica, you must create an S3 gateway endpoint in your VPC. For more information, see the AWS documentation.

   For example, the Vertica CFT has the following VPC endpoint:

```
"S3Endpoint" : {
    "Type" : "AWS::EC2::VPCEndpoint",
    "Properties" : {
        "PolicyDocument" : {
            "Version":"2012-10-17",
            "Statement" : [
            
```

Vertica Analytic Database (9.3.x)  Page 5306 of 6246
3. **Verify that your security group allows the AWS clusters to communicate.**

Check your security groups for both your source and destination AWS clusters. Verify that ports 5433 and 5434 are open. If one of your AWS clusters is on a separate VPC, verify that your network access control list (ACL) allows communication on port 5434.

**Note:**
This communication method exports and copies (imports) data across the Internet. You can alternatively use non-public IPs and gateways, or VPN to connect the source and destination clusters.

4. If there are one or more elastic load balancers (ELBs) between the clusters, verify that port 5433 is open between the ELBs and clusters.

5. If you use the Vertica client to connect to one or more ELBs, the ELBs only distribute incoming connections. The data transmission path occurs between clusters.

---

**Move from Hourly License to BYOL on AWS**

Vertica offers two licensing options through the Amazon Web Services Marketplace:

- **Bring Your Own License (BYOL):** Bring Your Own License (BYOL) deployments use long-term licenses, which you obtain through an online licensing portal. These deployments also work with a free Community Edition license, which Vertica automatically implements if you do not install a license that you purchased. (For more about Vertica licenses, see Managing Licenses and Understanding Vertica Licenses.)

- **Vertica by the Hour deployments of Vertica:** Vertica by the Hour deployments are pay-as-you-go environments. The hourly license deployment offers an alternative to purchasing a long-term license. If you want to crunch large volumes of data within a short period of time, this option might work better for you.
After implementing an hourly license, you may later decide to use a long-term BYOL license for your database. To purchase a BYOL license, follow the process described in Obtaining a License Key File.

After receiving your new long-term license, you must shut down your database in the hourly environment, and then revive or restore it in a BYOL environment.

Depending on your database mode and environment, the procedure differs.

- **Eon Mode databases:** Use either the command line or Management Console to switch licenses, shut down the database, and revive it in a new environment.

- **Enterprise Mode databases:** Use the command line to switch licenses, back up the database, shut down, and restore it in a new environment.

### Move to BYOL from Hourly License with Revive in the Command Line

In an Eon Mode database, follow this procedure to move to BYOL and revive your database using the command line.

1. Obtain a long-term BYOL license from the online licensing portal, described in Obtaining a License Key File

2. In Vertica, view the licenses table. Note the name of the hourly license listed in the name column, so you can check if it is still present during Step 4:

   ```sql
   => SELECT * FROM licenses;
   ```

3. After you purchase a license from Vertica, install the key in the database in your hourly license environment, as follows:

   ```sql
   => SELECT install_license('<BYOL license path>');
   ```

4. View the licenses table. If only the new BYOL license displays, skip to Step 6. If the hourly license whose name you noted during Step 2 still displays, copy the name and proceed to Step 5:

   ```sql
   => SELECT * FROM licenses;
   ```

5. If the hourly license was still present in Step 4, drop it from the database as follows:
6. Shut down the database as follows:

   => SELECT drop_license('<License name>);

7. From the Amazon Web Services Marketplace, from a Vertica BYOL product page, deploy your new BYOL environment.

8. When you revive the database, the BYOL is selected. For instructions on reviving a database, go to Shutting Down and Reviving An Eon Mode Database

9. After reviving the database on your new environment, terminate the instances for your hourly license environment. To do so, on the AWS CloudFormation Stacks page, select the hourly environment's stack (its collection of AWS resources) and click Actions > Delete Stack.

10. From the Amazon Web Services Marketplace, from a Vertica BYOL product page, deploy new instances for your BYOL Vertica environment.

11. Restore the database on your new instances. See Backing Up and Restoring the Database. When you restore the database, BYOL is selected.

**Move to BYOL from Hourly License with Revive in Management Console (MC)**

In an Eon Mode database monitored by MC, follow this procedure to move to BYOL and revive your database using MC:

1. Purchase a long-term BYOL license from the online licensing portal, following the steps detailed in Obtaining a License Key File

2. After you have purchased a license from Vertica, install the license key file in the database in your hourly license environment using MC:
   a. Log into MC and click your database to see its Overview page.
   b. Click the License tab.
   c. Take note of the name in the License Name column, so you can check if it is still present during Step 3.
d. Click the **Install New License** button at the top of the page. The Settings: License page opens.

e. Upload your new license key file on the Settings: License page.

f. Click the **Apply** button on the top right of the page.

**3.** Return to the **License** tab and view the Installed Licenses table. If only the new BYOL license appears, skip to Step 5. If the Hourly License also displays, take note of its name in the License column and proceed to Step 4.

**4.** If the Hourly License is still present in Step 3, drop it from the database as follows:
   
   a. Click the **Query Execution** tab.

   b. Execute the following function, replacing 'License name' with the name of the Hourly license:

   ```
   => SELECT drop_license('<License name>');
   ```

**5.** Stop the database. From the MC home page, click **View Your Infrastructure**. Select your database, and in the dialog that appears, click **Stop**.

**6.** From the [Amazon Web Services Marketplace](https://aws.amazon.com), from a Vertica BYOL product page, deploy a new Vertica Management Console.

**7.** From the new MC, revive the database. For information about the Management Console revive process, see [Reviving an Eon Mode Database on AWS in MC](https://docs.vertica.com/content/AWS_Eon_Recovery.htm).

**8.** After reviving the database on your new environment, terminate the instances for your hourly license environment. To do so, on the [AWS CloudFormation Stacks page](https://aws.amazon.com), select the hourly environment's stack (its collection of AWS resources) and click **Actions** > **Delete Stack**.

---

**Move to BYOL from Hourly License with Backup and Restore**

In an Enterprise Mode database, follow this procedure to move to BYOL, and then back up and restore your database:

1. Obtain a long-term BYOL license from the online licensing portal, following the steps in [Obtaining a License Key File](https://docs.vertica.com/content/AWS_License_Keys.htm)
2. In Vertica, view the licenses table. Note the name of the hourly license listed in the name column, so you can check if it is still present during Step 4:

```sql
=> SELECT * FROM licenses;
```

3. After you have purchased a long-term license from Vertica, install the license key in the database in your hourly license environment, as follows:

```sql
=> SELECT install_license('<BYOL license path>');
```

4. View the licenses table. If only the new BYOL license displays, skip to Step 6. If the hourly license also displays, note its name and proceed to Step 5:

```sql
=> SELECT * FROM licenses;
```

5. If the hourly license was still present in Step 4, drop it from the database as follows:

```sql
=> SELECT drop_license('<License name>');
```

6. Back up the database. See Backing Up and Restoring the Database.

7. From the Amazon Web Services Marketplace, from a Vertica BYOL product page, deploy new instances for your BYOL Vertica environment.

8. Restore the database on your new instances. See Backing Up and Restoring the Database. When you restore the database, BYOL is selected.

9. After restoring the database on your new environment, terminate the instances for your hourly license environment. To do so, on the AWS CloudFormation Stacks page, select the hourly environment's stack (its collection of AWS resources) and click Actions > Delete Stack.

After completing one of these procedures, see Viewing Your License Status to confirm the license drop and install were successful.

---

**Vertica on Microsoft Azure**

Welcome to the Vertica on Microsoft Azure guide. This section explains how you can create Vertica clusters on the Microsoft Azure Cloud Platform.
Overview of Vertica on Microsoft Azure

Vertica clusters on Microsoft Azure operate on virtual machines (VMs) within a virtual network. The instructions in this document apply to VMs in Azure that are built with Vertica.

For more information about Azure VMs, see the Azure documentation.

Recommended VM Types

Vertica supports a range of Microsoft Azure virtual machine (VM) types, each optimized for different purposes. Choose the VM type that best matches your performance and price needs as a user.

For the best performance in most common scenarios, use one of the following VMs:

<table>
<thead>
<tr>
<th>Optimization</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory optimized</td>
<td>DS13_v2</td>
</tr>
<tr>
<td></td>
<td>DS14_v2</td>
</tr>
<tr>
<td></td>
<td>DS15_v2</td>
</tr>
<tr>
<td></td>
<td>D8s_v3</td>
</tr>
<tr>
<td></td>
<td>D16s_v3</td>
</tr>
<tr>
<td></td>
<td>D32s_v3</td>
</tr>
<tr>
<td>High memory and I/O throughput</td>
<td>GS3</td>
</tr>
<tr>
<td></td>
<td>GS4</td>
</tr>
<tr>
<td></td>
<td>GS5</td>
</tr>
<tr>
<td></td>
<td>E8s_v3</td>
</tr>
<tr>
<td></td>
<td>E16s_v3</td>
</tr>
<tr>
<td></td>
<td>E32s_v3</td>
</tr>
</tbody>
</table>

Note:
The GS VMs are not available in all regions. Nor are they available on the Azure Marketplace, but you can use them by following the manual deployment steps described in Deploy.

<table>
<thead>
<tr>
<th></th>
<th>L8s</th>
<th>L16s</th>
<th>L32s</th>
</tr>
</thead>
</table>

**Note:**

Data stored on the drives of a VM exists only while that VM is powered on. After powering off a VM, data on temporary drives is lost.

**Supported Azure Operating Systems**

For best performance, use one of the following operating systems when deploying Vertica on Azure:

- Red Hat 7.3 or later
- CentOS 7.3 or later. The Azure Marketplace solution as of this writing (June 2017) is based on CentOS 7.3.1611.

For more information, see [Vertica Supported Platforms](#).

**Deploy Vertica from the Microsoft Azure Marketplace**

For customers looking to quickly deploy a Vertica cluster in the Microsoft Azure Cloud, this section describes an automated deployment solution that can be accessed from the Azure Marketplace at [Vertica Analytics Platform](#).

To deploy Vertica on Microsoft Azure, you need to upgrade from the Free Trial, which limits you to a 4-core quota, to Microsoft Azure’s Pay-As-You-Go subscription. The Pay-As-You-Go subscription requires a minimum quota of 12 cores which is what is needed for the Vertica Marketplace solution for Azure.

Check with Microsoft about the benefits and credits that you can carry over from the Free Trial to the Pay-As-You-Go subscription. For more information about upgrading a free Microsoft Azure trial account to Pay-As-You-Go, see [Azure pricing](#).
When you're ready, click Get It Now on Vertica Analytics Platform. The following sections describe the steps you need to take after you click that button.

**Basic Information that Azure Needs**

On the first plane (window) of the installer for your Vertica-Azure solution, enter the following information:

- **DBADMIN username**: The primary username for the virtual machines being created. This name is also used as the Vertica DBADMIN account.
- **Authentication Type**: VMs in Azure support either password or SSH public key authentication.
- **Password or SSH public key**: Enter either a password or a public key to be associated with the DBADMIN user.
- **Subscription**: Select an Azure subscription for the resources to be billed against.
- **Resource group**: Create a new resource group or select an existing resource group as the location to save all the Azure resources for your Vertica cluster.
- **Location**: Select an Azure data center to deploy the Vertica cluster. Make sure that you have enough quota assigned to that location.

**Infrastructure Settings**

In the second plane of the installer, make choices relating to the VMs. You need to choose two types of VMs, one to be used for the Vertica Management Console, and one to be used for the Vertica cluster nodes.

- **Management Console VM size**: Each Vertica deployment from the Azure marketplace includes a Vertica Management Console VM. This console is the jumping-off point to your cluster. During installation, the cluster configuration is automatically imported into the MC.
- **Number of Vertica cluster nodes**: This drop-down field allows you to choose the number of nodes for Azure to deploy for the cluster. The Marketplace solution allows you to create between 1 and 16 nodes. After the nodes have been created, the installer automatically forms your Vertica cluster, configures it, and creates your database. The Community Edition license is automatically applied to the cluster, and is limited to 1 TB of RAW data, and up to 3 Vertica nodes. For deployments where more than 3 Vertica Cluster nodes are chosen, the initial database is created on the first 3 nodes. To take advantage of deployments greater than 3 nodes, customers
need to obtain and apply an Enterprise license.

**Important:**
To maintain K-safety for your database, select at least three nodes.

- **Virtual machine size:** Vertica engineers have populated this selection with different VM types that are suitable for Vertica clusters. This list only includes VM types that are available in the selected location in the first plane. When you highlight this field, Azure displays those types and their specific characteristics.
- **Total RAW storage per node:** Each VM comes configured with a set of premium data disks for Vertica to use. This set is configured and presented as a single storage location. The choices in this drop-down are 768 GB, 3 TB, 6 TB, or 12 TB.

**Network Options**

The third installer plane contains the networking requirements for the Vertica cluster installation. These options are:

- **Virtual network:** The Azure Marketplace solution for Vertica allows you to create a new virtual network, or select an existing virtual network, in which to place the Vertica cluster. This control on the deployment provides a point-and-click navigation to do just that.
- **Subnets:** Based on the selection of the virtual network, the Subnets entry allows you to select or create the subnet you want to use within the virtual network.
- **Public IP address**—Each VM is configured with a publicly accessible IP address. This field allows you to specify the resource name for those IP addresses, and whether they are static or dynamic. When created, the first public IP address resource is created exactly as entered, and associated with the Vertica Management Console. Azure then appends a number from 1 to 16 to the resource name for each Vertica cluster node created. This number designates which VM that resource is associated with.
- **Domain name label:** Because each VM has a public IP address, each node is also required to have a DNS name. Enter a prefix for the name, such as vertnode. When created, the first DNS name is created exactly as entered and associated with the Vertica Management Console. Azure then appends a number from 1 to 16 to the DNS name. That number designates which VM it is associated with. Azure adds the remaining part of the fully qualified domain name based on the location where you created the cluster.
Validate Your Configuration

Review the settings on the installer Summary plane. Azure uses this plane to validate the values you entered. In addition, Azure checks your settings against the existing quota to make sure that your solution deploys correctly.

After you are satisfied with your choices and Azure has notified you that the validation passed, click OK.

Finalize the Purchase

On the final plane of the installer, agree to the Microsoft Terms of Use, and acknowledge that you agree to pay for the resources being created.

In addition, on this plane, review the Vertica Terms of Use and the privacy policy. After you click Purchase, the deployment begins.

Monitor the Deployment

After the deployment begins, you receive a notification that the deployment is in progress. When you click the notification, the Azure portal opens the deployment status page, which displays the resources for the cluster being created.

Access the Cluster After Deployment

After the deployment successfully completes, you receive a notification in the Azure portal. When you click the notification, the Azure portal opens the resource group and displays information about all the resources created.

Finalize the Cluster Installation

Take the following steps to finalize the cluster installation:
1. Open the resource group and locate the public IP address resource for the Vertica Management Console. The public IP address resource for the Vertica Management Console is the only public IP resource without a trailing number.

2. Copy the DNS name displayed in the public IP address resource for the Vertica Management Console.

3. From a browser, enter

   [https://<DNS_Name_of_VMC>:5450](https://<DNS_Name_of_VMC>:5450)

   where `<DNS_Name_of_VMC>` is the copied value of the DNS name in the public IP address of the Vertica Management Console.

4. The browser opens the login page for the Vertica Management Console for your cluster. Log on using the default username (`mcadmin`) and the default password (`password`).

5. Accept the End User License Agreement.

6. To open the initial database, click the database icon labeled `vdb` on the lower left-hand section of the Vertica Management Console.

For complete information about how to use the Vertica Management Console, see [Using Management Console](Vertica_Documentation.html) in the Vertica documentation.

---

**Access the Cluster VMs after Deployment**

To access the cluster VMs directly, take the following steps:

1. Open the resource group and locate the public IP address resource for any of the Vertica cluster VMs. The public IP address resource for the Vertica cluster VMs is the public IP resource with a trailing number after the resource name. The trailing number corresponds to the VM number. For example, `PublicIP1` maps to Vertica cluster node 1, and so on.

2. Copy the DNS name displayed in the public IP address resource for the Vertica cluster node.

3. Connect to the node using the `dbadmin` user you created. Log in with the authentication method you chose (public key or password) using an SSH connection tool.

At this point, your cluster is fully installed and you are ready to use your new database.
Deploy Vertica on Azure: Manual Steps

To start creating your Vertica cluster in Azure using manual steps, you first need to create a VM. During the VM creation process, you create and configure the other resources required for your cluster, which are then available for any additional VMs that you create.

Follow these procedures to deploy Vertica on Azure.

Configuring and Launching a New Instance

An Azure VM is similar to a traditional host. Just as with an on-premises cluster, you must prepare and configure the hardware settings for your cluster and network before you install Vertica.

The first steps are:

1. From the Azure marketplace, select an operating system that Vertica supports.
2. Select a VM type. See Recommended VM Types.
3. Choose a deployment model. For best results, choose the resource manager deployment model.

Configure Network Security Group

Vertica has specific network security group requirements, as described in Network Security Group Configurations.

Create and name your own network security group, following these guidelines.

You must configure SSH as:

- Protocol: TCP
- Source port range: Any
- Destination port range: 22
- Source: Any
- Destination: Any

You can make additional modifications, based on your specific requirements.
Add Disk Containers

Create an Azure storage account, which later contains your cluster storage disk containers.

For optimal throughput, select Premium storage and align the storage to a GS or DSv2 VM.

For more information about what a storage account is, and how to create one, refer to About Azure storage accounts.

Configure Credentials

Create a password or assign an SSH key pair to use with Vertica.

For information about how to use key pairs in Azure, see How to create and use an SSH public and private key pair for Linux VMs in Azure.

Assign a Public IP Address

A public IP is an IP address that you can use to connect to your cluster externally. For best results, assign a single static public IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using the internal IP addresses that Azure generated when you specified your virtual network settings.

By default, a public IP address is dynamic; it changes every time you shut down the server. You can choose a static IP address, but doing so can add cost to your deployment.

During a VM installation, you cannot set a DNS name. If you use dynamic public IPs, set the DNS name in the public IP resource for each VM after deployment.

For information about public IP addresses, refer to IP address types and allocation methods in Azure.

Create Additional VMs

If needed, to create additional VMs, repeat the previous instructions in this document.
Connect to a Virtual Machine

Before you can connect to any of the VMs you created, you must first make your virtual network externally accessible. To do so, you must attach the public IP address you created during network configuration to one of your VMs.

Connect to Your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the public IP address you created in the configuration steps.
2. Authenticate using the credentials and authentication method you specified during the VM creation process.

Connect to Other VMs

Connect to other virtual machines in your virtual network by first using SSH to connect to your publicly connected VM. Then, use SSH again from that VM to connect through the private IP addresses of your other VMs.

If you are using private key authentication, you may need to move your key file to the root directory of your publicly connected VM. Then, use PuTTY or WinSCP to connect to other VMs in your virtual network.

Prepare the Virtual Machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica License and Private Key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. These steps assume that the initial user you configured is the DBADMIN user.
1. As the DBADMIN user, copy your private key file from where you saved it locally onto your primary node.

Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the `install_` _vertica script fails with a message similar to the following:

```
Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.
```

If you receive a failure message, enter the following command to correct permissions on your private key file:

```
$ chmod 600 /<name-of-key>.pem
```

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

**Install Software Dependencies for Vertica on Azure**

In addition to the Vertica standard [Installing the Required Packages](#), as the root user, you must install the following packages before you install Vertica on Azure:

- `pstack`
- `mcelog`
- `sysstat`
- `dialog`

**Configure Storage**

Use a dedicated Azure storage account for node storage.

**Caution:** Do not store your information on the root volume, especially your data and catalog directories. Storing information on the root volume may result in data loss.

When configuring your storage, make sure to use a supported file system. For details, see [Recommended Storage Format Types](#).
**Attach Disk Containers to Virtual Machines (VMs)**

Using your previously created storage account, attach disk containers to your VMs that are appropriate to your needs.

For best performance, combine multiple storage volumes into RAID-0. For most RAID-0 implementations, attach 6 storage disk containers per VM.

**Combine Disk Containers for Storage**

If you are using RAID, follow these steps to create a RAID-0 drive on your VMs. The following example shows how you can create a RAID-0 volume named `md10` from 6 individual volumes named:

- sdc
- sdd
- sde
- sdf
- sdg
- sdh

1. Form a RAID-0 volume using the `mdadm` utility:
   ```bash
   $ mdadm --create /dev/md10 --level 0 --raid-devices=6 \
   /dev/sdc /dev/sdd /dev/sde /dev/sdf /dev/sdg /dev/sdh
   ```

2. Format the file system to be one that Vertica supports:
   ```bash
   $ mkfs.ext4 /dev/md10
   ```

3. Find the UUID on the newly-formed RAID volume using the `blkid` command. In the output, look for the device you assigned to the RAID volume:
   ```bash
   $ blkid
   .
   /dev/md10 : UUID="e7510a6f-2922-4413-b5fa-9dcd725967fd" TYPE="ext4" PARTUUID="fb9b7449-08c3-4231-9ee5-086f7b8c9001"
   .
   ``

4. The RAID device can be renamed after a reboot. To ensure the filesystem is mounted in a predictable location on your VM, create a directory to use as the mount point to mount the filesystem. For example, you can choose to create a mount point named
Create a Swap File

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file to operate. Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on Azure:

1. Install devnull and swapfile:

   ```bash
   $ install -o root -g root -m 0600 /dev/null /swapfile
   ```

2. Create the swap file:

   ```bash
   $ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
   ```
3. Prepare the swap file using mkswap:

```bash
$ mkswap /swapfile
```

4. Use swapon to instruct Linux to swap on the swap file:

```bash
$ swapon /swapfile
```

5. Persist the swapfile in FSTAB:

```bash
$ echo "/swapfile swap swap auto 0 0" >> /etc/fstab
```

Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

**For More Information**

- [About Azure storage accounts](#)
- [Prepare Disk Storage Locations](#)

**Download Vertica**

To download the Vertica server appropriate for your operating system and license type, go to [www.vertica.com/download/vertica](http://www.vertica.com/download/vertica).

Run the rpm to extract the files.

After you complete the download and extraction, the next section describes how to use the `install_vertica` script to form a cluster and install the Vertica database software.

**Form a Cluster and Install Vertica**

Use the `install_vertica` script to combine two or more individual VMs to form a cluster and install the Vertica database.

**Before You Start**

Before you run the `install_vertica` script:
**Check the Virtual Network page** for a list of current VMs and their associated private IP addresses.

- **Identify your storage location.** The installer assumes that you have mounted your storage to `/vertica/data`. To specify another location, use the `--data-dir` argument.
- **Identify your storage location.** To create your database's data directory on mounted RAID drive, when you run the `install_vertica` script, provide `/vertica/data` as the value of the `--data-dir` option.

**Caution:** Do not store your data on the root drive.

## Combine Virtual Machines (VMs)

The following example shows how to combine VMs using the `install_vertica` script.

1. **While connected to your primary node,** construct the following command to combine your nodes into a cluster.

   ```bash
   $ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-private-key>.pem --license <license.file>
   ```

2. **Substitute the IP addresses** for your VMs and include your root key file name, if applicable.

3. **Include the `--point-to-point` parameter** to configure spread to use direct point-to-point communication between all Vertica nodes, as required for clusters on Azure when installing or updating Vertica.

4. **If you are using Vertica Community Edition,** which limits you to three nodes, specify the `-L CE` option with no license file.

5. **After you combine your nodes,** to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the `shred` command:

   ```bash
   $ shred examplekey.pem
   ```

**Important:** You need your key file to perform future Vertica updates.

6. **Reboot your cluster** to complete the cluster formation and Vertica installation.
For complete information on the `install_vertica` script and its parameters, see *Installing Vertica with the Installation Script*.

**After Your Cluster is Up and Running**

Now that your cluster is configured and running, and Vertica is running, take these steps:

1. **Creating a Database.** When you installed Vertica, a database administrator user was created: DBADMIN.
2. Use this account to create and start a database. For detailed information about the DBADMIN role, see **DBADMIN**.
3. **Configuring the Database.** After the database is installed, it's important to configure its settings, schemas, and security.

**Using Management Console (MC) on Azure**

The Vertica solution in the Azure marketplace provides a Management Console (MC) virtual machine. The MC VM allows you to deploy a VM dedicated to running MC onto a Vertica cluster on Azure.

You can deploy an MC VM to your Vertica on Azure cluster at any time, as long as your cluster meets the following requirements:

- Your Azure cluster must be running Vertica version 8.0.x or later.
- Your MC version must be compatible with the Vertica version of your cluster.

**Deploy an MC VM**

To deploy MC onto your target Vertica cluster on Azure, perform these tasks:

1. Select the Vertica Management Console deployment from the Azure Marketplace.
2. Specify an admin username for your new MC VM.
3. Place your MC VM in the same location as your target cluster.
4. Place your MC VM in a resource group, separate from your target cluster.
5. Specify the virtual network and subnet of your target cluster.
6. Specify a DNS name and public IP address.
7. Configure the network security group for the MC VM.
The MC VM requires specific security group configurations in order to communicate with the Vertica cluster. Configure the security rules for the MC VM as described in Configuring and Launching a New Instance.

**Log in to MC and Manage Your Cluster**

After you have deployed your MC VM and configured your security group settings, enter the following into your browser navigation field. This command launches the Management Console:

```
https://[IP address or DNS name]:5450
```

Log in to Management Console using the public IP address that you specified during instance creation.

From there, you can manage your Vertica database on Azure using standard MC procedures.

**Uninstalling MC**

To uninstall MC on Azure, follow the procedures provided in Uninstalling Management Console before terminating the MC node.

**Vertica on Google Cloud Platform**

Welcome to the Vertica on Google Cloud Platform guide.

Vertica clusters on Google Cloud Platform (GCP) operate on top of virtual machines (VMs) as part of the Google Compute Engine interconnected using a virtual private cloud (VPC) network. The VMs are accessible using the Internet with standard SSH connections. To access the Vertica Management Console, use HTTPS on port 5450.

The following topics describe several deployment methods to run Vertica on Google Cloud Platform:
Overview of Vertica on Google Cloud Platform

Vertica clusters on Google Cloud Platform (GCP) operate on top of virtual machines (VMs) as part of the Google Compute Engine interconnected using a virtual private cloud (VPC) network. The VMs are accessible using the Internet with standard SSH connections. To access the Vertica Management Console, use HTTPS on port 5450.

The following topics describe several deployment methods to run Vertica on Google Cloud Platform:

- Deploy Vertica from the Google Cloud Launcher Marketplace
- Deploy Vertica on Google Cloud Platform: Manual Steps

Deploy Vertica from the Google Cloud Launcher Marketplace

Are you looking to quickly deploy a Vertica cluster in the Google Cloud Platform (GCP)? If so, this section describes a Vertica-developed automated solution that you can access from the [Vertica Analytics Platform Google Cloud Launcher](https://example.com).

The Vertica Cloud Launcher solution allows you to create a multi-node cluster. The solution includes the Vertica Management Console (MC) as the primary UI for you to get started.

Each deployment automatically creates an initial database called vdb using the Community Edition (CE) license. The CE license is limited to a maximum of 3 nodes. In cases where you want to use more than 3 nodes for deployment on GCP, the deployment creates the initial database on the first 3 nodes in the cluster.

After the launcher creates the initial database (vdb), it preconfigures the MC to attach to that database automatically.

Configure the Vertica Cloud Launcher Solution

To get started with a deployment of Vertica from the [Google Cloud Launcher](https://example.com), go to [Vertica Analytics Platform Google Cloud Launcher](https://example.com).

Follow these steps:
1. From the listing page, to start the solution launcher, click **LAUNCH ON COMPUTE ENGINE**.
2. Enter the following information:

   - **Deployment name**—Each deployment must have a unique name. That name is used as the prefix for the names of all VMs created during the deployment. The deployment name can only contain lowercase characters, numbers, and dashes. The name must start with a lowercase letter and cannot end with a dash.
   - **Zone**—GCP breaks its cloud data centers into regions and zones. *Regions* are a collection of zones in the same geographical location. *Zones* are collections of compute resources, which vary from zone to zone.

   For best results, pick the zone in your designated region that supports the latest Intel CPUs. For a complete listing of regions and zones, including supported processors, see [Regions and Zones](https://cloud.google.com/regions-zones).

   - **Machine type for Vertica Management Console**—The Vertica Analytics Platform in Cloud Launcher always deploys the Vertica Management Console (MC) as part of the solution.

     The default machine type for MC is the n1-standard-4. However, you can choose another machine type that better suits the needs requires by the MC node for additional purposes, such serving as a target node for backups, data transformation, or additional management tools.

   - **Node count for Vertica Cluster**—The total number of VMs you want to deploy in the Vertica Cluster. The default is 3.

   **Note:**

   The Cloud Launcher automatically deploys the Vertica Community Edition license, which limits the database to 3 nodes and up to 1 TB in raw data. If you intend to use the CE license, deployment of 4 or more nodes will result in an overpopulated cluster where VM resources are deployed (and incur costs) without being used by the database.

   - **Machine type for Vertica Cluster nodes**—The Cloud Launcher builds each node in the cluster using the same machine type. The default value is the n1-highmem-16 type. Modify the machine type for your nodes based on the needs and costs associated with your workloads.

   - **Data disk type**—GCP offers two types of persistent disk storage: Standard and SSD. The costs associated with Standard are less, but the performance of SSD
storage is much better. Vertica recommends you use SSD storage. For more information on Standard and SSD persistent disks, see [Storage Options](#).

- **Disk size for the Data disk**—Disk performance is directly tied to the disk size in GCP. The default value of 2000 GBs (2 TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.

  If you select a smaller disk size, the throughput performance decreases. If you select a large disk size, the performance remains the same as the 2 TB option.

- **Network name**—VMs in GCP must exist on a virtual private cloud (VPC). When you created your GCP account, a default VPC was created. Create additional VPCs to isolate solutions or projects from one another. The Vertica Analytics Platform creates all the nodes in the same VPC.

- **Subnetwork name**—Just as a GCP account may have multiple VPCs, each VPC may also have multiple subnets. Use additional subnets to group or isolate solutions within the same VPC.

After you have entered all the required information, click **Deploy** to begin the deployment process.

**Monitor the Deployment**

After the deployment begins, Google Cloud Launcher automatically opens a page that displays the status of the resources being created. Items that are still being processed have a spinning circle to the left of them and the text is a light gray color. Items that have been created are dark gray in color, with an icon designating that resource type on the left.

After the deployment completes, a green check mark appears next to the deployment name in the upper left-hand section of the screen.

**Accessing the Cluster After Deployment**

After the deployment completes, the right-hand section of the screen displays the following information:

- **dbadmin password**—A randomly generated password for the dbadmin account on the nodes. For security reasons, change the dbadmin password when you first log in to one of the Vertica cluster nodes.
• madmin password—A randomly generated password for the madmin account for accessing the Management Console. For security reasons, change the madmin password after you first log in to the MC.
• Vertica Node 1 IP address—The external IP address for the first node in the Vertica cluster is exposed here so that you can connect to the VM using a standard SSH client. To access the MC, press the Access Vertica MC button in the Get Started section of the dialog box. Copy the madmin password and paste it when asked.

For more information on using the MC, click Using Management Console.

Access the Cluster Nodes

There are two ways to access the cluster nodes directly:

• Use GCP’s integrated SSH shell by selecting the SSH button in the Get Started section. This shell opens a pop-up in your browser that runs GCP’s web-based SSH client. You are automatically logged on as the user you authenticated as in the GCP environment.

After you have access to the first Vertica cluster node, execute the su dbadmin command, and authenticate using the dbadmin password.

• In addition, use other standard SSH clients to connect directly to the first Vertica cluster node. Use the Vertica Node 1 IP address listed on the screen as the dbadmin user, and authenticate with the dbadmin password.

Follow the on-screen directions to log in using the madmin account and accept the EULA. After you've been authenticated, access the initial database by clicking the vdb icon (looks like a green cylinder) in the Recent Databases section.

When the cluster is fully deployed, check out the Getting Started Guide of the Vertica documentation.

Deploy Vertica on Google Cloud Platform:
Manual Steps

Before you create your Vertica cluster in Google Cloud Platform (GCP) using manual steps, you must create a virtual machine (VM) instance from the Compute Engine section of GCP.
Configure and Launch a New Instance

All VM instances that you create should be launched in the same virtual public cloud (VPC).

To configure and launch a new VM instance, follow these instructions:

1. From within the Compute Engine section of GCP, from the menu on the left-hand side of the screen, select **VM Instances**.
   
   GCP displays all the VM instances that you have created so far.

2. Select the **CREATE INSTANCE** link.

3. Enter a name for the new instance.

4. Select the zone where you plan to deploy the instance.
   
   GCP breaks its cloud data centers down by regions and zones. **Regions** are a collection of zones that are all in the same geographical location. Zones are collections of compute resources, which vary from zone to zone. Always pick the zone in your designated region that supports the latest Intel CPUs.
   
   For a complete listing of regions and zones, including supported processors, see **Regions and Zones**.

5. Select a machine type.
   
   GCE offers many different types of VM instances. For best results, only deploy Vertica on VM instances with 8 vCPUs or more and at least 30 GB of RAM.

6. Select the boot disk (image).
   
   You create VM instances from a public or custom image. If you are starting with Vertica in GCP for the first time, select either the CentOS 7 or RHEL 7 public image. Those images have been tested thoroughly with Vertica.
   
   For more information about deploying a VM instance, see **Creating and Starting an Instance**.

After you have configured the VM instance to be used as a Vertica cluster node, GCP allows you to convert that instance into a custom image. Doing so allows you to deploy multiple versions of that VM instance; each VM instance is identical except for the node name and IP address.

For more information about creating a custom image, see **Creating, Deleting, and Deprecating Custom Images**.
Connect to a Virtual Machine

Before you can connect to any of the VMs you created, you must first identify the external IP address. The VM instance section of GCP contains a list of all currently deployed VMs and their associated external IP addresses.

Connect to Your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the external IP address you created in the configuration steps.
2. Authenticate using the credentials and SSH key that you provided to your GCP account upon creation.

Connect to Other VMs

To connect to other virtual machines in your virtual network:

1. Use SSH to connect to your publicly connected VM.
2. Use SSH again from that VM to connect through the private IP addresses of your other VMs.

Because GCP forces the use of private key authentication, you may need to move your key file to the root directory of your publicly connected VM. Then, use SSH to connect to other VMs in your virtual network.

Prepare the Virtual Machines

After you create your VMs, you need to prepare them for cluster formation.
Add the Vertica License and Private Key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. The following steps assume that the initial user you configured is the DBADMIN user:

1. As the DBADMIN user, copy your private key file from where you saved it locally onto your primary node.

   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the install_vertica script fails with a message similar to the following:

   Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.

   If you see the previous failure message, enter the following command to correct permissions on your private key file:

   $ chmod 600 /<name-of-key>.pem

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

Install Software Dependencies for Vertica on GCP

In addition to the Vertica standard package dependencies, as the root user, you must install the following packages before you install Vertica:

- pstack
- mcelog
- sysstat
- dialog

Configure Storage

For best disk performance in GCP, Vertica recommends customers use SSD persistent storage, configured to at least 2TB (2000 GB) in size. Disk performance is directly tied to the
disk size in GCP. 2000 GBs (2TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.

⚠️ **Caution:**
Do not store your information on the root volume, especially in your data and catalog directories. Storing information on the root volume may result in data loss.

When configuring your storage, make sure to use a supported file system.

**Create a Swap File**

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file for the setup script to complete.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on GCP:

1. Install the devnull and swapfile files:

   ```
   $ install -o root -g root -m 0600 /dev/null /swapfile
   ```

2. Create the swap file:

   ```
   $ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
   ```

3. Prepare the swap file using mkswap:

   ```
   $ mkswap /swapfile
   ```

4. Use swapon to instruct Linux to swap on the swap file:

   ```
   $ swapon /swapfile
   ```

5. Persist the swapfile in FSTAB:

   ```
   $ echo "/swapfile swap swap auto 0 0" >> /etc/fstab
   ```

6. Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.
Download Vertica

To download the Vertica server appropriate for your operating system and license type, go to

Download the rpm and run the rpm to extract the files as described in Download and Install the Vertica Server Package in the Vertica documentation.

After you complete the download and extraction, use the install_vertica script to form a cluster and install the Vertica database software, as described in the next section.

Form a Cluster and Install Vertica

Use the install_vertica script to combine two or more individual VMs to form a cluster and install your Vertica database.

Before you run the install_vertica script, follow these steps:

1. Check the VM Instances page of the Compute Engine section on GCP to locate a list of current VMs and their associated internal IP addresses.
2. Identify your storage location on your VMs. The installer assumes that you have mounted your storage to /home/dbadmin. To specify another location, use the --data-dir argument.

Caution: Do not store your data on the root drive.

The following steps show how to combine virtual machines (VMs) into a cluster using the install_vertica script:

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.

   $ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-private-key>.pem --license <license.file>

2. Substitute the IP addresses for your VMs, and include your root key file name, if applicable.
3. Include the --point-to-point parameter to configure spread to use direct point-to-point communication among all Vertica nodes, as required for clusters on GCP when installing or updating Vertica.

4. If you are using Vertica Community Edition, which limits you to three nodes, specify -L CE with no license file.

5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the shred command:

    ```
    $ shred examplekey.pem
    ```

   **Important:**
   You need your key file to perform future Vertica updates.

For complete information about the install_vertica script and its parameters, see [Installing Vertica with the Installation Script](#).

**After Your Cluster is Up and Running**

Now that your cluster is configured and running, and Vertica is running, take these steps:

1. **Create a Database.**
   
   When you installed Vertica, a database administrator user was created: DBADMIN. Use this account to create and start a database.
   
   For detailed information about the DBADMIN role, see [DBADMIN Role](#).

2. **Configure the Database.** After the database is installed, it's important to configure its settings, schemas, and security.

**Adjusting Spread Daemon Timeouts For Virtual Environments**

You may see Vertica nodes leave the database even though they are still running. This issue can happen on networks that are prone to spikes in latency or in virtual environments where a node's VM may be paused for a short period of time. You can adjust a setting in Vertica to help prevent this issue from occurring.
Vertica relies on spread daemons to pass messages between database nodes. When a node fails to respond to a spread message after a timeout period, Vertica assumes the node is down and starts to remove it from the database.

The default Spread timeout depends on the number of configured Spread segments:

<table>
<thead>
<tr>
<th>Configured Spread segments</th>
<th>Default timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8 seconds</td>
</tr>
<tr>
<td>&gt; 1</td>
<td>25 seconds</td>
</tr>
</tbody>
</table>

If network delays or temporary pauses of a VM last longer than the spread timeout period, you may see UP nodes leave the database. In these cases, you can increase the spread timeout to reduce or eliminate instances where UP nodes leave the database.

### Azure's Memory-Preserving Updates and Spread Timeouts

In Azure, you might see running nodes leave the database due to scheduled maintenance. Azure's maintenance down time is usually well-defined. For example, Azure's memory-preserving updates can pause a VM for up to 30 seconds while performing maintenance on the system hosting the VM. This pause does not disrupt the node. It continues normal operation once Azure resumes it. See the Azure documentation's topic on Maintenance for virtual machines in Azure for more information about updates. If Azure pauses a node for longer than the spread timeout period, Vertica interprets the node's inability to respond to a spread message as the node going down, even though it will resume running normally.

#### Note:

If you deploy your Vertica cluster using the Azure Marketplace, the spread timeout defaults to 35 seconds. If you manually create your cluster in Azure, the spread timeout defaults to 8 or 25 seconds, as described earlier.

### Setting the Spread Timeout

When you know your network or nodes may be unable to respond for a specific amount of time, you can increase the spread timeout period to longer than this time. Adjust the
timeout to the period of time the node may be unable to respond, plus an additional 5 seconds as a safety margin.

For example, if you know Azure's memory-preserving maintenance can pause your VMs for up to 30 seconds, set the spread timeout to 35 seconds.

If you do not know exactly how long network or node disruptions can last, you can try increasing the spread timeout gradually, until you see reduced instances of UP nodes leaving the database. Be as conservative with this setting as you can.

**Important:**
Vertica cannot react to a node going down or being shut down improperly before the timeout period has elapsed. Changing spread’s timeout to a value too high can result in longer query restarts if a node goes down.

You can see the current setting of the spread timeout by querying system table `SPREAD_STATE`:

```sql
=> SELECT * FROM V_MONITOR.SPREAD_STATE;
```

```plaintext
+-----------+----------+
nodemame   | token_timeout |
+-----------+----------+
v_vmart_node0003 | 8000     |
v_vmart_node0001 | 8000     |
v_vmart_node0002 | 8000     |
+-----------+----------+
(3 rows)
```

You change the spread timeout calling the meta-function `SET_SPREAD_OPTION` to set the token timeout to a new value. This value is a string, and sets the timeout in milliseconds.

**Important:**
Changing spread settings with `SET_SPREAD_OPTION` has minor impact on your cluster as it pauses while the new settings are propagated across the entire cluster.

This example sets the timeout to 35 seconds (35000ms):

```sql
=> SELECT SET_SPREAD_OPTION( 'TokenTimeout', '35000');
```

```plaintext
NOTICE 9003: Spread has been notified about the change
SET_SPREAD_OPTION

Spread option 'TokenTimeout' has been set to '35000'.
```

(1 row)

```sql
=> SELECT * FROM V_MONITOR.SPREAD_STATE;
```

```plaintext
+-----------+----------+
nodemame   | token_timeout |
+-----------+----------+
v_vmart_node0001 | 35000     |
v_vmart_node0002 | 35000     |
+-----------+----------+
```

Vertica Documentation
Using Vertica on the Cloud
Note:
The changes you make to the spread timeout might not take effect immediately. It might take some time before you see the settings change in system table V_MONITOR.SPREAD_STATE table.

Integrating with Apache Hadoop

Apache™ Hadoop™, like Vertica, uses a cluster of nodes for distributed processing. The primary component of interest is HDFS, the Hadoop Distributed File System.

You can use Vertica with HDFS in several ways:

- You can import HDFS data into locally-stored ROS files.
- You can access HDFS data in place using external tables. You can define the tables yourself or get schema information from Hive, a Hadoop component.
- You can use HDFS as a storage location for ROS files.
- You can export data from Vertica to share with other Hadoop components using a Hadoop columnar format.

See Hadoop Interfaces for more information about these options.

Hadoop file paths are expressed as URLs in the hdfs or webhdfs URL scheme. For more about the hdfs scheme, see Using HDFS URLs.

Hadoop Distributions

Vertica can be used with Hadoop distributions from Hortonworks, Cloudera, and MapR. See Vertica Integrations for Hadoop for the specific versions that are supported.
If you are using Cloudera, you can manage your Vertica cluster using Cloudera Manager. See Integrating With Cloudera Manager.

If you are using MapR, see Integrating Vertica with the MapR Distribution of Hadoop.

## Cluster Layout

Vertica supports two cluster architectures for Hadoop integration. Which architecture you use affects the decisions you make about integration with HDFS. These options might also be limited by license terms.

- You can co-locate Vertica on some or all of your Hadoop nodes. Vertica can then take advantage of data locality.
- You can build a Vertica cluster that is separate from your Hadoop cluster. In this configuration, Vertica can fully use each of its nodes; it does not share resources with Hadoop.

With either architecture, if you are using the hdfs scheme to read ORC or Parquet files, you must do some additional configuration. See Configuring the hdfs Scheme.

## Co-Located Clusters

With co-located clusters, Vertica is installed on some or all of your Hadoop nodes. The Vertica nodes use a private network in addition to the public network used by all Hadoop nodes, as the following figure shows:

![Co-located Clusters Diagram](image)

You might choose to place Vertica on all of your Hadoop nodes or only on some of them. If you are using HDFS Storage Locations you should use at least three Vertica nodes, the minimum number for K-Safety.
Using more Vertica nodes can improve performance because the HDFS data needed by a query is more likely to be local to the node.

You can place Hadoop and Vertica clusters within a single rack, or you can span across many racks and nodes. If you do not co-locate Vertica on every node, you can improve performance by co-locating it on at least one node in each rack. See Configuring Rack Locality.

Normally, both Hadoop and Vertica use the entire node. Because this configuration uses shared nodes, you must address potential resource contention in your configuration on those nodes. See Configuring Hadoop for Co-Located Clusters for more information. No changes are needed on Hadoop-only nodes.

**Hardware Recommendations**

Hadoop clusters frequently do not have identical provisioning requirements or hardware configurations. However, Vertica nodes should be equivalent in size and capability, per the best-practice standards recommended in General Hardware and OS Requirements and Recommendations in Installing Vertica.

Because Hadoop cluster specifications do not always meet these standards, Vertica recommends the following specifications for Vertica nodes in your Hadoop cluster.

<table>
<thead>
<tr>
<th>Specifications For...</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Processor</td>
<td>For best performance, run:</td>
</tr>
<tr>
<td></td>
<td>- Two-socket servers with 8–14 core CPUs, clocked at or above 2.6 GHz for clusters over 10 TB</td>
</tr>
<tr>
<td></td>
<td>- Single-socket servers with 8–12 cores clocked at or above 2.6 GHz for clusters under 10 TB</td>
</tr>
<tr>
<td>Memory</td>
<td>Distribute the memory appropriately across all memory channels in the server:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Minimum</strong>—8 GB of memory per physical CPU core in the server</td>
</tr>
<tr>
<td></td>
<td>- <strong>High-performance applications</strong>—12–16 GB of memory per physical core</td>
</tr>
<tr>
<td></td>
<td>- <strong>Type</strong>—at least DDR3-1600, preferably DDR3-1866</td>
</tr>
<tr>
<td>Storage</td>
<td>Read/write:</td>
</tr>
</tbody>
</table>
- Minimum—40 MB/s per physical core of the CPU
- For best performance—60–80 MB/s per physical core

Storage post RAID: Each node should have 1–9 TB. For a production setting, Vertica recommends RAID 10. In some cases, RAID 50 is acceptable.

Because Vertica performs heavy compression and encoding, SSDs are not required. In most cases, a RAID of more, less-expensive HDDs performs just as well as a RAID of fewer SSDs.

If you intend to use RAID 50 for your data partition, you should keep a spare node in every rack, allowing for manual failover of a Vertica node in the case of a drive failure. A Vertica node recovery is faster than a RAID 50 rebuild. Also, be sure to never put more than 10 TB compressed on any node, to keep node recovery times at an acceptable rate.

| Network   | 10 GB networking in almost every case. With the introduction of 10 GB over cat6a (Ethernet), the cost difference is minimal. |

## Configuring Hadoop for Co-Located Clusters

If you are co-locating Vertica on any HDFS nodes, there are some additional configuration requirements.

### Hadoop Configuration Parameters

For best performance, set the following parameters with the specified minimum values:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Minimum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDFS block size</td>
<td>512MB</td>
</tr>
<tr>
<td>Namenode Java Heap</td>
<td>1GB</td>
</tr>
<tr>
<td>Datanode Java Heap</td>
<td>2GB</td>
</tr>
</tbody>
</table>
WebHDFS

Hadoop has two services that can provide web access to HDFS:

- WebHDFS
- httpFS

For Vertica, you must use the WebHDFS service.

YARN

The YARN service is available in newer releases of Hadoop. It performs resource management for Hadoop clusters. When co-locating Vertica on YARN-managed Hadoop nodes you must make some changes in YARN.

Vertica recommends reserving at least 16GB of memory for Vertica on shared nodes. Reserving more will improve performance. How you do this depends on your Hadoop distribution:

- If you are using Hortonworks, create a "Vertica" node label and assign this to the nodes that are running Vertica.
- If you are using Cloudera, enable and configure static service pools.

Consult the documentation for your Hadoop distribution for details. Alternatively, you can disable YARN on the shared nodes.

Hadoop Balancer

The Hadoop Balancer can redistribute data blocks across HDFS. For many Hadoop services, this feature is useful. However, for Vertica this can reduce performance under some conditions.

If you are using HDFS storage locations, the Hadoop load balancer can move data away from the Vertica nodes that are operating on it, degrading performance. This behavior can also occur when reading ORC or Parquet files if Vertica is not running on all Hadoop nodes. (If you are using separate Vertica and Hadoop clusters, all Hadoop access is over the network, and the performance cost is less noticeable.)
To prevent the undesired movement of data blocks across the HDFS cluster, consider excluding Vertica nodes from rebalancing. See the Hadoop documentation to learn how to do this.

**Replication Factor**

By default, HDFS stores three copies of each data block. Vertica is generally set up to store two copies of each data item through K-Safety. Thus, lowering the replication factor to 2 can save space and still provide data protection.

To lower the number of copies HDFS stores, set HadoopFSReplication, as explained in Troubleshooting HDFS Storage Locations.

**Disk Space for Non-HDFS Use**

You also need to reserve some disk space for non-HDFS use. To reserve disk space using Ambari, set dfs.datanode.du.reserved to a value in the hdfs-site.xml configuration file.

Setting this parameter preserves space for non-HDFS files that Vertica requires.

**Configuring Rack Locality**

**Note:** This feature is supported only for reading ORC and Parquet data on co-located clusters. It is only meaningful on Hadoop clusters that span multiple racks.

When possible, when planning a query Vertica automatically uses database nodes that are co-located with the HDFS nodes that contain the data. Moving query execution closer to the data reduces network latency and can improve performance. This behavior, called node locality, requires no additional configuration.

When Vertica is co-located on only a subset of HDFS nodes, sometimes there is no database node that is co-located with the data. However, performance is usually better if a query uses a database node in the same rack. If configured with information about Hadoop rack
structure, Vertica attempts to use a database node in the same rack as the data to be queried.

For example, the following diagram illustrates a Hadoop cluster with three racks each containing three data nodes. (Typical production systems have more data nodes per rack.) In each rack, Vertica is co-located on one node.

If you configure rack locality, Vertica uses db01 to query data on dn1, dn2, or dn3, and uses db02 and db03 for data on rack2 and rack3 respectively. Because HDFS replicates data, any given data block can exist in more than one rack. If a data block is replicated on dn2, dn3, and dn6, for example, Vertica uses either db01 or db02 to query it.

Hadoop components are rack-aware, so configuration files describing rack structure already exist in the Hadoop cluster. To use this information in Vertica, configure fault groups that describe this rack structure. Vertica uses fault groups in query planning.
Configuring Fault Groups

Vertica uses Fault Groups to describe physical cluster layout. Because your database nodes are co-located on HDFS nodes, Vertica can use the information about the physical layout of the HDFS cluster.

**Tip:**
For best results, ensure that each Hadoop rack contains at least one co-located Vertica node.

Hadoop stores its cluster-layout data in a topology mapping file in HADOOP_CONF_DIR. On HortonWorks the file is typically named topology_mappings.data. On Cloudera it is typically named topology.map. Use the data in this file to create an input file for the fault-group script. For more information about the format of this file, see Creating a Fault Group Input File.

Following is an example topology mapping file for the cluster illustrated previously:

```plaintext
[network_toplogy]
 dn1.example.com=/rack1
 10.20.41.51=/rack1
 dn2.example.com=/rack1
 10.20.41.52=/rack1
 dn3.example.com=/rack1
 10.20.41.53=/rack1
 dn4.example.com=/rack2
 10.20.41.71=/rack2
 dn5.example.com=/rack2
 10.20.41.72=/rack2
 dn6.example.com=/rack2
 10.20.41.73=/rack2
 dn7.example.com=/rack3
 10.20.41.91=/rack3
 dn8.example.com=/rack3
 10.20.41.92=/rack3
 dn9.example.com=/rack3
 10.20.41.93=/rack3
```

From this data, you can create the following input file describing the Vertica subset of this cluster:

```plaintext
/rack1 /rack2 /rack3
/rack1 = db01
/rack2 = db02
/rack3 = db03
```
This input file tells Vertica that the database node "db01" is on rack1, "db02" is on rack2, and "db03" is on rack3. In creating this file, ignore Hadoop data nodes that are not also Vertica nodes.

After you create the input file, run the fault-group tool:

```bash
$ python /opt/vertica/scripts/fault_group_ddl_generator.py dbName input_file > fault_group_ddl.sql
```

The output of this script is a SQL file that creates the fault groups. Execute it following the instructions in Creating Fault Groups Using the Fault Group Script.

You can review the new fault groups with the following statement:

```sql
=> SELECT member_name, node_address, parent_name FROM fault_groups
INNER JOIN nodes ON member_name=node_name ORDER BY parent_name;
```

<table>
<thead>
<tr>
<th>member_name</th>
<th>node_address</th>
<th>parent_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>db01</td>
<td>10.20.41.51</td>
<td>/rack1</td>
</tr>
<tr>
<td>db02</td>
<td>10.20.41.71</td>
<td>/rack2</td>
</tr>
<tr>
<td>db03</td>
<td>10.20.41.91</td>
<td>/rack3</td>
</tr>
</tbody>
</table>

(3 rows)

**Working With Multi-Level Racks**

A Hadoop cluster can use multi-level racks. For example, /west/rack-w1, /west/rack-2, and /west/rack-w3 might be served from one data center, while /east/rack-e1, /east/rack-e2, and /east/rack-e3 are served from another. Use the following format for entries in the input file for the fault-group script:

```plaintext
/west /east
/west = /rack-w1 /rack-w2 /rack-w3
/east = /rack-e1 /rack-e2 /rack-e3
/rack-w1 = db01
/rack-w2 = db02
/rack-w3 = db03
/rack-e1 = db04
/rack-e2 = db05
/rack-e3 = db06
```

Do not create entries using the full rack path, such as /west/rack-w1.
Auditing Results

To see how much data can be loaded with rack locality, use `EXPLAIN` with the query and look for statements like the following in the output:

100% of ORC data including co-located data can be loaded with rack locality.

Separate Clusters

With separate clusters, a Vertica cluster and a Hadoop cluster share no nodes. You should use a high-bandwidth network connection between the two clusters.

The following figure illustrates the configuration for separate clusters:

```
Vertica Cluster
Vertica
v_node1
Vertica
v_node2
Vertica
v_node3

Vertica Private Network

Hadoop Cluster
NodeMgr
h_node1
NodeMgr
h_node2
NodeMgr
h_node3
NodeMgr
h_node4
NodeMgr
h_node5

Shared Public Network
```
Network

The network is a key performance component of any well-configured cluster. When Vertica stores data to HDFS it writes and reads data across the network.

The layout shown in the figure calls for two networks, and there are benefits to adding a third:

- **Database Private Network:** Vertica uses a private network for command and control and moving data between nodes in support of its database functions. In some networks, the command and control and passing of data are split across two networks.
- **Database/Hadoop Shared Network:** Each Vertica node must be able to connect to each Hadoop data node and the NameNode. Hadoop best practices generally require a dedicated network for the Hadoop cluster. This is not a technical requirement, but a dedicated network improves Hadoop performance. Vertica and Hadoop should share the dedicated Hadoop network.
- **Optional Client Network:** Outside clients may access the clustered networks through a client network. This is not an absolute requirement, but the use of a third network that supports client connections to either Vertica or Hadoop can improve performance. If the configuration does not support a client network, then client connections should use the shared network.

Hadoop Configuration Parameters

For best performance, set the following parameters with the specified minimum values:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Minimum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDFS block size</td>
<td>512MB</td>
</tr>
<tr>
<td>Namenode Java Heap</td>
<td>1GB</td>
</tr>
<tr>
<td>Datanode Java Heap</td>
<td>2GB</td>
</tr>
</tbody>
</table>
Hadoop Interfaces

Vertica provides several ways to interact with data stored in HDFS, described below. Decisions about Cluster Layout can affect the decisions you make about which Hadoop interfaces to use.

Querying Data Stored in HDFS

Vertica can query data directly from HDFS without requiring you to copy data. Doing so allows you to explore a large data lake without copying data into Vertica for analysis (and keeping the copy up to date). Queries against data in columnar formats are optimized to reduce the amount of data that Vertica has to read.

To query data, you define an external table as for any other external data source. (This option does not make use of schema definitions from Hive.) See Working with External Data for more about creating external tables, and Reading ORC and Parquet Formats for more about optimizations specific to these native Hadoop file formats.

Vertica can query the data directly from the HDFS nodes, bypassing the WebHDFS service. To query data directly, Vertica needs access to HDFS configuration files. See Using HDFS URLs.

Querying Data Using the HCatalog Connector

The HCatalog Connector uses Hadoop services (Hive and HCatalog) to query data stored in HDFS. Using the HCatalog Connector, Vertica can use Hive's schema definitions. However, performance can be poor compared to defining your own external table and querying the data directly. The HCatalog Connector is also sensitive to changes in the Hadoop libraries on which it depends; upgrading your Hadoop cluster might affect your HCatalog connections.

See Using the HCatalog Connector.
Using ROS Data

Storing data in the Vertica native file format (ROS) delivers better query performance than reading externally-stored data. You can create storage locations on your HDFS cluster to hold ROS data. Even if your data is already stored in HDFS, you might choose to copy that data into an HDFS storage location for better performance. If your Vertica cluster also uses local file storage, you can use HDFS storage locations for lower-priority data.

See Using HDFS Storage Locations for information about creating and managing HDFS storage locations, and Using HDFS URLs for information about copying data into them.

Exporting Data

You might want to export data from Vertica, either to share it with other Hadoop-based applications or to move lower-priority data from ROS to less-expensive storage. You can export a table, or part of one, in Hadoop columnar format. After export you can still query the data using an external table, as for any other data.

See Exporting Data.

Accessing Kerberized HDFS Data

If your Hortonworks or Cloudera Hadoop cluster uses Kerberos authentication to restrict access to HDFS, Vertica must be granted access. If you use Kerberos authentication for your Vertica database, and database users have HDFS access, then you can configure Vertica to use the same principals to authenticate. However, not all Hadoop administrators want to grant access to all database users, preferring to manage access in other ways. In addition, not all Vertica databases use Kerberos.

Vertica provides the following options for accessing Kerberized Hadoop clusters:

- Using Vertica Kerberos principals.
- Using Hadoop proxy users combined with Vertica users.
- Using a user-specified delegation token which grants access to HDFS. Delegation tokens are issued by the Hadoop cluster.

Proxy users and delegation tokens both use a session parameter to manage identities. Vertica need not be Kerberized when using either of these methods.
Vertica does not support Kerberos for MapR.

To test your Kerberos configuration, see Verifying HDFS Configuration.

Using Kerberos with Vertica

If you use Kerberos for your Vertica cluster and your principals have access to HDFS, then you can configure Vertica to use the same credentials for HDFS.

Vertica authenticates with Hadoop in two ways that require different configurations:

- **User Authentication**—On behalf of the user, by passing along the user's existing Kerberos credentials. This method is also called user impersonation. Actions performed on behalf of particular users, like executing queries, generally use user authentication.
- **Vertica Authentication**—On behalf of system processes (such as the Tuple Mover), by using a special Kerberos credential stored in a keytab file.

Note: Vertica and Hadoop must use the same Kerberos server or servers (KDCs).

Vertica can interact with more than one Kerberos realm. To configure multiple realms, see Multi-realm Support in Security and Authentication.

Vertica attempts to automatically refresh Hadoop tokens before they expire. See Token Expiration.

User Authentication

To use Vertica with Kerberos and Hadoop, the client user first authenticates with one of the Kerberos servers (Key Distribution Center, or KDC) being used by the Hadoop cluster. A user might run kinit or sign in to Active Directory, for example.

A user who authenticates to a Kerberos server receives a Kerberos ticket. At the beginning of a client session, Vertica automatically retrieves this ticket. Vertica then uses this ticket to get a Hadoop token, which Hadoop uses to grant access. Vertica uses this token to access HDFS, such as when executing a query on behalf of the user. When the token expires, Vertica automatically renews it, also renewing the Kerberos ticket if necessary.
The user must have been granted permission to access the relevant files in HDFS. This permission is checked the first time Vertica reads HDFS data.

Vertica can use multiple KDCs serving multiple Kerberos realms, if proper cross-realm trust has been set up between realms.

**Vertica Authentication**

Automatic processes, such as the Tuple Mover, do not log in the way users do. Instead, Vertica uses a special identity (principal) stored in a keytab file on every database node. (This approach is also used for Vertica clusters that use Kerberos but do not use Hadoop.) After you configure the keytab file, Vertica uses the principal residing there to automatically obtain and maintain a Kerberos ticket, much as in the client scenario. In this case, the client does not interact with Kerberos.

Each Vertica node uses its own principal; it is common to incorporate the name of the node into the principal name. You can either create one keytab per node, containing only that node's principal, or you can create a single keytab containing all the principals and distribute the file to all nodes. Either way, the node uses its principal to get a Kerberos ticket and then uses that ticket to get a Hadoop token.

When creating HDFS storage locations Vertica uses the principal in the keytab file, not the principal of the user issuing the CREATE LOCATION statement. The HCatalog Connector sometimes uses the principal in the keytab file, depending on how Hive authenticates users.

**Configuring Users and the Keytab File**

If you have not already configured Kerberos authentication for Vertica, follow the instructions in Configure Vertica for Kerberos Authentication. Of particular importance for Hadoop integration:

1. Create one Kerberos principal per node.
2. Place the keytab files in the same location on each database node and set configuration parameter KerberosKeytabFile to that location.
3. Set KerberosServiceName to the name of the principal. (See Inform Vertica About the Kerberos Principal.)

If you are using the HCatalog Connector, follow the additional steps in Configuring Security in the HCatalog Connector documentation.
If you are using HDFS storage locations, follow the additional steps in Configuring Kerberos in the HDFS Storage Locations documentation.

**Proxy Users and Delegation Tokens**

An alternative to granting HDFS access to individual Vertica users is to use delegation tokens, either directly or with a proxy user. In this configuration, Vertica accesses HDFS on behalf of some other (Hadoop) user. The Hadoop users need not be Vertica users at all.

In Vertica, you can either specify the name of the Hadoop user to act on behalf of (doAs), or you can directly use a Kerberos delegation token that you obtain from HDFS (Bring Your Own Delegation Token). In the doAs case, Vertica obtains a delegation token for that user, so both approaches ultimately use delegation tokens to access files in HDFS.

Use the HadoopImpersonationConfig session parameter to specify a user or delegation token to use for HDFS access. Each session can use a different user and can use either doAs or a delegation token. The value of HadoopImpersonationConfig is a set of JSON objects. See HadoopImpersonationConfig Format for details.

When using delegation tokens of either type (more specifically, when HadoopImpersonationConfig is set), Vertica falls back to WebHDFS to access data. This fallback is automatic; continue to use the hdfs URL scheme when using delegation tokens.

**User Impersonation (doAs)**

You can use user impersonation to access data in an HDFS cluster from Vertica. This approach is called "doAs" (for "do as") because Vertica uses a single proxy user on behalf of another (Hadoop) user. The impersonated Hadoop user does not need to also be a Vertica user.

In the following illustration, Alice and Bob are Hadoop users but not Vertica users. They connect to Vertica as the proxy user, vertica-etl, in separate sessions. In each session, Vertica obtains a delegation token (DT) on behalf of the doAs user (Alice or Bob), and uses that delegation token to access HDFS.
You can use doAs with or without Kerberos, so long as HDFS and Vertica match. If HDFS uses Kerberos then Vertica must too.

**User Configuration**

The Hadoop administrator must create a proxy user and allow it to access HDFS on behalf of other users. Set values in core-site.xml as in the following example:

```xml
<name>hadoop.proxyuser.vertica-etl.users</name>
<value>*</value>
<name>hadoop.proxyuser.vertica-etl.hosts</name>
<value>*</value>
```

In Vertica, create a corresponding user.

**Session Configuration**

To make requests on behalf of a Hadoop user, first set the HadoopImpersonationConfig session parameter to specify the user and HDFS cluster. Vertica will access HDFS as that user until the session ends or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies an HDFS cluster and a Hadoop user. For the cluster, you can specify either a nameservice or an individual namenode. If you are using HA namenode, then you must either use a
nameservice or specify all namenodes. HadoopImpersonationConfig Format describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "vertica-etl" is a Vertica user.

```
$ vsql -U vertica-etl
=> ALTER SESSION SET HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"stephanie"}];
=> COPY nation FROM 'hdfs:///user/stephanie/nation.dat';

=> ALTER SESSION SET HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"bob"},
{"authority":"hadoop2:50070", "doAs":"rob"}];
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';
```

Vertica uses Hadoop delegation tokens, obtained from the namenode, to impersonate Hadoop users. In a long-running session, a token could expire. Vertica attempts to renew tokens automatically; see Token Expiration.

**Testing the Configuration**

You can use the HADOOP_IMPERSONATION_CONFIG_CHECK function to test your HDFS delegation tokens and HCATALOGCONNECTOR_CONFIG_CHECK to test your HCatalog Connector delegation token.

**Bring Your Own Delegation Token**

Instead of creating a proxy user and giving it access to HDFS for use with doAs, you can give Vertica a Hadoop delegation token to use. You must obtain this delegation token from the Hadoop NameNode. In this model, security is handled entirely on the Hadoop side, with Vertica just passing along a token. Vertica may or may not be Kerberized.

A typical workflow is:

- In an ETL front end, a user submits a query.
- The ETL system uses authentication and authorization services to verify that the user has sufficient permission to run the query.
- The ETL system requests a delegation token for the user from the NameNode.
- The ETL system makes a client connection to Vertica, sets the delegation token for the session, and runs the query.
When using a delegation token, clients can connect as any Vertica user. No proxy user is required.

In the following illustration, Bob and Carol have Hadoop-issued delegation tokens. They connect to Vertica and Vertica uses those delegation tokens to access files in HDFS.

**Session Configuration**

Set the HadoopImpersonationConfig session parameter to specify the delegation token and HDFS cluster. Vertica will access HDFS using that delegation token until the session ends, the token expires, or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies a delegation token ("token") in webhdfs format and an HDFS nameservice or namenode. [HadoopImpersonationConfig Format](#) describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "dbuser1" is a Vertica user with no special privileges.

```
$ vsql -U dbuser1
=> ALTER SESSION SET
    HadoopImpersonationConfig ='
    
    [{"authority":"hadoop1:50070","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB91gFg-zKEdY4gao4Bmh3YxtX1QqrhB8bbU4VScNg5WHQx3XRU3REZTIGR1b6VnyYXRp24RMTAuuMJzAwLjU0OjgwMJA"}];
=> COPY nation FROM 'hdfs:///user/stephanie/nation.dat';
```
=> ALTER SESSION SET
    HadoopImpersonationConfig = '[{"authority":"hadoop1:50070","token":"HgADdG9tA3RvbQCKAWDXJgAojFg-zAkE14ga14mhRo0Upq_jPxrvHvZ1NSMmodAQnhUthJ3XRJUZ7T1Gr1bGvnyXRpb24RMTAuMjAuMTAwLjU0OjgMjA"}];
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';

You can use the WebHDFS REST API to get delegation tokens:

$ curl -s -noproxy "*" --negotiate -u: -X GET
"http://hadoop1:50070/webhdfs/v1/?op=GETDELEGATIONTOKEN"

Vertica does not, and cannot, renew delegation tokens when they expire. You must either keep sessions shorter than token lifetime or implement a renewal scheme.

**Delegation Tokens and the HCatalog Connector**

HiveServer2 uses a different format for delegation tokens. To use the HCatalog Connector, therefore, you must set two delegation tokens, one as usual (authority) and one for HiveServer2 (schema). The HCatalog Connector uses the schema token to access metadata and the authority token to access data. The schema name is the same Hive schema you specified in CREATE HCATALOG SCHEMA. The following example shows how to use these two delegation tokens.

$ vsql -U dbuser1
-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
    HadoopImpersonationConfig = '[
        {"nameservice":"hadoopNS","token":"3QAHcmVsZwFzQdyZwl1YXNlAIoBYVJkJrYSKAWF2VzGEjgmzj_IUCLhir9b8Dq6awFThks5C-fHb8xS5VCSERGUYk3ZwxI22F0aW9uETEwLjIwLjQyLjEwOTo4MDIw"},
        {"schema":"access","token":"UwAHcmVsZwFzQdyZwl1YXNlI2hpdmUvZw5nLwc5LTEwMC52ZXJ0aW1hY29ycC5jb21AVkVSV1QNPUIuQ09NiFhUmNyToB0YXY2WN4b8jgETFKN2xPUrIn99Yy9tf-0neko051TzFvuh3VkVFREVMRudBVEIPT19Ut0tFTh2oaXZ1c2VydVYmKnsaWVudFVva2Vu"}];

-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';

-- uses both tokens
=> SELECT * FROM access.t1;

-- uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;

HiveServer2 does not provide a REST API for delegation tokens like WebHDFS does. See Getting a HiveServer2 Delegation Token for some tips.
Testing the Configuration

You can use the HADOOP_IMPERSONATION_CONFIG_CHECK function to test your HDFS delegation tokens and HCATALOGCONNECTOR_CONFIG_CHECK to test your HCatalog Connector delegation token.

Getting a HiveServer2 Delegation Token

To access Hive metadata using HiveServer2, you need a special delegation token. (See Bring Your Own Delegation Token.) HiveServer2 does not provide an easy way to get this token, unlike the REST API that grants HDFS (data) delegation tokens.

The following utility code shows a way to get this token. You will need to modify this code for your own cluster; in particular, change the value of the connectURL static.

```java
import java.io.FileWriter;
import java.io.PrintStream;
import java.io.PrintWriter;
import java.io.StringWriter;
import java.io.Writer;
import java.security.PrivilegedExceptionAction;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.hive.shims.Utils;
import org.apache.hadoop.security.UserGroupInformation;
import org.apache.hive.jdbc.HiveConnection;
import org.json.simple.JSONArray;
import org.json.simple.JSONObject;
public class JDBCTest {
    public static final String driverName = "org.apache.hive.jdbc.HiveDriver";
    public static String connectURL = "jdbc:hive2://node2.cluster0.example.com:2181,node1.cluster0.example.com:2181,node3.cluster0.example.com:2181;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2";
    public static String schemaName = "hcat";
    public static String verticaUser = "condor";
    public static String proxyUser = "condor-2";
    public static String krb5conf = "/home/server/kerberos/kt.keytab"

      System.out.println("In doas: " + UserGroupInformation.getLoginUser());
      Connection con = DriverManager.getConnection(JDBCTest.connectURL);
      JDBCTest.showUser(con);
      System.out.println("Getting delegation token for user");
      String token = ((HiveConnection) con).getDelegationToken(JDBCTest.proxyUser, "hive/_HOST@m", JDBCTest.realm);
      System.out.println("Got token: " + token);
      System.out.println("Closing original connection");
      con.close();

      System.out.println("Setting delegation token in UGI");
      Util.setTokenStr(Util.getUGI(), token, "hiveserver2ClientToken");
      con = DriverManager.getConnection(JDBCTest.connectURL + ";auth=delegationToken");
      System.out.println("Connected to HiveServer2 with delegation token");
      JDBCTest.showUser(con);
  });
}
private static void showUser(Connection con) throws Exception {
    String sql = "select current_user()";
    Statement stmt = con.createStatement();
    ResultSet res = stmt.executeQuery(sql);
    StringBuilder result = new StringBuilder();
    while (res.next()) {
        result.append(res.getString(1));
    }
    System.out.println("current_user: " + result.toString());
}

private static void writeDTJSON(String token) {
    JSONArray arr = new JSONArray();
    JSONObject obj = new JSONObject();
    obj.put("schema", schemaName);
    obj.put("token", token);
    arr.add(obj);
    try {
        FileWriter fileWriter = new FileWriter("hcat_delegation.json");
        fileWriter.write(arr.toJSONString());
        fileWriter.flush();
    } catch (Exception e) {
        e.printStackTrace();
    }
}

Following is an example call and its output:

$ java -cp hs2token.jar JDBCTest 'jdbc:hive2://test.example.com:10000/default;principal=hive/_HOST@EXAMPLE.COM' "defautl" "testuser" "test" "/etc/krb5.conf" "EXAMPLE.COM" "test/testuser.keytab"
current_user: testuser

HadoopImpersonationConfig Format

The value of the HadoopImpersonationConfig session parameter is a set of one or more JSON objects. Each object describes one doAs user or delegation token for one Hadoop destination.

**Syntax**

```
[ { "doAs": value, "token": value, "nameservice": value, "authority": value, "schema": value } ]
```

**Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>doAs</td>
<td>The name of a Hadoop user to impersonate.</td>
</tr>
<tr>
<td>token</td>
<td>A delegation token to use for HDFS access.</td>
</tr>
<tr>
<td>nameservice</td>
<td>A Hadoop nameservice. All access to this nameservice uses the doAs user or delegation token. You must use the hdfs URL scheme (for example, hdfs://ns-value/path).</td>
</tr>
<tr>
<td>authority</td>
<td>A namenode authority. All access to this authority uses the doAs user or delegation token. If the namenode fails over to another namenode, the doAs user or delegation token does not automatically apply to the failover namenode. If you are using HA namenode, use nameservice instead of authority or include objects for every namenode.</td>
</tr>
<tr>
<td>schema</td>
<td>A Hive schema, for use with the HCatalog Connector. Vertica uses this object’s doAs user or token to access Hive metadata only. For data access you must also specify a nameservice or authority object, just like for all other data access.</td>
</tr>
</tbody>
</table>
Examples

In the following example of doAs, Bob is a Hadoop user and vertica-etl is a Kerberized proxy user.

```bash
$ kinit vertica-etl -kt /home/dbadmin/vertica-etl.keytab
$ vsq1 -U vertica-etl

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"Bob"}];
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';
```

In the following example, the current Vertica user (it doesn't matter who that is) uses a Hadoop delegation token. This token belongs to Alice, but you never specify the user name here. Instead, you use it to get the delegation token from Hadoop.

```bash
$ vsq1 -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig = '{"nameservice":"hadoopNS","token":"JQAHcmVsZWFzZQdyZWxlYWNlAIoBYVJKrYs5KAwF2VzgEjgmgzj_IUCIrI9b8D9LSv5sV0VCREgUGyBxZw12f8a9uEJEwLj9YljeW0To4MDIw"};
=> COPY nation FROM 'hdfs:///user/alice/nation.dat';
```

In the following example, "authority" specifies the (single) namenode on a Hadoop cluster that does not use high availability.

```bash
$ vsq1 -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[{"authority":"hadoop1:50070", "doAs":"Stephanie"}];
=> COPY nation FROM 'webhdfs://hadoop1:50070/user/stephanie/nation.dat';
```

To access data in Hive you need to specify two delegation tokens. The first, for a nameservice or authority, is for data access as usual. The second is for the HiveServer2 metadata for the schema. HiveServer2 requires a delegation token in webhdfs format. The schema name is the Hive schema you specify with CREATE HCATALOG SCHEMA.

```bash
$ vsq1 -U dbuser1

-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
   HadoopImpersonationConfig='[
   {"nameservice":"hadoopNS","token":"TQAhcmVsZWFzZQdyZWxlYWNlAIoBYVJK62VzgEjgmgzj_IUCIrI9b8D9LSv5sV0VCREgUGyBxZw12f8a9uEJEwLj9YljeW0To4MDIw"},
   {"schema":"access","token":"UwAhcmVsZWFzZQdyZWxlYWNlAIoBYVJK62VzgEjgmgzj_IUCIrI9b8D9LSv5sV0VCREgUGyBxZw12f8a9uEJEwLj9YljeW0To4MDIw"}];
```
Each object in the HadoopImpersonationConfig collection specifies one connection to one Hadoop cluster. You can add as many connections as you like, including to more than one Hadoop cluster. The following example shows delegation tokens for two different Hadoop clusters. Vertica uses the correct token for each cluster when connecting.

```sql
$ vsq1 -U dbuser1

=> ALTER SESSION SET HadoopImpersonationConfig = '[
    {"nameservice": "productionNS", "token": "JAAGZG3lidGwxBmRiZXRsMQCKAWDXjgB9igFg-zKEFY4gao4BmhS3YXjWqRhBhbUn4V5cNgL8hWx3XRUJIREZTl6R1bGv8YX8p24RMTAuwH9AuMTAwlJU8OjgMjA"},
    {"nameservice": "testNS", "token": "HQAHcmVsZWFzZQdyyWx1YXFlAioBYV3KreYSKAWF2zvGEjmgmzIUCIrI9bBDqu6awFThk5c+fHBoxs5V0VC5ERGy98kZwlx12Z0aWkETEWlJiwLjQyLjEwOTo4MDIw"}]
]

=> COPY clicks FROM 'hdfs://productionNS/data/clickstream.dat';
=> COPY testclicks FROM 'hdfs://testNS/data/clickstream.dat';
```

### Token Expiration

Vertica uses Hadoop tokens when using Kerberos tickets ([Using Kerberos with Vertica](Using Kerberos with Vertica)) or doAs ([User Impersonation (doAs)](User Impersonation (doAs))). Vertica attempts to automatically refresh Hadoop tokens before they expire, but you can also set a minimum refresh frequency if you prefer. Use the HadoopFSTokenRefreshFrequency configuration parameter to specify the frequency in seconds:

```sql
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

If the current age of the token is greater than the value specified in this parameter, Vertica refreshes the token before accessing data stored in HDFS.

Vertica does not refresh delegation tokens ([Bring Your Own Delegation Token](Bring Your Own Delegation Token)).
Using HDFS URLs

Use the hdfs URL scheme when accessing files in HDFS. With this scheme, Vertica bypasses the slower, less-stable WebHDFS service when possible, and falls back to it when necessary. To use WebHDFS for all access, set the HDFSUseWebHDFS configuration parameter and continue to use hdfs URLs; you do not need to rewrite URLs to change connection methods. (See Apache Hadoop Parameters.)

You can use the hdfs scheme with COPY and with CREATE EXTERNAL TABLE AS COPY. When using the hdfs scheme with COPY, you do not need to specify ON ANY NODE.

Vertica requires access to certain configuration files from your HDFS cluster.

If the file you want to read resides on an HDFS cluster that uses Kerberos authentication, Vertica uses the current user's principal, session doAs user, or session delegation token. See Accessing Kerberized HDFS Data for more information about these options.

HDFS URL Format

You specify the location of a file in HDFS using a URL. In most cases, you use the hdfs:// URL prefix (three slashes) with COPY, and then specify the file path. The hdfs scheme uses the Libhdfs++ library to read files and is more efficient than WebHDFS.

Note:
Do not use hdfs:// when creating a storage location, because you do not want a storage location to depend on the value of HadoopConfDir, which can change. Use this shorthand only for reading external data.

The following example loads data stored in HDFS.

```sql
=> COPY users FROM 'hdfs:///data/users.csv';
```

Vertica uses the fs.defaultFS Hadoop configuration parameter to find the NameNode, which it uses to access the data. You can instead specify a host and port explicitly using the following format: hdfs://host:port/. The specified host is the NameNode, not an individual data node. If you are using High Availability (HA) NameNodes you should not use an explicit host because high availability is provided through nameservices instead.
Your HDFS cluster might use High Availability NameNodes or define nameservices. If so, you should use the nameservice instead of the host and port, in the format hdfs://nameservice/. The nameservice you specify must be defined in hdfs-site.xml.

The following example shows how you can use a nameservice, hadoopNS, with the hdfs scheme.

```
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
   AS COPY FROM 'hdfs://hadoopNS/data/users.csv';
```

If you are using Vertica to access data from more than one HDFS cluster, always use explicit nameservices or hosts in the URL. Using hdfs:// could produce unexpected results because Vertica uses the first value of fs.defaultFS that it finds. To access multiple HDFS clusters, you must use host and service names that are globally unique. See Configuring the hdfs Scheme for more information.

**Note:**

All characters in URLs that are not a–z, A–Z, 0–9, '-', '.', '_' or '~' must be converted to URL encoding (%NN where NN is a two-digit hexadecimal number). For example, use %20 for space.

## Configuring the hdfs Scheme

Vertica uses information from the Hadoop cluster configuration to support the hdfs scheme. Vertica nodes therefore must have access to certain Hadoop configuration files. To use a cluster with High Availability NameNode or to read from more than one Hadoop cluster, you must perform additional configuration.

For both co-located and separate clusters that use Kerberos authentication, configure Vertica for Kerberos as explained in Configure Vertica for Kerberos Authentication.

Using the hdfs scheme still requires access to the WebHDFS service. For some special cases, Vertica cannot use the hdfs scheme and falls back to webhdfs.

## Accessing Hadoop Configuration Files

To support the hdfs scheme, your Vertica nodes need access to certain Hadoop configuration files:
• If Vertica is co-located on HDFS nodes, then those configuration files are already present.

• If Vertica is running on a separate cluster, you must copy the required files to all database nodes. A simple way to do so is to configure your Vertica nodes as Hadoop edge nodes. Client applications run on edge nodes; from Hadoop's perspective, Vertica is a client application. You can use Ambari or Cloudera Manager to configure edge nodes. For more information, see the documentation from your Hadoop vendor.

Verify that the value of the HadoopConfDir configuration parameter (see Apache Hadoop Parameters) includes a directory containing the files listed in the following table. If you do not set a value, Vertica looks for the files in /etc/hadoop/conf. For all Vertica users, the directory is accessed by the Linux user under which the Vertica server process runs.

Vertica uses the following configuration files and properties. If a property is not defined, Vertica uses the defaults shown in the table. Your Hadoop configuration files must specify all properties that have no defaults.

<table>
<thead>
<tr>
<th>File</th>
<th>Properties</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>core-site.xml</td>
<td>fs.defaultFS</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>(for doAs users:) hadoop.proxyuser.username.users</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>(for doAs users:) hadoop.proxyuser.username.hosts</td>
<td>none</td>
</tr>
<tr>
<td>hdfs-site.xml</td>
<td>dfs.client.failover.max.attempts</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>dfs.client.failover.connection.retries.on.timeout</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>ipc.client.connect.timeout</td>
<td>30 seconds</td>
</tr>
<tr>
<td></td>
<td>ipc.client.connect.retry.interval</td>
<td>10 seconds</td>
</tr>
<tr>
<td></td>
<td>(For HA NN:) dfs.nameservices</td>
<td>none</td>
</tr>
</tbody>
</table>

### Using a Cluster with High Availability NameNodes

If your Hadoop cluster uses High Availability (HA) NameNodes, verify that the dfs.nameservices parameter and the individual NameNodes are defined in hdfs-site.xml.
Using More Than One Hadoop Cluster

In some cases, a Vertica cluster requires access to more than one HDFS cluster. For example, your business might use separate HDFS clusters for separate regions, or you might need data from both test and deployment clusters.

To support multiple clusters, perform the following steps:

1. Copy the configuration files from all HDFS clusters to your database nodes. You can place the copied files in any location readable by Vertica. However, as a best practice, you should place them all in the same directory tree, with one subdirectory per HDFS cluster. The locations must be the same on all database nodes.
2. Set the HadoopConfDir configuration parameter. The value is a colon-separated path containing the directories for all of your HDFS clusters.
3. Use an explicit NameNode or nameservice in the URL when creating an external table or copying data. Do not use hdfs:// because it could be ambiguous. For more information about URLs, see HDFS URL Format.

Vertica connects directly to a NameNode or nameservice; it does not otherwise distinguish among HDFS clusters. Therefore, names of HDFS NameNodes and nameservices must be globally unique.

Verifying the Configuration

Use the VERIFY_HADOOP_CONF_DIR function to verify that Vertica can find configuration files in HadoopConfDir.

Use the HDFS_CLUSTER_CONFIG_CHECK function to test access through the hdfs scheme.

For more information about testing your configuration, see Verifying HDFS Configuration.

Updating Configuration Files

If you update the configuration files after starting Vertica, use the following statement to refresh them:

```
=> SELECT CLEAR_HDFS_CACHES();
```
The **CLEAR_HDFS_CACHES** function also flushes information about which NameNode is active in a High Availability (HA) Hadoop cluster. Therefore, the first hdfs request after calling this function is slow, because the initial connection to the NameNode can take more than 15 seconds.

**Troubleshooting Reads from the hdfs Scheme**

You might encounter the following issues when using the hdfs URL scheme to access data in HDFS.

**WebHDFS Error When Using hdfs URLs**

When creating an external table or loading data and using the hdfs scheme, you might see errors from WebHDFS failures. Such errors indicate that Vertica was not able to use the hdfs scheme and fell back to webhdfs, but that the WebHDFS configuration is incorrect.

First verify the value of the HadoopConfDir configuration parameter, which can be set at the session level. Then verify that the HDFS configuration files found there have the correct WebHDFS configuration for your Hadoop cluster. See Configuring the hdfs Scheme for information about use of these files. See your Hadoop documentation for information about WebHDFS configuration.

**Queries Using hdfs:/// Show Unexpected Results**

If you are using hdfs:// to query external tables and see unexpected results, such as production data in your test cluster, verify that HadoopConfDir is set to the value you expect. The HadoopConfDir configuration parameter defines a path to search for the Hadoop configuration files that Vertica needs to resolve file locations. The HadoopConfDir parameter can be set at the session level, overriding the permanent value set in the database.

To debug problems with hdfs:// URLs, try replacing the URLs with ones that use an explicit nameservice or name node. If the explicit URL works, then the problem is with the resolution of hdfs://. If the explicit URL also does not work as expected, then the problem is elsewhere (such as your nameservice).
Queries Take a Long Time to Run When Using HA

The High Availability NameNode feature in HDFS allows a NameNode to fail over to a standby NameNode. The dfs.client.failover.max.attempts configuration parameter (in hdfs-site.xml) specifies how many attempts to make when failing over. Vertica uses a default value of 4 if this parameter is not set. After reaching the maximum number of failover attempts, Vertica concludes that the HDFS cluster is unavailable and aborts the operation. A second parameter, ipc.client.connect.retry.interval, specifies the time to wait between attempts, with typical values being 10 to 20 seconds.

Cloudera and Hortonworks both provide tools to automatically generate configuration files. These tools can set the maximum number of failover attempts to a much higher number (50 or 100). If the HDFS cluster is unavailable (all NameNodes are unreachable), Vertica can appear to hang for an extended period (minutes to hours) while trying to connect.

Failover attempts are logged in the QUERY_EVENTS system table. The following example shows how to query this table to find these events:

```sql
=> SELECT event_category, event_type, event_description, operator_name,
       event_details, count(event_type) AS count
       FROM query_events
       WHERE event_type ilike 'LibHDFS++ FAILOVER RETRY'
       GROUP BY event_category, event_type, event_description, operator_name, event_details;
```

<table>
<thead>
<tr>
<th>event_category</th>
<th>event_type</th>
<th>event_description</th>
<th>operator_name</th>
<th>event_details</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXECUTION</td>
<td>LibHDFS++ FAILOVER</td>
<td>LibHDFS++ Namnode failover and retry.</td>
<td>FileSystem</td>
<td>Libhdffs request failed on ns</td>
</tr>
<tr>
<td></td>
<td>RETRY</td>
<td></td>
<td></td>
<td>4</td>
</tr>
</tbody>
</table>

You can either wait for Vertica to complete or abort the connection, or set the dfs.client.failover.max.attempts parameter to a lower value.

Vertica Places Too Much Load on the NameNode

Large HDFS clusters can sometimes experience heavy load on the NameNode when clients, including Vertica, need to locate data. If your NameNode is sensitive to this load, you can instruct Vertica to distribute metadata about block locations to its nodes so that they do not have to contact the NameNode as often. Distributing this metadata can degrade database performance somewhat in deployments where the NameNode isn't contended. This performance effect is because the data must be serialized and distributed.
If protecting your NameNode from load is more important than query performance, set the EnableHDFSBlockInfoCache configuration parameter to 1 (true). (See Apache Hadoop Parameters.) Usually this applies to large HDFS clusters where NameNode contention is already an issue.

This setting applies to access through LibHDFS++ (hdfs scheme). Sometimes LibHDFS++ falls back to WebHDFS, which does not use this setting. If you have enabled this setting and you are still seeing high traffic on your NameNode from Vertica, check the QUERY_EVENTS system table for LibHDFS++ UNSUPPORTED OPERATION events.

**Verifying HDFS Configuration**

Use the EXTERNAL_CONFIG_CHECK function to test access to HDFS. This function calls several others. If you prefer to test individual components, or if some tests do not apply to your configuration, you can instead call the functions individually. For example, if you are not using the HCatalog Connector then you do not need to call that function. The functions are:

- **KERBEROS_CONFIG_CHECK**: tests the Vertica keytab and the user's Kerberos credential.
- **HADOOP_IMPERSONATION_CONFIG_CHECK**: shows the delegation tokens that are in use. This function does not test them.
- **HDFS_CLUSTER_CONFIG_CHECK**: tests access to the HDFS clusters found in HadoopConfDir, including using Kerberos and impersonation (delegation tokens).
- **HCATALOGCONNECTOR_CONFIG_CHECK**: tests HCatalog Connector access to HiveServer2.

To run all tests, call EXTERNAL_CONFIG_CHECK with no arguments:

```sql
=> SELECT EXTERNAL_CONFIG_CHECK();
```

To test only some authorities, nameservices, or Hive schemas, pass a single string argument. The format is a comma-separated list of "key=value" pairs, where keys are "authority", "nameservice", and "schema". The value is passed to all of the sub-functions; see those reference pages for details on how values are interpreted.

The following example tests the configuration of only the nameservice named "ns1":

```sql
=> SELECT EXTERNAL_CONFIG_CHECK('nameservice=ns1');
```
Exporting Data

You might want to export data from Vertica, either to share it with other Hadoop-based applications or to move lower-priority data from ROS to less-expensive storage. You can use the `EXPORT TO PARQUET` statement to export a table (or part of one) as Parquet data.

You can export data to HDFS, AWS S3, Google Cloud Storage (GCS), or the local file system. You can export ROS data or data that is readable through external tables. After exporting ROS data, you can drop affected ROS partitions to reclaim storage space.

Be careful to avoid concurrent exports to the same output destination. Doing so is an error on any file system and can produce incorrect results.

**Note:**

You cannot export data from an external table that contains external, non-native data types. See External Types.

After exporting data, you can define external tables to read that data in Vertica. See Working with External Data.

**Syntax**

Use the `EXPORT TO PARQUET` statement to export data specified by a SELECT statement, as in the following example:

```sql
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_data')
  AS SELECT * FROM public.sales;
Rows Exported
-----------
  14336
(1 row)
```

The directory argument specifies where to write the files and is required. You must have permission to write to the output directory. The directory must not already exist. You can export to HDFS, S3, GCS (gs URL scheme), or an NFS mount point on the local file system. For additional considerations specific to S3 and GCS, see Exporting to S3 and GCS.

**Note:**

You can only perform one export per output directory. If you perform more than one concurrent export to the same directory, only one will succeed.
You can use EXPORT TO PARQUET to write queries across multiple tables in Vertica and export the results. With this approach you can take advantage of powerful, fast query execution in Vertica while making the results available to other Hadoop clients:

```sql
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_by_region')
   AS SELECT sale.price, sale.date, store.region
   FROM public.sales sale
   JOIN public.vendor store ON sale.distribID = store.ID;
Rows Exported
-------------
    23301
(1 row)
```

**Query**

EXPORT TO PARQUET rewrites the query you specify, because the export is done by a user-defined transform function (UDTF). Because of this rewrite, there are some restrictions on the query you supply.

The query can contain only a single outer SELECT statement. For example, you cannot use UNION as in the following example.

```sql
=> EXPORT TO PARQUET(directory = '/mnt/shared_nfs/accounts/rm')
   OVER(PARTITION BY hash)
   AS
   SELECT 1 as account_id, '{}' as json, 0 hash
   UNION ALL
   SELECT 2 as account_id, '{}' as json, 1 hash;
ERROR 8975: Only a single outer SELECT statement is supported
HINT: Please use a subquery for multiple outer SELECT statements
```

Instead, rewrite the query to use a subquery:

```sql
=> EXPORT TO PARQUET(directory = '/mnt/shared_nfs/accounts/rm')
   OVER(PARTITION BY hash)
   AS
   SELECT
       account_id,
       json
   FROM
     (   SELECT 1 as account_id, '{}' as json, 0 hash
       UNION ALL
       SELECT 2 as account_id, '{}' as json, 1 hash
     ) a;
Rows Exported
-------------
    2
(1 row)
```
To use composite statements such as UNION, INTERSECT, and EXCEPT, rewrite them as subqueries.

When exporting data you can use an OVER() clause to partition and sort the data as described in Partitioning and Sorting Data. Partitioning and sorting can improve query performance.

**Parameters**

EXPORT TO PARQUET takes several optional parameters. The following example specifies no compression and limits row groups to 64MB.

```
=> EXPORT TO PARQUET(directory='s3://DataLake/sales_data',
                         compression = 'uncompressed', rowGroupSizeMB = 64)
               AS SELECT * FROM public.sales;
Rows Exported
-------------
  14336
(1 row)
```

The default compression type is Snappy.

The row-group size affects memory consumption during export. An export thread consumes at least double the row-group size. For example, an export thread consumes at least 1024MB of RAM if the value is 512. The default value of 512MB is a compromise between writing larger row groups and allowing enough free memory for other Vertica operations. If you perform exports when the database is not otherwise under heavy load, you can improve read performance on the exported data by increasing row-group size on export. However, row groups that span multiple blocks on HDFS decrease read performance by requiring more I/O, so do not set the row-group size to be larger than your HDFS block size.

You can limit the size of output files by using the optional fileSizeMB parameter. See the reference documentation.

If you are writing data to HDFS, you can specify file and directory permissions for the exported data using the optional FileMode and dirMode parameters. See the reference documentation.

After you export data, you can use the GET_METADATA function to inspect the results.
Partitioning and Sorting Data

When exporting, you can use the optional OVER clause in the SELECT statement to specify how to partition and/or sort the exported data. Partitioning reduces the sizes of the output data files and can improve performance when Vertica queries external tables containing this data. (See Using Partition Columns.) If you do not specify how to partition the data, Vertica optimizes the export for maximum parallelism.

To specify partition columns, use PARTITION BY in the OVER clause as in the following example:

```sql
=> EXPORT TO PARQUET(directory = 'hdfs:///data/export')
   OVER(PARTITION BY date) AS SELECT date, price FROM public.sales;
Rows Exported
--------------
28337
(1 row)
```

You can sort values within each partition for a further performance improvement. Sort table columns based on the likelihood of their occurrence in query predicates; columns that most frequently occur in comparison or range predicates should be sorted first. You can sort values within each partition using ORDER BY in the OVER clause:

```sql
=> EXPORT TO PARQUET(directory = 'hdfs:///data/export')
   OVER(PARTITION BY date ORDER BY price) AS SELECT date, price FROM public.sales;
Rows Exported
--------------
28337
(1 row)
```

You can use ORDER BY even without partitioning. Storing data in sorted order can improve data access and predicate evaluation performance.

Targets in the OVER clause must be column references; they cannot be expressions. For more information about OVER, see SQL Analytics.

If you are exporting data to a local file system, you might want to force a single node to write all of the files. To do so, use an empty OVER clause.
Exporting to S3 and GCS

Object-store file systems (S3 and GCS) have some differences from other file systems that affect data export. You must set some additional configuration parameters for authentication and region, and there are some restrictions on the output.

S3 Configuration Parameters

To access S3 you must create an IAM role and grant that role permission to access your S3 resources. For more information about IAM roles, see Amazon Web Services documentation.

Vertica uses several configuration parameters related to AWS, which can be set for the database or for a session. See S3 Parameters for the complete list. These parameters include:

- AWSRegion: the region containing the output S3 bucket. This configuration parameter affects all S3 access from the database, including reads, so if you are using S3 in other ways, set this as a session parameter to avoid conflicts.
- AWSAuth: the value is an ID (AccessKeyID) and a secret key (SecretAccessKey), formatted 'id:secret'. Use a session parameter to avoid storing credentials in the database.
- AWSSessionToken, if you are using multi-factor authentication: the value is a token generated by AWS STS. You must use a session parameter; AWS session tokens expire.

GCS Configuration Parameters

Vertica uses the following configuration parameter related to GCS, which can be set for the database or for a session. See Google Cloud Storage Parameters for more information.

- GCSAuth: the value is an ID (AccessKeyID) and a secret key (SecretAccessKey), formatted 'id:secret'. Use a session parameter to avoid storing credentials in the database.
Output Restrictions

Object-store file systems do not support renaming files in place; they implement a rename as a copy followed by a delete. On other file systems, EXPORT TO PARQUET supports atomicity by writing its output into a temporary directory and renaming it when complete. Such an approach is impractical for S3 and GCS, so EXPORT TO PARQUET writes directly to the destination path. It is therefore possible to begin reading the exported data before the export has finished, which could lead to errors. Be careful to wait for the export to finish before using the data.

On other file systems, Vertica retries a failed query if the database is K-safe. When exporting to S3 or GCS, Vertica does not retry the export and instead reports an error. For example, if a node goes down during export, Vertica returns Error 4142 (Node failure during execution).

If you cancel an export or an export fails, Vertica does not clean up the partial output. On S3 and GCS, that partial output costs you money, so after a cancellation or failure, delete the output files. Further, because the output path must not exist, you would need to delete the partial output before retrying the export with the same destination.

S3 limits buckets to 5TB. You might need to divide very large exports.

Monitoring Exports

You can review information about exports, including numbers of row groups, file sizes, and file names.

EXPORT TO PARQUET is a U Dx. The UDX_EVENTS system table records events logged during UDx execution, including timestamps, node names, and session IDs. This table contains a column (__RAW__), which holds a VMap of whatever additional data an individual UDx logged. Parquet export logs details about the exported files in this table. While you can work with this table directly and materialize values from the VMap column, you might prefer to define a view to simplify your access.

The following statement defines a view showing only the events from EXPORT TO PARQUET, materializing the VMap values.

```sql
=> CREATE VIEW parquet_export_events AS
SELECT
```
```sql
report_time,
node_name,
session_id,
user_id,
user_name,
transaction_id,
statement_id,
request_id,
udx_name,
file,
created,
closed,
rows,
row_groups,
size_mb
FROM
v_monitor.udx_events
WHERE
udx_name ilike 'ParquetExport%';
```

**EXPORT TO PARQUET** reports the following UDX-specific columns:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE</td>
<td>VARCHAR</td>
<td>Name of the output file.</td>
</tr>
<tr>
<td>CREATED</td>
<td>TIMESTAMPTZ</td>
<td>When the file was created.</td>
</tr>
<tr>
<td>CLOSED</td>
<td>TIMESTAMPTZ</td>
<td>When the file was closed after writing.</td>
</tr>
<tr>
<td>ROWS</td>
<td>INTEGER</td>
<td>The total number of rows in the file.</td>
</tr>
<tr>
<td>ROW_GROUPS</td>
<td>INTEGER</td>
<td>The number of row groups.</td>
</tr>
<tr>
<td>SIZE_MB</td>
<td>FLOAT</td>
<td>File size.</td>
</tr>
</tbody>
</table>

The following example shows the results of a single export.

```sql
=> SELECT file,rows,row_groups,size_mb FROM PARQUET_EXPORT_EVENTS;
```

```
+-----------+-------+--------+--------+
| file      | rows  | row_groups | size_mb |
|-----------+-------+--------+--------+
| /data/outgZxN3irt/450c4213-v_vmart_node0001-139770732459776-0.parquet | 29696 | 1       |        |
| 0.667203  |       |        |        |
| /data/outgZxN3irt/9df1c797-v_vmart_node0001-139770860660480-0.parquet | 29364 | 1       |        |
| 0.660922  |       |        |        |
| (2 rows)  |       |        |        |
```

In this table, the output directory name (/data/out) is appended with a generated string (gZxN3irt). For exports to HDFS or to local file systems (including NFS), **EXPORT TO PARQUET** first writes data into a scratch directory and then renames it at the end of the operation. The events are logged during export and so show the temporary name. Some
output destinations, such as AWS S3, do not support rename operations, so in those cases this table does not show generated names.

## Data Types

EXPORT TO PARQUET converts Vertica data types to Hive data types as shown in the following table.

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Hive Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER, BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>FLOAT, DECIMAL, SMALLINT, TINYINT, CHAR, BOOLEAN</td>
<td>Corresponding Hive type</td>
</tr>
<tr>
<td>VARCHAR, LONG VARCHAR</td>
<td>VARCHAR (max 64KB) or STRING (can be read as either)</td>
</tr>
<tr>
<td>BINARY, VARBINARY, LONG VARBINARY</td>
<td>BINARY</td>
</tr>
<tr>
<td>DATE</td>
<td>DATE if supported by your version of Hive, otherwise INT96 (can be read as TIMESTAMP)</td>
</tr>
<tr>
<td>TIMESTAMP, TIMESTAMPTZ</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td>TIME, TIMEZ, INTERVAL</td>
<td>Not supported</td>
</tr>
</tbody>
</table>

You cannot export columns with the TIME, TIMEZ, and INTERVAL data types. If your table includes columns of these types, exclude them by explicitly selecting the columns you can export:

```sql
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_data')
   AS SELECT date, transactionID, price FROM public.sales;
Rows Exported
--------------
14336
(1 row)
```

You cannot export data from an external table that contains external, non-native data types, such as ROW. See External Types. This restriction applies even if your SELECT statement does not include those columns.
Using the HCatalog Connector

The Vertica HCatalog Connector lets you access data stored in Apache's Hive data warehouse software the same way you access it within a native Vertica table.

If your files are in the Optimized Columnar Row (ORC) or Parquet format and do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. See Reading ORC and Parquet Formats for more information about these readers.

The HCatalog Connector performs predicate pushdown to improve query performance. Instead of reading all data across the network to evaluate a query, the HCatalog Connector moves the evaluation of predicates closer to the data. Predicate pushdown applies to Hive partition pruning, ORC stripe pruning, and Parquet row-group pruning. The HCatalog Connector supports predicate pushdown for the following predicates: >, >=, =, <>, <=, <.

Overview

There are several Hadoop components that you need to understand to use the HCatalog connector:

- Apache Hive lets you query data stored in a Hadoop Distributed File System (HDFS) the same way you query data stored in a relational database. Behind the scenes, Hive uses a set of serializer and deserializer (SerDe) classes to extract data from files stored in HDFS and break it into columns and rows. Each SerDe handles data files in a specific format. For example, one SerDe extracts data from comma-separated data files while another interprets data stored in JSON format.
- Apache HCatalog is a component of the Hadoop ecosystem that makes Hive's metadata available to other Hadoop components (such as Pig).
- HiveServer2 makes HCatalog and Hive data available via JDBC. Through it, a client can make requests to retrieve data stored in Hive, as well as information about the Hive schema. HiveServer2 can use authorization services (Sentry or Ranger). HiveServer2 can use Hive LLAP (Live Long And Process).

The Vertica HCatalog Connector lets you transparently access data that is available through HiveServer2. You use the connector to define a schema in Vertica that corresponds to a Hive database or schema. When you query data within this schema, the HCatalog Connector transparently extracts and formats the data from Hadoop into tabular data. Vertica supports authorization services and Hive LLAP.
**Note:**
You can use the WebHCat service instead of HiveServer2, but performance is usually better with HiveServer2. Support for WebHCat is deprecated. To use WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0. See [Apache Hadoop Parameters](https://webhcat.apache.org/). WebHCat does not support authorization services.

## HCatalog Connection Features

The HCatalog Connector lets you query data stored in Hive using the Vertica native SQL syntax. Some of its main features are:

- The HCatalog Connector always reflects the current state of data stored in Hive.
- The HCatalog Connector uses the parallel nature of both Vertica and Hadoop to process Hive data. The result is that querying data through the HCatalog Connector is often faster than querying the data directly through Hive.
- Because Vertica performs the extraction and parsing of data, the HCatalog Connector does not significantly increase the load on your Hadoop cluster.
- The data you query through the HCatalog Connector can be used as if it were native Vertica data. For example, you can execute a query that joins data from a table in an HCatalog schema with a native table.

## HCatalog Connector Considerations

There are a few things to keep in mind when using the HCatalog Connector:

- Hive's data is stored in flat files in a distributed file system, requiring it to be read and deserialized each time it is queried. This deserialization causes Hive performance to be much slower than that of Vertica. The HCatalog Connector has to perform the same process as Hive to read the data. Therefore, querying data stored in Hive using the HCatalog Connector is much slower than querying a native Vertica table. If you need to perform extensive analysis on data stored in Hive, you should consider loading it into Vertica. Vertica optimization often makes querying data through the HCatalog Connector faster than directly querying it through Hive.
- If Hive uses Kerberos security, the HCatalog Connector uses the querying user's credentials in queries by default. If Hive uses Sentry or Ranger to enforce security, then you must either disable this behavior in Vertica by setting EnableHCatImpersonation to 0 or grant users access to the underlying data in HDFS. (Sentry supports ACL synchronization to automatically grant access.) Alternatively,
you can specify delegation tokens for data and metadata access. See Configuring Security.

• Hive supports complex data types such as lists, maps, and structs that Vertica does not support. Columns containing these data types are converted to a JSON representation of the data type and stored as a VARCHAR. See Data Type Conversions from Hive to Vertica.

Note:
The HCatalog Connector is read-only. It cannot insert data into Hive.

How the HCatalog Connector Works

When planning a query that accesses data from a Hive table, the Vertica HCatalog Connector on the initiator node contacts HiveServer2 (or WebHCat) in your Hadoop cluster to determine if the table exists. If it does, the connector retrieves the table’s metadata from the metastore database so the query planning can continue. When the query executes, all nodes in the Vertica cluster directly retrieve the data necessary for completing the query from HDFS. They then use the Hive SerDe classes to extract the data so the query can execute. When accessing data in ORC or Parquet format, the HCatalog Connector uses Vertica’s internal readers for these formats instead of the Hive SerDe classes.
This approach takes advantage of the parallel nature of both Vertica and Hadoop. In addition, by performing the retrieval and extraction of data directly, the HCatalog Connector reduces the impact of the query on the Hadoop cluster.

For files in the Optimized Columnar Row (ORC) or Parquet format that do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. You can direct these readers to access custom Hive partition locations if Hive used them when writing the data. By default these extra checks are turned off to improve performance.

**HCatalog Connector Requirements**

Before you can use the HCatalog Connector, both your Vertica and Hadoop installations must meet the following requirements.

**Vertica Requirements**

All of the nodes in your cluster must have a Java Virtual Machine (JVM) installed. You must use the same Java version that the Hadoop cluster uses. See Installing the Java Runtime on Your Vertica Cluster.

You must also add certain libraries distributed with Hadoop and Hive to your Vertica installation directory. See Configuring Vertica for HCatalog.

**Hadoop Requirements**

Your Hadoop cluster must meet several requirements to operate correctly with the Vertica Connector for HCatalog:

- It must have Hive, HiveServer2, and HCatalog installed and running. See Apache's HCatalog page for more information.
- The HiveServer2 server and all of the HDFS nodes that store HCatalog data must be directly accessible from all of the hosts in your Vertica database. Verify that any firewall separating the Hadoop cluster and the Vertica cluster will pass HiveServer2, metastore database, and HDFS traffic.
- The data that you want to query must be in an internal or external Hive table.
• If a table you want to query uses a non-standard SerDe, you must install the SerDe's classes on your Vertica cluster before you can query the data. See Using Nonstandard SerDes.

## Installing the Java Runtime on Your Vertica Cluster

The HCatalog Connector requires a 64-bit Java Virtual Machine (JVM). The JVM must support Java 6 or later, and must be the same version as the one installed on your Hadoop nodes.

**Note:**
If your Vertica cluster is configured to execute User Defined Extensions (UDxs) written in Java, it already has a correctly-configured JVM installed. See Developing User-Defined Extensions (UDxs) in Extending Vertica for more information.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.

## Installing a Java Runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or OpenJDK. You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the Java Standard Edition (SE) Download Page. You usually run the installation package as root in order to install it. See the download page for instructions.
Once you have installed a JVM on each host, ensure that the `java` command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

**Note:**
Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

### Setting the JavaBinaryForUDx Configuration Parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a database superuser:

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
```

See `ALTER DATABASE` for more information on setting configuration parameters.
To view the current setting of the configuration parameter, query the `CONFIGURATION_PARAMETERS` system table:

```sql
=> \\x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[ RECORD 1 ]------------------------------------------------
| node_name | ALL |
| parameter_name | JavaBinaryForUDx |
| current_value | /usr/bin/java |
| default_value | |
| change_under_support_guidance | f |
| change_requires_restart | f |
| description | Path to the java binary for executing UDx written in Java |
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

**Note:**
Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

**Configuring Vertica for HCatalog**

Before you can use the HCatalog Connector, you must add certain Hadoop and Hive libraries to your Vertica installation. You must also copy the Hadoop configuration files that specify various connection properties. Vertica uses the values in those configuration files to make its own connections to Hadoop.

You need only make these changes on one node in your cluster. After you do this you can install the HCatalog connector.

**Copy Hadoop Libraries and Configuration Files**

Vertica provides a tool, hcatUtil, to collect the required files from Hadoop. This tool copies selected libraries and XML configuration files from your Hadoop cluster to your Vertica cluster. This tool might also need access to additional libraries:
If you plan to use Hive to query files that use Snappy compression, you need access to the Snappy native libraries, libhadoop*.so and libsnappy*.so.

If you plan to use Hive to query files that use LZO compression, you need access to the hadoop-lzo-*.jar and libgplcompression.so* libraries. In core-site.xml you must also edit the io.compression.codecs property to include com.hadoop.compression.lzo.LzopCodec.

If you plan to use a JSON SerDe with a Hive table, you need access to its library. This is the same library that you used to configure Hive; for example:

```
hive> add jar /home/release/json-serde-1.3-jar-with-dependencies.jar;
```

```
hive> create external table nationjson (id int,name string,rank int,text string) ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe' LOCATION '/user/release/vt/nationjson';
```

If you are using any other libraries that are not standard across all supported Hadoop versions, you need access to those libraries.

If any of these cases applies to you, do one of the following:

- Include the path(s) in the path you specify as the value of --hcatLibPath, or
- Copy the file(s) to a directory already on that path.

If Vertica is not co-located on a Hadoop node, you should do the following:

1. Copy /opt/vertica/packages/hcat/tools/hcatUtil to a Hadoop node and run it there, specifying a temporary output directory. Your Hadoop, HIVE, and HCatalog lib paths might be different. In newer versions of Hadoop the HCatalog directory is usually a subdirectory under the HIVE directory, and Cloudera creates a new directory for each revision of the configuration files. Use the values from your environment in the following command:

```
hcatUtil --copyJars
    --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
    --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
    --hcatLibPath="/tmp/hadoop-files"
```

If you are using Hive LLAP, specify the hive2 directories.

2. Verify that all necessary files were copied:

```
hcatUtil --verifyJars --hcatLibPath="/tmp/hadoop-files"
```

3. Copy that output directory (/tmp/hadoop-files, in this example) to /opt/vertica/packages/hcat/lib on the Vertica node you will connect to when
installing the HCatalog connector. If you are updating a Vertica cluster to use a new Hadoop cluster (or a new version of Hadoop), first remove all JAR files in /opt/vertica/packages/hcat/lib except vertica-hcatalogudl.jar.

4. Verify that all necessary files were copied:

        hcatUtil --verifyJars --hcatLibPath=/opt/vertica/packages/hcat

If Vertica is co-located on some or all Hadoop nodes, you can do this in one step on a shared node. Your Hadoop, Hive, and HCatalog lib paths might be different; use the values from your environment in the following command:

        hcatUtil --copyJars
        --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
        --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
        --hcatLibPath="/opt/vertica/packages/hcat/lib"

The hcatUtil script has the following arguments:

- **-c, --copyJars**: Copy the required JAR files from hadoopHiveHome and configuration files from hadoopHiveConfPath.

- **-v, --verifyJars**: Verify that the required files are present in hcatLibPath. Check the output of hcatUtil for error and warning messages.

- **--hadoopHiveHome=\"value1;value2;...\"**: Paths to the Hadoop, Hive, and HCatalog home directories. Separate directories by semicolons (;). Enclose paths in double quotes.

  **Note:** Always place $HADOOP_HOME on the path before $HIVE_HOME. In some Hadoop distributions, these two directories contain different versions of the same library.

- **--hadoopHiveConfPath=\"value1;value2;...\"**: Paths of the following configuration files:
  - hive-site.xml
  - core-site.xml
  - yarn-site.xml
  - webhcat-site.xml (optional with the default configuration; required if you use WebHCat instead of HiveServer2)
hdfs-site.xml

Separate directories by semicolons (;). Enclose paths in double quotes.

In previous releases of Vertica this parameter was optional under some conditions. It is now required.

-hcatLibPath="value"

Output path for the libraries and configuration files. On a Vertica node, use /opt/vertica/packages/hcat/lib. If you have previously run hcatUtil with a different version of Hadoop, first remove the old JAR files from the output directory (all except vertica-hcatalogudl.jar).

After you have copied the files and verified them, install the HCatalog connector.

**Install the HCatalog Connector**

On the same node where you copied the files from hcatUtil, install the HCatalog connector by running the install.sql script. This script resides in the ddl/ folder under your HCatalog connector installation path. This script creates the library and VHCatSource and VHCatParser.

**Note:**
The data that was copied using hcatUtil is now stored in the database. If you change any of those values in Hadoop, you need to rerun hcatUtil and install.sql. The following statement returns the names of the libraries and configuration files currently being used:

```
=> SELECT dependencies FROM user_libraries WHERE lib_name='VHCatalogLib';
```

Now you can create HCatalog schema parameters, which point to your existing Hadoop services, as described in Defining a Schema Using the HCatalog Connector.

**Upgrading to a New Version of Vertica**

After upgrading to a new version of Vertica, perform the following steps:
1. Uninstall the HCatalog Connector using the uninstall.sql script. This script resides in the ddl/ folder under your HCatalog connector installation path.

2. Delete the contents of the hcatLibPath directory except for vertica-hcatalogudl.jar.

3. Rerun hcatUtil.

4. Reinstall the HCatalog Connector using the install.sql script.

For more information about upgrading Vertica, see Upgrade Vertica.

**Additional Options for Hadoop Columnar File Formats**

When reading Hadoop columnar file formats (ORC or Parquet), the HCatalog Connector attempts to use the built-in readers. When doing so, it uses the hdfs scheme by default. In order to use the hdfs scheme, you must perform the configuration described in Configuring the hdfs Scheme.

To have the HCatalog Connector use the webhdfs scheme instead, use ALTER DATABASE to set HDFSUseWebHDFS to 1. This setting applies to all HDFS access, not just the HCatalog Connector.

**Configuring Security**

You can use any of the security options described in Accessing Kerberized HDFS Data to access Hive data. This topic describes additional steps needed specifically for using the HCatalog Connector.

If you use Kerberos from Vertica, the HCatalog Connector can use an authorization service (Sentry or Ranger). If you use delegation tokens, you must manage authorization yourself.

**Kerberos**

You can use Kerberos from Vertica as described in Using Kerberos with Vertica.

How you configure the HCatalog Connector depends on how Hive manages authorization.
• If Hive uses Sentry to manage authorization, and if Sentry uses ACL synchronization, then the HCatalog Connector must access HDFS as the current user. Verify that the EnableHCatImpersonation configuration parameter is set to 1 (the default). ACL synchronization automatically provides authorized users with read access to the underlying HDFS files.

• If Hive uses Sentry without ACL synchronization, then the HCatalog Connector must access HDFS data as the Vertica principal. (The user still authenticates and accesses metadata normally.) Set the EnableHCatImpersonation configuration parameter to 0. The Vertica principal must have read access to the underlying HDFS files.

• If Hive uses Ranger to manage authorization, and the Vertica users have read access to the underlying HDFS files, then you can use user impersonation. Verify that the EnableHCatImpersonation configuration parameter is set to 1 (the default). You can, instead, disable user impersonation and give the Vertica principal read access to the HDFS files.

• If Hive does not use an authorization service, or if you are connecting to Hive using WebHCat instead of HiveServer2, then the HCatalog Connector accesses Hive as the current user. Verify that EnableHCatImpersonation is set to 1. All users must have read access to the underlying HDFS files.

In addition, in your Hadoop configuration files (core-site.xml in most distributions), make sure that you enable all Hadoop components to impersonate the Vertica user. The easiest way to do so is to set the proxyuser property using wildcards for all users on all hosts and in all groups. Consult your Hadoop documentation for instructions. Make sure you set this property before running hcatUtil (see Configuring Vertica for HCatalog).

**Delegation Tokens**

You can use delegation tokens for a session as described in Bring Your Own Delegation Token. When using the HCatalog Connector you specify two delegation tokens, one for the data and one for the metadata. The metadata token is tied to a Hive schema. See HadoopImpersonationConfig Format for information about how to specify these two delegation tokens.
Verifying Security Configuration

To verify that the HCatalog Connector can access Hive data, use the HCATALOGCONNECTOR_CONFIG_CHECK function.

For more information about testing your configuration, see Verifying HDFS Configuration.

Defining a Schema Using the HCatalog Connector

After you set up the HCatalog Connector, you can use it to define a schema in your Vertica database to access the tables in a Hive database. You define the schema using the CREATE HCATALOG SCHEMA statement.

When creating the schema, you must supply the name of the schema to define in Vertica. Other parameters are optional. If you do not supply a value, Vertica uses default values. Vertica reads some default values from the HDFS configuration files; see Configuration Parameters.

To create the schema, you must have read access to all Hive data. Verify that the user creating the schema has been granted access, either directly or through an authorization service such as Sentry or Ranger. The dbadmin user has no automatic special privileges.

After you create the schema, you can change many parameters using the ALTER HCATALOG SCHEMA statement.

After you define the schema, you can query the data in the Hive data warehouse in the same way you query a native Vertica table. The following example demonstrates creating an HCatalog schema and then querying several system tables to examine the contents of the new schema. See Viewing Hive Schema and Table Metadata for more information about these tables.

=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
   HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
   SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin';
CREATE SCHEMA
=> \x
Expanded display is on.

=> SELECT * FROM v_catalog.hcatalog_schemata;
### Configuration Parameters

The HCatalog Connector uses the following values from the Hadoop configuration files if you do not override them when creating the schema.
### Using Partitioned Data

Hive supports partitioning data, as in the following example:

```sql
hive> create table users (name varchar(64), address string, city varchar(64))
partitioned by (state varchar(64)) stored as orc;
```

Vertica takes advantage of partitioning information for formats that provide it in metadata (ORC and Parquet). Queries can skip irrelevant partitions entirely (partition pruning), and Vertica does not need to materialize partition columns. For more about use of partitions, see [Improving Query Performance](#) and [Using Partition Columns](#).

By default Hive stores partition information under the path for the table definition, which might be local to Hive. However, a Hive user can choose to store partition information elsewhere, such as in a shared location like S3, as in the following example:
hive> alter table users add partition (state='MA')
location 's3a://DataLake/partitions/users/state=MA';

During query execution, therefore, Vertica must query Hive for the location of a table's partition information.

Because the additional Hive queries can be expensive, Vertica defaults to looking for partition information only in Hive's default location. If your Hive table specified a custom location, use the CUSTOM_PARTITIONS parameter:

=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
   HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
   SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin'
   CUSTOM_PARTITIONS='yes';

Vertica can access partition locations in the S3 and S3a schemes, and does not support the S3n scheme.

The HIVE_CUSTOM_PARTITIONS_ACCESSED system table records all custom partition locations that have been used in queries.

Using the HCatalog Connector with WebHCat

By default the HCatalog Connector uses HiveServer2 to access Hive data. If you are instead using WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0 before creating the schema as in the following example.

=> ALTER DATABASE DEFAULT SET PARAMETER HCatalogConnectorUseHiveServer2 = 0;
=> CREATE HCATALOG SCHEMA hcat WITH WEBSERVICE_HOSTNAME='webhcat.example.com';

If you have previously used WebHCat, you can switch to using HiveServer2 by setting the configuration parameter to 1 and using ALTER HCATALOG SCHEMA to set HIVESERVER2_HOSTNAME. You do not need to remove the WebHCat values; the HCatalog Connector uses the value of HCatalogConnectorUseHiveServer2 to determine which parameters to use.

Querying Hive Tables Using HCatalog Connector

Once you have defined the HCatalog schema, you can query data from the Hive database by using the schema name in your query.
Since the tables you access through the HCatalog Connector act like Vertica tables, you can perform operations that use both Hive data and native Vertica data, such as a join:

```sql
=> SELECT u.FirstName, u.LastName, d.time, d.Message FROM UserData u
   -> JOIN hcat.messages d ON u.UserID = d.UserID LIMIT 10;
   => SELECT * from hcat.messages limit 10;

**Viewing Hive Schema and Table Metadata**

When using Hive, you access metadata about schemas and tables by executing statements written in HiveQL (Hive's version of SQL) such as `SHOW TABLES`. When using the HCatalog Connector, you can get metadata about the tables in the Hive database through several Vertica system tables.

There are four system tables that contain metadata about the tables accessible through the HCatalog Connector:

- **HCATALOG_SCHEMA** lists all of the schemas that have been defined using the HCatalog Connector.
- **HCATALOG_TABLE_LIST** contains an overview of all of the tables available from all schemas defined using the HCatalog Connector. This table only shows the tables that the user querying the table can access. The information in this table is retrieved using
a single call to HiveServer2 for each schema defined using the HCatalog Connector, which means there is a little overhead when querying this table.

- `HCATALOG_TABLES` contains more in-depth information than `HCATALOG_TABLE_LIST`.
- `HCATALOG_COLUMNS` lists metadata about all of the columns in all of the tables available through the HCatalog Connector. As for `HCATALOG_TABLES`, querying this table results in one call to HiveServer2 per table, and therefore can take a while to complete.

The following example demonstrates querying the system tables containing metadata for the tables available through the HCatalog Connector.

```sql
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost'
-> HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT * FROM HCATALOG_SCHEMATA;

Synchronizing an HCatalog Schema or Table With a Local Schema or Table

Querying data from an HCatalog schema can be slow due to Hive performance issues. This slow performance can be especially annoying when you want to examine the structure of the tables in the Hive database. Getting this information from Hive requires you to query the HCatalog schema's metadata using the HCatalog Connector.

To avoid this performance problem you can use the SYNC_WITH_HCATALOG_SCHEMA function to create a snapshot of the HCatalog schema's metadata within a Vertica schema. You supply this function with the name of a pre-existing Vertica schema, typically the one created through CREATE HCATALOG SCHEMA, and a Hive schema available through the HCatalog Connector. You must have permission both in Vertica to write the data and in Hive and HDFS to read it.

**Note:**
To synchronize a schema, you must have read permission for the underlying files in HDFS. If Hive uses Sentry to manage authorization, then you can use ACL synchronization to manage HDFS access. Otherwise, the user of this function must have read access in HDFS.

The function creates a set of external tables within the Vertica schema that you can then use to examine the structure of the tables in the Hive database. Because the metadata in the Vertica schema is local, query planning is much faster. You can also use standard Vertica statements and system-table queries to examine the structure of Hive tables in the HCatalog schema.

**Caution:**
The SYNC_WITH_HCATALOG_SCHEMA function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

When SYNC_WITH_HCATALOG_SCHEMA creates tables in Vertica, it matches Hive's STRING and BINARY types to Vertica's VARCHAR(65000) and VARBINARY(65000) types. You might want to change these lengths, using ALTER TABLE SET DATA TYPE, in two cases:

- If the value in Hive is larger than 65000 bytes, increase the size and use LONG VARCHAR or LONG VARBINARY to avoid data truncation. If a Hive string uses
multi-byte encodings, you must increase the size in Vertica to avoid data truncation. This step is needed because Hive counts string length in characters while Vertica counts it in bytes.

- If the value in Hive is much smaller than 65000 bytes, reduce the size to conserve memory in Vertica.

The Vertica schema is just a snapshot of the HCatalog schema's metadata. Vertica does not synchronize later changes to the HCatalog schema with the local schema after you call SYNC_WITH_HCATALOG_SCHEMA. You can call the function again to re-synchronize the local schema to the HCatalog schema. If you altered column data types, you will need to repeat those changes because the function creates new external tables.

By default, SYNC_WITH_HCATALOG_SCHEMA does not drop tables that appear in the local schema that do not appear in the HCatalog schema. Thus, after the function call the local schema does not reflect tables that have been dropped in the Hive database since the previous call. You can change this behavior by supplying the optional third Boolean argument that tells the function to drop any table in the local schema that does not correspond to a table in the HCatalog schema.

Instead of synchronizing the entire schema, you can synchronize individual tables by using SYNC_WITH_HCATALOG_SCHEMA_TABLE. If the table already exists in Vertica the function overwrites it. If the table is not found in the HCatalog schema, this function returns an error. In all other respects this function behaves in the same way as SYNC_WITH_HCATALOG_SCHEMA.

If you change the settings of any HCatalog Connector configuration parameters (Apache Hadoop Parameters), you must call this function again.

**Examples**

The following example demonstrates calling SYNC_WITH_HCATALOG_SCHEMA to synchronize the HCatalog schema in Vertica with the metadata in Hive. Because it synchronizes the HCatalog schema directly, instead of synchronizing another schema with the HCatalog schema, both arguments are the same.

```sql
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost' HCATALOG_SCHEMA='default'
    HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema
-----------------------------
Schema hcat synchronized with hcat
tables in hcat = 56
```
tables altered in hcat = 0
tables created in hcat = 56
stale tables in hcat = 0
table changes erred in hcat = 0
(1 row)

=> -- Use vsql's \d command to describe a table in the synced schema

=> \d hcat.messages

<td>f</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(4 rows)

This example shows synchronizing with a schema created using
CREATE HCATALOG SCHEMA. Synchronizing with a schema created using CREATE SCHEMA is also supported.

You can query tables in the local schema that you synchronized with an HCatalog schema. However, querying tables in a synchronized schema isn't much faster than directly querying the HCatalog schema, because SYNC_WITH_HCatalOG_SCHEMA only duplicates the HCatalog schema's metadata. The data in the table is still retrieved using the HCatalog Connector.

Data Type Conversions from Hive to Vertica

The data types recognized by Hive differ from the data types recognized by Vertica. The following table lists how the HCatalog Connector converts Hive data types into data types compatible with Vertica.

<table>
<thead>
<tr>
<th>Hive Data Type</th>
<th>Vertica Data Type</th>

### Data-Width Handling Differences Between Hive and Vertica

The HCatalog Connector relies on Hive SerDe classes to extract data from files on HDFS. Therefore, the data read from these files are subject to Hive's data width restrictions. For example, suppose the SerDe parses a value for an INT column into a value that is greater than $2^{32} - 1$ (the maximum value for a 32-bit integer). In this case, the value is rejected even if it would fit into a Vertica's 64-bit INTEGER column because it cannot fit into Hive's 32-bit INT.

<td>VARCHAR (65000) containing a JSON-format representation of the map.</td>
</tr>
<tr>
<td>STRUCT</td>
<td>VARCHAR (65000) containing a JSON-format representation of the struct.</td>
</tr>
</tbody>
</table>
Hive measures CHAR and VARCHAR length in characters and Vertica measures them in bytes. Therefore, if multi-byte encodings are being used (like Unicode), text might be truncated in Vertica.

Once the value has been parsed and converted to a Vertica data type, it is treated as native data. This treatment can result in some confusion when comparing the results of an identical query run in Hive and in Vertica. For example, if your query adds two INT values that result in a value that is larger than $2^{32}-1$, the value overflows its 32-bit INT data type, causing Hive to return an error. When running the same query with the same data in Vertica using the HCatalog Connector, the value will probably still fit within Vertica's 64-int value. Thus the addition is successful and returns a value.

### Using Nonstandard SerDes

Hive stores its data in unstructured flat files located in the Hadoop Distributed File System (HDFS). When you execute a Hive query, it uses a set of serializer and deserializer (SerDe) classes to extract data from these flat files and organize it into a relational database table. For Hive to be able to extract data from a file, it must have a SerDe that can parse the data the file contains. When you create a table in Hive, you can select the SerDe to be used for the table's data.

Hive has a set of standard SerDes that handle data in several formats such as delimited data and data extracted using regular expressions. You can also use third-party or custom-defined SerDes that allow Hive to process data stored in other file formats. For example, some commonly-used third-party SerDes handle data stored in JSON format.

The HCatalog Connector directly fetches file segments from HDFS and uses Hive's SerDes classes to extract data from them. The Connector includes all Hive's standard SerDes classes, so it can process data stored in any file that Hive natively supports. If you want to query data from a Hive table that uses a custom SerDe, you must first install the SerDe classes on the Vertica cluster.

### Determining Which SerDe You Need

If you have access to the Hive command line, you can determine which SerDe a table uses by using Hive's SHOW CREATE TABLE statement. This statement shows the HiveQL statement needed to recreate the table. For example:
In the example, ROW FORMAT SERDE indicates that a special SerDe is used to parse the data files. The next row shows that the class for the SerDe is named org.apache.hadoop.hive.contrib.serde2.JsonSerde. You must provide the HCatalog Connector with a copy of this SerDe class so that it can read the data from this table.

You can also find out which SerDe class you need by querying the table that uses the custom SerDe. The query will fail with an error message that contains the class name of the SerDe needed to parse the data in the table. In the following example, the portion of the error message that names the missing SerDe class is in bold.

Installing the SerDe on the Vertica Cluster

You usually have two options to getting the SerDe class file the HCatalog Connector needs:
Find the installation files for the SerDe, then copy those over to your Vertica cluster. For example, there are several third-party JSON SerDes available from sites like Google Code and GitHub. You may find the one that matches the file installed on your Hive cluster. If so, then download the package and copy it to your Vertica cluster.

- Directly copy the JAR files from a Hive server onto your Vertica cluster. The location for the SerDe JAR files depends on your Hive installation. On some systems, they may be located in `/usr/lib/hive/lib`.

Wherever you get the files, copy them into the `/opt/vertica/packages/hcat/lib` directory on every node in your Vertica cluster.

**Important:**
If you add a new host to your Vertica cluster, remember to copy every custom SerDe JAR file to it.

## Troubleshooting HCatalog Connector Problems

You may encounter the following issues when using the HCatalog Connector.

### Connection Errors

The HCatalog Connector can encounter errors both when you define a schema and when you query it. The types of errors you get depend on which CREATE HCATALOG SCHEMA parameters are incorrect. Suppose you have incorrect parameters for the metastore database, but correct parameters for HiveServer2. In this case, HCatalog-related system table queries succeed, while queries on the HCatalog schema fail. The following example demonstrates creating an HCatalog schema with the correct default HiveServer2 information. However, the port number for the metastore database is incorrect.

```
=> CREATE HCATALOG SCHEMA hcat2 WITH hostname='hcathost'
  HCATALOG_SCHEMA='default' HCATALOG_USER='hive' PORT=1234;
CREATE SCHEMA
=> SELECT * FROM HCATALOG_TABLE_LIST;
-[-[ RECORD 1 ]------------------------
  table_schema_id | 45035996273864536
  table_schema     | hcat2
  hcatalog_schema  | default
  table_name       | test
```
To resolve these issues, you must drop and recreate the schema or alter the schema to correct the parameters. If you still have issues, determine whether there are connectivity issues between your Vertica cluster and your Hadoop cluster. Such issues can include a firewall that prevents one or more Vertica hosts from contacting the HiveServer2, metastore, or HDFS hosts.

**UDx Failure When Querying Data: Error 3399**

You might see an error message when querying data (as opposed to metadata like schema information). This might be accompanied by a ClassNotFoundException in the log. This can happen for the following reasons:

- You are not using the same version of Java on your Hadoop and Vertica nodes. In this case you need to change one of them to match the other.
- You have not used hcatUtil to copy all Hadoop and Hive libraries and configuration files to Vertica, or you ran hcatutil and then changed your version of Hadoop or Hive.
- You upgraded Vertica to a new version and did not rerun hcatutil and reinstall the HCatalog Connector.
- The version of Hadoop you are using relies on a third-party library that you must copy manually.
- You are reading files with LZO compression and have not copied the libraries or set the io.compression.codecs property in core-site.xml.
- You are reading Parquet data from Hive, and columns were added to the table after some data was already present in the table. Adding columns does not update existing data, and the ParquetSerDe provided by Hive and used by the HCatalog Connector does not handle this case. This error is due to a limitation in Hive and there is no workaround.
The query is taking too long and is timing out. If this is a frequent problem, you can increase the value of the UDxFencedBlockTimeout configuration parameter. See General Parameters.

If you did not copy the libraries or configure LZO compression, follow the instructions in Configuring Vertica for HCatalog.

If the Hive jars that you copied from Hadoop are out of date, you might see an error message like the following:

```
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource], error code: 0 Error message is [ Found interface org.apache.hadoop.mapreduce.JobContext, but class was expected ]
HINT hive metastore service is thrift://localhost:13433 (check UDxLogs/UDxFencedProcessesJava.log in the catalog directory for more information)
```

This error usually signals a problem with hive-hcatalog-core jar. Make sure you have an up-to-date copy of this file. Remember that if you rerun hcatUtil you also need to re-create the HCatalog schema.

You might also see a different form of this error:

```
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource], error code: 0 Error message is [ javax/servlet/Filter ]
```

This error can be reported even if hcatUtil reports that your libraries are up to date. The javax.servlet.Filter class is in a library that some versions of Hadoop use but that is not usually part of the Hadoop installation directly. If you see an error mentioning this class, locate servlet-api-*.jar on a Hadoop node and copy it to the hcat/lib directory on all database nodes. If you cannot locate it on a Hadoop node, locate and download it from the Internet. (This case is rare.) The library version must be 2.3 or higher.

After you have copied the jar to the hcat/lib directory, reinstall the HCatalog connector as explained in Configuring Vertica for HCatalog.

**Authentication Error When Querying Data**

You might have successfully created a schema using CREATE HCATALOG SCHEMA but get errors at query time such as the following:

```
=> SELECT * FROM hcat.clickdata;
ERROR 6776: Failed to glob [hdfs:///user/hive/warehouse/click-*parquet] because of error: hdfs:///user/hive/warehouse/click-12214.parquet: statAll failed; error: AuthenticationFailed
```
You might see this error if Hive uses an authorization service. If the permissions on the underlying files in HDFS match those in the authorization service, then Vertica must use user impersonation when accessing that data. To enable user impersonation, set the EnableHCatImpersonation configuration parameter to 1.

Vertica uses the database principal to access HDFS. Therefore, if EnableHCatImpersonation is 0, the Vertica database principal must have access to the data inside the hive warehouse on HDFS. If it does not, you might see the following error:

```sql
=> SELECT * FROM hcat.salesdata;
ERROR 6776: Failed to glob [vertica_hdfs:///hive/warehouse/sales/*/*]
because of error: vertica_hdfs:///hive/warehouse/sales/: listStat failed;
error: Permission denied: user=vertica, access=EXECUTE, inode="/hive/warehouse/sales":hdfs:hdfs:d----
-----
```

The URL scheme in this error message has been changed from hdfs to vertica_hdfs. This is an internal scheme and is not valid in URLs outside of Vertica. You cannot use this scheme when specifying paths in HDFS.

**Differing Results Between Hive and Vertica Queries**

Sometimes, running the same query on Hive and on Vertica through the HCatalog Connector can return different results. There are a few common causes of this problem.

This discrepancy is often caused by the differences between the data types supported by Hive and Vertica. See [Data Type Conversions from Hive to Vertica](#) for more information about supported data types.

If Hive string values are being truncated in Vertica, this might be caused by multi-byte character encodings in Hive. Hive reports string length in characters, while Vertica records it in bytes. For a two-byte encoding such as Unicode, you need to double the column size in Vertica to avoid truncation.

Discrepancies can also occur if the Hive table uses partition columns of types other than string.

If the Hive table stores partition data in custom locations instead of the default, you will see different query results if you do not specify the CUSTOM_PARTITIONS parameter when creating the Vertica schema. See [Using Partitioned Data](#). Further, even when using custom partitions, there are differences between Vertica and Hive:

- If a custom partition is unavailable at query time, Hive ignores it and returns the rest of the results. Vertica reports an error.
• If a partition is altered in Hive to use a custom location after table creation, Hive reads data from only the new location while Vertica reads data from both the default and the new locations.
• If a partition value and its corresponding directory name disagree, Hive uses the value in its metadata while Vertica uses the value in the directory name.

The following example illustrates these differences. A table in Hive, partitioned on the state column, starts with the following data:

```
hive> select * from inventory;
        +-------+-------+-------+
        | ID    | quant | state |
        +-------+-------+-------+
        | 2      | 300   | CA    |
        | 4      | 400   | CA    |
        | 5      | 500   | DC    |
        | 1      | 100   | PA    |
        | 2      | 200   | PA    |
        +-------+-------+-------+
```

The partition for one state, CA, is then moved. This directory contains some data already.

Note that the query now returns different results for the CA partitions.

```
hive> ALTER TABLE inventory PARTITION (state='CA') SET LOCATION 'hdfs:///partitions/inventory/state=MD';
hive> select * from inventory;
        +-------+-------+-------+
        | ID    | quant | state |
        +-------+-------+-------+
        | 20     | 30000 | CA    |
        | 40     | 40000 | CA    |
        | 5      | 500   | DC    |
        | 1      | 100   | PA    |
        | 2      | 200   | PA    |
        +-------+-------+-------+
5 rows selected (0.399 seconds)
```

The CA partitions were moved to a directory named state=MD. Vertica reports the state for the first two rows, the ones in the new partition location, as MD because of the directory name. It also reports the CA values from the original location in addition to the new one:

```
=> SELECT * FROM hcat.inventory;
        ID  | quant | state |
        +----+-------+-------+
        | 20 | 30000 | MD    |
        | 40 | 40000 | MD    |
        | 2  | 300   | CA    |
        | 4  | 400   | CA    |
        | 1  | 100   | PA    |
        | 2  | 200   | PA    |
        | 5  | 500   | DC    |
        +----+-------+-------+
(7 rows)
```
**HCatalog Connector Installation Fails on MapR**

If you mount a MapR file system as an NFS mount point and then install the HCatalog Connector, it could fail with a message like the following:

```
ROLLBACK 2929: Couldn't create new UDx side process, failed to get UDx side process info from zygote: Broken pipe
```

This might be accompanied by an error like the following in dbLog:

```
java.io.IOException: Couldn't get lock for /home/dbadmin/node02_catalog/UDxLogs/UDxFencedProcessesJava.log
    at java.util.logging.FileHandler.openFiles(FileHandler.java:389)
    at java.util.logging.FileHandler.<init>(FileHandler.java:287)
    at com.vertica.udxfence.UDxLogger.setup(UDxLogger.java:78)
    at com.vertica.udxfence.UDxSideProcess.go(UDxSideProcess.java:75)
    ...
```

This error occurs if you locked your NFS mount point when creating it. Locking is the default. If you use the HCatalog Connector with MapR mounted as an NFS mount point, you must create the mount point with the `-o no lock` option. For example:

```
sudo mount -o no lock -t nfs MaprCLDBserviceHostname:/mapr/ClusterName/vertica/$(hostname -f)/vertica
```

You can use the HCatalog Connector with MapR without mounting the MapR file system. If you mount the MapR file system, you must do so without a lock.

**Excessive Query Delays**

Network issues or high system loads on the HiveServer2 server can cause long delays while querying a Hive database using the HCatalog Connector. While Vertica cannot resolve these issues, you can set parameters that limit how long Vertica waits before canceling a query on an HCatalog schema. You can set these parameters globally using Vertica configuration parameters. You can also set them for specific HCatalog schemas in the `CREATE HCATALOG SCHEMA` statement. These specific settings override the settings in the configuration parameters.

The `HCatConnectionTimeout` configuration parameter and the `CREATE HCATALOG SCHEMA` statement's `HCATALOG_CONNECTION_TIMEOUT` parameter control how many seconds the HCatalog Connector waits for a connection to the HiveServer2 server. A value of 0 (the default setting for the configuration parameter) means to wait indefinitely. If the server
does not respond by the time this timeout elapses, the HCatalog Connector breaks the connection and cancels the query. If you find that some queries on an HCatalog schema pause excessively, try setting this parameter to a timeout value, so the query does not hang indefinitely.

The HCatSlowTransferTime configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG_SLOW_TRANSFER_TIME parameter specify how long the HCatalog Connector waits for data after making a successful connection to the server. After the specified time has elapsed, the HCatalog Connector determines whether the data transfer rate from the server is at least the value set in the HCatSlowTransferLimit configuration parameter (or by the CREATE HCATALOG SCHEMA statement's HCATALOG_SLOW_TRANSFER_LIMIT parameter). If it is not, then the HCatalog Connector terminates the connection and cancels the query.

You can set these parameters to cancel queries that run very slowly but do eventually complete. However, query delays are usually caused by a slow connection rather than a problem establishing the connection. Therefore, try adjusting the slow transfer rate settings first. If you find the cause of the issue is connections that never complete, you can alternately adjust the Linux TCP socket timeouts to a suitable value instead of relying solely on the HCatConnectionTimeout parameter.

**SerDe Errors**

Errors can occur if you attempt to query a Hive table that uses a nonstandard SerDe. If you have not installed the SerDe JAR files on your Vertica cluster, you receive an error similar to the one in the following example:

```sql
=> SELECT * FROM hcat.jsontable;
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not initialized, setOutput has to be called. Cause : java.io.IOException:
java.lang.RuntimeException: MetaException(message:org.apache.hive.serde2.SerDeException
SerDe com.cloudera.hive.serde.JSONSerDe does not exist) ] HINT If error message is not descriptive or local, may be we cannot read metadata from hive metastore service thrift://hcathost:9083 or HDFS namenode (check U DxLogs/UDxFencedProcessesJava.log in the catalog directory for more information)
at com.vertica.hcatalogudl.HCatalogSplitsNoOpSourceFactory.plan
(HCatalogSplitsNoOpSourceFactory.java:98)
at com.vertica.udxfence.UDxExecContext.planUDSource(UDxExecContext.java:898)
...```
In the error message, you can see that the root cause is a missing SerDe class (shown in bold). To resolve this issue, install the SerDe class on your Vertica cluster. See Using Nonstandard SerDes for more information.

This error may occur intermittently if just one or a few hosts in your cluster do not have the SerDe class.

**Using HDFS Storage Locations**

Vertica stores data in its native format, ROS, in storage locations. You can place storage locations on the local Linux file system or in HDFS. If you are using Premium Edition, you typically use HDFS storage locations for lower-priority data. Doing so frees space on your Vertica cluster for higher-priority data. If you are using Vertica for SQL on Apache Hadoop, you typically place ROS data only on HDFS.

If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

**Requirements for HDFS Storage Locations**

**Caution:**

If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

To store Vertica's data on HDFS, verify that:

- Your Hadoop cluster has WebHDFS enabled.
- All of the nodes in your Vertica cluster can connect to all of the nodes in your Hadoop cluster. Any firewall between the two clusters must allow connections on the ports used by HDFS.
- If your HDFS cluster is unsecured, you have a Hadoop user whose username matches the name of the Vertica database superuser (usually named dbadmin). This Hadoop user must have read and write access to the HDFS directory where you want Vertica to store its data.
• If your HDFS cluster uses Kerberos authentication, you have a Kerberos principal for Vertica, and it has read and write access to the HDFS directory that will be used for the storage location. See Configuring Kerberos. The Kerberos KDC must also be running.
• Your HDFS cluster has enough storage available for Vertica data. See HDFS Space Requirements below for details.
• The data you store in an HDFS-backed storage location does not expand your database's size beyond any data allowance in your Vertica license. Vertica counts data stored in an HDFS-backed storage location as part of any data allowance set by your license. See Managing Licenses in the Administrator's Guide for more information.

**HDFS Space Requirements**

If your Vertica database is K-safe, HDFS-based storage locations contain two copies of the data you store in them. One copy is the primary projection, and the other is the buddy projection. If you have enabled HDFS's data-redundancy feature, Hadoop stores both projections multiple times. This duplication might seem excessive. However, it is similar to how a RAID level 1 or higher stores redundant copies of both the primary and buddy projections. The redundant copies also help the performance of HDFS by enabling multiple nodes to process a request for a file.

Verify that your HDFS installation has sufficient space available for redundant storage of both the primary and buddy projections of your K-safe data. You can adjust the number of duplicates stored by HDFS by setting the HadoopFSReplication configuration parameter. See Troubleshooting HDFS Storage Locations for details.

**Additional Requirements for Backing Up Data Stored on HDFS**

To back up your data stored in HDFS storage locations, your Hadoop cluster must have snapshotting enabled for the directories to be used for backups. The easiest way to do this is to give the database administrator's account superuser privileges in Hadoop, so that snapshotting can be set automatically. Alternatively, use Hadoop to enable snapshotting for each directory before using it for backups.

In addition, your Vertica database must:
• Have enough Hadoop components and libraries installed to run the Hadoop distcp command as the Vertica database-administrator user (usually dbadmin).
• Have the JavaBinaryForUDx and HadoopHome configuration parameters set correctly.

**Caution:**
After you have created an HDFS storage location, full database backups will fail with the error message:

```plaintext
ERROR 5127: Unable to create snapshot
No such file /usr/bin/hadoop:
check the HadoopHome configuration parameter
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back up these locations. After you configure Vertica and Hadoop, you can once again perform full database backups.

See [Backing Up HDFS Storage Locations](#) for details on configuring your Vertica and Hadoop clusters to enable HDFS storage location backup.

---

### Best Practices for SQL on Apache Hadoop

If you are using the Vertica for SQL on Apache Hadoop product, Vertica recommends the following best practices for storage locations:

• Place only data type storage locations on HDFS storage.
• Place temp space directly on the local Linux file system, not in HDFS.
• For the best performance, place the Vertica catalog directly on the local Linux file system.
• Create the database first on a local Linux file system. Then, you can extend the database to HDFS storage locations and set storage policies that exclusively place data blocks on the HDFS storage location.
• For better performance, if you are running Vertica only on a subset of the HDFS nodes, do not run the HDFS balancer on them. The HDFS balancer can move data blocks farther away, causing Vertica to read non-local data during query execution. Queries run faster if they do not require network I/O.

Generally, HDFS requires approximately 2 GB of memory for each node in the cluster. To support this requirement in your Vertica configuration:

1. Create a 2-GB resource pool.
2. Do not assign any Vertica execution resources to this pool. This approach reserves the space for use by HDFS.
Alternatively, use Ambari or Cloudera Manager to find the maximum heap size required by HDFS and set the size of the resource pool to that value.

For more about how to configure resource pools, see Managing Workloads.

**Configuring Kerberos**

To use a storage location in HDFS with Kerberos, take the following steps:

1. Create a Kerberos principal for each Vertica node as explained in Using Kerberos with Vertica.
2. Give all node principals read and write permission to the HDFS directory you will use as a storage location.

If you plan to back up your HDFS storage locations, take the following additional steps:

1. Grant Hadoop superuser privileges to the new principals.
2. Configure backups, including setting the HadoopConfDir configuration parameter, following the instructions in Configuring Hadoop and Vertica to Enable Backup of HDFS Storage.
3. Configure user impersonation to be able to restore from backups following the instructions in "Setting Kerberos Parameters" in Configuring Vertica to Restore HDFS Storage Locations.

Because the keytab file supplies the principal used to create the location, you must have it in place before creating the storage location. After you deploy keytab files to all database nodes, use the CREATE LOCATION statement to create the storage location as usual.

**How the HDFS Storage Location Stores Data**

Vertica stores data in storage locations on HDFS similarly to the way it stores data in the Linux file system. See Managing Storage Locations in the Administrator's Guide for more information about storage locations. When you create a storage location on HDFS, Vertica stores the ROS containers holding its data on HDFS. You can choose which data uses the HDFS storage location: from the data for just a single table or partition to all of the database's data.

When Vertica reads data from or writes data to an HDFS storage location, the node storing or retrieving the data contacts the Hadoop cluster directly to transfer the data. If a single ROS container file is split among several HDFS nodes, the Vertica node connects to each of
them. The Vertica node retrieves the pieces and reassembles the file. Because each node fetches its own data directly from the source, data transfers are parallel, increasing their efficiency. Having the Vertica nodes directly retrieve the file splits also reduces the impact on the Hadoop cluster.

**What You Can Store in HDFS**

Use HDFS storage locations to store only data. You cannot store catalog information in an HDFS storage location.

⚠️ **Caution:**
While it is possible to use an HDFS storage location for temporary data storage, you must never do so. Using HDFS for temporary storage causes severe performance issues.

**What HDFS Storage Locations Cannot Do**

Because Vertica uses storage locations to store ROS containers in a proprietary format, MapReduce and other Hadoop components cannot access your Vertica ROS data stored in HDFS. Never allow another program that has access to HDFS to write to the ROS files. Any outside modification of these files can lead to data corruption and loss. Applications must use the [Vertica client libraries](https://www.vertica.com/docs/9.3.x/Content/HomeFolder/) to access Vertica data. If you want to share ROS data with other Hadoop components, you can export it (see [Exporting Data](https://www.vertica.com/docs/9.3.x/Content/Vertica-9.3.x-Release-Notes/Exporting-Data.html)).

The storage location stores and reads only ROS containers. It cannot read data stored in native formats in HDFS. See [Hadoop Interfaces](https://www.vertica.com/docs/9.3.x/Content/Vertica-9.3.x-Release-Notes/Hadoop-Interface.html) for other ways to read data stored in HDFS.

**Creating an HDFS Storage Location**

Use the `CREATE LOCATION` statement to create an HDFS storage location. Make the following changes from creating local storage locations:

- For the path, use the `hdfs://` URL, adding a nameservice or name node, for the HDFS directory where you want Vertica to store the location's data. See [HDFS URL Format](https://www.vertica.com/docs/9.3.x/Content/Vertica-9.3.x-Release-Notes/Vertica-URL-Format.html) for information about the URL format. Do not use `hdfs:////` (three slashes) in URLs for storage locations.
Include the ALL NODES SHARED keywords, as all HDFS storage locations are shared storage. This is required even if you have only one HDFS node in your cluster.

Caution:
If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

Creating the Storage Location

To create an HDFS storage location, first create the location on all nodes and then set its storage policy to HDFS. To create the location in HDFS on all nodes:

=> CREATE LOCATION 'hdfs://hadoopNS/vertica/colddata' ALL NODES SHARED USAGE 'data' LABEL 'coldstorage';

Next, set the storage policy for your database objects to use this location:

=> SELECT SET_OBJECT_STORAGE_POLICY('SchemaName','coldstorage');

This causes all data in the named schema to be written to the HDFS storage location (coldestorage) instead of the local disk. You can set storage policies for a schema, a table, a partition, or the entire database.

For more information, see Managing Storage Locations.

Adding HDFS Storage Locations to New Nodes

If you add nodes to your Vertica cluster, they do not automatically have access to existing HDFS storage locations. You must manually create the storage location for the new node using the CREATE LOCATION statement. Do not use the ALL NODES keyword in this statement. Instead, use the NODE keyword with the name of the new node to tell Vertica that just that node needs to add the shared location.

Caution:
You must manually create the storage location. Otherwise, the new node uses the default storage policy (usually, storage on the local Linux file system) to store data that the other nodes store in HDFS. As a result, the...
A node can run out of disk space.

The following example shows how to add the storage location from the preceding example to a new node named v_vmart_node0004:

```sql
=> CREATE LOCATION 'hdfs://hadoopNS/vertica/colddata' NODE 'v_vmart_node0004'
    SHARED USAGE 'data' LABEL 'coldstorage';
```

Any active standby nodes in your cluster when you create an HDFS-based storage location automatically create their own instances of the location. When the standby node takes over for a down node, it uses its own instance of the location to store data for objects using the HDFS-based storage policy. Treat standby nodes added after you create the storage location as any other new node. You must manually define the HDFS storage location.

## Creating a Storage Policy for HDFS Storage Locations

After you create an HDFS storage location, you assign database objects to the location by setting storage policies. Based on these storage policies, database objects such as partition ranges, individual tables, whole schemas, or even the entire database store their data in the HDFS storage location. Use the `SET_OBJECT_STORAGE_POLICY` function to assign objects to an HDFS storage location. In the function call, supply the label you assigned to the HDFS storage location as the location label argument. You do so using the CREATE LOCATION statement's LABEL keyword.

The following example demonstrates using `SET_OBJECT_STORAGE_POLICY` to store a table in an HDFS storage location. The example statement sets the policy for an existing table, named messages, to store its data in an HDFS storage location, named coldstorage.

```sql
=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'coldstorage');
```

This table's data is moved to the HDFS storage location with the next merge-out. Alternatively, you can have Vertica move the data immediately by using the `enforce-storage-move` parameter.

You can query the `STORAGE_CONTAINERS` system table and examine the location_label column to verify that Vertica has moved the data:

```sql
=> SELECT node_name, projection_name, location_label, total_row_count
    FROM V_MONITOR.STORAGE_CONTAINERS
    WHERE projection_name ILIKE 'messages%';
```
<table>
<thead>
<tr>
<th>node_name</th>
<th>projection_name</th>
<th>location_label</th>
<th>total_row_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>messages_b0</td>
<td>coldstorage</td>
<td>366057</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>messages_b1</td>
<td>coldstorage</td>
<td>366511</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>messages_b0</td>
<td>coldstorage</td>
<td>367432</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>messages_b1</td>
<td>coldstorage</td>
<td>366057</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>messages_b0</td>
<td>coldstorage</td>
<td>366511</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>messages_b1</td>
<td>coldstorage</td>
<td>367432</td>
</tr>
</tbody>
</table>

(6 rows)

See [Creating Storage Policies](#) in the Administrator's Guide for more information about assigning storage policies to objects.

## Backing Up HDFS Storage Locations

**Caution:**

It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

Vertica recommends that you regularly back up the data in your Vertica database. This recommendation includes data stored in your HDFS storage locations. The Vertica backup script (vbr) can back up HDFS storage locations. However, you must perform several configuration steps before it can back up these locations.

**Caution:**

After you have created an HDFS storage location, full database backups will fail with the error message:

```
ERROR 5127: Unable to create snapshot
No such file /usr/bin/hadoop:
check the HadoopHome configuration parameter
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back up these locations. After you configure Vertica and Hadoop, you can once again perform full database backups.

There are several considerations for backing up HDFS storage locations in your database:

- HDFS storage locations do not support object-level backups. You must perform a full database backup to back up the data in your HDFS storage locations.
- Data in an HDFS storage location is backed up to HDFS. This backup guards against accidental deletion or corruption of data. It does not prevent data loss in the case of a
catastrophic failure of the entire Hadoop cluster. To prevent data loss, you must have a backup and disaster recovery plan for your Hadoop cluster.

Data stored on the Linux native file system is still backed up to the location you specify in the backup configuration file. It and the data in HDFS storage locations are handled separately by the vbr backup script.

- You must configure your Vertica cluster to restore database backups containing an HDFS storage location. See Configuring Vertica to Restore HDFS Storage Locations for the configuration steps you must take.
- The HDFS directory for the storage location must have snapshotting enabled. You can either directly configure this yourself or enable the database administrator’s Hadoop account to do it for you automatically. See Configuring Hadoop and Vertica to Enable Backup of HDFS Storage for more information.

The topics in this section explain the configuration steps you must take to enable the backup of HDFS storage locations.

**Configuring Hadoop and Vertica to Enable Backup of HDFS Storage**

The Vertica backup script uses HDFS's snapshotting feature to create a backup of HDFS storage locations. A directory must allow snapshotting before HDFS can take a snapshot. Only a Hadoop superuser can enable snapshotting on a directory. Vertica can enable snapshotting automatically if the database administrator is also a Hadoop superuser.

If HDFS is unsecured, the following instructions apply to the database administrator account, usually dbadmin. If HDFS uses Kerberos security, the following instructions apply to the principal stored in the Vertica keytab file, usually vertica. The instructions below use the term "database account" to refer to this user.

We recommend that you make the database administrator or principal a Hadoop superuser. If you are not able to do so, you must enable snapshotting on the directory before configuring it for use by Vertica.

The steps you need to take to make the Vertica database administrator account a superuser depend on the distribution of Hadoop you are using. Consult your Hadoop distribution's documentation for details.
Manually Enabling Snapshotting for a Directory

If you cannot grant superuser status to the database account, you can instead enable snapshotting of each directory manually. Use the following command:

```
hdfs dfsadmin -allowSnapshot path
```

Issue this command for each directory on each node. Remember to do this each time you add a new node to your HDFS cluster.

Nested snapshottable directories are not allowed, so you cannot enable snapshotting for a parent directory to automatically enable it for child directories. You must enable it for each individual directory.

Additional Requirements for Kerberos

If HDFS uses Kerberos, then in addition to granting the keytab principal access, you must set a Vertica configuration parameter. In Vertica, set the HadoopConfDir parameter to the location of the directory containing the core-site.xml, hdfs-site.xml, and yarn-site.xml configuration files. The value can be a path, if the files are in multiple directories.

```
=> ALTER DATABASE exampledb SET HadoopConfDir = '/etc/hadoop/conf';
```

All three configuration files must be present on this path.

If your Vertica nodes are not co-located on HDFS nodes, then you must copy these files from an HDFS node to each Vertica node. Use the same path on every database node, because HadoopConfDir is a global value.

Testing the Database Account's Ability to Make HDFS Directories Snapshottable

After making the database account a Hadoop superuser, verify that the account can set directories snapshottable:
1. Log into the Hadoop cluster as the database account (dbadmin by default).
2. Determine a location in HDFS where the database administrator can create a directory. The /tmp directory is usually available. Create a test HDFS directory using the command:

```
$ hdfs dfs -mkdir /path/testdir
```

3. Make the test directory snapshottable using the command:

```
$ hdfs dfsadmin -allowSnapshot /path/testdir
```

The following example demonstrates creating an HDFS directory and making it snapshottable:

```
$ hdfs dfs -mkdir /tmp/snaptest
$ hdfs dfsadmin -allowSnapshot /tmp/snaptest
Allowing snapshot on /tmp/snaptest succeeded
```

## Configuring Vertica to Restore HDFS Storage Locations

Your Vertica cluster must be able to run the Hadoop distcp command to restore a backup of an HDFS storage location. The easiest way to enable your cluster to run this command is to install several Hadoop packages on each node. These packages must be from the same distribution and version of Hadoop that is running on your Hadoop cluster.

The steps you need to take depend on:

- The distribution and version of Hadoop running on the Hadoop cluster containing your HDFS storage location.
- The distribution of Linux running on your Vertica cluster.

**Note:**

Installing the Hadoop packages necessary to run distcp does not turn your Vertica database into a Hadoop cluster. This process installs just enough of the Hadoop support files on your cluster to run the distcp command. There is no additional overhead placed on the Vertica cluster, aside from a small amount of additional disk space consumed by the Hadoop support files.
**Configuration Overview**

The steps for configuring your Vertica cluster to restore backups for HDFS storage location are:

1. If necessary, install and configure a Java runtime on the hosts in the Vertica cluster.
2. Find the location of your Hadoop distribution's package repository.
3. Add the Hadoop distribution's package repository to the Linux package manager on all hosts in your cluster.
4. Install the necessary Hadoop packages on your Vertica hosts.
5. Set two configuration parameters in your Vertica database related to Java and Hadoop.
6. If your HDFS storage location uses Kerberos, set additional configuration parameters to allow Vertica user credentials to be proxied.
7. Confirm that the Hadoop distcp command runs on your Vertica hosts.

The following sections describe these steps in greater detail.

**Installing a Java Runtime**

You Vertica cluster must have a Java Virtual Machine (JVM) installed to run the Hadoop distcp command. It already has a JVM installed if you have configured it to:

- Execute user-defined extensions developed in Java. See [Developing User-Defined Extensions (UDxs)](Vertica%20SDKs) for more information.
- Access Hadoop data using the HCatalog Connector. See [Using the HCatalog Connector](Vertica%20SDKs) for more information.

If your Vertica database has a JVM installed, verify that your Hadoop distribution supports it. See your Hadoop distribution's documentation to determine which JVMs it supports.

If the JVM installed on your Vertica cluster is not supported by your Hadoop distribution you must uninstall it. Then you must install a JVM that is supported by both Vertica and your Hadoop distribution. See [Vertica SDKs](Vertica%20SDKs) in Supported Platforms for a list of the JVMs compatible with Vertica.

If your Vertica cluster does not have a JVM (or its existing JVM is incompatible with your Hadoop distribution), follow the instructions in [Installing the Java Runtime on Your Vertica Cluster](Vertica%20SDKs).
Finding Your Hadoop Distribution’s Package Repository

Many Hadoop distributions have their own installation system, such as Cloudera’s Manager or Hortonwork's Ambari. However, they also support manual installation using native Linux packages such as RPM and .deb files. These package files are maintained in a repository. You can configure your Vertica hosts to access this repository to download and install Hadoop packages.

Consult your Hadoop distribution's documentation to find the location of its Linux package repository. This information is often located in the portion of the documentation covering manual installation techniques:

Each Hadoop distribution maintains separate repositories for each of the major Linux package management systems. Find the specific repository for the Linux distribution running on your Vertica cluster. Be sure that the package repository that you select matches the version of Hadoop distribution installed on your Hadoop cluster.

Configuring Vertica Nodes to Access the Hadoop Distribution’s Package Repository

Configure the nodes in your Vertica cluster so they can access your Hadoop distribution's package repository. Your Hadoop distribution's documentation should explain how to add the repositories to your Linux platform. If the documentation does not explain how to add the repository to your packaging system, refer to your Linux distribution's documentation.

The steps you need to take depend on the package management system your Linux platform uses. Usually, the process involves:

- Downloading a configuration file.
- Adding the configuration file to the package management system's configuration directory.
- For Debian-based Linux distributions, adding the Hadoop repository encryption key to the root account keyring.
- Updating the package management system's index to have it discover new packages.

You must add the Hadoop repository to all hosts in your Vertica cluster.
Installing the Required Hadoop Packages

After configuring the repository, you are ready to install the Hadoop packages. The packages you need to install are:

- hadoop
- hadoop-hdfs
- hadoop-client

The names of the packages are usually the same across all Hadoop and Linux distributions. These packages often have additional dependencies. Always accept any additional packages that the Linux package manager asks to install.

To install these packages, use the package manager command for your Linux distribution. The package manager command you need to use depends on your Linux distribution:

- On Red Hat and CentOS, the package manager command is yum.
- On Debian and Ubuntu, the package manager command is apt-get.
- On SUSE the package manager command is zypper.

Consult your Linux distribution's documentation for instructions on installing packages.

Setting Configuration Parameters

You must set two configuration parameters to enable Vertica to restore HDFS data:

- JavaBinaryForUDx is the path to the Java executable. You may have already set this value to use Java UDxs or the HCatalog Connector. You can find the path for the default Java executable from the Bash command shell using the command:

  ```bash
  which java
  ```

- HadoopHome is the path where Hadoop is installed on the Vertica hosts. This is the directory that contains bin/hadoop (the bin directory containing the Hadoop executable file). The default value for this parameter is /usr. The default value is correct if your Hadoop executable is located at /usr/bin/hadoop.

The following example shows how to set and then review the values of these parameters:

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
=> SELECT current_value FROM configuration_parameters WHERE parameter_name = 'JavaBinaryForUDx';
current_value
-------------------
'/'usr/bin/java'
```
You can also set the following parameters:

- **HadoopFSReadRetryTimeout** and **HadoopFSWriteRetryTimeout** specify how long to wait before failing. The default value for each is 180 seconds. If you are confident that your file system will fail more quickly, you can improve performance by lowering these values.

- **HadoopFSReplication** specifies the number of replicas HDFS makes. By default, the Hadoop client chooses this; Vertica uses the same value for all nodes.

  **Caution:**

  Do not change this setting unless directed otherwise by Vertica support.

- **HadoopFSBlockSizeBytes** is the block size to write to HDFS; larger files are divided into blocks of this size. The default is 64MB.

### Setting Kerberos Parameters

If your Vertica nodes are co-located on HDFS nodes and you are using Kerberos, you must change some Hadoop configuration parameters. These changes are needed in order for restoring from backups to work. In `yarn-site.xml` on every Vertica node, set the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>yarn.resourcemanager.proxy-user-privileges.enabled</code></td>
<td>true</td>
</tr>
<tr>
<td><code>yarn.resourcemanager.proxyusers.*.groups</code></td>
<td>*</td>
</tr>
<tr>
<td><code>yarn.resourcemanager.proxyusers.*.hosts</code></td>
<td>*</td>
</tr>
<tr>
<td><code>yarn.resourcemanager.proxyusers.*.users</code></td>
<td>*</td>
</tr>
<tr>
<td><code>yarn.timeline-service.http-authentication.proxyusers.*.groups</code></td>
<td>*</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value</td>
</tr>
<tr>
<td>--------------------------------------------------------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>yarn.timeline-service.http-authentication.proxyusers.*.hosts</td>
<td>*</td>
</tr>
<tr>
<td>yarn.timeline-service.http-authentication.proxyusers.*.users</td>
<td>*</td>
</tr>
</tbody>
</table>

No changes are needed on HDFS nodes that are not also Vertica nodes.

**Confirming that distcp Runs**

After the packages are installed on all hosts in your cluster, your database should be able to run the Hadoop distcp command. To test it:

1. Log into any host in your cluster as the **database superuser**.
2. At the Bash shell, enter the command:
   
   ```
   $ hadoop distcp
   ```

3. The command should print a message similar to the following:

   ```
   usage: distcp OPTIONS [source_path...] <target_path>
   OPTIONS
   -async            Should distcp execution be blocking
   -atomic           Commit all changes or none
   -bandwidth <arg>  Specify bandwidth per map in MB
   -delete           Delete from target, files missing in source
   -f <arg>          List of files that need to be copied
   -filelimit <arg>  (Deprecated!) Limit number of files copied to <= n
   -i                Ignore failures during copy
   -log <arg>        Folder on DFS where distcp execution logs are saved
   -m <arg>          Max number of concurrent maps to use for copy
   -mapredSslConf <arg>  Configuration for ssl config file, to use with https://
   -overwrite       Choose to overwrite target files unconditionally, even if they exist.
   -p <arg>          preserve status (rbugpc)(replication, block-size, user, group, permission, checksum-type)
   -sizelimit <arg>  (Deprecated!) Limit number of files copied to <= n bytes
   -skipCRCcheck     Whether to skip CRC checks between source and target paths.
   -strategy <arg>   Copy strategy to use. Default is dividing work based on file sizes
   -tmp <arg>        Intermediate work path to be used for atomic commit
   -update           Update target, copying only missing files or directories
   ```
4. Repeat these steps on the other hosts in your database to verify that all of the hosts can run distcp.

Troubleshooting

If you cannot run the distcp command, try the following steps:

- If Bash cannot find the hadoop command, you may need to manually add Hadoop's bin directory to the system search path. An alternative is to create a symbolic link in an existing directory in the search path (such as /usr/bin) to the hadoop binary.
- Ensure the version of Java installed on your Vertica cluster is compatible with your Hadoop distribution.
- Review the Linux package installation tool's logs for errors. In some cases, packages may not be fully installed, or may not have been downloaded due to network issues.
- Ensure that the database administrator account has permission to execute the hadoop command. You may need to add the account to a specific group in order to allow it to run the necessary commands.

Performing Backups Containing HDFS Storage Locations

After you configure Hadoop and Vertica, HDFS storage locations are automatically backed up when you perform a full database backup. If you already have a backup configuration file for a full database backup, you do not need to make any changes to it. You just run the vbr backup script as usual to perform the full database backup. See Creating Full Backups in the Administrator's Guide for instructions on running the vbr backup script.

If you do not have a backup configuration file for a full database backup, you must create one to back up the data in your HDFS storage locations. See Sample VBR .ini Files and Configuration File Reference in the Administrator's Guide for more information.

Removing HDFS Storage Locations

The steps to remove an HDFS storage location are similar to standard storage locations:

1. Remove any existing data from the HDFS storage location by using SET_OBJECT_STORAGE_POLICY to change each object's storage location. Alternatively, you can use CLEAR_OBJECT_STORAGE_POLICY. Because the Tuple Mover runs infrequently, set
the `enforce-storage-move` parameter to `true` to make the change immediately.

2. Retire the location on each host that has the storage location defined by using `RETIRE_LOCATION`. Set `enforce-storage-move` to `true`.

3. Drop the location on each host that has the storage location defined by using `DROP_LOCATION`.

4. Optionally remove the snapshots and files from the HDFS directory for the storage location.

For more information about changing storage policies, changing usage, retiring locations, and dropping locations, see Managing Storage Locations in the Administrator's Guide.

**Important:**

If you have backed up the data in the HDFS storage location you are removing, you must perform a full database backup after you remove the location. If you do not and restore the database to a backup made before you removed the location, the location's data is restored.

---

**Removing Storage Location Files from HDFS**

Dropping an HDFS storage location does not automatically clean the HDFS directory that stored the location's files. Any snapshots of the data files created when backing up the location are also not deleted. These files consume disk space on HDFS and also prevent the directory from being reused as an HDFS storage location. Vertica refuses to create a storage location in a directory that contains existing files or subdirectories. You must log into the Hadoop cluster to delete the files from HDFS. An alternative is to use some other HDFS file management tool.

**Removing Backup Snapshots**

HDFS returns an error if you attempt to remove a directory that has snapshots:

```
$ hdfs dfs -rm -r -f -skipTrash /user/dbadmin/v_vmart_node0001
rm: The directory /user/dbadmin/v_vmart_node0001 cannot be deleted since /user/dbadmin/v_vmart_node0001 is snapshottable and already has snapshots
```

The Vertica backup script creates snapshots of HDFS storage locations as part of the backup process. See Backing Up HDFS Storage Locations for more information. If you made backups of your HDFS storage location, you must delete the snapshots before removing the directories.
HDFS stores snapshots in a subdirectory named `.snapshot`. You list the snapshots in the directory using the standard HDFS `ls` command. The following example demonstrates listing the snapshots defined for node0001.

```bash
$ hdfs dfs -ls /user/dbadmin/v_vmart_node0001/.snapshot
Found 1 items
  drwxrwx---  dbadmin supergroup  0 2014-09-02 10:13 /user/dbadmin/v_vmart_node0001/.snapshot/s20140902-101358.629
```

To remove snapshots, use the command:

```bash
hdfs dfs -removeSnapshot directory snapshotname
```

The following example demonstrates the command to delete the snapshot shown in the previous example:

```bash
$ hdfs dfs -deleteSnapshot /user/dbadmin/v_vmart_node0001 s20140902-101358.629
```

You must delete each snapshot from the directory for each host in the cluster. After you have deleted the snapshots, you can delete the directories in the storage location.

**Important:**

Each snapshot's name is based on a timestamp down to the millisecond. Nodes independently create their own snapshot. They do not synchronize snapshot creation, so their snapshot names differ. You must list each node's snapshot directory to learn the names of the snapshots it contains.

See Apache's [HDFS Snapshot documentation](http://hadoop.apache.org/docs/current/hadoop-project-dist/hadoop-common/UsingSnapshots.html) for more information about managing and removing snapshots.

### Removing the Storage Location Directories

You can remove the directories that held the storage location's data by either of the following methods:

- Use an HDFS file manager to delete directories. See your Hadoop distribution's documentation to determine if it provides a file manager.
- Log into the Hadoop NameNode using the database administrator’s account and use HDFS's `rmr` command to delete the directories. See Apache's [File System Shell Guide](http://hadoop.apache.org/docs/current/hadoop-project-dist/hadoop-common/RMOptions.html) for more information.

The following example uses the HDFS `rmr` command from the Linux command line to delete the directories left behind in the HDFS storage location directory `/user/dbadmin`. It uses the `-skipTrash` flag to force the immediate deletion of the files.

```bash
$ hdfs dfs -rmr /user/dbadmin
```
Troubleshooting HDFS Storage Locations

This topic explains some common issues with HDFS storage locations.

HDFS Storage Disk Consumption

By default, HDFS makes three copies of each file it stores. This replication helps prevent data loss due to disk or system failure. It also helps increase performance by allowing several nodes to handle a request for a file.

A Vertica database with a **K-Safety** value of 1 or greater also stores its data redundantly using buddy projections.

When a K-Safe Vertica database stores data in an HDFS storage location, its data redundancy is compounded by HDFS's redundancy. HDFS stores three copies of the primary projection's data, plus three copies of the buddy projection for a total of six copies of the data.

If you want to reduce the amount of disk storage used by HDFS locations, you can alter the number of copies of data that HDFS stores. The Vertica configuration parameter named HadoopFSReplication controls the number of copies of data HDFS stores.

You can determine the current HDFS disk usage by logging into the Hadoop NameNode and issuing the command:

```
hdfs dfsadmin -report
```

This command prints the usage for the entire HDFS storage, followed by details for each node in the Hadoop cluster. The following example shows the beginning of the output from this command, with the total disk space highlighted:
$ hdfs dfsadmin -report
Configured Capacity: 51495516981 (47.96 GB)
Present Capacity: 32087212032 (29.88 GB)
DFS Remaining: 31565144064 (29.40 GB)
DFS Used: 52067968 (497.88 MB)
DFS Used%: 1.63%
Under replicated blocks: 0
Blocks with corrupt replicas: 0
Missing blocks: 0
...

After loading a simple million-row table into a table stored in an HDFS storage location, the report shows greater disk usage:

Configured Capacity: 51495516981 (47.96 GB)
Present Capacity: 32085299338 (29.88 GB)
DFS Remaining: 31373565952 (29.22 GB)
DFS Used: 711733386 (678.76 MB)
DFS Used%: 2.22%
Under replicated blocks: 0
Blocks with corrupt replicas: 0
Missing blocks: 0
...

The following Vertica example demonstrates:

1. Creating the storage location on HDFS.
2. Dropping the table in Vertica.
3. Setting the HadoopFSReplication configuration option to 1. This tells HDFS to store a single copy of an HDFS storage location's data.
4. Recreating the table and reloading its data.

=> CREATE LOCATION 'hdfs://hadoopNS/user/dbadmin' ALL NODES SHARED
   USAGE 'data' LABEL 'hdfs';
CREATE LOCATION

=> DROP TABLE messages;
DROP TABLE

=> ALTER DATABASE DEFAULT SET PARAMETER HadoopFSReplication = 1;

=> CREATE TABLE messages (id INTEGER, text VARCHAR);
CREATE TABLE

=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'hdfs');
SET_OBJECT_STORAGE_POLICY
-----------------------------
Object storage policy set.
(1 row)

=> COPY messages FROM '/home/dbadmin/messages.txt' DIRECT;
Rows Loaded
-------------
1000000

Running the HDFS report on Hadoop now shows less disk space use:
Caution:
Reducing the number of copies of data stored by HDFS increases the risk of data loss. It can also negatively impact the performance of HDFS by reducing the number of nodes that can provide access to a file. This slower performance can impact the performance of Vertica queries that involve data stored in an HDFS storage location.

ERROR 6966: StorageBundleWriter

You might encounter Error 6966 when loading data into a storage location on a small Hadoop cluster (5 or fewer data nodes). This error is caused by the way HDFS manages the write pipeline and replication. You can mitigate this problem by reducing the number of replicas as explained in HDFS Storage Disk Consumption. For configuration changes you can make in the Hadoop cluster instead, see this blog post from Hortonworks.

Kerberos Authentication When Creating a Storage Location

If HDFS uses Kerberos authentication, then the CREATE LOCATION statement authenticates using the Vertica keytab principal, not the principal of the user performing the action. If the creation fails with an authentication error, verify that you have followed the steps described in Configuring Kerberos to configure this principal.

When creating an HDFS storage location on a Hadoop cluster using Kerberos, CREATE LOCATION reports the principal being used as in the following example:

```sql
=> CREATE LOCATION 'hdfs://hadoopNS/user/dbadmin' ALL NODES SHARED
   USAGE 'data' LABEL 'coldstorage';
NOTICE 0: Performing HDFS operations using kerberos principal [vertica/hadoop.example.com]
CREATE LOCATION
```
Backup or Restore Fails When Using Kerberos

When backing up an HDFS storage location that uses Kerberos, you might see an error such as:

```
createSnapshot: Failed on local exception: java.io.IOException: java.lang.IllegalArgumentException: Server has invalid Kerberos principal: hdfs/test.example.com@EXAMPLE.COM;
```

When restoring an HDFS storage location that uses Kerberos, you might see an error such as:

```
Error msg: Initialization thread logged exception: Distcp failure!
```

Either of these failures means that Vertica could not find the required configuration files in the HadoopConfDir directory. Usually this is because you have set the parameter but not copied the files from an HDFS node to your Vertica node. You could also see this error if HadoopConfDir has been changed at the session level to an incompatible value. Check the value of the parameter, and then check that the necessary files are present in that location. See "Additional Requirements for Kerberos" in Configuring Hadoop and Vertica to Enable Backup of HDFS Storage.

Integrating With Cloudera Manager

The Cloudera distribution of Hadoop includes Cloudera Manager, a web-based tool for managing a Hadoop cluster. Cloudera Manager can manage any service for which a service description is available, including Vertica.

You can use Cloudera Manager to start, stop, and monitor individual database nodes or the entire database. You can manage both co-located and separate Vertica clusters—Cloudera can manage services on nodes that are not part of the Hadoop cluster.

You must install and configure your Vertica database before proceeding; you cannot use Cloudera Manager to create the database.
Installing the Service

Note: Because the service has to send the database password over the network, you should enable encryption on your Hadoop cluster before proceeding.

A Cloudera Service Description (CSD) file describes a service that Cloudera can manage. The Vertica CSD is in /opt/vertica/share/CSD on a database node.

To install the Vertica CSD, follow these steps:

1. On a Vertica node, follow the instructions in VerticaAPIKey to generate an API key. You need this key to finish the installation of the CSD.
2. On the Hadoop node that hosts Cloudera Manager, copy the CSD file into /opt/cloudera/csd.
3. Restart Cloudera Manager:

   $ service cloudera-scm-server restart

4. In a web browser, go to Cloudera Manager and restart the Cloudera Management Service.
5. If your Vertica cluster is separate from your Hadoop cluster (not co-located on it): Use Cloudera Manager to add the hosts for your database nodes. If your cluster is co-located, skip this step.
6. Use Cloudera Manager to add the Vertica service.
7. On the "Role Assignment" page, select the hosts that are database nodes.
8. On the "Configuration" page, specify values for the following fields:
   - database name
   - agent port (accept the default if you're not sure)
   - API key
   - database user to run as (usually dbadmin) and password

About the Agent

When you manage Vertica through Cloudera Manager, you are actually interacting with the Vertica Agent, not the database directly. The Agent runs on all database nodes and interacts with the database on your behalf. Management Console uses the same agent. Most of the time this extra indirection is transparent to you.
A Cloudera-managed service contains one or more roles. In this case the service is "Vertica" and the single role is "Vertica Node".

**Available Operations**

Cloudera Manager shows two groups of operations. Service-level operations apply to the service on all nodes, while role-level operations apply only to a single node.

You can perform the following service-level operations on all nodes:

- Start: Starts the agent and, if it is not already running, the database.
- Stop: Stops the database and agent.
- Restart: Calls Stop and then Start.
- Add Role Instances: Adds new database nodes to Cloudera Manager. The nodes must already be part of the Vertica cluster, and the hosts must already be known to Cloudera Manager.
- Enter Maintenance Mode: Suppresses health alerts generated by Cloudera Manager.
- Exit Maintenance Mode: Resumes normal reporting.
- Update Memory Pool Size: Applies memory-pool settings from the Static Service Pools configuration page.

You can perform all of these operations except Add Role Instances on individual nodes as role-level operations.

**Managing Memory Pools**

Cloudera Manager allows you to change resource allocations, such as memory and CPU, for the nodes it manages. If you are using co-located clusters, centrally managing resources can simplify your cluster management. If you are using separate Hadoop and Vertica clusters, you might prefer to manage Vertica separately as described in Managing the Database in the Administrator's Guide.

Use the Cloudera Manager "Static Service Pools" configuration page to configure resource allocations. The "Vertica Memory Pool" value, specified in GB, is the maximum amount of memory to allocate to the database on each node. If the configuration page includes "Cgroup Memory Hard Limit", set it to the same value as "Vertica Memory Pool".

After you have set these values, you can use the "Update Memory Pool Size" operation to apply the value to the managed nodes. This operation is equivalent to `ALTER RESOURCE`
POOL GENERAL MAXMEMORYSIZE. Configuration changes in "Static Service Pools" do not take effect in Vertica until you perform this operation.

### Uninstalling the Service

To uninstall the Vertica CSD, follow these steps:

1. Stop the Vertica service and then remove it from Cloudera Manager.
2. Remove the CSD file from /opt/cloudera/csd.
3. From the command line, restart the Cloudera Manager server.
4. In Cloudera Manager, restart the Cloudera Management Service.

### Integrating Vertica with the MapR Distribution of Hadoop

MapR is a distribution of Apache Hadoop produced by MapR Technologies that extends the standard Hadoop components with its own features. Vertica can integrate with MapR in the following ways:

- You can read data from MapR through an NFS mount point. After you mount the MapR file system as an NFS mount point, you can use `CREATE EXTERNAL TABLE AS COPY` or `COPY` to access the data as if it were on the local file system. For ORC or Parquet data, see also Reading ORC and Parquet Formats. This option provides the best performance for reading data.
- You can use the HCatalog Connector to read Hive data. Do not use the HCatalog Connector with ORC or Parquet data in MapR for performance reasons. Instead, mount the MapR file system as an NFS mount point and create external tables without using the Hive schema. For more about reading Hive data, see Using the HCatalog Connector.
- You can create a storage location to store data in MapR using the native Vertica format (ROS). Mount the MapR file system as an NFS mount point and then use `CREATE LOCATION`...ALL NODES SHARED to create a storage location. (CREATE LOCATION does not support NFS mount points in general, but does support them for MapR.)

**Note:**
If you create a Vertica database and place its initial storage location on MapR, Vertica designates the storage location for both DATA and TEMP.
Vertica does not support TEMP storage locations on MapR, so after you create the location, you must alter it to store only DATA files. See Altering Location Use. Ensure that you have a TEMP location on the Linux file system.

Other Vertica integrations for Hadoop are not available for MapR.

For information on mounting the MapR file system as an NFS mount point, see Accessing Data with NFS and Configuring Vertica Analytics Platform with MapR on the MapR website. In particular, you must configure MapR to add Vertica as a MapR service.

Examples

In the following examples, the MapR file system has been mounted as /mapr.

The following statement creates an external table from ORC data:

```
=> CREATE EXTERNAL TABLE t (a1 INT, a2 VARCHAR(20))
    AS COPY FROM '/mapr/data/file.orc' ORC;
```

The following statement creates an external table from Parquet data and takes advantage of partition pruning (see Using Partition Columns):

```
=> CREATE EXTERNAL TABLE t2 (id int, name varchar(50), created date, region varchar(50))
    AS COPY FROM '/mapr/*/*/*' PARQUET(hive_partition_cols='created,region');
```

The following statement loads ORC data from MapR into Vertica:

```
=> COPY t FROM '/mapr/data/*.orc' ON ANY NODE ORC;
```

The following statements create a storage location to hold ROS data in the MapR file system:

```
=> CREATE LOCATION '/mapr/my.cluster.com/data' SHARED USAGE 'DATA' LABEL 'maprfs';
```

```
=> SELECT ALTER_LOCATION_USE('/mapr/my.cluster.com/data', '', 'DATA');
```
Integrating with Apache Kafka

Welcome to the Vertica Data Streaming Integration Guide.

Audience

This book is intended for anyone who wants to load data from an existing data streaming message bus into a Vertica database.

Prerequisites

This document assumes that you have installed and configured Vertica as described in Installing Vertica and the Configuring the Database section of the Administrator's Guide. In addition, you must have Java 7.0 or later installed on your Vertica node. Refer to the Vertica product documentation to learn more.

In addition, this guide assumes you have installed and configured your data streaming platform. For details on installing and using third party applications, please to refer to the documentation for that application.
How Vertica and Data Streaming Work Together

Vertica provides a high-performance mechanism for streaming data both to and from third party message buses. Data streaming provides high volumes of data with low latency.

This feature lets you:

- Store and analyze data that is generated by any application that writes to the message bus. With a message bus, you do not need to worry about individually configuring each application to connect to Vertica.
- Send Vertica data to any application that can read from the message bus. There are two types of data you can send to a data bus:
  - Vertica tables and results of queries. This feature lets you export the results of Vertica analytics to any other application connected to the message bus.
  - Data from Vertica's Data Collector tables. You can use this data to monitor your Vertica database's performance and health via third-party monitoring tools.

Because Vertica can both receive and send data to a streaming message bus, you can use it as part of an automated analytics workflow. Vertica can retrieve data from the message bus, perform analytics on it, and then send the results back to the message bus for consumption by other applications.

Common Uses of Data Streaming with Vertica

There are many cases where you could use Vertica to process data from a streaming data source. This document will use the following two cases as examples:

- Retrieving and processing data from an e-commerce site. This includes raw access logs from a web server farm, clickstream data generated by a JavaScript-based Web 2.0 interface, and even back-end fulfillment processing.
- An Internet of Things (IOT) network where device sensor data is sent from many individual devices to the message bus via web API calls.
Data Streaming Integration Terms

Vertica uses the following terms to describe its streaming feature. These are general terms, which may differ from each specific streaming platform's terminology.

**Terminology**

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>A data streaming server.</td>
</tr>
<tr>
<td>Source</td>
<td>A feed of messages in a common category which streams into the same Vertica target tables. In Apache Kafka, a source is known as a topic.</td>
</tr>
<tr>
<td>Partition</td>
<td>Unit of parallelism within data streaming. Data streaming splits a source into multiple partitions, which can each be served in parallel to consumers such as a Vertica database. Within a partition, messages are usually ordered chronologically.</td>
</tr>
<tr>
<td>Offset</td>
<td>An index into a partition. This index is the position within an ordered queue of messages, not an index into an opaque byte stream.</td>
</tr>
<tr>
<td>Message</td>
<td>A unit of data within data streaming. The data is typically in JSON or Avro format. Messages are loaded as rows into Vertica tables, and are uniquely identified by their source, partition, and offset.</td>
</tr>
</tbody>
</table>

**Data Loader Terminology**

<table>
<thead>
<tr>
<th>Data Loader Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheduler</td>
<td>An external tool that schedules data loads from a streaming data source into Vertica.</td>
</tr>
<tr>
<td>Data Loader Term</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Microbatch</strong></td>
<td>A microbatch represents a single segment of a data load from a streaming data source. It encompasses all of the information the scheduler needs to perform a load from a streaming data source into Vertica.</td>
</tr>
<tr>
<td><strong>Frame</strong></td>
<td>The window of time during which a Scheduler executes microbatches to load data. This window controls the duration of each COPY statement the scheduler runs as a part of the microbatch. The during the frame, the scheduler gives an active microbatch from each source an opportunity to load data. It gives priority to microbatches that need more time to load data based on the history of previous microbatches.</td>
</tr>
<tr>
<td><strong>Stream</strong></td>
<td>A feed of messages that is identified by a source and partition. The offset uniquely identifies the position within a particular source-partition stream.</td>
</tr>
<tr>
<td><strong>Lane</strong></td>
<td>A thread within a job scheduler instance that issues microbatches to perform the load. The number of lanes available is based on the PlannedConcurrency of the job scheduler's resource pool. Multiple lanes allow the scheduler to run microbatches for different sources in parallel during a frame.</td>
</tr>
</tbody>
</table>

**Vertica and Apache Kafka**

Currently, the only data streaming platform that Vertica supports is Apache Kafka. Kafka is an open-source distributed real-time streaming platform. See Apache's [main Kafka page](https://kafka.apache.org/) for more information. By integrating Kafka and Vertica, you can load data from any application that produces Kafka messages.

The integration features between Vertica and Kafka consist of:

- A U Dx library containing functions that load and parse data from Kafka topics into Vertica.
• A job scheduler that uses the UDL library to continuously consume data from your message bus with exactly-once semantics
• Push-based Monitoring Vertica Using Notifiers that send data collector messages from Vertica to Kafka
• A KafkaExport function that sends Vertica data to Kafka.

**Consuming Data from Kafka**

There are two ways to load data from Kafka:

• Manually, by directly executing a COPY statement. You use this method to load a finite amount of data. Some reasons you may want to manually load data:
  • Managing a streaming data load with greater control than using a scheduler. Schedulers can manage data loads in many cases. However, you may find you need greater control over the data load than is available through the scheduler.
  • Loading specific chunks of data you want to analyze, rather than constantly streaming data. For example, you may want to load web server logs from a specific time period to perform in-depth analytics.
  • Manually testing your Kafka and Vertica configuration before creating a streaming data load. See Manually Copying Data From Kafka for more information.
Automatically via job schedulers. The schedulers constantly load data from Kafka and ensure each Kafka message is loaded exactly once. See Automatically Copying Data From Kafka for more information.

Producing Data for Kafka

Vertica can send data to Kafka for processing by other consumers of Kafka's data streams. There are two ways you can send data to Kafka:

- You use notifiers to send Vertica health and performance data stored in the Data Collector tables. This feature is useful to stream data to third-party monitoring tools.
- You use the KafkaExport function to export Vertica data to Kafka. See Producing Data Using KafkaExport for more information.

Configuring Vertica and Kafka

Both Vertica and Kafka have settings you can use to optimize your streaming data loads. The topics in this section explain these settings.

Kafka and Vertica Configuration Settings

The following sections lists settings for Vertica and Kafka that you can set to optimize performance.

Vertica Producer Settings

These settings change how Vertica acts as a Kafka producer when using either the KafkaExport function or through notifiers. How you change these settings depends on the method you are using to export data (KafkaExport or Notifiers).

<table>
<thead>
<tr>
<th>Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>queue.buffering.max.messages</td>
<td>Specifies the size of the Vertica producer queue. If Vertica generates too many messages too quickly, the</td>
</tr>
<tr>
<td>Setting</td>
<td>Notes</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>queue can fill, resulting in dropped messages. Increasing this value consumes more memory, but reduces the chance of lost messages.</td>
<td></td>
</tr>
<tr>
<td>queue.buffering.max.ms</td>
<td>Specifies the frequency with which Vertica flushes the producer message queue. Lower values decrease latency at the cost of throughput. Higher values increase throughput, but can cause the producer queue (set by queue.buffering.max.messages) to fill more frequently, resulting in dropped messages.</td>
</tr>
<tr>
<td>message.max.bytes</td>
<td>Specifies the maximum size of a Kafka protocol request message batch. This values should be the same on your sources, brokers, and producers.</td>
</tr>
<tr>
<td>message.send.max.retries</td>
<td>Specifies the number of attempts the producer makes to deliver the message to a broker. Higher values increase the chance of success.</td>
</tr>
<tr>
<td>retry.backoff.ms</td>
<td>Specifies the interval Vertica waits before resending a failed message.</td>
</tr>
<tr>
<td>request.required.acks</td>
<td>Specifies how many broker replica acknowledgments Kafka requires before it considers message delivery successful. Requiring acknowledgments increases latency. Removing acknowledgments increases the risk of message loss.</td>
</tr>
<tr>
<td>request.timeout.ms</td>
<td>Specifies the interval that the producer waits for a response from the broker. Broker response time is affected by server load and the number of message acknowledgments you require. Higher values increase latency.</td>
</tr>
</tbody>
</table>

**Kafka Broker Settings**

Kafka brokers receive messages from producers and distribute them among Kafka consumers. Configure these settings on the brokers themselves. These settings function
independently of your producer and consumer settings. For detailed information on Apache Kafka broker settings, refer to the [Apache Kafka documentation](#).

<table>
<thead>
<tr>
<th>Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>message.max.bytes</td>
<td>Specifies the maximum size of a Kafka protocol request message batch. This values should be the same on your sources, brokers, and producers.</td>
</tr>
<tr>
<td>num.io.threads</td>
<td>Specifies the number of network threads the broker uses to receive and process requests. More threads can increase your concurrency.</td>
</tr>
<tr>
<td>num.network.threads</td>
<td>Specifies the number of network threads the broker uses to accept network requests. More threads can increase your concurrency.</td>
</tr>
</tbody>
</table>

### Vertica Consumer Settings

The following settings changes how Vertica acts when it consumes data from Kafka. You can set this value using the `kafka_conf` parameter on the KafkaSource UDL when directly executing a COPY statement. For schedulers, use the `--message_max_bytes` settings in the [scheduler tool](#).

<table>
<thead>
<tr>
<th>Setting</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>message.max.bytes</td>
<td>Specifies the maximum size of a Kafka protocol request message batch. Set this value to a high enough value to prevent the overhead of fetching batches of messages interfering with loading data. Defaults to 24MB for newly-created load specs.</td>
</tr>
</tbody>
</table>

**Important:**
The meaning of this setting changed between Kafka version 0.10 and 0.11. If you have a scheduler you created using Vertica version 9.1.0 or earlier, see [Changes to the message.max.bytes Setting in Kafka Version 0.11 and Later](#) for settings you may need to change.
Directly Setting Kafka Library Options

Vertica relies on the open source rdkafka library to communicate with Apache Kafka. This library contains many options for controlling how Vertica and Kafka interact. You set the most common rdkafka library options through the settings in the vkconfig utility and the Kafka integration functions such as KafkaSource.

There are some rdkafka settings that cannot be directly set from within the Vertica. Under normal circumstances, you do not need to change them. However, if you find that you need to set a specific rdkafka setting that is not directly available from Vertica, you can directly pass options to the rdkafka library through the kafka_conf options.

The kafka_conf argument is supported when using a scheduler to load data from Kafka. You can set the values in the following ways (listed in order of lower to higher precedence):

- The Linux environment variable VERTICA_RDKAFKA_CONF set on the host where you run the vkconfig utility.
- The Linux environment variable VERTICA_RDKAFKA_CONF_KAFKA_CLUSTER set on the host where you run the vkconfig utility. The KAFKA_CLUSTER portion of the variable name is the name of a Kafka cluster you have defined using vkconfig's cluster_utility. The settings in this environment variable only affect the specific Kafka cluster you name in KAFKA_CLUSTER.
- The --kafka_conf option of the vkconfig utility. This option can be set in the cluster, source, launch, and sync tools. Note that the setting only applies to each vkconfig utility call—it does not carry over to other vkconfig utility calls. For example, if you need to supply an option to the cluster and source tool, you must supply the kafka_conf option to both of them.

**Note:**

Using an environment variable to set your rdkafka options helps to keep your settings consistent. It is easy to forget to set the --kafka_conf option for each call to the vkconfig script.

All of these options cascade, so setting an option using the --kafka_conf argument to the cluster tool overrides the same option that was set in the environment variables.

You can also directly set rdkafka options when directly calling KafkaExport, KafkaSource, and several other Kafka integration functions. These functions accept a parameter named kafka_conf.
The kafka_conf Option Settings

The format for the kafka_conf setting is an option name, an equal sign, and a value. You can supply multiple options by separating them with a semicolon. For example, the --kafka_conf option to the vkconfig utility looks like this:

```
--kafka_conf 'option1=value1;option2=value2'
```

See the [rdkafka project on github](https://github.com/edenosystems/rdkafka) for a list of the configuration options supported by the rdkafka library.

Important:
Arbitrarily setting options via kafka_conf can result in errors or unpredictable behavior. If you encounter a problem loading messages after setting an rdkafka option using the kafka_conf option, roll back your change to see if that was the source of the problem. To prevent confusion, never set options via the kafka_conf parameter that can be set directly through scheduler options. For example, do not use the kafka_conf option to set Kafka's message.max.bytes setting. Instead, use the load-spec tool's --message-max-bytes option.

Example

The following example demonstrates disabling rdkafka's api.version.request option when manually loading messages using KafkaSource. You should always disable this option when accessing Kafka cluster running version 0.9 or earlier. See Configuring Vertica for Apache Kafka Version 0.9 and Earlier for more information.

```
=> CREATE FLEX TABLE iot_data();
CREATE TABLE
=> COPY public.iot_data SOURCE KafkaSource(stream='iot_json|0|-2',
    brokers='kafka-01.example.com:9092',
    stop_on_eof=True,
    kafka_conf='api.version.request=false')
PARSER KafkaJSONParser();
Rows Loaded
-------------
5000
(1 row)
```
This example demonstrates setting two options when calling the cluster tool. It disables the `api.version.request` option and enables CRC checks of messages from Kafka using the `check.crcs` option:

```
$ vkconfig cluster --create --cluster StreamCluster1 \
    --hosts kafka01.example.com:9092,kafka02.example.com:9092 \
    --conf myscheduler.config \
    --kafka_conf 'api.version.request=false;check.crcs=true'
```

The following example demonstrates setting the same options using an environment variable:

```
$ export VERTICA_RDKAFKA_CONF=api.version.request=false;check.crcs=true
$ vkconfig cluster --create --cluster StreamCluster1 \
    --hosts kafka01.example.com:9092,kafka02.example.com:9092 \
    --conf myscheduler.config
```

**Important:**
Setting the `check.crcs` option is just an example. Vertica does not suggest you enable the CRC check in your schedulers under normal circumstances. It adds additional overhead and can result in slower performance.

### Configuring Vertica for Apache Kafka Version 0.9 and Earlier

Apache Kafka version 0.10 introduced a new feature that allows consumers to determine which version of the Kafka API the Kafka brokers support. Consumers that support this feature send an initial API version query to the Kafka broker to determine the API version to use when communicating with them. Kafka brokers running version 0.9.0 or earlier cannot respond to the API query. If the consumer does not receive a reply from the Kafka broker within a timeout period (set to 10 seconds by default) the consumer can assume the Kafka broker is running Kafka version 0.9.0 or earlier.

The Vertica integration with Kafka supports this API query feature starting in version 9.1.1. This API check can cause problems if you are connecting Vertica to a Kafka cluster running 0.9.0 or earlier. You may notice poorer performance loading messages from Kafka and may experience errors as the 10 second API request timeout can cause parts of the Kafka integration feature to time out and report errors.

For example, if you run the `vkconfig source` utility to configure a source on a Kafka 0.9 cluster, you may get the following error:
Disabling the API Version Request When Using the Streaming Job Scheduler

To avoid these problems, you must disable the API version request feature in the rdkafka library that Vertica uses to communicate with Kafka. The easiest way to disable this setting when using the scheduler is to set a Linux environment variable on the host on which you run the vkconfig script. Using the environment variable ensures that each call to vkconfig includes the setting to disable the API version request. The vkconfig script checks two variables:

- **VERTICA_RDKAFKA_CONF** applies to all Kafka clusters that the scheduler running on the host communicates with.
- **VERTICA_RDKAFKA_CONF_CLUSTER_NAME** applies to just the Kafka cluster named **CLUSTER_NAME**. Use this variable if your scheduler communicates with several Kafka clusters, some of which are not running version 0.9 or earlier.

If you set both variables, the cluster-specific one takes precedence. This feature is useful if most of the clusters your scheduler connects to are running Kafka 0.9 or earlier, but a few run 0.10 or later. This case, you can disable the API version check for most clusters using the **VERTICA_RDKAFKA_CONF** variable and re-enable the check for specific clusters using **VERTICA_RDKAFKA_CONF_CLUSTER_NAME**.
If just a few of your Kafka clusters run version 0.9 or earlier, you can just set the cluster-specific variables for them, and leave the default values in place for the majority of your clusters.

The content of the environment variable is the setting to tell the rdkafka library to not to query the Kafka cluster for the API version it supports:

```
api.version.request=false
```

To set the environment variable in BASH, use the export command:

```
$ export VERTICA_RDKAFKA_CONF=api.version.request=false
```

If you wanted the setting to just affect a cluster named kafka_weblog, the command is:

```
$ export VERTICA_RDKAFKA_CONF_kafka_weblog=api.version.request=false
```

You can add the command to any of the common user environment configuration files such as `~/.bash_profile` or the system-wide files such as `/etc/profile`. You must ensure that the same setting is used for all users who may run the vkconfig script, including any calls made by daemon processes such as `init`. You can also directly include this command in any script you use to set configure or start your scheduler.

**Disabling the API Version Request When Directly Loading Messages**

You can disable the API request when you directly call KafkaSource to load messages by using the `kafka_conf` parameter:

```sql
=> CREATE FLEX TABLE iot_data();
CREATE TABLE
=> COPY public.iot_data SOURCE KafkaSource(stream='iot_json|0|-2',
                                           brokers='kafka-01.example.com:9092',
                                           stop_on_eof=True,
                                           kafka_conf='api.version.request=false')
PARSER KafkaJSONParser();
Rows Loaded
----------
  5000
(1 row)
```
Changes to the message.max.bytes Setting in Kafka Version 0.11 and Later

In Kafka version 0.10 and earlier, the message.max.bytes setting configured the maximum allowable size for an individual message. Starting in version 0.11, Kafka began grouping messages into batches. This version changed the meaning of this setting to be the largest allowable size of a message batch.

This change can have a significant impact on how fast your Vertica database loads messages from Kafka 0.11 and later. If you created your streaming job scheduler using Vertica version 9.1.0 or earlier, you may find that its load spec's message.max.bytes value is set too low. Upgrading your scheduler does not automatically adjust this setting.

To prevent slow throughput when using Vertica with Kafka 0.11 and later, manually adjust the message.max.bytes setting in scheduler's load spec. Testing by Vertica suggests the best value for this setting is 25165824 (24 × 1024 × 1024) bytes.

The following example demonstrates updating the message.max.bytes setting in the load spec named weblog_load of an existing scheduler that is defined using the configuration file named weblog.conf:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update \
   --load-spec weblog_load --conf weblog.conf --message-max-bytes 25165824
```

Manually Copying Data From Kafka

You can manually stream data from Kafka into Vertica using a COPY statement. This technique is similar to copying data from other sources, such as the local file system, a client system, or from Apache Hadoop. See Bulk-Loading Data and the COPY statement reference for more information about using the COPY statement.
Manually copying data from Kafka is useful when you have a specific set of messages that you want to analyze. It is also useful when you want to explore the data in a Kafka stream before setting up a scheduler to continuously stream the data into Vertica.

Manually copying data from Kafka also gives you more control over the data load than using a scheduler. For example, suppose you want to perform business logic or custom rejection handling during the data load from Kafka. The scheduler does not support performing additional processing during its transactions. Instead, you may choose to periodically run a transaction that executes a COPY statement to load data from Kafka and then perform additional processing.

Unlike other copy methods, copying from Kafka usually implies your COPY statement loads data for a set period of time, rather than loading all of the data from a file or other source. For example, you can choose to COPY all of the messages sent to a Kafka topic for one minute. Vertica copies just the data streamed during that one minute period. After the duration is up, the COPY statement ends and Vertica does not load any further data.

**Important:**
The durations you set for your data load is not exact. The duration actually controls how long the KafkaSource process runs. The actual COPY statement may run for a shorter period of time.

If you start a long-duration COPY statement from Kafka and need to stop it, you can call one of the functions that closes its session, such as `CLOSE_ALL_SESSIONS`.

You can also choose specific ranges of messages to load from a topic using offsets. Kafka stores a backlog of messages for topics. How long it stores these messages is configured by the Kafka administrator. Copying using offsets lets you load this previously sent data. You can even choose to load all of the messages that Kafka has stored for a topic and also load the messages sent over a period of time.

When copying data from Kafka, the source of your COPY statement is always `KafkaSource`. Your COPY statement usually uses one of three parsers: `KafkaParser`, `KafkaJSONParser`, or `KafkaAvroParser`. The other parsers (such as the Flex FCSVPARSER) are not directly compatible with the output of KafkaSource. You must alter KafkaSource’s output using filters before other parsers can process the data. See Parsing Custom Formats for more information.

This example demonstrates copying data from Kafka into a Vertica table:

```sql
=> COPY public.from_kafka
       SOURCE KafkaSource(stream='iot_data|0|--2,iot_data|1|--2',
                           brokers='kafka01.example.com:9092',
                           duration=interval '10000 milliseconds')
```
**PARSER KafkaAvroParser(schema_registry_url='http://localhost:8081/subjects/iot_data-value/versions/1')**

REJECTED DATA AS TABLE public.rejections
DIRECT NO COMMIT;

In the previous example:

- The data is copied into a table named from_kafka in the public schema.
- The KafkaSource streams data from partitions 0 and 1 of the topic named iot_data.
- The streaming starts from the earliest available message in the stream set by the -2 in the stream offset parameter. This is a special offset value indicating that the load should start from the earliest possible message.
- KafkaSource reads the data from the Kafka broker running on the host named kafka01.example.com on port 9092.
- COPY loads data for 10000 milliseconds (10 seconds). If it loads all of the existing data in the topic in this time, it waits for any streaming data to arrive until the 10 seconds has elapsed.
- The stream is parsed as Avro data.
- The schema that the Avro parser uses to parse the data is retrieved from a schema registry running on the local system.
- Rejected data is saved in a table named public.rejections.

For more information, see the KafkaSource reference topic.

When you use COPY TRICKLE, Vertica recommends enabling the ReflexiveMoveout configuration parameter to trigger a Tuple Mover moveout task every time a commit occurs:

```sql
=> ALTER DATABASE dbname SET ReflexiveMoveout=1;
```

**Note:**

If you are copying data containing default values into a flex table, you must identify the default value column as __raw__. For more information, refer to "Handling Default Values During Loading" in Bulk Loading Data into Flex Tables.

**Manually Loading Kafka Data Example**

This example demonstrates loading JSON-encoded data from a Kafka topic named web_hits that streams server logs of requests from a web site. The messages in the topic look like this:
In order to load this data, you first need a table to receive it. At first glance, the data seems rather uniform, so you could load it into a standard Vertica table. However, as this is JSON data, some messages may have added values that aren't apparent from a small sample. It is safer in this case to load the data into flex table. Flex tables can dynamically accept additional fields that appear in the data. For more information about flex tables, see Using Flex Tables.

The following example creates a flex table named `web_hits` to hold the Kafka data:

```sql
=> CREATE FLEX TABLE web_hits();
```

Before you load data from Kafka, you must determine the values for your call to the KafkaSource UDL based on your Kafka cluster and the topic you are loading:

- What are the host names (or IP addresses) and port numbers of the brokers in your Kafka cluster? The Kafka brokers are the service Vertica accesses in order to retrieve the Kafka data. In this example, the Kafka cluster has a single broker named `kafka01.example.com`, running on port 6667. This value is set in the brokers parameter.
- What topic will you be loading from, and from what partitions in that topic? Kafka topics split their messages into different partitions to get scalable throughput. As mentioned earlier, this example loads data from a topic named `web_hits`. There is a single partition in `web_hits`, so this example uses 0 for the partition. This value is set in the stream parameter.
- What offset within the topic do you want to start loading data? Kafka keeps a backlog of messages. The Kafka administrator sets the length of this backlog. You can choose to load some or all of the messages in the backlog, or just load the currently streamed messages. You can also choose to end loading at a specific offset. This example starts loading data at the earliest possible message. The offset value to load the entire backlog is -2. This value is also set in the stream parameter.
- When should the COPY statement stop loading data? Copying data from Kafka is unlike most other sources (such as files), because streamed data is constantly arriving. You can choose to:
  - copy as much data as possible during a set amount of time.
  - have the COPY statement load data until no new data arrives within a timeout period.
  - load all of the data that is available, and not wait for any further data to arrive.
  - load a specific set of data from a starting offset to an ending offset.
This example has COPY run for 10000 milliseconds (10 seconds) to get a sample of the data. If the COPY statement is able to load the entire backlog of data in under 10 seconds, it will spend the remaining time loading streaming data as it arrives. This values is set in the duration parameter.

- How many threads should Vertica use to load the data from Kafka? Usually, you want to use 1 thread per partition being loaded from the Kafka topic. You can choose to not specify a value and let Vertica determine the number of threads to use based on the number of partitions and the resources available in the resource pool. This value is set in the KafkaSource's executionparallelism parameter. In this example, there is only one partition, so there's no need for additional threads to load data.

**Note:**
The EXECUTIONPARALLELISM setting on the resource pool assigned is the upper limit on the number of threads your COPY statement can use. Setting the executionparallelism parameter on the KafkaSource function call to a value that is higher than that of the resource pool's EXECUTIONPARALLELISM setting does not increase the number of threads Vertica uses beyond the limits of the resource pool.

- What parser do you need to parse the data? Kafka does not enforce any sort of formatting on the messages it sends. They are often in Avro or JSON format. However, they could be in any format. In this example, the data in the web_hits is encoded in JSON format, so it uses the KafkaJSONParser. This value is set in the COPY statement's PARSER clause.
- Where should rejected data be sent? Vertica saves raw Kafka messages that the parser cannot parse to a rejects table along with information on why it was rejected. This table is created by the COPY statement. This example saves rejects to the table named web_hits_rejections. This value is set in the COPY statement's REJECTED DATA AS TABLE clause.

The following statement loads the data using these options:

```sql
=> COPY web_hits SOURCE KafkaSource(
    stream='web_hits|0|-2',
    brokers='kafka01.example.com:6667',
    duration=interval '10000 milliseconds')
   PARSER KafkaJSONParser()
   REJECTED DATA AS TABLE public.web_hits_rejections DIRECT;

Rows Loaded
----------
 20000
(1 row)
=> SELECT compute_flextable_keys('web_hits');
   compute_flextable_keys
```
A few things to note in the example statement:

- The stream parameter combines the name of the topic, the topic partition to load from, and the offset into a list delimited by a pipe character (|). To load from additional partitions in the same topic, or even additional topics, supply a comma separated list of topic name, partition number, and offset values delimited by pipe characters. For example, to load from partitions 0 through 2, your stream argument would be:

  stream='web_hits|0|-2,web_hits|1|-2,web_hits|2|-2'

**Note:**

While you can load messages from different Kafka topics in the same COPY statement, you must ensure the data from the different topics is compatible with the target table's schema. The schema is less of a concern if you are loading data into a flex table, which can accommodate almost any data you want to load.

- The KafkaJSONParser accepts parameters that let you control how JSON data is transformed. See KafkaJSONParser for more information.
Automatically Copying Data From Kafka

Vertica offers a scheduler that loads streamed messages from one or more Kafka topics. Automatically loading streaming data has a number of advantages over manually using COPY:

- The streamed data automatically appears in your database. The frequency with which new data appears in your database is governed by the scheduler's frame duration.
- The scheduler provides an exactly-once consumption process. The schedulers manage offsets for you so that each message sent by Kafka is consumed once.
- You can configure backup schedulers to provide high-availability. Should the primary scheduler fail for some reason, the backup scheduler automatically takes over loading data.
- The scheduler manages resources for the data load. You control its resource usage through the settings on the resource pool you assign to it. When loading manually, you must take into account the resources your load consumes.

There are a few drawbacks to using a scheduler which may make it unsuitable for your needs. You may find that schedulers do not offer the flexibility you need for your load process. For example, schedulers cannot perform business logic during the load transaction. If you need to perform this sort of processing, you are better off creating your own load process. This process would periodically run COPY statements to load data from Kafka. Then it would perform the business logic processing you need before committing the transaction.

For information on job scheduler requirements, refer to Vertica Integration for Apache Kafka.

What the Job Scheduler Does

The scheduler is responsible for scheduling loads of data from Kafka. The scheduler's basic unit of processing is a frame, which is a period of time. Within each frame, the scheduler assigns a slice of time for each active microbatch to run. Each microbatch is responsible for loading data from a single source. Once the frame ends, the scheduler starts the next frame. The scheduler continues this process until you stop it.
The Anatomy of a Scheduler

Each scheduler has several groups of settings, each of which control an aspect of the data load. These groups are:

- The scheduler itself, which defines the configuration schema, frame duration, and resource pool.
- Clusters, which define the hosts in the Kafka cluster that the scheduler contacts to load data. Each scheduler can contain multiple clusters, allowing you to load data from multiple Kafka clusters with a single scheduler.
- Sources, which define the Kafka topics and partitions in those topics to read data from.
- Targets, which define the tables in Vertica that will receive the data. These tables can be traditional Vertica database tables, or they can be flex tables.
- Load specs, which define setting Vertica uses while loading the data. These settings include the parsers and filters Vertica needs to use to load the data. For example, if you are reading a Kafka topic that is in Avro format, your load spec needs to specify the Avro parser.
- Microbatches, which represent an individual segment of a data load from a Kafka stream. They combine the definitions for your cluster, source, target, and load spec that you create using the other vkconfig tools. The scheduler uses all of the information in the microbatch to execute COPY statements using the KafkaSource UDL function to transfer data from Kafka to Vertica. The statistics on each microbatch's load is stored in the stream_microbatch_history table.

The vkconfig Script

You use a Linux command-line script named vkconfig to create, configure, and run schedulers. This script is installed on your Vertica hosts along with the Vertica server in the following path:

/opt/vertica/packages/kafka/bin/vkconfig

Note:
You can install and use the vkconfig utility on a non-Vertica host. You may want to do this if:
You do not want the scheduler to use Vertica host resources.
You want users who do not have shell accounts on the Vertica hosts to be able to set up and alter schedulers.

The easiest way to install vkconfig on a host is to install the Vertica server RPM. You must use the RPM that matches the version of Vertica installed on your database cluster. Do not create a database after installing the RPM. The vkconfig utility and its associated files will be in the /opt/vertica/packages/kafka/bin directory on the host.

The vkconfig script contains multiple tools. The first argument to the vkconfig script is always the tool you want to use. Each tool performs one function, such as changing one group of settings (such as clusters or sources) or starting and stopping the scheduler. For example, to create or configure a scheduler, you use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler other options...
```

**What Happens When You Create a Scheduler**

When you create a new scheduler, the vkconfig script takes the following steps:

- Creates a new Vertica schema using the name you specified for the scheduler. You use this name to identify the scheduler during configuration.
- Creates the tables needed to manage the Kafka data load in the newly-created schema. See Data Streaming Schema Tables for more information.
- Sets the LOCKTIMEOUT session configuration parameter to 0 for the session running the microbatches. When LOCKTIMEOUT is 0, data loads continuously because the scheduler does not have to wait for a lock to be released. If a table is already locked, Vertica cancels the frame and records an error in the events table.
- Creates the kafka_default_pool resource pool if it does not already exist. Schedulers use this resource pool if you do not assign them a pool of their own. Vertica recommends that you always create a resource pool for the exclusive use of your scheduler. See Create a Resource Pool for Your Scheduler for more information.

**Validating Schedulers**

When you create or configure a scheduler, it validates the following settings:
• Confirms that all brokers in the specified cluster exist.
• Connects to the specified host or hosts and retrieves the list of all brokers in the Kafka cluster. Getting this list always ensures that the scheduler has an up-to-date list of all the brokers. If the host is part of a cluster that has already been defined, the scheduler cancels the configuration.
• Confirms that the specified source exists.
• Retrieves the number of partitions in the source. If no number of partitions is specified, Vertica sets the value to the number of partitions the source has in the cluster.

You can disable validation using the \(--\text{validation-type}\) option in the \(\text{vkconfig}\) script's scheduler tool. See \(\text{Scheduler Tool Options}\) for more information.

**Synchronizing Schedulers**

By default, the scheduler automatically synchronizes its configuration and source information with Kafka host clusters. You can configure the synchronization interval using the \(--\text{config-refresh}\) scheduler utility option. Each interval, the scheduler:

• Checks for updates to the scheduler's configuration by querying its settings in its Vertica configuration schema.
• Performs all of the checks listed in \(\text{Validating Schedulers}\).

You can configure synchronization settings using the \(--\text{auto-sync}\) option using the \(\text{vkconfig}\) script's scheduler tool. \(\text{Scheduler Tool Options}\) for details.

**Launching a Scheduler**

You use the \(\text{vkconfig}\) script's launch tool to launch a scheduler.

When you launch a scheduler, it collects data from your sources, starting at the specified offset. You can view the \(\text{stream\_microbatch\_history}\) table to see what the scheduler is doing at any given time.

To learn how to create, configure, and launch a scheduler, see \(\text{Setting up a Scheduler}\) in this guide.
You can also choose to bypass the scheduler. For example, you might want to do a single load with a specific range of offsets. For more information, see Manually Copying Data From Kafka in this guide.

Managing a Running Scheduler

When you launch a scheduler from the command line, it runs in the foreground. It will run until you kill it (or the host shuts down). Usually, you want to start the scheduler as a daemon process that starts it when the host operating system starts, or after the Vertica database has started.

You shut down a running scheduler using the vkconfig script's shutdown tool. See Shutdown Tool Options for details.

You can change most of a scheduler's settings (adding or altering clusters, sources, targets, and microbatches for example) while it is running. The scheduler automatically acts on the configuration updates.

Launching Multiple Job Schedulers for High Availability

For high availability, you can launch two or more identical schedulers that target the same configuration schema. You differentiate the schedulers using the launch tool's --instance-name option (see Launch Tool Options). The scheduler not in use remains in stand-by mode until the active scheduler fails or is disabled. If the active scheduler fails, the backup scheduler takes over loading data from Kafka where the primary left off.

Passing Options to the Scheduler's JVM

The scheduler uses a Java Virtual Machine to connect to Vertica via JDBC. You can pass command-line options to the JVM through a Linux environment variable named VKCONFIG_JVM_OPTS. This option is useful when configuring a scheduler to use TLS/SSL encryption when connecting to Vertica. See Configuring Your Scheduler for TLS/SSL Connections for more information.
Viewing Schedulers from the MC

You can view the status of Kafka jobs from the MC. For more information, refer to Viewing Load History.

Setting up a Scheduler

You set up a scheduler using the Linux command line. Usually you perform the configuration on the host where you want your scheduler to run. It can be one of your Vertica hosts, or a separate host where you have installed the vkconfig utility (see The vkconfig Script for more information).

Follow these steps to set up and start a scheduler to stream data from Kafka to Vertica:

1. Create a Config File (Optional)
2. Add the vkconfig Directory to Your Path (Optional)
3. Create a Resource Pool for Your Scheduler
4. Create the Scheduler
5. Create a Cluster
6. Create a Data Table
7. Create a Source
8. Create a Target
9. Create a Load-Spec
10. Create a Microbatch
11. Launch the Scheduler

These steps are explained in the following sections. These sections will use the example of loading web log data (hits on a web site) from Kafka into a Vertica table.

Create a Config File (Optional)

Many of the arguments you supply to the vkconfig script while creating a scheduler do not change. For example, you often need to pass a username and password to Vertica to authorize the changes to be made in the database. Adding the username and password to each call to vkconfig is tedious and error-prone.
Instead, you can pass the vkconfig utility a configuration file using the \texttt{-\ -conf} option that specifies these arguments for you. It can save you a lot of typing and frustration.

The config file is a text file with a \texttt{keyword=value} pair on each line. Each keyword is a vkconfig command-line option, such as the ones listed in Common vkconfig Script Options

The following example shows a config file named weblog.conf that will be used to define a scheduler named weblog\_sched. This config file is used throughout the rest of this example.

```
# The configuraton options for the weblog\_sched scheduler.
username=dbadmin
password=mypassword
dbhost=vertica01.example.com
dbport=5433
config\_schema=weblog\_sched
```

**Add the vkconfig Directory to Your Path (Optional)**

The vkconfig script is located in the \texttt{/opt/vertica/packages/kafka/bin} directory. Typing this path for each call to vkconfig is tedious. You can add vkconfig to your search path for your current Linux session using the following command:

```
$ export PATH=/opt/vertica/packages/kafka/bin:$PATH
```

For the rest of your session, you are able to call vkconfig without specifying its entire path:

```
$ vkconfig
Invalid tool
Valid options are scheduler, cluster, source, target, load-spec, microbatch, sync, launch, shutdown, help
```

If you want to make this setting permanent, add the export statement to your \texttt{~/.profile} file. The rest of this example assumes that you have added this directory to your shell's search path.

**Create a Resource Pool for Your Scheduler**

Vertica recommends you always create a resource pool specifically for your scheduler. Schedulers assume they have exclusive use of the resource pool they are assigned. Using a separate pool for a scheduler lets you fine-tune its impact on your Vertica cluster's performance. You create resource pools within Vertica using the \texttt{CREATE RESOURCE POOL} statement.
One key setting in the resource pool for a scheduler is `PLANNEDCONCURRENCY`. This value tells Vertica how many simultaneous tasks (such as loads) will be using the resource pool. This value allows the scheduler to load from each topic simultaneously. This setting controls the number of simultaneous COPY statements the scheduler runs during each microbatch. Set this value to at least the number of topics the scheduler is reading data from. Setting it slightly higher than the number of topics is a good practice. The higher `PLANNEDCONCURRENCY` allocates resources for the scheduler's own internal processes, preventing them from impacting the data load.

Another important setting is the pool's `EXECUTIONPARALLELISM` which controls the number of threads that Vertica uses to load data from the topic. Ideally, you set this value to reflect the number of partitions within the topic. Often, a topic has too many partitions to assign a thread to each one. In these cases, you should set the `EXECUTIONPARALLELISM` to a value so the threads have an equal number of partitions to read from. For example, suppose the topic your scheduler is reading from has 100 partitions. Then you could set `EXECUTIONPARALLELISM` to 10, so that each thread will be reading from 10 partitions.

Finally, set the `QUEUETIMEOUT` parameter to 0. A value of 0 allows data to load continuously. If the scheduler has to wait for resources, it cannot progress, compromising scheduling configurations. By exclusively allocating a resource pool for your scheduler, you do not have to worry about it oversubscribing and causing queuing.

Leave reflexive moveout enabled. This option is on automatically when you create a scheduler. With reflexive moveout turned on, the Tuple Mover automatically performs a moveout operation when data is committed so that your WOS always has space to load data. For large volumes of data (>100 MB) use a load method of DIRECT. Not allocating enough resources to your schedulers can result in errors. For example, you may get `OVERSHOT DEADLINE FOR FRAME` errors if the scheduler is not able to load data from all of the topics it is supposed to in a data frame.

If you do not create and assign a resource pool for your scheduler, it will use the default resource pool named `kafka_default_pool`.

See Resource Pool Architecture for more information about resource pools.

**Create the Scheduler**

Vertica includes a default scheduler named `stream_config`. You can use this scheduler or create a new scheduler using the `vkconfig` script's `scheduler tool` with the `--create` and `--config-schema` options:
$ vkconfig scheduler --create --config-schema scheduler_name --conf conf_file

The --create and --config-schema options are the only ones required to add a scheduler with default options. This command creates a new schema in Vertica that holds the scheduler's configuration. See What Happens When You Create a Scheduler for details on the creation of the scheduler's schema.

You can use additional configuration parameters to further customize your scheduler. See Scheduler Tool Options for more information.

The following example:

- Creates a scheduler named weblog_sched using the --config-schema option.
- Grants privileges to configure and run the scheduler to the Vertica user named kafka_user with the --operator option. The dbadmin user must specify additional privileges separately.
- Specifies a frame duration of thirty seconds with the --frame-duration option.
- Sets the resource pool that the scheduler uses to the weblog_pool created earlier:

$ vkconfig scheduler --create --config-schema weblog_sched --operator kafka_user \--frame-duration '00:00:30' --resource-pool weblog_pool --conf weblog.conf

**Note:**
Technically, the previous example doesn't need to supply the --config-schema argument because it is set in the weblog.conf file. It appears in this example for clarity. There's no harm in supplying it on the command line as well as in the configuration file, as long as the values match. If they do not match, the value given on the command line takes priority.

**Create a Cluster**

You must associate at least one Kafka cluster with your scheduler. Schedulers can access more than one Kafka cluster. To create a cluster, you supply a name for the cluster and host names and ports the Kafka cluster's brokers.

When validating your settings, the scheduler connects to the cluster and automatically retrieves the list of all brokers in the cluster. Therefore, you do not have to list every single broker in the --hosts parameter.

The following example creates a cluster named kafka_weblog, with two Kafka broker hosts: kafka01 and kafka03 in the example.com domain. The Kafka brokers are running on port 9092.
$ vkconfig cluster --create --cluster kafka_weblog \
  --hosts kafka01.example.com:9092,kafka03.example.com:9092 --conf weblog.conf

See Cluster Tool Options for more information.

Create a Source

Next, create at least one source for your scheduler to read. The source defines the Kafka topic the scheduler loads data from as well as the number of partitions the topic contains.

To create and associate a source with a configured scheduler, use the source tool. When you create a source, Vertica connects to the Kafka cluster to verify that the topic exists. So, before you create the source, make sure that the topic already exists in your Kafka cluster. Because Vertica verifies the existence of the topic, you must supply the previously-defined cluster name using the --cluster option.

The following example creates a source for the Kafka topic named web_hits on the cluster created in the previous step. This topic has a single partition.

$ vkconfig source --create --cluster kafka_weblog --source web_hits --partitions 1 --conf weblog.conf

**Note:**
The --partitions parameter is the number of partitions to load, not a list of individual partitions. For example, if you set this parameter to 3, the scheduler will load data from partitions 0, 1, 2, and 3.

See Source Tool Options for more information.

Create a Data Table

Before you can create a target for your scheduler, you must create a target table in your Vertica database. This is the table Vertica uses to store the data the scheduler loads from Kafka. You must decide which type of table to create for your target:

- A standard Vertica database table, which you create using the CREATE TABLE statement. This type of table stores data efficiently. However, you must ensure that its columns match the data format of the messages in Kafka topic you are loading. You cannot load complex types of data into a standard Vertica table.
- A flex table, which you create using CREATE FLEXIBLE TABLE. A flex table is less efficient than a standard Vertica database table. However, it is flexible enough to deal
with data whose schema varies and changes. It also can load most complex data types that (such as maps and lists) that standard Vertica tables cannot.

**Important:**
Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before it is loaded by the scheduler.

The data in this example is in a set format, so the best table to use is a standard Vertica table. The following example creates a table named `web_hits` to hold four columns of data. This table is located in the public schema.

```
=> CREATE TABLE web_hits (ip VARCHAR(16), url VARCHAR(256), date DATETIME, user_agent VARCHAR(1024));
```

**Note:**
You do not need to create a rejection table to store rejected messages. The scheduler creates the rejection table automatically.

### Create a Target

Once you have created your target table, you can create your scheduler's target. The target tells your scheduler where to store the data it retrieves from Kafka. This table must exist when you create your target. You use the `vkconfig` script's `target` tool with the `--target-schema` and `--target-table` options to specify the Vertica target table's schema and name. The following example adds a target for the table created in the previous step.

```
$ vkconfig target --create --target-schema public --target-table web_hits --conf weblog.conf
```

See [Target Tool Options](#) for more information.

### Create a Load Spec

The scheduler's load spec provides parameters that Vertica uses when parsing the data loaded from Kafka. The most important option is `--parser` which sets the parser that Vertica uses to parse the data. You have three parser options:
• **KafkaAvroParser** for data in Avro format.
• **KafkaJSONParser** for data in JSON format.
• **KafkaParser** to load each message into a single VARCHAR field. See Parsing Custom Formats for more information.

In this example, the data being loaded from Kafka is in JSON format. The following command creates a load spec named **weblog_load** and sets the parser to KafkaJSONParser.

```bash
$ vkconfig load-spec --create --parser KafkaJSONParser --load-spec weblog_load --conf weblog.conf
```

See Load Spec Tool Options for more information.

### Create a Microbatch

The microbatch combines all of the settings added to the scheduler so far to define the individual COPY statements that the scheduler uses to load data from Kafka.

The following example uses all of the settings created in the previous examples to create a microbatch called **weblog**.

```bash
$ vkconfig microbatch --create --microbatch weblog --target-schema public --target-table web_hits \
    --add-source web_hits --add-source-cluster kafka_weblog --load-spec weblog_load \
    --conf weblog.conf
```

See Microbatch Tool Options for more information.

### Launch the Scheduler

Once you've created at least one microbatch, you can run your scheduler. You start your scheduler using the launch tool, passing it the name of the scheduler's schema. The scheduler begins scheduling microbatch loads for every enabled microbatch defined in its schema.

The following example launches the **weblog** scheduler defined in the previous steps.

```bash
$ vkconfig launch --conf weblog.conf &
```

**Important:**

Vertica does not recommend specifying a password on the command line. Passwords on the command line can be exposed by the system's list of...
processes, which shows the command line for each process. Instead, put the password in a configuration file. Make sure the configuration file's permissions only allow it to be read by the user.

See Launch Tool Options for more information.

Checking that the Scheduler is Running

Once you have launched your scheduler, you can verify that it is running by querying the stream_microbatch_history table in the scheduler's schema. This table lists the results of each microbatch the scheduler has run.

For example, this query lists the microbatch name, the start and end times of the microbatch, the start and end offset of the batch, and why the batch ended. The results are ordered to start from when the scheduler was launched:

```
=> SELECT microbatch, batch_start, batch_end, start_offset, 
    end_offset, end_reason 
    FROM weblog_sched.stream_microbatch_history 
    ORDER BY batch_start DESC LIMIT 10;
```

```

Limiting Loads Using Offsets

Kafka maintains a user-configurable backlog of messages. By default, a newly-created scheduler reads all of the messages in a Kafka topic, including all of the messages in the backlog, not just the messages that are streamed out after the scheduler starts. Often, this is what you want.

In some cases, however, you may want to stream just a section of a source into a table. For example, suppose you want to analyze the web traffic of your e-commerce site starting at specific date and time. However, your Kafka topic contains web access records from much further back in time than you want to analyze. In this case, you can use an offset to stream just the data you want into Vertica for analysis.

Another common use case is when you have already loaded data some from Kafka manually (see ManuallyCopying Data From Kafka). Now you want to stream all of the newly-arriving data. By default, your scheduler will reload all of the previously loaded data (assuming it is still available from Kafka). You can use an offset to tell your scheduler to start automatically loading data at the point where your manual data load left off.

Configuring a Scheduler to Start Streaming From an Offset

The vkconfig script's microbatch tool has an --offset option that lets you specify the index of the message in the source where you want the scheduler to begin loading. This option accepts a comma-separated list of index values. You must supply one index value for each partition in the source unless you use the --partition option. This option lets you choose the partitions the offsets apply to. The scheduler cannot be running when you set an offset in the microbatch.

If your microbatch defines more than one cluster, use the --cluster option to select which one the offset option applies to. Similarly, if your microbatch has more than one source, you must select one using the --source option.

For example, suppose you want to load just the last 1000 messages from a source named web_hits. To make things easy, suppose the source contains just a single partition, and the microbatch defines just a single cluster and single topic.
Your first task is to determine the current offset of the end of the stream. You can do this on one of the Kafka nodes by calling the GetOffsetShell class with the time parameter set to -1 (the end of the topic):

```bash
$ path to kafka/bin/kafka-run-class.sh kafka.tools.GetOffsetShell \   --broker-list kafka01:9092,kafka03:9092 --time -1 \   --topic web_hits

{metadata.broker.list=kafka01:9092,kafka03:9092, request.timeout.ms=1000, client.id=GetOffsetShell, security.protocol=PLAINTEXT}
web_hits:0:8932
```

You can also use GetOffsetShell to find the offset in the stream that occurs before a timestamp.

In the above example, the web_hits topic's single partition has an ending offset of 8932. If we want to load the last 1000 messages from the source, we need to set the microbatch's offset to 8932 - 1001 or 7931.

**Note:**

The start of an offset is inclusive in the Vertica COPY statement. Kafka's native starting offset is exclusive. Therefore, you must add one to the offset to get the correct number of messages.

With the offset calculated, you are ready to set it in the microbatch's configuration. The following example:

- Shuts down the scheduler whose configuration information stored in the weblog.conf file.
- Sets the starting offset using the microbatch utility.
- Restarts the scheduler.

```bash
$ vkconfig shutdown --conf weblog.conf
$ vkconfig microbatch --microbatch weblog --update --conf weblog.conf --offset 7931
$ vkconfig launch --conf weblog.conf &
```

If the target table was empty or truncated before the scheduler started, it will have 1000 rows in the table in it (until more messages are streamed through the source):

```sql
=> select count(*) from web_hits;
   count
  -------
   1000
(1 row)
```

**Note:**

The last example assumes that the offset values for the last 1000 messages
in the Kafka topic were assigned consecutively. This assumption is not always be true. A Kafka topic can have gaps in its offset numbering for a variety of reasons. Offsets refer to the key value assigned to a message by Kafka, not its position in the topic.

**Ending a COPY From Kafka at an Offset**

When you manually copy data from a Kafka source into Vertica, the COPY statement defaults to loading all of the messages in the topic. You can specify a maximum offset the COPY should load to by supplying an end offset value in addition to the starting offset in the KafkaSource's source parameter.

**Updating Schedulers After Vertica Upgrades**

A scheduler is only compatible with the version of Vertica that created it. Between Vertica versions, the scheduler's configuration schema or the UDx function the scheduler calls may change. After you upgrade Vertica, you must update your schedulers to account for these changes.

When you upgrade Vertica to a new major version or service pack, use the `vkconfig` scheduler tool's `-upgrade` option to update your scheduler. If you do not update a scheduler, you receive an error message if you try to launch it. For example:

```
$ vkconfig launch --conf weblog.conf
com.vertica.solutions.kafka.exception.FatalException: Configured scheduler schema and current scheduler configuration schema version do not match. Upgrade configuration by running:
  vkconfig scheduler --upgrade
    at com.vertica.solutions.kafka.scheduler.StreamCoordinator.assertVersion(StreamCoordinator.java:54)
    at com.vertica.solutions.kafka.scheduler.StreamCoordinator.run(StreamCoordinator.java:125)
    at com.vertica.solutions.kafka.Launcher.run(Launcher.java:285)
    at com.vertica.solutions.kafka.Launcher.main(Launcher.java:258)
$ vkconfig scheduler --upgrade --conf weblog.conf
Checking if UPGRADE necessary...
UPGRADE required, running UPGRADE...
UPGRADE completed successfully, now the scheduler configuration schema version is v8.1.1
$ vkconfig launch --conf weblog.conf
  ...
```
Vertica Eon Mode and Kafka

You can use the Vertica integration with Apache Kafka when Vertica is running in Eon Mode. See Using Eon Mode for more information about Eon Mode.

There are differences between Vertica running in Eon Mode verses Enterprise Mode that you must take into account when streaming data from Kafka to Vertica:

- In Eon Mode, Vertica does not have a **WOS** to temporarily store the data it is loading. Not having a WOS means that using the **COPY** statement to load data from **KafkaSource** always uses **DIRECT** mode, even if you specify a **TRICKLE** load. Similarly, telling the scheduler to use TRICKLE loads (which is its default behavior) has no effect. It always loads data using DIRECT mode.
- Consider using a larger frame duration for your schedulers in Eon Mode clusters. Cloud infrastructures lead to larger latencies overall, especially when storage layers are separated from compute layers. If you leave the scheduler's frame size at the default 10 seconds, you will experience a lower data throughput, as more of the frame's time is lost to overhead caused by the cloud environment. Using a longer frame length can also help prevent Vertica from creating many small ROS containers when loading data from Kafka. The trade off when you use a larger frame length is that your data load experiences more latency.

Monitoring Message Consumption

You can monitor the progress of your data streaming from Kafka several ways:

- Monitoring the consumer groups to which Vertica reports its progress. This technique is best if the tools you want to use to monitor your data load work with Kafka.
- Use the monitoring APIs built into the vkconfig tool. These APIs report the configuration and consumption of your streaming scheduler in JSON format. These APIs are useful if you are developing your own monitoring scripts, or your monitoring tools can consume status information in JSON format.
Monitoring Vertica Message Consumption with Consumer Groups

Apache Kafka has a feature named consumer groups that helps distribute message consumption loads across sets of consumers. When using consumer groups, Kafka evenly divides up messages based on the number of consumers in the group. Consumers report back to the Kafka broker which messages it read successfully. This reporting helps Kafka to manage message offsets in the topic's partitions, so that no consumer in the group is sent the same message twice.

Vertica does not rely on Kafka's consumer groups to manage load distribution or preventing duplicate loads of messages. The streaming job scheduler manages topic partition offsets on its own.

Even though Vertica does not need consumer groups to manage offsets, it does report back to the Kafka brokers which messages it consumed. This feature lets you use third-party tools to monitor the Vertica cluster's progress as it loads messages. By default, Vertica reports its progress to a consumer group named vertica-\textit{databaseName}, where \textit{databaseName} is the name of the Vertica database. You can change the name of the consumer group that Vertica reports its progress to when defining a scheduler or during manual loads of data. Third party tools can query the Kafka brokers to monitor the Vertica cluster's progress when loading data.

For example, you can use Kafka's kafka-consumer-groups.sh script (located in the bin directory of your Kafka installation) to view the status of the Vertica consumer group. The following example demonstrates listing the consumer groups available defined in the Kafka cluster and showing the details of the Vertica consumer group:

```
$ cd /opt/kafka/bin
$ ./kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

vertica-vmart
$ ./kafka-consumer-groups.sh --describe --group vertica-vmart \
   --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-vmart' has no active members.

<table>
<thead>
<tr>
<th>TOPIC</th>
<th>PARTITION</th>
<th>CURRENT-OFFSET</th>
<th>LOG-END-OFFSET</th>
<th>LAG</th>
<th>CONSUMER-ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>web_hits</td>
<td>0</td>
<td>24500</td>
<td>30000</td>
<td>5500</td>
<td>-</td>
</tr>
</tbody>
</table>
```

Note: This will not show information about old Zookeeper-based consumers.
From the output, you can see that Vertica reports its consumption of messages back to the vertica-vmart consumer group. This group is the default consumer group when Vertica has the example VMart database loaded. The second command lists the topics being consumed by the vertica-vmart consumer group. You can see that the Vertica cluster has read 24500 of the 30000 messages in the topic's only partition. Later, running the same command will show the Vertica cluster's progress:

```
$ cd /opt/kafka/bin
$ ./kafka-consumer-groups.sh --describe --group vertica-vmart \
   --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-vmart' has no active members.
```

### TOPIC PARTITION CURRENT-OFFSET LOG-END-OFFSET LAG CONSUMER-ID

</tr>
</tbody>
</table>

## Changing the Consumer Group Where Vertica Reports its Progress

You can change the consumer group to which Vertica reports its progress when consuming messages. When using a scheduler, you set the consumer group by setting the `-consumer-group-id` argument to the `vkconfig` script's `scheduler` or `microbatch` utilities. For example, suppose you want the example scheduler shown in Setting up a Scheduler to report its consumption to the consumer group name vertica-database. Then you could use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --update \ 
   --conf weblog.conf --microbatch weblog --consumer-group-id vertica-database
```

When the scheduler begins loading data, it will start updating the new consumer group. You can see this on a Kafka node using `kafka-consumer-groups.sh`:

```
$ /opt/kafka/bin/kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

vertica-database
vertica-vmart
$ /opt/kafka/bin/kafka-consumer-groups.sh --describe --group vertica-database \
   --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-database' has no active members.
```

<table>
<thead>
<tr>
<th>Topic</th>
<th>Partition</th>
<th>Current-Offset</th>
<th>Log-End-Offset</th>
<th>LAG</th>
<th>Consumer-ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>web_hits</td>
<td>0</td>
<td>30000</td>
<td>30000</td>
<td>0</td>
<td>-</td>
</tr>
</tbody>
</table>
To change the consumer group when manually loading data, use the group_id parameter of KafkaSource function:

```sql
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
   brokers='kafka01.example.com:9092',
   stop_on_eof=True,
   group_id='vertica_database')
   PARSER KafkaJsonParser();
Rows Loaded
------------
50000
(1 row)
```

### Using Consumer Group Offsets When Loading Messages

You can choose to have your scheduler, manual load, or custom loading script start loading messages from the consumer group's offset. You tell the scheduler or KafkaSource function to load messages from the last offset stored in the consumer group using the special -3 offset value.

This example demonstrates loading messages from the web_hits topic based on the saved offset in a consumer group named vertica_manual. This consumer group is created by the first COPY statement, as it did not exist in Kafka previously. So, this initial COPY statement is identical to using the special -2 offset to load all of the messages currently in the Topic's partition because there was no previously-saved offset. The second COPY statement is run almost immediately after the first, before any more messages have arrived, so it does not load any messages. The third COPY statement is run some time after that, after new messages have arrived:

```sql
=> TRUNCATE TABLE web_hits;
TRUNCATE TABLE
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-3',
   brokers='kafka01.example.com:9092',
   stop_on_eof=True,
   group_id='vertica_manual')
   PARSER KafkaJsonParser();
Rows Loaded
------------
50000
(1 row)
```
You can have your scheduler start loading messages from the consumer group's saved offset. Use the `--offset` argument of the `vkconfig` script's microbatch tool to set the offset to `-3` from all topic partitions your scheduler reads from. Once it starts its initial load, the scheduler still manages its offsets on its own.

**Disabling Consumer Group Reporting**

Vertica reports the offsets of the messages it consumes to Kafka by default. If you do not specifically configure a consumer group for Vertica, it still reports its offsets to a consumer group named `vertica_database-name` (where `database-name` is the name of the database Vertica is currently running).

If you want to completely disable having Vertica report its consumption back to Kafka, you can set the consumer group to an empty string or `NULL`. For example:

```sql
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
    brokers='kafka01.example.com:9092',
    stop_on_eof=True,
    group_id=NULL)
PARSER KafkaJsonParser();
Rows Loaded
----------
60000
(1 row)
```
Getting Configuration and Statistics Information From vkconfig

The vkconfig tool has two features that help you examine your scheduler's configuration and monitor your data load:

- The vkconfig tools that configure your scheduler (scheduler, cluster, source, target, load-spec, and microbatch) have a \(-\)-read argument that has them output their current settings in the scheduler.
- The vkconfig statistics tool lets you get statistics on your microbatches. You can filter the microbatch records based on a date and time range, cluster, partition, and other criteria.

Both of these features output their data in JSON format. You can use third-party tools that can consume JSON data or write your own scripts to process the configuration and statics data.

You can also access the data provided by these vkconfig options by querying the configuration tables in the scheduler's schema. However, you may find these options easier to use as they do not require you to connect to the Vertica database.

Getting Configuration Information

You pass the \(-\)-read option to vkconfig's configuration tools to get the current settings for the options that the tool can set. This output is in JSON format. This example demonstrates getting the configuration information from the scheduler and cluster tools for the scheduler defined in the weblog.conf configuration file:

```
$ vkconfig scheduler --read --conf weblog.conf
{"version":"v9.2.0", "frame_duration":"00:00:10", "resource_pool":"weblog_pool", "config_refresh":"00:05:00", "new_source_policy":"FAIR", "pushback_policy":"LINEAR", "pushback_max_count":5, "auto_sync":true, "consumer_group_id":null}
```

```
$ vkconfig cluster --read --conf weblog.conf
{"cluster":"kafka_weblog", "hosts":"kafka01.example.com:9092,kafka02.example.com:9092"}
```

The \(-\)-read option lists all of values created by the tool in the scheduler schema. For example, if you have defined multiple targets in your scheduler, the \(-\)-read option lists all of them.
$ vkconfig target --list --conf weblog.conf
{"target_schema"="public", "target_table"="health_data"}
{"target_schema"="public", "target_table"="iot_data"}
{"target_schema"="public", "target_table"="web_hits"}

You can filter the --read option output using the other arguments that the vkconfig tools accept. For example, in the cluster tool, you can use the --host argument to limit the output to just show clusters that contain a specific host. These arguments support LIKE-predicate wildcards, so you can match partial values. See LIKE predicate for more information about using wildcards.

The following example demonstrates how you can filter the output of the --read option of the cluster tool using the --host argument. The first call shows the unfiltered output. The second call filters the output to show only those clusters that start with "kafka":

$ vkconfig cluster --read --conf weblog.conf
{"cluster"="some_cluster", "hosts"="host01.example.com"}
{"cluster"="iot_cluster", "hosts"="kafka-iot01.example.com:9092,kafka-iot02.example.com:9092"}
{"cluster"="weblog", "hosts"="web01.example.com:9092,web02.example.com:9092"}
{"cluster"="streamcluster1", "hosts"="kafka-a-01.example.com:9092,kafka-a-02.example.com:9092"}
{"cluster"="test_cluster", "hosts"="test01.example.com:9092,test02.example.com:9092"}

$ vkconfig cluster --read --conf weblog.conf --hosts kafka%
{"cluster"="iot_cluster", "hosts"="kafka-iot01.example.com:9092,kafka-iot02.example.com:9092"}
{"cluster"="streamcluster1", "hosts"="kafka-a-01.example.com:9092,kafka-a-02.example.com:9092"}

See the Cluster Tool Options, Load Spec Tool Options, Microbatch Tool Options, Scheduler Tool Options, Target Tool Options, and Source Tool Options for more information.

Getting Streaming Data Load Statistics

The vkconfig script's statistics tool lets you view the history of your scheduler's microbatches. You can filter the results using any combination of the following criteria:

- The name of the microbatch
- The Kafka cluster that was the source of the data load
- The name of the topic
- The partition within the topic
- The Vertica schema and table targeted by the data load
- A date and time range
- The latest microbatches
See Statistics Tool Options for all of the options available in this tool.

This example gets the last two microbatches that the scheduler ran:

```bash
$ vkconfig statistics --last 2 --conf weblog.conf
{
    "microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
    "source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
    "start_offset":73300, "end_offset":73399, "end_reason":"END_OF_STREAM",
    "end_reason_message":null, "partition_bytes":10588, "partition_messages":100,
    "timeslice":"00:00:00.000000", "batch_start":"2018-11-02 13:22:08.825295",
    "batch_end":"2018-11-02 13:22:08.135299", "source_duration":"00:00:00.219619",
    "consecutive_error_count":null, "transaction_id":45035996273976123,
    "frame_start":"2018-11-02 13:22:20.601", "frame_end":null}
{
    "microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
    "source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
    "start_offset":73200, "end_offset":73299, "end_reason":"END_OF_STREAM",
    "end_reason_message":null, "partition_bytes":19781, "partition_messages":100,
    "timeslice":"00:00:00.056100", "batch_start":"2018-11-02 13:21:58.44698",
    "batch_end":"2018-11-02 13:21:58.335431", "source_duration":"00:00:00.214868",
    "consecutive_error_count":null, "transaction_id":45035996273976095,
    "frame_start":"2018-11-02 13:21:57.561", "frame_end":null}
```

This example gets the microbatches from the source named web_hits between 13:21:00 and 13:21:20 on November 2nd 2018:

```bash
$ vkconfig statistics --source "web_hits" --from-timestamp \n    "2018-11-02 13:21:00" --to-timestamp "2018-11-02 13:21:20" \n    --conf weblog.conf
{
    "microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
    "source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
    "start_offset":72800, "end_offset":72899, "end_reason":"END_OF_STREAM",
    "end_reason_message":null, "partition_bytes":19989, "partition_messages":100,
    "timeslice":"00:00:00.000000", "batch_start":"2018-11-02 13:21:17.581606",
    "batch_end":"2018-11-02 13:21:18.850705", "source_duration":"00:00:01.218932",
    "consecutive_error_count":null, "transaction_id":45035996273975997,
    "frame_start":"2018-11-02 13:21:17.34", "frame_end":null}
{
    "microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
    "source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
    "start_offset":72700, "end_offset":72799, "end_reason":"END_OF_STREAM",
    "end_reason_message":null, "partition_bytes":19640, "partition_messages":100,
    "timeslice":"00:00:00.000000", "batch_start":"2018-11-02 13:21:07.478834",
    "batch_end":"2018-11-02 13:21:08.732255", "source_duration":"00:00:01.253422",
    "consecutive_error_count":null, "transaction_id":45035996273975978,
    "frame_start":"2018-11-02 13:21:07.309", "frame_end":null}
```

See Statistics Tool Options for more examples of using this tool.

### Parsing Custom Formats

Vertica supports the use of user-defined filters to manipulate data arriving from your streaming message bus. You can apply these filters to data before you parse it. By default, data that flows from the source does not contain message boundaries. The default Kafka parsers can locate the message boundaries on their own. However, other user-defined and

Vertica Analytic Database (9.3.x)
Vertica parsers are not designed to recognize the message boundaries. Two Kafka-specific filters let you insert message boundary information to the data stream (such as delimiters) so that parsers are able to extract and parse individual messages.

**Filters for Use with Kafka Data**

Vertica includes the following filters:

- **KafkaInsertDelimiters** — Transforms the Kafka data stream by inserting a user-specified delimiter between each message. The delimiter can contain any characters and be of any length. This parser uses the following syntax:

  ```
  KafkaInsertDelimiters(delimiter = 'delimiter')
  ```

- **KafkaInsertLengths** — Transforms the Kafka data stream by inserting the length of the following record in bytes at the beginning of the record. Vertica writes lengths as 4-byte uint32 values in Big Endian network byte order. For example, a 100-byte record would be preceded by 0x00000064.

  ```
  KafkaInsertLengths()
  ```

**Note:**

The Vertica provided filters are mutually exclusive. You cannot use both to process a Kafka data stream in the same COPY statement.

Vertica also supports the use of additional Vertica and user-defined filters. If you are using a Vertica filter, it must appear first in the filter list. Use a comma to delimit multiple filters. If you are using a non-Kafka parser, you must use at least one filter to prepare your content for that parser. If you do not provide a filter, the parser fails with the message:

```
Input is not from Kafka source.
```

**Example**

The following example demonstrates loading comma-separated values from two partitions in a topic named iot-data. The load processes all of the messages in the two partitions, and exits when it reaches the end of the messages currently in Kafka. The example uses the KafkaInsertDelimiters filter to insert newlines between Kafka messages, turning them into traditional rows of data. It relies on the standard COPY parser to parse the CSV values by telling it to use a comma as the column delimiter.
Using a Schema Registry with Kafka

Vertica supports the use of a Confluent schema registry for Avro schemas with the KafkaAvroParser. By using a schema registry, you enable the Avro parser to parse and decode messages written by the registry and to retrieve schemas stored in the registry. In addition, a schema registry enables Vertica to process streamed data without sending a copy of the schema with each record. Vertica can access a schema registry in the following ways:

- schema ID
- subject and version

**Note:**
If you use the compatibility config resource in your schema registry, you should specify a value of at least BACKWARD. You may also choose to use a stricter compatibility setting. For more information on installing and configuring a schema registry, refer to the Confluent documentation.

Schema ID Loading

In schema ID based loading, the Avro parser checks the schema ID associated with each message to identify the correct schema to use. A single COPY statement can reference multiple schemas. Because each message is not validated, Vertica recommends that you use a flex table as the target table for schema ID based loading.

The following example shows a COPY statement that refers to a schema registry located on the same host.

```sql
=> COPY logs source kafkasource(stream='simple|0|0', stop_on_eof=true, duration=interval '10 seconds') parser KafkaAvroParser(schema_registry_url='http://localhost:8081/');
```
Subject and Version Loading

In subject and version loading, you specify a subject and version in addition to the schema registry URL. The addition of the subject and version identifies a single schema to use for all messages in the COPY. If any message in the statement is incompatible with the schema, the COPY fails. Because all messages are validated prior to loading, Vertica recommends that you use a standard Vertica table as the target for subject and version loading.

The following example shows a COPY statement that identifies a schema subject and schema version as well as a schema registry.

```
=> COPY t source kafkasource(stream='simpleEvolution|0|0',
stop_on_eof=true, duration=interval '10 seconds') parser
KafkaAvroParser(schema_registry_url='http://repository:8081/schema-repo/','
schema_registry_subject='simpleEvolution-value',schema_registry_version='1')
REJECTED DATA AS TABLE "t_rejects";
```

Using Vertica to Produce Data for Kafka

In addition to consuming data from Kafka, Vertica can produce data for Kafka. There are two ways you can have Vertica stream data to Kafka:

- Using the KafkaExport function to send Vertica data to a Kafka topic. Use this feature to export arbitrary data to Kafka for consumption by any other application that is a Kafka consumer.
- Using notifiers to send Vertica diagnostic data from the data collector tables. You use this method primarily to let third-party monitoring applications view the status of your Vertica cluster. See Monitoring Vertica Using Notifiers.

The topics in this section explain how to use these methods in greater detail.

Producing Data Using KafkaExport

The KafkaExport function lets you stream data from Vertica to Kafka. You pass this function three arguments and two or three parameters:

```
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
USING PARAMETERS brokers='host[:port][,host...]','
```
The `partitionColumn` and `keyColumn` arguments set the Kafka topic's partition and key value, respectively. You can set either or both of these values to NULL. If you set the partition to NULL, Kafka uses its default partitioning scheme (either randomly assigning partitions if the key value is NULL, or based on the key value if it is not).

The `valueColumn` argument is a LONG VARCHAR containing message data that you want to send to Kafka. Kafka does not impose structure on the message content. Your only restriction on the message format is what the consumers of the data are able to parse.

You are free to convert your data into a string in any way you like. For simple messages (such as a comma-separated list), you can use functions such as `CONCAT` to assemble your values into a message. If you need a more complex data format, such as JSON, consider writing a UDX function that accepts columns of data and outputs a LONG VARCHAR containing the data in the format you require. See Developing User-Defined Extensions (UDxs) for more information.

The data exported from Vertica using KafkaExport is sent to Kafka in JSON format.

See KafkaExport for detailed information about KafkaExport's syntax.

**Export Example**

This example shows you how to perform a simple export of several columns of a table. Suppose you have the following table containing a simple set of Internet of things (IOT) data:

```
=> SELECT * FROM iot_report LIMIT 10;
server | date       | location       | id
-------+------------+----------------+---
1      | 2016-10-11 04:09:28 | -14.86058, 112.75848 | 70982027
1      | 2017-07-02 12:37:48 | -21.42197, -127.17672 | 49494918
1      | 2017-10-19 14:04:33 | -71.72156, -36.27381 | 94328189
1      | 2018-08-30 08:09:45 | 83.97962, 162.83848 | 967212
2      | 2017-01-20 03:05:24 | 37.17372, 136.14026 | 36670100
2      | 2017-07-29 11:38:37 | -38.99517, 171.72671 | 52049116
2      | 2018-04-19 13:06:58 | 69.28989, 133.98275 | 36059826
2      | 2018-08-28 01:09:51 | -59.71784, -144.97142 | 77310139
2      | 2018-09-14 23:16:15 | 58.07275, 111.87354 | 4198109
(10 rows)
```
You want to send the data in this table to a Kafka topic named `iot_results` for consumption by other applications. Looking at the data and the structure of the `iot_report`, you may decide the following:

- The server column is a good match for the partitions in `iot_report`. There are three partitions in the Kafka topic, and the values in server column are between 1 and 3. Suppose the partition column had a larger range of values (for example, between 1 and 100). Then you could use the modulo operator (%) to coerce the values into the same range as the number of partitions (server % 3).
  A complication with these values is that the values in the server are 1-based (the lowest value in the column is 1). Kafka's partition numbering scheme is zero-based. So, you must adjust the values in the server column by subtracting 1 from them.
- The id column can act as the key. This column has a data type of INTEGER. The KafkaExport function expects the key value to be a VARCHAR. Vertica does not automatically cast INTEGER values to VARCHAR, so you must explicitly cast the value in your function call.
- The consumers of the `iot_report` topic expect values in comma-separated format. You can combine the values from the date and location columns into a single VARCHAR using nested calls to the CONCAT function.

The final piece of information you need to know is the host names and port numbers of the brokers in your Kafka cluster. In this example, there are two brokers named kafka01 and kafka03, running on port 6667 (the port that Hortonworks clusters use). Once you have all of this information, you are ready to export your data.

The following example shows how you might export the contents of `iot_report`:

```sql
=> SELECT KafkaExport(server - 1, id::VARCHAR,
       CONCAT(CONCAT(date, ', '), location)
       USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
       topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
```

KafkaExport returned 0 rows which means Vertica was able to send all of your data to Kafka without any errors.

Other things to note about the example:
The CONCAT function automatically converts the date column's DATETIME value to a VARCHAR for you, so you do not need to explicitly cast it.

Two nested CONCAT functions are necessary to concatenate the date field with a comma, and the resulting string with the location field.

Adding a third column to the message field would require two additional CONCAT function calls (one to concatenate a comma after the location column, and one to concatenate the additional column's value). Using CONCAT becomes messy after just a few column's worth of data.

On the Kafka side, you will see whatever you sent as the valueColumn (third) argument of the KafkaExport function. In the above example, this is a CSV list. If you started a console consumer for iot_results topic before running the example query, you would see the following output when the query runs:

```
$ /opt/kafka/bin/kafka-console-consumer.sh --topic iot_results --zookeeper localhost
2017-10-10 12:08:33, 78.84883, -137.56584
2017-12-06 16:50:57, -25.33024, -157.91389
2018-08-19 00:02:18, 13.00436, 85.44815
2016-10-11 04:09:28, -14.86058, 112.75848
2017-10-19 14:04:33, -71.72156, -36.27381
2018-07-11 19:35:18, -9.41315, 102.36866
2018-08-30 08:09:45, 83.97962, 162.83848
2017-01-20 03:05:24, 37.17372, 136.14026
2017-07-20 11:38:37, -38.99517, 171.72671
2018-08-28 01:09:51, -59.71784, -144.97142
2018-09-14 23:16:15, 58.07275, 111.07354
```

**KafkaExport's Return Value**

KafkaExport outputs any rows that Kafka rejected. For example, suppose you forgot to adjust the partition column to be zero-based in the previous example. Then some of the rows exported to Kafka would specify a partition that does not exist. In this case, Kafka rejects these rows, and KafkaExport reports them in table format:

```
=> SELECT KafkaExport(server, id::VARCHAR,
    CONCAT(CONCAT(date, ', '), location)
    USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
    topic='iot_results',
    OVER (PARTITION BEST) FROM iot_report;
    partition | key | message | failure_reason
    ---------------+-----+---------+-------------------
    3            | 40492866 | 2017-10-10 12:08:33, 78.84883, -137.56584, | Local: Unknown partition
    3            | 7384606 | 2017-12-06 16:50:57, -25.33024, -157.91389, | Local: Unknown partition
    3            | 27462612 | 2018-08-19 00:02:18, 13.00436, 85.44815, | Local: Unknown partition
```
Another common reason for Kafka rejecting a row is that its message value is longer than Kafka's message.max.bytes setting.

You can capture this output by creating a table to hold the rejects. Then use an INSERT statement to insert KafkaExport's results:

```sql
=> CREATE TABLE export_rejects (partition INTEGER, key VARCHAR, message LONG VARCHAR, failure_reason VARCHAR);
CREATE TABLE
=> INSERT INTO export_rejects SELECT KafkaExport(server, id::VARCHAR, 
CONCAT(CONCAT(date, ', '), location)
  USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
  topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
OUTPUT
--------
4
(1 row)
=> SELECT * FROM export_rejects;
partition | key          | message                     | failure_reason
-----------|--------------|-----------------------------|---------------------
3          | 27462612     | 2018-08-19 00:02:18, 13.00436, 85.44815 | Local: Unknown partition
3          | 48492866     | 2017-10-10 12:08:33, 78.84883, -137.56584 | Local: Unknown partition
3          | 73846066     | 2017-12-06 16:50:57, -25.33024, -157.91389 | Local: Unknown partition
(4 rows)
```

### Producing Kafka Messages Using Notifiers

You can use notifiers to help you monitor your Vertica database using third-party Kafka-aware tools by producing messages to a Kafka topic. You can directly publish messages (for example, from a SQL script to indicate a long-running query has finished). Notifiers can also automatically send messages when a component in the data collector tables is updated.

### Creating a Notifier

You must create a notifier before you can use it. At a minimum, a notifier defines:

- A unique name.
- A message protocol. This is `kafka://` when sending messages to Kafka.
The server to communicate with. For Kafka, this is the address and port number of a Kafka broker.
The maximum message buffer size. If the queue of messages to be sent via the notifier exceed this limit, messages are dropped.

You create the notifier using the `CREATE NOTIFIER` statement. This example creates a notifier named `load_progress_notifier` that sends messages via the Kafka broker running on kafka01.example.com on port 9092:

```
=> CREATE NOTIFIER load_progress_notifier
    ACTION 'kafka://kafka01.example.com:9092'
    MAXMEMORYSIZE '10M';
```

### Sending Individual Messages Via a Notifier

You can send an individual message via a notifier using the `NOTIFY` function. This feature is useful for reporting the progress of SQL scripts such as ETL tasks to third-party reporting tools.

You pass this function three string values:

- The message to send.
- The name of the notifier to send the message.
- The Kafka topic to receive the message.

For example, suppose you want to send the message "Daily load finished" to the `vertica_notifications` topic of the Kafka cluster defined in the `load_progress_notifier` notifier created earlier. Then you could execute the following statement:

```
=> SELECT NOTIFY('Daily load finished.',
    'load_progress_notifier',
    'vertica_notifications');
```

The message the notifier sends to Kafka is in JSON format. You can see the resulting message by using the console consumer on a Kafka node. For example:

```
$ /opt/kafka/bin/kafka-console-consumer.sh --bootstrap-server localhost:9092 \
    --from-beginning \
    --topic vertica_notifications \
    --max-messages 1
```
Automatically Sending Notifications of DC Table Changes

The Vertica Data Collector (DC) tables monitor many different database functions. You can have a notifier automatically send a message when a DC component updates. You can query the DATA_COLLECTOR table to get a list of the DC components.

You configure the notifier to send DC component updates to Kafka using the function SET_DATA_COLLECTOR_NOTIFY_POLICY.

The following example demonstrates creating a notifier, then sends it notifications each time the LoginFailures component updates. This component updates every time there is a failed attempt to log into the Vertica database.

```
=> CREATE NOTIFIER vertica_stats ACTION 'kafka://kafka01.example.com:9092' MAXMEMORYSIZE '10M';
CREATE NOTIFIER
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', true);
SET_DATA_COLLECTOR_NOTIFY_POLICY
------------------------------------------
SET (1 row)
```

Like the messages sent via the NOTIFY function, the data sent to Kafka from the DC components is in JSON format. The previous example results in messages like the following being sent to the vertica_notifications Kafka topic:

```
{"_db":"vmart","_schema":"v_internal","_table":"dc_login_failures","channel":"vertica_notifications","message":"Login attempt failed when user "alice" attempted to log in from the host ::1 with a rejected authentication method. The user name was dbadmin."}
```

Processed a total of 1 messages
Seeing Automatic Notification Policies for a DC Component

Use the `GET_DATA_COLLECTOR_NOTIFY_POLICY` function to list the policies set for a DC component.

```sql
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
GET_DATA_COLLECTOR_NOTIFY_POLICY
-----------------------------
Notifiable; Notifier: vertica_stats; Channel: vertica_notifications
(1 row)
```

Disabling a Notification Policy

Call the `SET_DATA_COLLECTOR_NOTIFY_POLICY` function with its fourth argument set to FALSE to disable a notification policy. For example, the following statement disables the notify policy for the LoginFailures component:

```sql
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', false);
SET
(1 row)

=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
GET_DATA_COLLECTOR_NOTIFY_POLICY
-----------------------------
Not notifiable;
(1 row)
```

Using TLS/SSL Encryption with Kafka

You can use TLS/SSL encryption between Vertica, your scheduler, and Kafka. This encryption prevents others from accessing the data that is sent between Kafka and Vertica. It can also verify the identity of all parties involved in data streaming, so no impostor can pose as your Vertica cluster or a Kafka broker.

Note:

Many people often confuse the terms TLS and SSL. SSL is an older encryption protocol that has been largely replace with the newer and more secure TLS standard. However, many people still use the term SSL to refer to encryption between servers and applications, even when that encryption is
actually TLS. For example, Java and Kafka use the term SSL exclusively, even when dealing with TLS. This document uses SSL/TLS and SSL interchangeably.

Some common cases where you want to use SSL encryption between Vertica and Kafka are:

- Your Vertica database and Kafka communicate over an insecure network. For example, suppose your Kafka cluster is located in a cloud service and your Vertica cluster is within your internal network. In this case, any data you read from Kafka travels over an insecure connection across the Internet.
- You are required by security policies, laws, or other requirements to encrypt all of your network traffic.

For more information about TLS/SSL encryption in Vertica, see **TLS Protocol**.

### Using TLS/SSL Between the Scheduler and Vertica

The scheduler connects to Vertica the same way other client applications do. There are two ways you can configure Vertica to use SSL/TLS authentication and encryption with clients:

- If Vertica is configured to use SSL/TLS server authentication, you can choose to have your scheduler confirm the identity of the Vertica server.
- If Vertica is configured to use mutual SSL/TLS authentication, you can configure your scheduler identify itself to Vertica as well as have it verify the identity of the Vertica server. Depending on your database's configuration, the Vertica server may require your scheduler to use TLS when connecting. See [Implementing Client Self-Authentication](#) for more information.

For information on encrypted client connections with Vertica, refer to **TLS Protocol**.

The scheduler runs on a Java Virtual Machine (JVM) and uses JDBC to connect to Vertica. It acts like any other JDBC client when connecting to Vertica. To use TLS/SSL encryption for the scheduler's connection to Vertica, use the Java keystore and truststore mechanism to hold the keys and certificates the scheduler uses to identify itself and Vertica.

- The keystore contains your scheduler's private encryption key and its certificate (public key).
- The truststore contains CAs that you trust. If you enable authentication, the scheduler uses these CAs to verify the identity of the Vertica cluster it connects to. If one of the
CAAs in the trust store was used to sign the server's certificate, then the Scheduler knows it can trust the identity of the Vertica server.

You can pass options to the JVM that executes the scheduler through the Linux environment variable named VKCONFIG_JVM_OPTS. You add the parameters to this variable that alter the scheduler's JDBC settings (such as the truststore and keystore for the scheduler's JDBC connection). See Kafka TLS-SSL Example Part 5: Configure the Scheduler for an example.

You can also use the --jdbc-url scheduler option to alter the JDBC configuration. See Common vkconfig Script Options for more information about the scheduler options and JDBC Connection Properties for more information about the properties they can alter.

### Using TLS/SSL Between Vertica and Kafka

You can stream data from Kafka into Vertica two ways: manually using a `COPY` statement and the KafkaSource UD source function, or automatically using the scheduler.

To directly copy data from Kafka via an SSL connection, you set session variables containing an SSL key and certificate. When KafkaSource finds that you have set these variables, it uses the key and certificate to create a secure connection to Kafka. See Kafka TLS/SSL Example Part 4: Loading Data Directly From Kafka for details.

When automatically streaming data from Kafka to Vertica, you configure the scheduler the same way you do to use an SSL connection to Vertica. When the scheduler executes `COPY` statements to load data from Kafka, it uses its own keystore and truststore to create an SSL connection to Kafka.

To use an SSL connection when producing data from Vertica to Kafka, you set the same session variables you use when directly streaming data from Kafka via an SSL connection. The KafkaExport function uses these variables to establish a secure connection to Kafka.

**Note:**

Notifiers do not currently support using TLS/SSL connections.

See the Apache Kafka documentation for more information about using SSL/TLS authentication with Kafka.
Planning TLS/SSL Encryption Between Vertica and Kafka

Some things to consider before you begin configuring TLS/SSL:

- Which connections between the scheduler, Vertica, and Kafka needs to be encrypted? In some cases, you may only need to enable encryption between Vertica and Kafka. This scenario is common when Vertica and the Kafka cluster are on different networks. For example, suppose Kafka is hosted in a cloud provider and Vertica is hosted in your internal network. Then the data must travel across the unsecured Internet between the two. However, if Vertica and the scheduler are both in your local network, you may decide that configuring them to use SSL/TLS is unnecessary. In other cases, you will want all parts of the system to be encrypted. For example, you want to encrypt all traffic when Kafka, Vertica, and the scheduler are all hosted in a cloud provider whose network may not be secure.

- Which connections between the scheduler, Vertica, and Kafka require trust? You can opt to have any of these connections fail if one system cannot verify the identity of another. See Verifying Identities below.

- Which CAs will you be using to sign each certificate? The simplest way to configure the scheduler, Kafka, and Vertica is to use the same CA to sign all of the certificates you will use when setting up TLS/SSL. Using the same root CA to sign the certificates requires you to be able to edit the configuration of Kafka, Vertica, and the scheduler. If you cannot use the same CA to sign all certificates, all truststores must contain the entire chain of CAs used to sign the certificates, all the way up to the root CA. Including the entire chain of trust ensures each system can verify each other's identities.

Verifying Identities

Your primary challenge when configuring TLS/SSL encryption between Vertica, the scheduler, and Kafka is making sure the scheduler, Kafka, and Vertica can all verify each other's identity. The most common problem people have encountered when setting up TLS/SSL encryption is ensuring the remote system can verify the authenticity of a system's certificate. The best way to prevent this problem is to ensure that the all systems have their certificates signed by a CA that all of the systems explicitly trust.
When a system attempts to start an encrypted connection with another system, it sends its certificate to the remote system. This certificate can be signed by one or more Certificate Authorities (CA) that help identify the system making the connection. These signatures form a "chain of trust." A certificate is signed by a CA. That CA, in turn, could have been signed by another CA, and so forth. Often, the chain ends with a CA (referred to as the root CA) from a well-known commercial provider of certificates, such as Comodo SSL or DigiCert, that are trusted by default on many platforms such as operating systems and web browsers.

If the remote system finds a CA in the chain that it trusts, it verifies the identity of the system making the connection, and the connection can continue. If the remote system cannot find the signature of a CA it trusts, it may block the connection, depending on its configuration. Systems can be configured to only allow connections from systems whose identity has been verified.

**Note:**
Verifying the identity of another system making a TLS/SSL connection is often referred to as "authentication." Do not confuse this use of authentication with other forms of authentication used with Vertica. For example, TLS/SSL's authentication of a client connection has nothing to do with Vertica user authentication. Even if you successfully establish a TLS/SSL connection to Vertica using a client, Vertica still requires you to provide a user name and password before you can interact with it.

**Configuring Your Scheduler for TLS/SSL Connections**

The scheduler can use SSL for two different connections: the one it makes to Vertica, and the connection it creates when running COPY statements to retrieve data from Kafka. Because the scheduler is a Java application, you supply the SSL key and the certificate used to sign it in a keystore. You also supply a truststore that contains in the certificates that the scheduler should trust. Both the connection to Vertica and to Kafka can use the same keystore and truststore. You can also choose to use separate keystores and truststores for these two connections by setting different JDBC settings for the scheduler. See [JDBC Connection Properties](#) for a list of these settings.

See [Kafka TLS-SSL Example Part 5: Configure the Scheduler](#) for detailed steps on configuring your scheduler to use SSL.
Important:
If you choose to use a file format other than the standard Java Keystore (JKS) format for your keystore or truststore files, you must use the correct file extension in the filename. For example, suppose you choose to use a keystore and truststore saved in PKCS#12 format. Then your keystore and trustore files must end with the .pfx or .p12 extension. If the scheduler does not recognize the file's extension (or there is no extension in the file name), it assumes that the file is in JKS format. If the file is not in JKS format, you will see an error message when starting the scheduler, similar to "Failed to create an SSLSocketFactory when setting up TLS: keystore not found."

Using TLS/SSL When Directly Loading Data from Kafka

You can manually load data from Kafka using the COPY statement and the KafkaSource user-defined load function (see Manually Copying Data From Kafka). To have KafkaSource open a secure connection to Kafka, you must supply it with an SSL key and other information.

When starting, the KafkaSource function checks if several user session variables are defined. These variables contain the SSL key, the certificate used to sign the key, and other information that the function needs to create the SSL connection. See Kafka User-Defined Session Parameters for a list of these variables. If KafkaSource finds these variables are defined, it uses them to create an SSL connection to Kafka.

See Kafka TLS/SSL Example Part 4: Loading Data Directly From Kafka for a step-by-step guide on configuring and using an SSL connection when directly copying data from Kafka.

These variables are also used by the KafkaExport function to establish a secure connection to Kafka when exporting data.
Kafka TLS/SSL Example Overview

The following topics step you through the process of setting up TLS/SSL between Vertica, Kafka, and the scheduler. In this example:

- All certificates are signed by a single self-signed root CA. Using the same CA is the easiest way of configuring TLS/SSL, as all of the systems can use the same CA verify each other’s identity.
- Vertica, the scheduler, and Kafka verify each other's identity. This verification provides the most security.

The steps in this example are

1. Kafka TLS/SSL Example Part 1: Create the Root CA.
5. Kafka TLS-SSL Example Part 5: Configure the Scheduler.

In your own environment, you may not need to follow all of these steps depending on which connections you want encrypted.

Kafka TLS/SSL Example Part 1: Create the Root CA

This example uses the same self-signed root CA to sign all of the certificates used by the scheduler, Kafka brokers, and Vertica. If you cannot use the same CA to sign the keys for all of these systems, make sure you include the entire chain of trust in your keystores.

The following Linux commands create a self-signed root CA. They are run by the dbadmin user on the Linux command line of one of the Vertica nodes.

1. Generate a private key named root.key.

```
$ openssl genrsa -out root.key
Generating RSA private key, 2048 bit long modulus
..........................................................+++ 
.....................................................+++ 
.....................................................+++ 
.....................................................+++ 
```

Vertica Analytic Database (9.3.x)
2. Generating a self-signed root CA named root.crt.

    $ openssl req -new -x509 -key root.key -out root.crt
    You are about to be asked to enter information that will be incorporated into your certificate request.
    What you are about to enter is what is called a Distinguished Name or a DN.
    There are quite a few fields but you can leave some blank
    For some fields there will be a default value,
    If you enter '.', the field will be left blank.
    ----
    Country Name (2 letter code) [AU]:US
    State or Province Name (full name) [Some-State]:MA
    Locality Name (eg, city) []:Cambridge
    Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
    Organizational Unit Name (eg, section) []:
    Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
    Email Address []:myemail@mycompany.com

3. Change permissions on the files to prevent others from reading the root key, and preventing changes to the root certificate.

    $ ls
    root.crt  root.key
    $ chmod 600 root.key
    $ chmod 644 root.crt

Kafka TLS/SSL Example Part 2: Configure Vertica for Mutual Authentication

The following steps demonstrate setting up Vertica for mutual TLS/SSL authentication:

- **Step 1: Create Server Key and Certificate**
- **Step 2: Create Client Key and Certificate**
- **Step 3: Distribute Keys and Certificates**

For details on steps in this example, see [TLS Protocol](#).
Step 1: Create Server Key and Certificate

The following example creates a key and certificate for the Vertica server. It signs the certificate using the root CA created in the previous step.

1. Generate the private key for the server:

   ```
   $ openssl genrsa -out server.key
   Generating RSA private key, 2048 bit long modulus
   ..............................................+++ 
   e is 65537 (0x10001)
   ```

2. Create a certificate request. In this step, set the Common Name field to a wildcard value for your domain—for example, *.yourdomain.tld. Using a wildcard instead of a fully-qualified domain name here ensures that this certificate is accepted for all of the Vertica nodes in your cluster:

   ```
   $ openssl req -new -key server.key -out serverreqout.txt
   You are about to be asked to enter information that will be incorporated into your certificate request.
   What you are about to enter is what is called a Distinguished Name or a DN.
   There are quite a few fields but you can leave some blank
   For some fields there will be a default value,
   If you enter '.', the field will be left blank.
   -----
   Country Name (2 letter code) [AU]: US
   State or Province Name (full name) [Some-State]: MA
   Locality Name (eg, city) []: Cambridge
   Organization Name (eg, company) [Internet Widgits Pty Ltd]: My Company
   Organizational Unit Name (eg, section) []:
   Common Name (e.g. server FQDN or YOUR name) []: *.mycompany.com
   Email Address []: myaddress@mycompany.com
   
   Please enter the following 'extra' attributes to be sent with your certificate request
   A challenge password []: server_key_password
   An optional company name []:
   ```

3. Sign the certificate request with the root CA:

   ```
   $ openssl x509 -req -in serverreqout.txt -days 3650 -sha256 -CAcreateserial -CA root.crt -CAkey root.key -out server.crt
   Signature ok
   subject=/C=US/ST=MA/L=Cambridge/O=My Company/CH=*.mycompany.com/emailAddress=myaddress@mycompany.com
   Getting CA Private Key
   ```
Step 2: Create Client Key and Certificate

After you enable mutual authentication mode on Vertica, you must have a key and certificate for your client in order to connect to the database. The steps to create a client certificate are the same as creating the server certificate:

```bash
$ openssl genrsa -out client.key
Generating RSA private key, 2048 bit long modulus
.................................................................+++  
e is 65537 (0x10001)

$ openssl req -new -key client.key -out client_reqout.txt
You are about to be asked to enter information that will be incorporated into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.  
There are quite a few fields but you can leave some blank  
For some fields there will be a default value,  
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com

Please enter the following 'extra' attributes to be sent with your certificate request
A challenge password []:client_key_password
An optional company name []:

$ openssl x509 -req -in client_reqout.txt -days 3650 -sha256 -CAcreateserial -CA root.crt 
-CAkey root.key -out client.crt
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=My Company/CN=*.mycompany.com/emailAddress=myemail@mycompany.com
Getting CA Private Key
```

Step 3: Distribute Keys and Certificates

With the server and client keys created, you are ready to deploy the keys to your Vertica cluster:
1. Set permissions on the certificates and key files and cleans up temporary key files:

```bash
$ ls
client.crt  client.key  client_reqout.txt  root.crt  root.key  root.srl  server.crt
server.key  server_reqout.txt
$ chmod 600 client.key  server.key
$ chmod 644 client.crt  server.crt
$ rm client_reqout.txt  server_reqout.txt
```

2. Log into Vertica using vsq1:

```bash
$ vsq1
Password: dbadmin_password
Welcome to vsq1, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsq1 commands
\g or terminate with semicolon to execute query
\q to quit
```

3. Enables SSL on the Vertica server and then exit:

```bash
=> ALTER DATABASE DEFAULT SET PARAMETER EnableSSL = 1;
WARNING 9138: Cannot initialize TLS until SSLCertificate and SSLSecretKey config
parameters are set
=> \q
```

4. Shut down the database. You must shut down it down in order to distribute the
encryption keys and to have the EnableSSL configuration parameter take effect.

```bash
$ adminTools --tool stop_db -d VMart -p dbadmin_password
Connecting to database
Issuing shutdown command to database
Database VMart stopped successfully
```

5. Add the server key and certificate to Vertica using the Admin Tools' command line
set_ssl_params tool:

```bash
$ adminTools --tool set_ssl_params -d VMart -k server.key -c server.crt -a root.crt -p dbadmin_password
Success. Change committed on a quorum of nodes.
```

6. Restart the database so the configuration change takes effect:

```bash
$ adminTools --tool start_db -d VMart -p vertica
Starting nodes:
v_vmart_node0001 (10.20.110.7)
v_vmart_node0002 (10.20.110.8)
v_vmart_node0003 (10.20.110.9)
Starting Vertica on all nodes. Please wait, databases with a large catalog may take
a while to initialize.
```
Node Status: v_vmart_node0001: (DOWN) v_vmart_node0002: (DOWN) v_vmart_node0003: (DOWN)
Node Status: v_vmart_node0001: (DOWN) v_vmart_node0002: (DOWN) v_vmart_node0003: (DOWN)
